Chapter 12: Partial Differential Equations Support

Trigonometric Transform Routines.....	3093
---------------------------------------	------

Transforms Implemented.....	3094
Sequence of Invoking TT Routines.....	3095
Interface Description.....	3097
TT Routines.....	3097
?_init_trig_transform.....	3097
?_commit_trig_transform.....	3098
?_forward_trig_transform.....	3101
?_backward_trig_transform.....	3102
free_trig_transform.....	3104
Common Parameters.....	3105
Implementation Details.....	3108
Fast Poisson Solver Routines	3110
Poisson Solver Implementation.....	3110
Sequence of Invoking Poisson Solver Routines.....	3117
Interface Description.....	3119
Routines for the Cartesian Solver.....	3119
?_init_Helmholtz_2D/?_init_Helmholtz_3D.....	3119
_commit_Helmholtz_2D/?_commit_Helmholtz_3D.....	3122
?_Helmholtz_2D/?_Helmholtz_3D.....	3125
free_Helmholtz_2D/free_Helmholtz_3D.....	3128
Routines for the Spherical Solver.....	3128
?_init_sph_p/?_init_sph_np.....	3129
?_commit_sph_p/?_commit_sph_np.....	3130
?_sph_p/?_sph_np.....	3132
free_sph_p/free_sph_np.....	3134
Common Parameters.....	3135
ipar.....	3135
dpar and spar.....	3139
Caveat on Parameter Modifications.....	3141
Parameters That Define Boundary Conditions.....	3142
Implementation Details.....	3145
Calling PDE Support Routines from Fortran.....	3151

Chapter 13: Nonlinear Optimization Problem Solvers

Organization and Implementation.....	3153
Routine Naming Conventions.....	3154
Nonlinear Least Squares Problem without Constraints.....	3154
?trnlsp_init.....	3155
?trnlsp_check.....	3157
?trnlsp_solve.....	3159
?trnlsp_get.....	3161
?trnlsp_delete.....	3162
Nonlinear Least Squares Problem with Linear (Bound) Constraints.....	3163
?trnlspbc_init.....	3163
?trnlspbc_check.....	3165
?trnlspbc_solve.....	3168
?trnlspbc_get.....	3170
?trnlspbc_delete.....	3171
Jacobian Matrix Calculation Routines.....	3172
?jacobi_init.....	3172

?jacobi_solve.....	3173
?jacobi_delete.....	3175
?jacobi.....	3175
?jacobix.....	3177

Chapter 14: Support Functions

Using a Fortran Interface Module for Support Functions.....	3184
Version Information.....	3184
mkl_get_version.....	3184
mkl_get_version_string.....	3186
Threading Control.....	3187
mkl_set_num_threads.....	3188
mkl_domain_set_num_threads.....	3189
mkl_set_num_threads_local.....	3191
mkl_set_dynamic.....	3193
mkl_get_max_threads.....	3194
mkl_domain_get_max_threads.....	3195
mkl_get_dynamic.....	3196
Error Handling.....	3198
Error Handling for Linear Algebra Routines.....	3198
xerbla.....	3198
pxerbla.....	3199
Handling Fatal Errors.....	3200
mkl_set_exit_handler.....	3200
Character Equality Testing.....	3201
Isame.....	3202
Isamen.....	3202
Timing.....	3203
second/dsecnd.....	3203
mkl_get_cpu_clocks.....	3204
mkl_get_cpu_frequency.....	3205
mkl_get_max_cpu_frequency.....	3206
mkl_get_clocks_frequency.....	3206
Memory Management.....	3207
mkl_free_buffers.....	3207
mkl_thread_free_buffers.....	3208
mkl_disable_fast_mm.....	3209
mkl_mem_stat.....	3210
mkl_peak_mem_usage.....	3211
mkl_malloc.....	3212
mkl_calloc.....	3213
mkl_realloc.....	3214
mkl_free.....	3215
Usage Examples for the Memory Functions.....	3216
Single Dynamic Library Control.....	3219
mkl_set_interface_layer.....	3219
mkl_set_threading_layer.....	3220
mkl_set_xerbla.....	3221
mkl_set_progress.....	3222
Intel Many Integrated Core Architecture Support.....	3223

mkl_mic_enable.....	3224
mkl_mic_disable.....	3225
mkl_mic_get_device_count.....	3225
mkl_mic_set_workdivision.....	3226
mkl_mic_get_workdivision.....	3228
mkl_mic_set_max_memory.....	3229
mkl_mic_free_memory.....	3231
mkl_mic_register_memory.....	3232
mkl_mic_set_device_num_threads.....	3233
mkl_mic_set_resource_limit.....	3235
mkl_mic_get_resource_limit.....	3238
mkl_mic_set_offload_report.....	3239
Conditional Numerical Reproducibility Control.....	3239
mkl_cbwr_set.....	3240
mkl_cbwr_get.....	3241
mkl_cbwr_get_auto_branch.....	3242
Named Constants for CNR Control.....	3243
Reproducibility Conditions.....	3244
Usage Examples for CNR Support Functions.....	3245
Miscellaneous.....	3246
mkl_progress.....	3246
mkl_enable_instructions.....	3248
mkl_set_env_mode.....	3249
mkl_verbose.....	3250

Chapter 15: BLACS Routines

Matrix Shapes.....	3253
Repeatability and Coherence.....	3254
BLACS Combine Operations.....	3257
?gamx2d.....	3258
?gamm2d.....	3259
?gsum2d.....	3261
BLACS Point To Point Communication.....	3262
?gesd2d.....	3264
?trsd2d.....	3264
?gerv2d.....	3265
?trrv2d.....	3266
BLACS Broadcast Routines.....	3266
?gebs2d.....	3268
?trbs2d.....	3268
?gebr2d.....	3269
?trbr2d.....	3270
BLACS Support Routines.....	3271
Initialization Routines.....	3271
blacs_pinfo.....	3271
blacs_setup.....	3272
blacs_get.....	3272
blacs_set.....	3273
blacs_gridinit.....	3275
blacs_gridmap.....	3276

Destruction Routines.....	3277
blacs_freebuff.....	3278
blacs_gridexit.....	3278
blacs_abort.....	3278
blacs_exit.....	3279
Informational Routines.....	3279
blacs_gridinfo.....	3280
blacs_pnum.....	3280
blacs_pcoord.....	3280
Miscellaneous Routines.....	3281
blacs_barrier.....	3281
Examples of BLACS Routines Usage.....	3282

Chapter 16: Data Fitting Functions

Naming Conventions.....	3293
Data Types.....	3294
Mathematical Conventions for Data Fitting Functions.....	3294
Data Fitting Usage Model.....	3297
Data Fitting Usage Examples.....	3297
Task Status and Error Reporting.....	3303
Task Creation and Initialization Routines.....	3305
df?newtask1d.....	3305
Task Configuration Routines.....	3307
df?editppspline1d.....	3308
df?editptr.....	3315
dfieditval.....	3316
df?editidxptr.....	3318
df?queryptr.....	3320
dfiqueryval.....	3321
df?queryidxptr.....	3322
Computational Routines.....	3323
df?construct1d.....	3324
df?interpolate1d/df?interpolateex1d.....	3325
df?integrate1d/df?integrateex1d.....	3332
df?searchcells1d/df?searchcellsex1d.....	3337
df?interpcallback.....	3340
df?integrcallback.....	3341
df?searchcellscallback.....	3343
Task Destructors.....	3345
dfdeletetask.....	3345

Appendix A: Linear Solvers Basics

Sparse Linear Systems.....	3347
Matrix Fundamentals.....	3347
Direct Method.....	3348
Sparse Matrix Storage Formats.....	3352

Appendix B: Routine and Function Arguments

Vector Arguments in BLAS.....	3365
Vector Arguments in VML.....	3366
Matrix Arguments.....	3366

Appendix C: Specific Features of Fortran 95 Interfaces for LAPACK Routines

Interfaces Identical to Netlib.....	3373
Interfaces with Replaced Argument Names.....	3374
Modified Netlib Interfaces.....	3376
Interfaces Absent From Netlib.....	3377
Interfaces of New Functionality.....	3380

Appendix D: FFTW Interface to Intel® Math Kernel Library

Introducing the Intel® Math Kernel Library

The Intel® Math Kernel Library (Intel® MKL) improves performance with math routines for software applications that solve large computational problems. Intel MKL provides BLAS and LAPACK linear algebra routines, fast Fourier transforms, vectorized math functions, random number generation functions, and other functionality.

Intel MKL is optimized for the latest Intel processors, including processors with multiple cores (see the *Intel MKL Release Notes* for the full list of supported processors). Intel MKL also performs well on non-Intel processors.

For more details about functionality provided by Intel MKL, see the [Function Domains](#) section.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Getting Help and Support

Intel MKL provides a product web site that offers timely and comprehensive product information, including product features, white papers, and technical articles. For the latest information, check: <http://www.intel.com/software/products/support>.

Intel also provides a support web site that contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more (visit <http://www.intel.com/software/products/>).

Registering your product entitles you to one year of technical support and product updates through Intel® Premier Support. Intel Premier Support is an interactive issue management and communication web site providing these services:

- Submit issues and review their status.
- Download product updates anytime of the day.

To register your product, contact Intel, or seek product support, please visit <http://www.intel.com/software/products/support>.

What's New

This Reference Manual documents Intel® Math Kernel Library (Intel® MKL) 11.2 update 2 release.

The manual has been updated to reflect enhancements to the product, and minor improvements have been made.

Additionally, minor updates have been made to correct errors in the manual.

Notational Conventions

This manual uses the following terms to refer to operating systems:

Windows* OS	This term refers to information that is valid on all supported Windows* operating systems.
Linux* OS	This term refers to information that is valid on all supported Linux* operating systems.
OS X*	This term refers to information that is valid on Intel®-based systems running the OS X* operating system.

This manual uses the following notational conventions:

- Routine name shorthand (for example, `?ungqr` instead of `cungqr/zungqr`).
- Font conventions used for distinction between the text and the code.

Routine Name Shorthand

For shorthand, names that contain a question mark "?" represent groups of routines with similar functionality. Each group typically consists of routines used with four basic data types: single-precision real, double-precision real, single-precision complex, and double-precision complex. The question mark is used to indicate any or all possible varieties of a function; for example:

`?swap` Refers to all four data types of the vector-vector `?swap` routine:
`sswap`, `dswap`, `cswap`, and `zswap`.

Font Conventions

The following font conventions are used:

UPPERCASE COURIER	Data type used in the description of input and output parameters for Fortran interface. For example, <code>CHARACTER*1</code> .
lowercase courier	Code examples: <code>a(k+i,j) = matrix(i,j)</code> and data types for C interface, for example, <code>const float*</code>
lowercase courier mixed with uppercase courier	Function names for C interface; for example, <code>vmlSetMode</code>
lowercase courier italic	Variables in arguments and parameters description. For example, <code>incx</code> .
*	Used as a multiplication symbol in code examples and equations and where required by the programming language syntax.

Function Domains

The Intel® Math Kernel Library includes Fortran routines and functions optimized for Intel® processor-based computers running operating systems that support multiprocessing. In addition to the Fortran interface, Intel MKL includes a C-language interface for the Discrete Fourier transform functions, as well as for the Vector Mathematical Library and Vector Statistical Library functions. For hardware and software requirements to use Intel MKL, see *Intel® MKL Release Notes*.

The Intel® Math Kernel Library includes the following groups of routines:

- Basic Linear Algebra Subprograms (BLAS):
 - vector operations
 - matrix-vector operations
 - matrix-matrix operations
- Sparse BLAS Level 1, 2, and 3 (basic operations on sparse vectors and matrices)
- LAPACK routines for solving systems of linear equations
- LAPACK routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations
- Auxiliary, utility, and test LAPACK routines
- ScaLAPACK computational, driver and auxiliary routines (only in Intel MKL for Linux* and Windows* operating systems)
- PBLAS routines for distributed vector, matrix-vector, and matrix-matrix operation
- Direct and Iterative Sparse Solver routines, including a solver based on the PARDISO* sparse solver and the Intel MKL Parallel Direct Sparse Solver for Clusters
- Direct Sparse Solver (DSS)
- Extended Eigensolver routines for solving symmetric standard or generalized symmetric definite eigenvalue problems using the Feast algorithm
- Vector Mathematical Library (VML) functions for computing core mathematical functions on vector arguments (with Fortran and C interfaces)
- Vector Statistical Library (VSL) functions for generating vectors of pseudorandom numbers with different types of statistical distributions and for performing convolution and correlation computations
- General Fast Fourier Transform (FFT) Functions, providing fast computation of Discrete Fourier Transform via the FFT algorithms and having Fortran and C interfaces
- Cluster FFT functions (only in Intel MKL for Linux* and Windows* operating systems)
- Tools for solving partial differential equations - trigonometric transform routines and Poisson solver
- Optimization Solver routines for solving nonlinear least squares problems through the Trust-Region (TR) algorithms and computing Jacobi matrix by central differences
- Basic Linear Algebra Communication Subprograms (BLACS) that are used to support a linear algebra oriented message passing interface
- Data Fitting functions for spline-based approximation of functions, derivatives and integrals of functions, and search

For specific issues on using the library, also see the *Intel® MKL Release Notes*.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

BLAS Routines

The BLAS routines and functions are divided into the following groups according to the operations they perform:

- [BLAS Level 1 Routines](#) perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- [BLAS Level 2 Routines](#) perform matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- [BLAS Level 3 Routines](#) perform matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Starting from release 8.0, Intel® MKL also supports the Fortran 95 interface to the BLAS routines.

Starting from release 10.1, a number of [BLAS-like Extensions](#) are added to enable the user to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations.

Sparse BLAS Routines

The [Sparse BLAS Level 1 Routines and Functions](#) and [Sparse BLAS Level 2 and Level 3 Routines](#) routines and functions operate on sparse vectors and matrices. These routines perform vector operations similar to the BLAS Level 1, 2, and 3 routines. The Sparse BLAS routines take advantage of vector and matrix sparsity: they allow you to store only non-zero elements of vectors and matrices. Intel MKL also supports Fortran 95 interface to Sparse BLAS routines.

LAPACK Routines

The Intel® Math Kernel Library fully supports LAPACK 3.5 set of computational, driver, auxiliary and utility routines.

The original versions of LAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/lapack/index.html>. The authors of LAPACK are E. Anderson, Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen.

The LAPACK routines can be divided into the following groups according to the operations they perform:

- Routines for solving systems of linear equations, factoring and inverting matrices, and estimating condition numbers (see [LAPACK Routines: Linear Equations](#)).
- Routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations (see [LAPACK Routines: Least Squares and Eigenvalue Problems](#)).
- Auxiliary and utility routines used to perform certain subtasks, common low-level computation or related tasks (see [LAPACK Auxiliary Routines](#) and [LAPACK Utility Functions and Routines](#)).

Starting from release 8.0, Intel MKL also supports the Fortran 95 interface to LAPACK computational and driver routines. This interface provides an opportunity for simplified calls of LAPACK routines with fewer required arguments.

ScaLAPACK Routines

The ScaLAPACK package (included only with the Intel® MKL versions for Linux* and Windows* operating systems, see [Chapter 6](#) and [Chapter 7](#)) runs on distributed-memory architectures and includes routines for solving systems of linear equations, solving linear least squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

The original versions of ScaLAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/scalapack/index.html>. The authors of ScaLAPACK are L. Blackford, J. Choi, A. Cleary, E. D'Azevedo, J. Demmel, I. Dhillon, J. Dongarra, S. Hammarling, G. Henry, A. Petitet, K. Stanley, D. Walker, and R. Whaley.

The Intel MKL version of ScaLAPACK is optimized for Intel® processors and uses MPICH version of MPI as well as Intel MPI.

PBLAS Routines

The PBLAS routines perform operations with distributed vectors and matrices.

- [PBLAS Level 1 Routines](#) perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- [PBLAS Level 2 Routines](#) perform distributed matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- [PBLAS Level 3 Routines](#) perform distributed matrix-matrix operations, such as matrix-matrix multiplication, rank- k update, and solution of triangular systems.

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (part of the ScaLAPACK package, see http://www.netlib.org/scalapack/html/pblas_qref.html).

Sparse Solver Routines

Direct sparse solver routines in Intel MKL (see [Chapter 8](#)) solve symmetric and symmetrically-structured sparse matrices with real or complex coefficients. For symmetric matrices, these Intel MKL subroutines can solve both positive-definite and indefinite systems. Intel MKL includes a solver based on the PARDISO* sparse solver, referred to as Intel MKL PARDISO, as well as an alternative set of user callable direct sparse solver routines.

If you use the Intel MKL PARDISO sparse solver, please cite:

O.Schenk and K.Gartner. Solving unsymmetric sparse systems of linear equations with PARDISO. *J. of Future Generation Computer Systems*, 20(3):475-487, 2004.

Intel MKL provides also an iterative sparse solver (see [Chapter 8](#)) that uses Sparse BLAS level 2 and 3 routines and works with different sparse data formats.

Extended Eigensolver Routines

The [Extended Eigensolver functionality](#) is a set of high-performance numerical routines for solving standard ($Ax = \lambda x$) and generalized ($Ax = \lambda Bx$) eigenvalue problems, where A and B are symmetric or Hermitian. It yields all the eigenvalues and eigenvectors within a given search interval. It is based on the Feast algorithm, an innovative fast and stable numerical algorithm presented in [\[Polizzi09\]](#), which deviates fundamentally from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [\[Bai00\]](#)) or other Davidson-Jacobi techniques [\[Sleijpen96\]](#). The Feast algorithm is inspired by the density-matrix representation and contour integration technique in quantum mechanics.

It is free from orthogonalization procedures. Its main computational tasks consist of solving very few inner independent linear systems with multiple right-hand sides and one reduced eigenvalue problem orders of magnitude smaller than the original one. The Feast algorithm combines simplicity and efficiency and offers many important capabilities for achieving high performance, robustness, accuracy, and scalability on parallel architectures. This algorithm is expected to significantly augment numerical performance in large-scale modern applications.

Some of the characteristics of the Feast algorithm [\[Polizzi09\]](#) are:

- Converges quickly in 2-3 iterations with very high accuracy
- Naturally captures all eigenvalue multiplicities
- No explicit orthogonalization procedure
- Can reuse the basis of pre-computed subspace as suitable initial guess for performing outer-refinement iterations

This capability can also be used for solving a series of eigenvalue problems that are close one another.

- The number of internal iterations is independent of the size of the system and the number of eigenpairs in the search interval
- The inner linear systems can be solved either iteratively (even with modest relative residual error) or directly

VML Functions

The Vector Mathematical Library (VML) functions (see [Chapter 9](#)) include a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic, etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VML include nonlinear programming software, integrals computation, and many others. VML provides interfaces both for Fortran and C languages.

Statistical Functions

The Vector Statistical Library (VSL) contains three sets of functions (see [Chapter 10](#)) providing:

- Pseudorandom, quasi-random, and non-deterministic random number generator subroutines implementing basic continuous and discrete distributions. To provide best performance, the VSL subroutines use calls to highly optimized Basic Random Number Generators (BRNGs) and a library of vector mathematical functions.
- A wide variety of convolution and correlation operations.
- Initial statistical analysis of raw single and double precision multi-dimensional datasets.

Fourier Transform Functions

The Intel® MKL multidimensional Fast Fourier Transform (FFT) functions with mixed radix support (see [Chapter 11](#)) provide uniformity of discrete Fourier transform computation and combine functionality with ease of use. Both Fortran and C interface specification are given. There is also a cluster version of FFT functions, which runs on distributed-memory architectures and is provided only in Intel MKL versions for the Linux* and Windows* operating systems.

The FFT functions provide fast computation via the FFT algorithms for arbitrary lengths. See the *Intel® MKL User's Guide* for the specific radices supported.

Partial Differential Equations Support

Intel® MKL provides tools for solving Partial Differential Equations (PDE) (see [Chapter 13](#)). These tools are Trigonometric Transform interface routines and Poisson Solver.

The Trigonometric Transform routines may be helpful to users who implement their own solvers similar to the Intel MKL Poisson Solver. The users can improve performance of their solvers by using fast sine, cosine, and staggered cosine transforms implemented in the Trigonometric Transform interface.

The Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The Trigonometric Transform interface, which underlies the solver, is based on the Intel MKL FFT interface (refer to [Chapter 11](#)), optimized for Intel® processors.

Nonlinear Optimization Problem Solvers

Intel® MKL provides Nonlinear Optimization Problem Solver routines (see [Chapter 14](#)) that can be used to solve nonlinear least squares problems with or without linear (bound) constraints through the Trust-Region (TR) algorithms and compute Jacobi matrix by central differences.

Support Functions

The Intel® MKL support functions (see [Chapter 15](#)) are used to support the operation of the Intel MKL software and provide basic information on the library and library operation, such as the current library version, timing, setting and measuring of CPU frequency, error handling, and memory allocation.

Starting from release 10.0, the Intel MKL support functions provide additional threading control.

Starting from release 10.1, Intel MKL selectively supports a *Progress Routine* feature to track progress of a lengthy computation and/or interrupt the computation using a callback function mechanism. The user application can define a function called `mkl_progress` that is regularly called from the Intel MKL routine supporting the progress routine feature. See [the Progress Routines](#) section in [Chapter 15](#) for reference. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

BLACS Routines

The Intel® Math Kernel Library implements routines from the BLACS (Basic Linear Algebra Communication Subprograms) package (see [Chapter 16](#)) that are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The original versions of BLACS from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/blacs/index.html>. The authors of BLACS are Jack Dongarra and R. Clint Whaley.

Data Fitting Functions

The Data Fitting component includes a set of highly-optimized implementations of algorithms for the following spline-based computations:

- spline construction
- interpolation including computation of derivatives and integration
- search

The algorithms operate on single and double vector-valued functions set in the points of the given partition. You can use Data Fitting algorithms in applications that are based on data approximation. See [Data Fitting Functions](#) for more information.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Performance Enhancements

The Intel® Math Kernel Library has been optimized by exploiting both processor and system features and capabilities. Special care has been given to those routines that most profit from cache-management techniques. These especially include matrix-matrix operation routines such as `dgemm()`.

In addition, code optimization techniques have been applied to minimize dependencies of scheduling integer and floating-point units on the results within the processor.

The major optimization techniques used throughout the library include:

- Loop unrolling to minimize loop management costs

- Blocking of data to improve data reuse opportunities
- Copying to reduce chances of data eviction from cache
- Data prefetching to help hide memory latency
- Multiple simultaneous operations (for example, dot products in `dgemm`) to eliminate stalls due to arithmetic unit pipelines
- Use of hardware features such as the SIMD arithmetic units, where appropriate

These are techniques from which the arithmetic code benefits the most.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Parallelism

In addition to the performance enhancements discussed above, Intel® MKL offers performance gains through parallelism provided by the symmetric multiprocessing performance (SMP) feature. You can obtain improvements from SMP in the following ways:

- One way is based on user-managed threads in the program and further distribution of the operations over the threads based on data decomposition, domain decomposition, control decomposition, or some other parallelizing technique. Each thread can use any of the Intel MKL functions (except for the deprecated `?lacon` LAPACK routine) because the library has been designed to be thread-safe.
- Another method is to use the FFT and BLAS level 3 routines. They have been parallelized and require no alterations of your application to gain the performance enhancements of multiprocessing. Performance using multiple processors on the level 3 BLAS shows excellent scaling. Since the threads are called and managed within the library, the application does not need to be recompiled thread-safe (see also [Fortran 95 Interface Conventions](#) in Chapter 2).
- Yet another method is to use *tuned LAPACK routines*. Currently these include the single- and double precision flavors of routines for QR factorization of general matrices, triangular factorization of general and symmetric positive-definite matrices, solving systems of equations with such matrices, as well as solving symmetric eigenvalue problems.

For instructions on setting the number of available processors for the BLAS level 3 and LAPACK routines, see [Intel® MKL User's Guide](#).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

C Datatypes Specific to Intel MKL

The `mkl_types.h` file defines datatypes specific to Intel MKL.

C/C++ Type	Fortran Type	LP32 Equivalent (Size in Bytes)	LP64 Equivalent (Size in Bytes)	ILP64 Equivalent (Size in Bytes)
<code>MKL_INT</code> (MKL integer)	<code>INTEGER</code> (default <code>INTEGER</code>)	C/C++: <code>int</code> Fortran: <code>INTEGER*4</code> (4 bytes)	C/C++: <code>int</code> Fortran: <code>INTEGER*4</code> (4 bytes)	C/C++: <code>long long</code> (or define <code>MKL_ILP64</code> macros) Fortran: <code>INTEGER*8</code> (8 bytes)
<code>MKL_UINT</code> (MKL unsigned integer)	N/A	C/C++: <code>unsigned int</code> (4 bytes)	C/C++: <code>unsigned int</code> (4 bytes)	C/C++: <code>unsigned long long</code> (8 bytes)
<code>MKL_LONG</code> (MKL long integer)	N/A	C/C++: <code>long</code> (4 bytes)	C/C++: <code>long</code> (Windows: 4 bytes) (Linux, Mac: 8 bytes)	C/C++: <code>long</code> (8 bytes)
<code>MKL_Complex8</code> (Like C99 complex float)	<code>COMPLEX*8</code>	(8 bytes)	(8 bytes)	(8 bytes)
<code>MKL_Complex16</code> (Like C99 complex double)	<code>COMPLEX*16</code>	(16 bytes)	(16 bytes)	(16 bytes)

You can redefine datatypes specific to Intel MKL. One reason to do this is if you have your own types which are binary-compatible with Intel MKL datatypes, with the same representation or memory layout. To redefine a datatype, use one of these methods:

- Insert the `#define` statement redefining the datatype before the `mkl.h` header file `#include` statement. For example,

```
#define MKL_INT size_t
#include "mkl.h"
```

- Use the compiler `-D` option to redefine the datatype. For example,

```
...-DMKL_INT=size_t...
```

NOTE

As the user, if you redefine Intel MKL datatypes you are responsible for making sure that your definition is compatible with that of Intel MKL. If not, it might cause unpredictable results or crash the application.

BLAS and Sparse BLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the BLAS and Sparse BLAS routines, and BLAS-like extensions. The routine descriptions are arranged in several sections:

- [BLAS Level 1 Routines](#) (vector-vector operations)
- [BLAS Level 2 Routines](#) (matrix-vector operations)
- [BLAS Level 3 Routines](#) (matrix-matrix operations)
- [Sparse BLAS Level 1 Routines](#) (vector-vector operations).
- [Sparse BLAS Level 2 and Level 3 Routines](#) (matrix-vector and matrix-matrix operations)
- [BLAS-like Extensions](#)

Each section presents the routine and function group descriptions in alphabetical order by routine or function group name; for example, the `?asum` group, the `?axpy` group. The question mark in the group name corresponds to different character codes indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

When BLAS or Sparse BLAS routines encounter an error, they call the error reporting routine `xerbla`.

In BLAS Level 1 groups `i?amax` and `i?amin`, an "i" is placed before the data-type indicator and corresponds to the index of an element in the vector. These groups are placed in the end of the BLAS Level 1 section.

BLAS Routines

Routine Naming Conventions

BLAS routine names have the following structure:

`<character> <name> <mod> ()`

The `<character>` field indicates the data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `scasum` uses a complex input array and returns a real value.

The `<name>` field, in BLAS level 1, indicates the operation type. For example, the BLAS level 1 routines `?dot`, `?rot`, `?swap` compute a vector dot product, vector rotation, and vector swap, respectively.

In BLAS level 2 and 3, `<name>` reflects the matrix argument type:

<code>ge</code>	general matrix
<code>gb</code>	general band matrix
<code>sy</code>	symmetric matrix

sp	symmetric matrix (packed storage)
sb	symmetric band matrix
he	Hermitian matrix
hp	Hermitian matrix (packed storage)
hb	Hermitian band matrix
tr	triangular matrix
tp	triangular matrix (packed storage)
tb	triangular band matrix.

The $\langle mod \rangle$ field, if present, provides additional details of the operation. BLAS level 1 names can have the following characters in the $\langle mod \rangle$ field:

c	conjugated vector
u	unconjugated vector
g	Givens rotation construction
m	modified Givens rotation
mg	modified Givens rotation construction

BLAS level 2 names can have the following characters in the $\langle mod \rangle$ field:

mv	matrix-vector product
sv	solving a system of linear equations with a single unknown vector
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

BLAS level 3 names can have the following characters in the $\langle mod \rangle$ field:

mm	matrix-matrix product
sm	solving a system of linear equations with multiple unknown vectors
rk	rank- k update of a matrix
r2k	rank- $2k$ update of a matrix.

The examples below illustrate how to interpret BLAS routine names:

ddot	$\langle d \rangle \langle dot \rangle$: double-precision real vector-vector dot product
cdotc	$\langle c \rangle \langle dot \rangle \langle c \rangle$: complex vector-vector dot product, conjugated
scasum	$\langle sc \rangle \langle asum \rangle$: sum of magnitudes of vector elements, single precision real output and single precision complex input
cdotu	$\langle c \rangle \langle dot \rangle \langle u \rangle$: vector-vector dot product, unconjugated, complex
sgemv	$\langle s \rangle \langle ge \rangle \langle mv \rangle$: matrix-vector product, general matrix, single precision

ztrmm	<code><z> <tr> <mm></code> : matrix-matrix product, triangular matrix, double-precision complex.
-------	--

Sparse BLAS level 1 naming conventions are similar to those of BLAS level 1. For more information, see [Naming Conventions](#).

Fortran 95 Interface Conventions

Fortran 95 interface to BLAS and Sparse BLAS Level 1 routines is implemented through wrappers that call respective FORTRAN 77 routines. This interface uses such features of Fortran 95 as assumed-shape arrays and optional arguments to provide simplified calls to BLAS and Sparse BLAS Level 1 routines with fewer parameters.

NOTE

For BLAS, Intel MKL offers two types of Fortran 95 interfaces:

- using `mkl blas.fi` only through `include 'mkl.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
 - using `blas.f90` that includes improved interfaces. This file is used to generate the module files `blas95.mod` and `f95_precision.mod`. See also section "Fortran 95 interfaces and wrappers to LAPACK and BLAS" of *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the BLAS interface: `use blas95` and `use f95_precision`.
-

The main conventions used in Fortran 95 interface are as follows:

- The names of parameters used in Fortran 95 interface are typically the same as those used for the respective generic (FORTRAN 77) interface. In rare cases formal argument names may be different.
- Some input parameters such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.
- A parameter can be skipped if its value is completely defined by the presence or absence of another parameter in the calling sequence, and the restored value is the only meaningful value for the skipped parameter.
- Parameters specifying the increment values `incx` and `incy` are skipped. In most cases their values are equal to 1. In Fortran 95 an increment with different value can be directly established in the corresponding parameter.
- Some generic parameters are declared as optional in Fortran 95 interface and may or may not be present in the calling sequence. A parameter can be declared optional if it satisfies one of the following conditions:
 1. It can take only a few possible values. The default value of such parameter typically is the first value in the list; all exceptions to this rule are explicitly stated in the routine description.
 2. It has a natural default value.

Optional parameters are given in square brackets in Fortran 95 call syntax.

The particular rules used for reconstructing the values of omitted optional parameters are specific for each routine and are detailed in the respective "Fortran 95 Notes" subsection at the end of routine specification section. If this subsection is omitted, the Fortran 95 interface for the given routine does not differ from the corresponding FORTRAN 77 interface.

Note that this interface is not implemented in the current version of Sparse BLAS Level 2 and Level 3 routines.

C Interface Conventions

CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS), provides a C language interface to BLAS routines for Intel MKL. While you can call the Fortran implementation of BLAS, for coding in C the CBLAS interface has some advantages such as allowing you to specify column-major or row-major ordering with the `layout` parameter.

For more information about calling Fortran routines from C in general, and specifically about calling BLAS and CBLAS routines, see " Mixed-language Programming with the Intel Math Kernel Library" in the *Intel Math Kernel Library User's Guide*.

In CBLAS, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

WARNING

Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

NOTE

This interface is not implemented in the Sparse BLAS Level 2 and Level 3 routines.

The arguments of CBLAS functions comply with the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.
- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_LAYOUT` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_LAYOUT {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */

enum CBLAS_TRANSPOSE {
    CblasNoTrans=111, /* trans='N' */
    CblasTrans=112, /* trans='T' */
    CblasConjTrans=113}; /* trans='C' */

enum CBLAS_UPLO {
    CblasUpper=121, /* uplo ='U' */
    CblasLower=122}; /* uplo ='L' */

enum CBLAS_DIAG {
    CblasNonUnit=131, /* diag ='N' */
    CblasUnit=132}; /* diag ='U' */

enum CBLAS_SIDE {
    CblasLeft=141, /* side ='L' */
    CblasRight=142}; /* side ='R' */
```

Matrix Storage Schemes

Matrix arguments of BLAS routines can use the following storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: a band matrix is stored compactly in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

For more information on matrix storage schemes, see [Matrix Arguments](#) in Appendix B.

Row-Major and Column-Major Ordering

The BLAS routines follow the Fortran convention of storing two-dimensional arrays using column-major ordering. When calling BLAS routines from C, remember that they require arrays to be in column-major format, not the row-major format that is the convention for C.

The CBLAS interface allows you to specify either column-major or row-major ordering for BLAS Level 2 and Level 3 routines, by setting the `layout` parameter to `CblasColMajor` or `CblasRowMajor`.

BLAS Level 1 Routines and Functions

BLAS Level 1 includes routines and functions, which perform vector-vector operations. [Table “BLAS Level 1 Routine Groups and Their Data Types”](#) lists the BLAS Level 1 routine and function groups and the data types associated with them.

BLAS Level 1 Routine and Function Groups and Their Data Types

Routine or Function Group	Data Types	Description
?asum	s, d, sc, dz	Sum of vector magnitudes (functions)
?axpy	s, d, c, z	Scalar-vector product (routines)
?copy	s, d, c, z	Copy vector (routines)
?dot	s, d	Dot product (functions)
?sdot	sd, d	Dot product with double precision (functions)
?dotc	c, z	Dot product conjugated (functions)
?dotu	c, z	Dot product unconjugated (functions)
?nrm2	s, d, sc, dz	Vector 2-norm (Euclidean norm) (functions)
?rot	s, d, cs, zd	Plane rotation of points (routines)
?rotg	s, d, c, z	Generate Givens rotation of points (routines)
?rotm	s, d	Modified Givens plane rotation of points (routines)
?rotmg	s, d	Generate modified Givens plane rotation of points (routines)
?scal	s, d, c, z, cs, zd	Vector-scalar product (routines)
?swap	s, d, c, z	Vector-vector swap (routines)
i?amax	s, d, c, z	Index of the maximum absolute value element of a vector (functions)
i?amin	s, d, c, z	Index of the minimum absolute value element of a vector (functions)

Routine or Function Group	Data Types	Description
?cabs1	s, d	Auxiliary functions, compute the absolute value of a complex number of single or double precision

?asum

Computes the sum of magnitudes of the vector elements.

Syntax

FORTRAN 77:

```
res = sasum(n, x, incx)
res = scasum(n, x, incx)
res = dasum(n, x, incx)
res = dzasum(n, x, incx)
```

Fortran 95:

```
res = asum(x)
```

C:

```
float cblas_sasum (const MKL_INT n, const float *x, const MKL_INT incx);
float cblas_scasum (const MKL_INT n, const void *x, const MKL_INT incx);
double cblas_dasum (const MKL_INT n, const double *x, const MKL_INT incx);
double cblas_dzasum (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?asum routine computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

```
res = |Re x1| + |Im x1| + |Re x2| + |Im x2| + ... + |Re xn| + |Im xn|,
```

where x is a vector with n elements.

Input Parameters

n	INTEGER. Specifies the number of elements in vector x.
x	REAL for sasum DOUBLE PRECISION for dasum COMPLEX for scasum DOUBLE COMPLEX for dzasum

Array, size at least $(1 + (n-1) * \text{abs}(incx))$.

incx INTEGER. Specifies the increment for indexing vector *x*.

Output Parameters

<i>res</i>	REAL for sasum
	DOUBLE PRECISION for dasum
	REAL for scasum
	DOUBLE PRECISION for dzasum
	Contains the sum of magnitudes of real and imaginary parts of all elements of the vector.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `asum` interface are the following:

<i>x</i>	Holds the array of size <i>n</i> .
----------	------------------------------------

?axpy

Computes a vector-scalar product and adds the result to a vector.

Syntax

FORTRAN 77:

```
call saxpy(n, a, x, incx, y, incy)
call daxpy(n, a, x, incx, y, incy)
call caxpy(n, a, x, incx, y, incy)
call zaxpy(n, a, x, incx, y, incy)
```

Fortran 95:

```
call axpy(x, y [, a])
```

C:

```
void cblas_saxpy (const MKL_INT n, const float a, const float *x, const MKL_INT incx,
float *y, const MKL_INT incy);
void cblas_daxpy (const MKL_INT n, const double a, const double *x, const MKL_INT incx,
double *y, const MKL_INT incy);
void cblas_caxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,
void *y, const MKL_INT incy);
void cblas_zaxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,
void *y, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?axpy routines perform a vector-vector operation defined as

```
y := a*x + y
```

where:

a is a scalar

x and *y* are vectors each with a number of elements that equals *n*.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>a</i>	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Specifies the scalar <i>a</i> .
<i>x</i>	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, size at least (1 + (n-1)*abs(incx)).
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, size at least (1 + (n-1)*abs(incy)).
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>y</i>	Contains the updated vector <i>y</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpy` interface are the following:

<code>x</code>	Holds the array of size n .
<code>y</code>	Holds the array of size n .
<code>a</code>	The default value is 1.

?copy

Copies vector to another vector.

Syntax

FORTRAN 77:

```
call scopy(n, x, incx, y, incy)
call dcopy(n, x, incx, y, incy)
call ccopy(n, x, incx, y, incy)
call zcopy(n, x, incx, y, incy)
```

Fortran 95:

```
call copy(x, y)
```

C:

```
void cblas_scopy (const MKL_INT n, const float *x, const MKL_INT incx, float *y, const
MKL_INT incy);
void cblas_dcopy (const MKL_INT n, const double *x, const MKL_INT incx, double *y,
const MKL_INT incy);
void cblas_ccopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const
MKL_INT incy);
void cblas_zcopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const
MKL_INT incy);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The `?copy` routines perform a vector-vector operation defined as

```
y = x,
```

where x and y are vectors.

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in vectors x and y .
<code>x</code>	REAL for <code>scopy</code> DOUBLE PRECISION for <code>dcopy</code>

COMPLEX for `ccopy`
 DOUBLE COMPLEX for `zcopy`
 Array, size at least $(1 + (n-1) * \text{abs}(incx))$.

incx INTEGER. Specifies the increment for the elements of *x*.

y REAL for `scopy`
 DOUBLE PRECISION for `dcopy`
 COMPLEX for `ccopy`
 DOUBLE COMPLEX for `zcopy`
 Array, size at least $(1 + (n-1) * \text{abs}(incy))$.

incy INTEGER. Specifies the increment for the elements of *y*.

Output Parameters

y Contains a copy of the vector *x* if *n* is positive. Otherwise, parameters are unaltered.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `copy` interface are the following:

x Holds the vector with the number of elements *n*.
y Holds the vector with the number of elements *n*.

?dot

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = sdot(n, x, incx, y, incy)
res = ddot(n, x, incx, y, incy)
```

Fortran 95:

```
res = dot(x, y)
```

C:

```
float cblas_sdot (const MKL_INT n, const float *x, const MKL_INT incx, const float *y,
const MKL_INT incy);

double cblas_ddot (const MKL_INT n, const double *x, const MKL_INT incx, const double
*y, const MKL_INT incy);
```

Include Files

- Fortran: `mkl.fi`

- Fortran 95: blas.f90
- C: mkl.h

Description

The ?dot routines perform a vector-vector reduction operation defined as

$$res = \sum_{i=1}^n x_i * y_i,$$

where x_i and y_i are elements of vectors x and y .

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors x and y .
<i>x</i>	REAL for sdot DOUBLE PRECISION for ddot Array, size at least $(1+(n-1)*abs(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of x .
<i>y</i>	REAL for sdot DOUBLE PRECISION for ddot Array, size at least $(1+(n-1)*abs(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of y .

Output Parameters

<i>res</i>	REAL for sdot DOUBLE PRECISION for ddot Contains the result of the dot product of x and y , if n is positive. Otherwise, <i>res</i> contains 0.
------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dot` interface are the following:

<i>x</i>	Holds the vector with the number of elements n .
<i>y</i>	Holds the vector with the number of elements n .

?sdot

Computes a vector-vector dot product with double precision.

Syntax

FORTRAN 77:

```
res = sdsdot(n, sb, sx, incx, sy, incy)
res = dsdot(n, sx, incx, sy, incy)
```

Fortran 95:

```
res = sdot(sx, sy)
res = sdot(sx, sy, sb)
```

C:

```
float cblas_sdsdot (const MKL_INT n, const float sb, const float *sx, const MKL_INT
incx, const float *sy, const MKL_INT incy);

double cblas_dsdot (const MKL_INT n, const float *sx, const MKL_INT incx, const float
*sy, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?sdot routines compute the inner product of two vectors with double precision. Both routines use double precision accumulation of the intermediate results, but the `sdsdot` routine outputs the final result in single precision, whereas the `dsdot` routine outputs the double precision result. The function `sdsdot` also adds scalar value `sb` to the inner product.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the input vectors <code>sx</code> and <code>sy</code> .
<i>sb</i>	REAL. Single precision scalar to be added to inner product (for the function <code>sdsdot</code> only).
<i>sx</i> , <i>sy</i>	REAL. Arrays, size at least $(1+(n-1)*\text{abs}(incx))$ and $(1+(n-1)*\text{abs}(incy))$, respectively. Contain the input single precision vectors.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <code>sx</code> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <code>sy</code> .

Output Parameters

<i>res</i>	REAL for <code>sdsdot</code> DOUBLE PRECISION for <code>dsdot</code> Contains the result of the dot product of <code>sx</code> and <code>sy</code> (with <code>sb</code> added for <code>sdsdot</code>), if <i>n</i> is positive. Otherwise, <i>res</i> contains <code>sb</code> for <code>sdsdot</code> and 0 for <code>dsdot</code> .
------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sdot` interface are the following:

<code>sx</code>	Holds the vector with the number of elements n .
<code>sy</code>	Holds the vector with the number of elements n .

NOTE

Note that scalar parameter `sb` is declared as a required parameter in Fortran 95 interface for the function `sdot` to distinguish between function flavors that output final result in different precision.

?dotc

Computes a dot product of a conjugated vector with another vector.

Syntax

FORTRAN 77:

```
res = cdotc(n, x, incx, y, incy)
res = zdotc(n, x, incx, y, incy)
```

Fortran 95:

```
res = dotc(x, y)
```

C:

```
void cblas_cdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void
*y, const MKL_INT incy, void *dotc);
void cblas_zdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void
*y, const MKL_INT incy, void *dotc);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The `?dotc` routines perform a vector-vector operation defined as:

$$res = \sum_{i=1}^n \text{conjg}(x_i) * y_i,$$

where x_i and y_i are elements of vectors x and y .

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in vectors x and y .
<code>x</code>	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code>
	Array, size at least $(1 + (n - 1) * \text{abs}(incx))$.

<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	COMPLEX for cdotc DOUBLE COMPLEX for zdotc Array, size at least $(1 + (n - 1) * \text{abs}(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>res</i>	COMPLEX for cdotc DOUBLE COMPLEX for zdotc Contains the result of the dot product of the conjugated <i>x</i> and unconjugated <i>y</i> , if <i>n</i> is positive. Otherwise, it contains 0.
------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotc` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .

?dotu

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = cdotu(n, x, incx, y, incy)
res = zdotu(n, x, incx, y, incy)
```

Fortran 95:

```
res = dotu(x, y)
```

C:

```
void cblas_cdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);
void cblas_zdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The `?dotu` routines perform a vector-vector reduction operation defined as

$$res = \sum_{i=1}^n x_i * y_i$$

where x_i and y_i are elements of complex vectors x and y .

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in vectors x and y .
<code>x</code>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Array, size at least $(1 + (n - 1) * \text{abs}(incx))$.
<code>incx</code>	INTEGER. Specifies the increment for the elements of x .
<code>y</code>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Array, size at least $(1 + (n - 1) * \text{abs}(incy))$.
<code>incy</code>	INTEGER. Specifies the increment for the elements of y .

Output Parameters

<code>res</code>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Contains the result of the dot product of x and y , if n is positive. Otherwise, it contains 0.
------------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotu` interface are the following:

<code>x</code>	Holds the vector with the number of elements n .
<code>y</code>	Holds the vector with the number of elements n .

?nrm2

Computes the Euclidean norm of a vector.

Syntax

FORTRAN 77:

```
res = snrm2(n, x, incx)
res = dnrm2(n, x, incx)
res = scnrm2(n, x, incx)
```

```
res = dznrm2(n, x, incx)
```

Fortran 95:

```
res = nrm2(x)
```

C:

```
float cblas_snrm2 (const MKL_INT n, const float *x, const MKL_INT incx);
double cblas_dnrm2 (const MKL_INT n, const double *x, const MKL_INT incx);
float cblas_scnrm2 (const MKL_INT n, const void *x, const MKL_INT incx);
double cblas_dznrm2 (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?nrm2 routines perform a vector reduction operation defined as

```
res = ||x||,
```

where:

x is a vector,

res is a value containing the Euclidean norm of the elements of *x*.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vector <i>x</i> .
<i>x</i>	REAL for snrm2 DOUBLE PRECISION for dnrm2 COMPLEX for scnrm2 DOUBLE COMPLEX for dznrm2 Array, size at least (1 + (n -1)*abs (incx)).
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

Output Parameters

<i>res</i>	REAL for snrm2 DOUBLE PRECISION for dnrm2 REAL for scnrm2 DOUBLE PRECISION for dznrm2 Contains the Euclidean norm of the vector <i>x</i> .
------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `nrm2` interface are the following:

`x` Holds the vector with the number of elements `n`.

?rot

Performs rotation of points in the plane.

Syntax

FORTRAN 77:

```
call srot(n, x, incx, y, incy, c, s)
call drot(n, x, incx, y, incy, c, s)
call csrot(n, x, incx, y, incy, c, s)
call zdrot(n, x, incx, y, incy, c, s)
```

Fortran 95:

```
call rot(x, y, c, s)
```

C:

```
void cblas_srot (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT incy, const float c, const float s);
void cblas_drot (const MKL_INT n, double *x, const MKL_INT incx, double *y, const MKL_INT incy, const double c, const double s);
void cblas_csrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy, const float c, const float s);
void cblas_zdrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy, const double c, const double s);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

Given two complex vectors x and y , each vector element of these vectors is replaced as follows:

$$x_i = c^*x_i + s^*y_i$$

$$y_i = c^*y_i - s^*x_i$$

Input Parameters

`n` INTEGER. Specifies the number of elements in vectors x and y .

`x` REAL for `srot`

DOUBLE PRECISION for `drot`

COMPLEX for `csrot`

DOUBLE COMPLEX for `zdrot`

Array, size at least $(1 + (n-1) * \text{abs}(incx))$.

<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	REAL for srot DOUBLE PRECISION for drot COMPLEX for csrot DOUBLE COMPLEX for zdrot Array, size at least $(1 + (n - 1) * \text{abs}(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .
<i>c</i>	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.
<i>s</i>	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.

Output Parameters

<i>x</i>	Each element is replaced by $c*x + s*y$.
<i>y</i>	Each element is replaced by $c*y - s*x$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rot` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .

?rotg

Computes the parameters for a Givens rotation.

Syntax

FORTRAN 77:

```
call srotg(a, b, c, s)
call drotg(a, b, c, s)
call crotg(a, b, c, s)
```

```
call zrotg(a, b, c, s)
```

Fortran 95:

```
call rotg(a, b, c, s)
```

C:

```
void cblas_srotg (float *a, float *b, float *c, float *s);
void cblas_drotg (double *a, double *b, double *c, double *s);
void cblas_crotg (void *a, const void *b, float *c, void *s);
void cblas_zrotg (void *a, const void *b, double *c, void *s);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

Given the Cartesian coordinates (a, b) of a point, these routines return the parameters c, s, r , and z associated with the Givens rotation. The parameters c and s define a unitary matrix such that:

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

The parameter z is defined such that if $|a| > |b|$, z is s ; otherwise if c is not 0 z is $1/c$; otherwise z is 1.

See a more accurate LAPACK version [?lartg](#).

Input Parameters

a REAL **for** srotg
 DOUBLE PRECISION **for** drotg
 COMPLEX **for** crotg
 DOUBLE COMPLEX **for** zrotg
 Provides the x-coordinate of the point p.

b REAL **for** srotg
 DOUBLE PRECISION **for** drotg
 COMPLEX **for** crotg
 DOUBLE COMPLEX **for** zrotg
 Provides the y-coordinate of the point p.

Output Parameters

a Contains the parameter r associated with the Givens rotation.
b Contains the parameter z associated with the Givens rotation.
c REAL **for** srotg

```

DOUBLE PRECISION for drotg
REAL for crotg
DOUBLE PRECISION for zrotg
Contains the parameter c associated with the Givens rotation.

s
REAL for srotg
DOUBLE PRECISION for drotg
COMPLEX for crotg
DOUBLE COMPLEX for zrotg
Contains the parameter s associated with the Givens rotation.
```

?rotm

Performs modified Givens rotation of points in the plane.

Syntax**FORTRAN 77:**

```
call srotm(n, x, incx, y, incy, param)
call drotm(n, x, incx, y, incy, param)
```

Fortran 95:

```
call rotm(x, y, param)
```

C:

```
void cblas_srotm (const MKL_INT n, float *x, const MKL_INT incx, float *y, const
MKL_INT incy, const float *param);
void cblas_drotm (const MKL_INT n, double *x, const MKL_INT incx, double *y, const
MKL_INT incy, const double *param);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

Given two vectors *x* and *y*, each vector element of these vectors is replaced as follows:

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = H \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

for *i*=1 to *n*, where *H* is a modified Givens transformation matrix whose values are stored in the *param*(2) through *param*(5) array. See discussion on the *param* argument.

Input Parameters

n INTEGER. Specifies the number of elements in vectors *x* and *y*.

x REAL for srotm

DOUBLE PRECISION for drotm

Array, size at least $(1 + (n - 1) * \text{abs}(incx))$.

incx INTEGER. Specifies the increment for the elements of *x*.

y REAL for srotm

DOUBLE PRECISION for drotm

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$.

incy INTEGER. Specifies the increment for the elements of *y*.

param REAL for srotm

DOUBLE PRECISION for drotm

Array, size 5.

The elements of the *param* array are:

param(1) contains a switch, *flag*. *param*(2-5) contain *h11*, *h21*, *h12*, and *h22*, respectively, the components of the array *H*.

Depending on the values of *flag*, the components of *H* are set as follows:

$$\text{flag} = -1. : H = \begin{bmatrix} h11 & h12 \\ h21 & h22 \end{bmatrix}$$

...i!!!!!! ...i!!! ...i!!!!!!

$$\text{flag} = 1. : H = \begin{bmatrix} h11 & 1. \\ -1 & h22 \end{bmatrix}$$

...i!!!!!! ...i!!! ...i!!!!!!

In the last three cases, the matrix entries of 1., -1., and 0. are assumed based on the value of *flag* and are not required to be set in the *param* vector.

Output Parameters

x Each element $x(i)$ is replaced by $h11*x(i) + h12*y(i)$.

y Each element $y(i)$ is replaced by $h21*x(i) + h22*y(i)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rotm` interface are the following:

x Holds the vector with the number of elements *n*.

y Holds the vector with the number of elements *n*.

?rotmg

Computes the parameters for a modified Givens rotation.

Syntax

FORTRAN 77:

```
call srotmg(d1, d2, x1, y1, param)
call drotmg(d1, d2, x1, y1, param)
```

Fortran 95:

```
call rotmg(d1, d2, x1, y1, param)
```

C:

```
void cblas_srotmg (float *d1, float *d2, float *x1, const float y1, float *param);
void cblas_drotmg (double *d1, double *d2, double *x1, const double y1, double *param);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

Given Cartesian coordinates $(x1, y1)$ of an input vector, these routines compute the components of a modified Givens transformation matrix H that zeros the y -component of the resulting vector:

$$\begin{bmatrix} x1 \\ 0 \end{bmatrix} = H \begin{bmatrix} x1\sqrt{d1} \\ y1\sqrt{d1} \end{bmatrix}$$

Input Parameters

<i>d1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the <i>x</i> -coordinate of the input vector.
<i>d2</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the <i>y</i> -coordinate of the input vector.
<i>x1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>x</i> -coordinate of the input vector.
<i>y1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>y</i> -coordinate of the input vector.

Output Parameters

<i>d1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the first diagonal element of the updated matrix.
<i>d2</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the second diagonal element of the updated matrix.
<i>x1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>x</i> -coordinate of the rotated vector before scaling.
<i>param</i>	REAL for srotmg DOUBLE PRECISION for drotmg Array, size 5. The elements of the <i>param</i> array are: <i>param</i> (1) contains a switch, <i>flag</i> . <i>param</i> (2–5) contain <i>h11</i> , <i>h21</i> , <i>h12</i> , and <i>h22</i> , respectively, the components of the array <i>H</i> . Depending on the values of <i>flag</i> , the components of <i>H</i> are set as follows:

$$\text{flag} = -1. : H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

[View Source](#) | [Download ZIP](#)

$$flag = 1. : H = \begin{bmatrix} h_{11} & 1. \\ -1 & h_{22} \end{bmatrix}$$

[View Source](#) | [Download ZIP](#)

In the last three cases, the matrix entries of 1., -1., and 0. are assumed based on the value of *flag* and are not required to be set in the *param* vector.

?scal

Computes the product of a vector by a scalar.

Syntax

FORTRAN 77:

```
call sscal(n, a, x, incx)
call dscal(n, a, x, incx)
call cscal(n, a, x, incx)
call zscal(n, a, x, incx)
call csscal(n, a, x, incx)
call zdscal(n, a, x, incx)
```

Fortran 95:

```
call scal(x, a)
```

C:

```
void cblas_sscal (const MKL_INT n, const float a, float *x, const MKL_INT incx);
void cblas_dscal (const MKL_INT n, const double a, double *x, const MKL_INT incx);
void cblas_cscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_zscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_csscal (const MKL_INT n, const float a, void *x, const MKL_INT incx);
void cblas_zdscal (const MKL_INT n, const double a, void *x, const MKL_INT incx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?scal routines perform a vector operation defined as

```
x = a*x
```

where:

a is a scalar, *x* is an *n*-element vector.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vector <i>x</i> .
<i>a</i>	REAL for sscal and csscal DOUBLE PRECISION for dscal and zdscal COMPLEX for cscal DOUBLE COMPLEX for zscal Specifies the scalar <i>a</i> .
<i>x</i>	REAL for sscal DOUBLE PRECISION for dscal COMPLEX for cscal and csscal DOUBLE COMPLEX for zscal and zdscal Array, size at least (1 + (n -1)*abs(<i>incx</i>)).
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

Output Parameters

<i>x</i>	Updated vector <i>x</i> .
----------	---------------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine scal interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
----------	---

?swap

Swaps a vector with another vector.

Syntax

FORTRAN 77:

```
call sswap(n, x, incx, y, incy)
call dswap(n, x, incx, y, incy)
call cswap(n, x, incx, y, incy)
call zswap(n, x, incx, y, incy)
```

Fortran 95:

```
call swap(x, y)
```

C:

```
void cblas_sswap (const MKL_INT n, float *x, const MKL_INT incx, float *y, const
MKL_INT incy);

void cblas_dswap (const MKL_INT n, double *x, const MKL_INT incx, double *y, const
MKL_INT incy);

void cblas_cswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT
incy);

void cblas_zswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT
incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

Given two vectors x and y , the ?swap routines return vectors y and x swapped, each replacing the other.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors x and y .
<i>x</i>	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap DOUBLE COMPLEX for zswap Array, size at least $(1 + (n-1) * \text{abs}(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of x .
<i>y</i>	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap DOUBLE COMPLEX for zswap Array, size at least $(1 + (n-1) * \text{abs}(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of y .

Output Parameters

<i>x</i>	Contains the resultant vector x , that is, the input vector y .
<i>y</i>	Contains the resultant vector y , that is, the input vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `swap` interface are the following:

<code>x</code>	Holds the vector with the number of elements n .
<code>y</code>	Holds the vector with the number of elements n .

i?amax

Finds the index of the element with maximum absolute value.

Syntax

FORTRAN 77:

```
index = isamax(n, x, incx)
index = idamax(n, x, incx)
index = icamax(n, x, incx)
index = izamax(n, x, incx)
```

Fortran 95:

```
index = iamax(x)
```

C:

```
CBLAS_INDEX cblas_isamax (const MKL_INT n, const float *x, const MKL_INT incx);
CBLAS_INDEX cblas_idamax (const MKL_INT n, const double *x, const MKL_INT incx);
CBLAS_INDEX cblas_icamax (const MKL_INT n, const void *x, const MKL_INT incx);
CBLAS_INDEX cblas_izamax (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

Given a vector x , the `i?amax` functions return the position of the vector element $x(i)$ that has the largest absolute value for real flavors, or the largest sum $|\text{Re}(x(i))| + |\text{Im}(x(i))|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in vector x .
<code>x</code>	REAL for <code>isamax</code> DOUBLE PRECISION for <code>idamax</code> COMPLEX for <code>icamax</code> DOUBLE COMPLEX for <code>izamax</code> Array, size at least $(1+(n-1) * \text{abs}(incx))$.

incx INTEGER. Specifies the increment for the elements of *x*.

Output Parameters

index INTEGER. Contains the position of vector element that has the largest absolute value such that *x(index)* has the largest absolute value.

Fortran 95 Interface Notes

Functions and routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the function `iamax` interface are the following:

x Holds the vector with the number of elements *n*.

i?amin

Finds the index of the element with the smallest absolute value.

Syntax

FORTRAN 77:

```
index = isamin(n, x, incx)
index = idamin(n, x, incx)
index = icamin(n, x, incx)
index = izamin(n, x, incx)
```

Fortran 95:

```
index = iamin(x)
```

C:

```
CBLAS_INDEX cblas_isamin (const MKL_INT n, const float *x, const MKL_INT incx);
CBLAS_INDEX cblas_idamin (const MKL_INT n, const double *x, const MKL_INT incx);
CBLAS_INDEX cblas_icamin (const MKL_INT n, const void *x, const MKL_INT incx);
CBLAS_INDEX cblas_izamin (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

Given a vector *x*, the `i?amin` functions return the position of the vector element *x(i)* that has the smallest absolute value for real flavors, or the smallest sum $|\operatorname{Re}(x(i))| + |\operatorname{Im}(x(i))|$ for complex flavors.

If *n* is not positive, 0 is returned.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

Input Parameters

<i>n</i>	INTEGER. On entry, <i>n</i> specifies the number of elements in vector <i>x</i> .
<i>x</i>	REAL for <i>isamin</i> DOUBLE PRECISION for <i>idamin</i> COMPLEX for <i>icamin</i> DOUBLE COMPLEX for <i>izamin</i> Array, size at least $(1 + (n-1) * \text{abs}(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

Output Parameters

<i>index</i>	INTEGER. Indicates the position of vector element with the smallest absolute value such that <i>x(index)</i> has the smallest absolute value.
--------------	---

Fortran 95 Interface Notes

Functions and routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the function *iamin* interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
----------	---

?cabs1

Computes absolute value of complex number.

Syntax

FORTRAN 77:

```
res = scabs1(z)
res = dcabs1(z)
```

Fortran 95:

```
res = cabs1(z)
```

C:

```
float cblas_scabs1 (const void *z);
double cblas_dcabs1 (const void *z);
```

Include Files

- Fortran: mkl.fi

Description

The `?cabs1` is an auxiliary routine for a few BLAS Level 1 routines. This routine performs an operation defined as

```
res=|Re(z)|+|Im(z)|,
```

where z is a scalar, and res is a value containing the absolute value of a complex number z .

Input Parameters

z	COMPLEX scalar for <code>scabs1</code> .
	DOUBLE COMPLEX scalar for <code>dcabs1</code> .

Output Parameters

res	REAL for <code>scabs1</code> .
	DOUBLE PRECISION for <code>dcabs1</code> .
	Contains the absolute value of a complex number z .

BLAS Level 2 Routines

This section describes BLAS Level 2 routines, which perform matrix-vector operations. [Table “BLAS Level 2 Routine Groups and Their Data Types”](#) lists the BLAS Level 2 routine groups and the data types associated with them.

BLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
<code>?gbmv</code>	s, d, c, z	Matrix-vector product using a general band matrix
<code>?gemv</code>	s, d, c, z	Matrix-vector product using a general matrix
<code>?ger</code>	s, d	Rank-1 update of a general matrix
<code>?gerc</code>	c, z	Rank-1 update of a conjugated general matrix
<code>?geru</code>	c, z	Rank-1 update of a general matrix, unconjugated
<code>?hbmv</code>	c, z	Matrix-vector product using a Hermitian band matrix
<code>?hemv</code>	c, z	Matrix-vector product using a Hermitian matrix
<code>?her</code>	c, z	Rank-1 update of a Hermitian matrix
<code>?her2</code>	c, z	Rank-2 update of a Hermitian matrix
<code>?hpmv</code>	c, z	Matrix-vector product using a Hermitian packed matrix
<code>?hpr</code>	c, z	Rank-1 update of a Hermitian packed matrix
<code>?hpr2</code>	c, z	Rank-2 update of a Hermitian packed matrix
<code>?sbmv</code>	s, d	Matrix-vector product using symmetric band matrix
<code>?spmv</code>	s, d	Matrix-vector product using a symmetric packed matrix
<code>?spr</code>	s, d	Rank-1 update of a symmetric packed matrix
<code>?spr2</code>	s, d	Rank-2 update of a symmetric packed matrix
<code>?symv</code>	s, d	Matrix-vector product using a symmetric matrix

Routine Groups	Data Types	Description
?syr	s, d	Rank-1 update of a symmetric matrix
?syr2	s, d	Rank-2 update of a symmetric matrix
?tbtmv	s, d, c, z	Matrix-vector product using a triangular band matrix
?tbsv	s, d, c, z	Solution of a linear system of equations with a triangular band matrix
?tpmv	s, d, c, z	Matrix-vector product using a triangular packed matrix
?tpsv	s, d, c, z	Solution of a linear system of equations with a triangular packed matrix
?trmv	s, d, c, z	Matrix-vector product using a triangular matrix
?trs	s, d, c, z	Solution of a linear system of equations with a triangular matrix

?gbmv

Computes a matrix-vector product using a general band matrix

Syntax**FORTRAN 77:**

```
call sgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call dgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call cgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call zgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call gbm(a, x, y [,kl] [,m] [,alpha] [,beta] [,trans])
```

C:

```
void cblas_sgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);

void cblas_dgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);

- Fortran 95: blas.f90
- C: mkl.h

Description

The ?gbmv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

or

$$y := \alpha * A' * x + \beta * y,$$

or

$$y := \alpha * \text{conjg}(A') * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* band matrix, with *kl* sub-diagonals and *ku* super-diagonals.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>trans</i>	CHARACTER*1. Specifies the operation: If <i>trans</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>trans</i> = 'T' or 't', then $y := \alpha * A' * x + \beta * y$ If <i>trans</i> = 'C' or 'c', then $y := \alpha * \text{conjg}(A') * x + \beta * y$
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>kl</i>	INTEGER. Specifies the number of sub-diagonals of the matrix <i>A</i> . The value of <i>kl</i> must satisfy $0 \leq kl$.
<i>ku</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>ku</i> must satisfy $0 \leq ku$.
<i>alpha</i>	REAL for sgbmv DOUBLE PRECISION for dgbmv COMPLEX for cgbmv DOUBLE COMPLEX for zgbmv Specifies the scalar <i>alpha</i> .

a

```
REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
Array, size (lda, n).
```

Before entry, the leading $(k_l + k_u + 1)$ by *n* part of the array *a* must contain the matrix of coefficients. This matrix must be supplied column-by-column, with the leading diagonal of the matrix in row $(k_u + 1)$ of the array, the first super-diagonal starting at position 2 in row *k_u*, the first sub-diagonal starting at position 1 in row $(k_u + 2)$, and so on. Elements in the array *a* that do not correspond to elements in the band matrix (such as the top left *k_u* by *k_u* triangle) are not referenced.

The following program segment transfers a band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```
do 20, j = 1, n
      k = k_u + 1 - j
      do 10, i = max(1, j-k_u), min(m, j+k_l)
            a(k+i, j) = matrix(i,j)
10          continue
20          continue
```

lda INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k_l + k_u + 1)$.

x

```
REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
Array, size at least  $(1 + (n - 1) * \text{abs}(incx))$  when trans= 'N' or 'n', and at least  $(1 + (m - 1) * \text{abs}(incx))$  otherwise. Before entry, the array x must contain the vector x.
```

incx INTEGER. Specifies the increment for the elements of *x*. *incx* must not be zero.

beta

```
REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
Specifies the scalar beta. When beta is equal to zero, then y need not be set on input.
```

y

```
REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
```

Array, size at least $(1 + (m - 1) * \text{abs}(incy))$ when $\text{trans} = 'N'$ or ' n ' and at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry, the incremented array y must contain the vector y .

incy INTEGER. Specifies the increment for the elements of y .
The value of *incy* must not be zero.

Output Parameters

y Updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbmv` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(kl+ku+1, n)$. Contains a banded matrix $m*n$ with kl lower diagonal and ku upper diagonal.
<i>x</i>	Holds the vector with the number of elements <i>rx</i> , where $rx = n$ if $\text{trans} = 'N'$, $rx = m$ otherwise.
<i>y</i>	Holds the vector with the number of elements <i>ry</i> , where $ry = m$ if $\text{trans} = 'N'$, $ry = n$ otherwise.
<i>trans</i>	Must be ' N ', ' C ', or ' T '. The default value is ' N '.
<i>kl</i>	If omitted, assumed $kl = ku$, that is, the number of lower diagonals equals the number of the upper diagonals.
<i>ku</i>	Restored as $ku = lda - kl - 1$, where <i>lda</i> is the leading dimension of matrix <i>A</i> .
<i>m</i>	If omitted, assumed $m = n$, that is, a square matrix.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?gemv

Computes a matrix-vector product using a general matrix

Syntax

FORTRAN 77:

```
call sgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call dgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call cgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call zgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
```

```
call scgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call dzgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call gemv(a, x, y [,alpha] [,beta] [,trans])
```

C:

```

void cblas_sgmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);

void cblas_dgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);

void cblas_cgmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);

void cblas_zgmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);

```

Include Files

- Fortran: mkl.fi
 - Fortran 95: blas.f90
 - C: mkl.h

Description

The `?gemv` routines perform a matrix-vector operation defined as

$y := alpha * A * x + beta * y,$

or

$y := alpha * A' * x + beta * y,$

or

$y := \text{alpha}^* \text{conjg}(A')^* x + \text{beta}^* y,$

where:

alpha and *beta* are scalars,

x and y are vectors,

A is an m -by- n matrix.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

trans

CHARACTER*1. Specifies the operation:

if $trans = 'N'$ or $'n'$, then $y := alpha * A * x + beta * y$;

if $trans = 'T'$ or $'t'$, then $y := alpha * A' * x + beta * y$

if *trans*= 'C' or 'c', then *y* := *alpha* *conjg(*A*')**x* + *beta***y*.

m INTEGER. Specifies the number of rows of the matrix *A*. The value of *m* must be at least zero.

n INTEGER. Specifies the number of columns of the matrix *A*. The value of *n* must be at least zero.

alpha REAL **for** sgemv

DOUBLE PRECISION **for** dgemv

COMPLEX **for** cgemv, scgemv

DOUBLE COMPLEX **for** zgemv, dzgemv

Specifies the scalar *alpha*.

a REAL **for** sgemv, scgemv

DOUBLE PRECISION **for** dgemv, dzgemv

COMPLEX **for** cgemv

DOUBLE COMPLEX **for** zgemv

Array, size (*lda*, *n*). Before entry, the leading *m*-by-*n* part of the array *a* must contain the matrix of coefficients.

lda INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least max(1, *m*).

x REAL **for** sgemv

DOUBLE PRECISION **for** dgemv

COMPLEX **for** cgemv, scgemv

DOUBLE COMPLEX **for** zgemv, dzgemv

Array, size at least (1+(*n*-1)*abs(*incx*)) when *trans*= 'N' or 'n' and at least (1+(*m* - 1)*abs(*incx*)) otherwise. Before entry, the incremented array *x* must contain the vector *x*.

incx INTEGER. Specifies the increment for the elements of *x*.

The value of *incx* must not be zero.

beta REAL **for** sgemv

DOUBLE PRECISION **for** dgemv

COMPLEX **for** cgemv, scgemv

DOUBLE COMPLEX **for** zgemv, dzgemv

Specifies the scalar *beta*. When *beta* is set to zero, then *y* need not be set on input.

y REAL **for** sgemv

DOUBLE PRECISION **for** dgemv

COMPLEX **for** cgemv, scgemv

DOUBLE COMPLEX for zgemv, dzgemv
 Array, size at least $(1 + (m - 1) * \text{abs}(incy))$ when $\text{trans} = 'N'$ or ' n '
 and at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry with non-zero β , the incremented array y must contain the vector y .

$incy$ INTEGER. Specifies the increment for the elements of y .
 The value of $incy$ must not be zero.

Output Parameters

y Updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemv` interface are the following:

a	Holds the matrix A of size (m,n) .
x	Holds the vector with the number of elements rx where $rx = n$ if $\text{trans} = 'N'$, $rx = m$ otherwise.
y	Holds the vector with the number of elements ry where $ry = m$ if $\text{trans} = 'N'$, $ry = n$ otherwise.
$trans$	Must be ' N ', ' C ', or ' T '. The default value is ' N '.
$alpha$	The default value is 1.
$beta$	The default value is 0.

?ger

Performs a rank-1 update of a general matrix.

Syntax

FORTRAN 77:

```
call sger(m, n, alpha, x, incx, y, incy, a, lda)
call dger(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call ger(a, x, y [,alpha])
```

C:

```
void cblas_sger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const
float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy,
float *a, const MKL_INT lda);
```

```
void cblas_dger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const
double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT
incy, double *a, const MKL_INT lda);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?ger routines perform a matrix-vector operation defined as

```
A := alpha*x*y' + A,
```

where:

alpha is a scalar,
x is an *m*-element vector,
y is an *n*-element vector,
A is an *m*-by-*n* general matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sger DOUBLE PRECISION for dger Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for sger DOUBLE PRECISION for dger Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>m</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for sger DOUBLE PRECISION for dger Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

The value of *incy* must not be zero.

<i>a</i>	REAL for sger DOUBLE PRECISION for dger Array, size (<i>lda</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.

Output Parameters

<i>a</i>	Overwritten by the updated matrix.
----------	------------------------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ger* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>x</i>	Holds the vector with the number of elements <i>m</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>alpha</i>	The default value is 1.

?gerc

Performs a rank-1 update (conjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgerc(m, n, alpha, x, incx, y, incy, a, lda)
call zgerc(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call gerc(a, x, y [,alpha])
```

C:

```
void cblas_cgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
void cblas_zgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?gerc routines perform a matrix-vector operation defined as

```
A := alpha*x*conjg(y') + A,
```

where:

alpha is a scalar,
x is an *m*-element vector,
y is an *n*-element vector,
A is an *m*-by-*n* matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cgerc DOUBLE COMPLEX for zgerc Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cgerc DOUBLE COMPLEX for zgerc Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>m</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for cgerc DOUBLE COMPLEX for zgerc Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for cgerc

DOUBLE COMPLEX for zgerc

Array, size (*lda, n*).

Before entry, the leading m -by- n part of the array *a* must contain the matrix of coefficients.

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, m)$.

Output Parameters

a

Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gerc* interface are the following:

a

Holds the matrix *A* of size (*m,n*).

x

Holds the vector with the number of elements *m*.

y

Holds the vector with the number of elements *n*.

alpha

The default value is 1.

?geru

Performs a rank-1 update (unconjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgeru(m, n, alpha, x, incx, y, incy, a, lda)
call zgeru(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call geru(a, x, y [,alpha])
```

C:

```
void cblas_cgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
void cblas_zgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90

- C: mkl.h

Description

The ?geru routines perform a matrix-vector operation defined as

$$A := \alpha * x * y' + A,$$

where:

α is a scalar,
 x is an m -element vector,
 y is an n -element vector,
 A is an m -by- n matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>m</i>	INTEGER. Specifies the number of rows of the matrix A . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix A . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Specifies the scalar α .
<i>x</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the m -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the n -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Array, size (lda, n) .

Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.

Output Parameters

a Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geru` interface are the following:

a	Holds the matrix A of size (m,n) .
x	Holds the vector with the number of elements m .
y	Holds the vector with the number of elements n .
$alpha$	The default value is 1.

?hbmv

Computes a matrix-vector product using a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
call zhbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call hbmv(a, x, y [,uplo][,alpha] [,beta])
```

C:

```
void cblas_chbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x,
const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);

void cblas_zhbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x,
const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- C: `mkl.h`

Description

The `?hbmv` routines perform a matrix-vector operation defined as $y := \alpha A^*x + \beta y$,

where:

alpha and *beta* are scalars,
x and *y* are *n*-element vectors,
A is an *n*-by-*n* Hermitian band matrix, with *k* super-diagonals.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian band matrix <i>A</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$.
<i>alpha</i>	COMPLEX for chbmv DOUBLE COMPLEX for zhbmv Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for chbmv DOUBLE COMPLEX for zhbmv Array, size (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading $(k + 1)$ by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row <i>k</i> , and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced. The following program segment transfers the upper triangular part of a Hermitian band matrix from conventional full matrix storage (<i>matrix</i>) to band storage (<i>a</i>):

```

      do 20, j = 1, n
        m = k + 1 - j
        do 10, i = max( 1, j - k ), j
          a( m + i, j ) = matrix( i, j )
10      continue
20      continue

```

Before entry with *uplo* = 'L' or 'l', the leading $(k + 1)$ by *n* part of the array *a* must contain the lower triangular band part of the Hermitian matrix, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right *k* by *k* triangle of the array *a* is not referenced.

The following program segment transfers the lower triangular part of a Hermitian band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min( n, j + k )
        a( m + i, j ) = matrix( i, j )
10         continue
20         continue

```

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

lda INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k + 1)$.

x COMPLEX for chbmv

DOUBLE COMPLEX for zhbmv

Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array *x* must contain the vector *x*.

incx INTEGER. Specifies the increment for the elements of *x*.

The value of *incx* must not be zero.

beta COMPLEX for chbmv

DOUBLE COMPLEX for zhbmv

Specifies the scalar *beta*.

y COMPLEX for chbmv

DOUBLE COMPLEX for zhbmv

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array *y* must contain the vector *y*.

incy INTEGER. Specifies the increment for the elements of *y*.

The value of *incy* must not be zero.

Output Parameters

y Overwritten by the updated vector *y*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbmv* interface are the following:

a Holds the array *a* of size $(k+1,n)$.

x Holds the vector with the number of elements *n*.

y Holds the vector with the number of elements *n*.

<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?hemv

Computes a matrix-vector product using a Hermitian matrix.

Syntax

FORTRAN 77:

```
call chemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call zhemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call hemv(a, x, y [,uplo] [,alpha] [,beta])
```

C:

```
void cblas_chemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT
incx, const void *beta, void *y, const MKL_INT incy);

void cblas_zhemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT
incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?hemv routines perform a matrix-vector operation defined as

```
y := alpha*A*x + beta*y,
```

where:

alpha and *beta* are scalars,
x and *y* are *n*-element vectors,
A is an *n*-by-*n* Hermitian matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used.

If $uplo = 'L'$ or $'l'$, then the low triangular of the array a is used.

n INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.

α COMPLEX for chemv

DOUBLE COMPLEX for zhemv

Specifies the scalar α .

a COMPLEX for chemv

DOUBLE COMPLEX for zhemv

Array, size (lda, n) .

Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced. Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of a is not referenced.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.

x COMPLEX for chemv

DOUBLE COMPLEX for zhemv

Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .

$incx$ INTEGER. Specifies the increment for the elements of x .

The value of $incx$ must not be zero.

β COMPLEX for chemv

DOUBLE COMPLEX for zhemv

Specifies the scalar β . When β is supplied as zero then y need not be set on input.

y COMPLEX for chemv

DOUBLE COMPLEX for zhemv

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .

$incy$ INTEGER. Specifies the increment for the elements of y .

The value of $incy$ must not be zero.

Output Parameters

y Overwritten by the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hemv` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>x</code>	Holds the vector with the number of elements n .
<code>y</code>	Holds the vector with the number of elements n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>alpha</code>	The default value is 1.
<code>beta</code>	The default value is 0.

?her

Performs a rank-1 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher(uplo, n, alpha, x, incx, a, lda)
call zher(uplo, n, alpha, x, incx, a, lda)
```

Fortran 95:

```
call her(a, x [,uplo] [, alpha])
```

C:

```
void cblas_cher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
void cblas_zher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The `?her` routines perform a matrix-vector operation defined as

```
A := alpha*x*conjg(x') + A,
```

where:

`alpha` is a real scalar,

`x` is an n -element vector,

`A` is an n -by- n Hermitian matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for cher DOUBLE PRECISION for zher Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cher DOUBLE COMPLEX for zher Array, dimension at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>a</i>	COMPLEX for cher DOUBLE COMPLEX for zher Array, size (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero.
----------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>x</code>	Holds the vector with the number of elements n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>alpha</code>	The default value is 1.

?her2

Performs a rank-2 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher2(uplo, n, alpha, x, incx, y, incy, a, lda)
call zher2(uplo, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call her2(a, x, y [,uplo][,alpha])
```

C:

```
void cblas_cher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *a, const MKL_INT lda);

void cblas_zher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *a, const MKL_INT lda);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The `?her2` routines perform a matrix-vector operation defined as

$$A := \alpha *x*\text{conjg}(y') + \text{conjg}(\alpha)*y * \text{conjg}(x') + A,$$

where:

`alpha` is a scalar,

`x` and `y` are n -element vectors,

`A` is an n -by- n Hermitian matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cher2 DOUBLE COMPLEX for zher2 Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cher2 DOUBLE COMPLEX for zher2 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for cher2 DOUBLE COMPLEX for zher2 Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for cher2 DOUBLE COMPLEX for zher2 Array, size (lda, n) . Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

- a*
- With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.
- With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.
- The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2` interface are the following:

- | | |
|--------------|---|
| <i>a</i> | Holds the matrix <i>A</i> of size (<i>n,n</i>). |
| <i>x</i> | Holds the vector with the number of elements <i>n</i> . |
| <i>y</i> | Holds the vector with the number of elements <i>n</i> . |
| <i>uplo</i> | Must be 'U' or 'L'. The default value is 'U'. |
| <i>alpha</i> | The default value is 1. |

?hpmv

Computes a matrix-vector product using a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
call zhpmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
```

Fortran 95:

```
call hpmv(ap, x, y [,uplo][,alpha][,beta])
```

C:

```
void cblas_chpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void
*beta, void *y, const MKL_INT incy);

void cblas_zhpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void
*beta, void *y, const MKL_INT incy);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The ?hpmv routines perform a matrix-vector operation defined as

```
y := alpha*A*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Specifies the scalar <i>alpha</i> .
<i>ap</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Array, size at least ((<i>n</i> *(<i>n</i> + 1))/2). Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1, 2) and <i>a</i> (2, 2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2, 1) and <i>a</i> (3, 1) respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>x</i>	COMPLEX for chpmv DOUBLE PRECISION COMPLEX for zhpmv Array, size at least (1 + (<i>n</i> - 1)*abs(<i>incx</i>)). Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for chpmv

```
void cblas_zhpr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const void *x, const MKL_INT incx, void *ap);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?hpr routines perform a matrix-vector operation defined as

```
A := alpha*x*conjg(x') + A,
```

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for chpr DOUBLE PRECISION for zhpr Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for chpr DOUBLE COMPLEX for zhpr Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>ap</i>	COMPLEX for chpr DOUBLE COMPLEX for zhpr Array, size at least $((n * (n + 1)) / 2)$.

Before entry with $\text{uplo} = \text{'U'}$ or 'u' , the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $\text{ap}(1)$ contains $a(1, 1)$, $\text{ap}(2)$ and $\text{ap}(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on.

Before entry with $\text{uplo} = \text{'L'}$ or 'l' , the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $\text{ap}(1)$ contains $a(1, 1)$, $\text{ap}(2)$ and $\text{ap}(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

ap

With $\text{uplo} = \text{'U'}$ or 'u' , overwritten by the upper triangular part of the updated matrix.

With $\text{uplo} = \text{'L'}$ or 'l' , overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr` interface are the following:

ap

Holds the array ap of size $(n*(n+1)/2)$.

x

Holds the vector with the number of elements n .

uplo

Must be 'U' or 'L' . The default value is 'U' .

alpha

The default value is 1.

?hpr2

Performs a rank-2 update of a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpr2(uplo, n, alpha, x, incx, y, incy, ap)
call zhpr2(uplo, n, alpha, x, incx, y, incy, ap)
```

Fortran 95:

```
call hpr2(ap, x, y [,uplo][,alpha])
```

C:

```
void cblas_chpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *ap);
```

```
void cblas_zhpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *ap);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?hpr2 routines perform a matrix-vector operation defined as

```
A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A,
```

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for chpr2 DOUBLE COMPLEX for zhpr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for chpr2 DOUBLE COMPLEX for zhpr2 Array, dimension at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for chpr2 DOUBLE COMPLEX for zhpr2

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .

incy INTEGER. Specifies the increment for the elements of y .

The value of *incy* must not be zero.

ap COMPLEX for chpr2

DOUBLE COMPLEX for zhpr2

Array, size at least $((n * (n + 1)) / 2)$.

Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1, 1)$, *ap*(2) and *ap*(3) contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on.

Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1, 1)$, *ap*(2) and *ap*(3) contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.

With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements need be set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr2` interface are the following:

ap Holds the array *ap* of size $(n * (n + 1) / 2)$.

x Holds the vector with the number of elements *n*.

y Holds the vector with the number of elements *n*.

uplo Must be 'U' or 'L'. The default value is 'U'.

alpha The default value is 1.

?sbmv

Computes a matrix-vector product using a symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
call dsbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call sbmv(a, x, y [,uplo][,alpha] [,beta])
```

C:

```
void cblas_ssbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float *x,
const MKL_INT incx, const float beta, float *y, const MKL_INT incy);

void cblas_dsbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const double alpha, const double *a, const MKL_INT lda, const double
*x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?sbmv routines perform a matrix-vector operation defined as

$$y := \alpha A^* x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric band matrix, with *k* super-diagonals.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is used: if <i>uplo</i> = 'U' or 'u' - upper triangular part; if <i>uplo</i> = 'L' or 'l' - low triangular part.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$.
<i>alpha</i>	REAL for ssbmv DOUBLE PRECISION for dsbmv Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssbmv

DOUBLE PRECISION for dsbmv

Array, size (lda, n). Before entry with $uplo = 'U'$ or ' u ', the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array a is not referenced.

The following program segment transfers the upper triangular part of a symmetric band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```
do 20, j = 1, n
      m = k + 1 - j
      do 10, i = max( 1, j - k ), j
            a( m + i, j ) = matrix( i, j )
10          continue
20          continue
```

Before entry with $uplo = 'L'$ or ' l ', the leading $(k + 1)$ by n part of the array a must contain the lower triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array a is not referenced.

The following program segment transfers the lower triangular part of a symmetric band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```
do 20, j = 1, n
      m = 1 - j
      do 10, i = j, min( n, j + k )
            a( m + i, j ) = matrix( i, j )
10          continue
20          continue
```

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k + 1)$.

x

REAL for ssbmv

DOUBLE PRECISION for dsbmv

Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array *x* must contain the vector *x*.

incx

INTEGER. Specifies the increment for the elements of *x*.

The value of *incx* must not be zero.

beta

REAL for ssbmv

DOUBLE PRECISION for dsbmv

Specifies the scalar *beta*.

y

REAL for ssbmv

DOUBLE PRECISION for dsbmv

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the vector y .

$incy$ INTEGER. Specifies the increment for the elements of y .
The value of $incy$ must not be zero.

Output Parameters

y Overwritten by the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbmv` interface are the following:

a	Holds the array a of size $(k+1,n)$.
x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
$alpha$	The default value is 1.
$beta$	The default value is 0.

?spmv

Computes a matrix-vector product using a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
call dspmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
```

Fortran 95:

```
call spmv(ap, x, y [,uplo][,alpha] [,beta])
```

C:

```
void cblas_sspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *ap, const float *x, const MKL_INT incx, const float
beta, float *y, const MKL_INT incy);

void cblas_dspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *ap, const double *x, const MKL_INT incx, const double
beta, double *y, const MKL_INT incy);
```

Include Files

- Fortran: `mkl.fi`

- Fortran 95: blas.f90
- C: mkl.h

Description

The ?spmv routines perform a matrix-vector operation defined as

```
y := alpha*A*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sspmv DOUBLE PRECISION for dspmv Specifies the scalar <i>alpha</i> .
<i>ap</i>	REAL for sspmv DOUBLE PRECISION for dspmv Array, size at least ((n*(n + 1))/2). Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1,2) and <i>a</i> (2, 2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2,1) and <i>a</i> (3,1) respectively, and so on.
<i>x</i>	REAL for sspmv DOUBLE PRECISION for dspmv Array, size at least (1 + (n - 1)*abs(<i>incx</i>)). Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

The value of *incx* must not be zero.

<i>beta</i>	REAL for sspmv DOUBLE PRECISION for dspmv Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for sspmv DOUBLE PRECISION for dspmv Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spmv` interface are the following:

<i>ap</i>	Holds the array <i>ap</i> of size $(n*(n+1)/2)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?spr

Performs a rank-1 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr(uplo, n, alpha, x, incx, ap)
call dspr(uplo, n, alpha, x, incx, ap)
```

Fortran 95:

```
call spr(ap, x [,uplo] [, alpha])
```

C:

```
void cblas_sspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, float *ap);

void cblas_dspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, double *ap);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?spr routines perform a matrix-vector operation defined as

```
a := alpha*x*x' + A,
```

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sspr DOUBLE PRECISION for dspr Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for sspr DOUBLE PRECISION for dspr Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>ap</i>	REAL for sspr DOUBLE PRECISION for dspr

Before entry with `uplo = 'U'` or `'u'`, the array `ap` must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that `ap(1)` contains $a(1, 1)$, `ap(2)` and `ap(3)` contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on.

Before entry with `uplo = 'L'` or `'l'`, the array `ap` must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that `ap(1)` contains $a(1, 1)$, `ap(2)` and `ap(3)` contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

Output Parameters

`ap`

With `uplo = 'U'` or `'u'`, overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L'` or `'l'`, overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spr` interface are the following:

`ap` Holds the array `ap` of size $(n*(n+1)/2)$.

`x` Holds the vector with the number of elements n .

`uplo` Must be `'U'` or `'L'`. The default value is `'U'`.

`alpha` The default value is 1.

?spr2

Performs a rank-2 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr2(uplo, n, alpha, x, incx, y, incy, ap)
call dspr2(uplo, n, alpha, x, incx, y, incy, ap)
```

Fortran 95:

```
call spr2(ap, x, y [,uplo][,alpha])
```

C:

```
void cblas_sspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT
incy, float *ap);

void cblas.dspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT
incy, double *ap);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?spr2 routines perform a matrix-vector operation defined as

```
A := alpha*x*y' + alpha*y*x' + A,
```

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

ap REAL for sspr2
 DOUBLE PRECISION for dspr2

Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1, 1)$, *ap*(2) and *ap*(3) contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on.

Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1, 1)$, *ap*(2) and *ap*(3) contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spr2* interface are the following:

<i>ap</i>	Holds the array <i>ap</i> of size $(n*(n+1)/2)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?symv

Computes a matrix-vector product for a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call dsymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call symv(a, x, y [,uplo] [,alpha] [,beta])
```

C:

```
void cblas_ssymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx,
const float beta, float *y, const MKL_INT incy);
```

```
void cblas_dsymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx,
const double beta, double *y, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?symv routines perform a matrix-vector operation defined as

```
y := alpha*A*x + beta*y,
```

where:

alpha and *beta* are scalars,
x and *y* are *n*-element vectors,
A is an *n*-by-*n* symmetric matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for ssymv DOUBLE PRECISION for dsymv Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssymv DOUBLE PRECISION for dsymv Array, size (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least <code>max(1, n)</code> .
<i>x</i>	REAL for ssymv

DOUBLE PRECISION for `dsymv`
 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .

incx INTEGER. Specifies the increment for the elements of x .
 The value of *incx* must not be zero.

beta REAL for `ssymv`
 DOUBLE PRECISION for `dsymv`
 Specifies the scalar *beta*.
 When *beta* is supplied as zero, then y need not be set on input.

y REAL for `ssymv`
 DOUBLE PRECISION for `dsymv`
 Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .

incy INTEGER. Specifies the increment for the elements of y .
 The value of *incy* must not be zero.

Output Parameters

y Overwritten by the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `symv` interface are the following:

<i>a</i>	Holds the matrix A of size (n,n) .
<i>x</i>	Holds the vector with the number of elements n .
<i>y</i>	Holds the vector with the number of elements n .
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?syr

Performs a rank-1 update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr(uplo, n, alpha, x, incx, a, lda)
call dsyr(uplo, n, alpha, x, incx, a, lda)
```

Fortran 95:

```
call syr(a, x [,uplo] [, alpha])
```

C:

```
void cblas_ssyr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, float *a, const MKL_INT lda);
void cblas_dsy (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, double *a, const MKL_INT lda);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?syr routines perform a matrix-vector operation defined as

$$A := \alpha x x' + A,$$

where:

α is a real scalar,

x is an n -element vector,

A is an n -by- n symmetric matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for ssyr DOUBLE PRECISION for dsy Specifies the scalar α .
<i>x</i>	REAL for ssyr DOUBLE PRECISION for dsy Array, size at least $(1 + (n-1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the n -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>a</i>	REAL for ssyr

DOUBLE PRECISION for `dsyr`

Array, size (`lda, n`).

Before entry with `uplo = 'U'` or `'u'`, the leading n -by- n upper triangular part of the array `a` must contain the upper triangular part of the symmetric matrix A and the strictly lower triangular part of `a` is not referenced.

Before entry with `uplo = 'L'` or `'l'`, the leading n -by- n lower triangular part of the array `a` must contain the lower triangular part of the symmetric matrix A and the strictly upper triangular part of `a` is not referenced.

`lda`

INTEGER. Specifies the leading dimension of `a` as declared in the calling (sub)program. The value of `lda` must be at least `max(1, n)`.

Output Parameters

`a`

With `uplo = 'U'` or `'u'`, the upper triangular part of the array `a` is overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L'` or `'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syr` interface are the following:

`a` Holds the matrix A of size (n,n) .

`x` Holds the vector with the number of elements n .

`uplo` Must be `'U'` or `'L'`. The default value is `'U'`.

`alpha` The default value is 1.

?syr2

Performs a rank-2 update of symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr2(uplo, n, alpha, x, incx, y, incy, a, lda)
call dsyr2(uplo, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call syr2(a, x, y [,uplo] [,alpha])
```

C:

```
void cblas_ssyr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT
incy, float *a, const MKL_INT lda);
```

```
void cblas_dsy2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT incy,
double *a, const MKL_INT lda);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?syr2 routines perform a matrix-vector operation defined as

```
A := alpha*x*y' + alpha*y*x' + A,
```

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .

<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, size (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix.
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syr2* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n,n</i>).
<i>x</i>	Holds the vector <i>x</i> of length <i>n</i> .
<i>y</i>	Holds the vector <i>y</i> of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?tbmv

Computes a matrix-vector product using a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call dtbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call ctbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call ztbmv(uplo, trans, diag, n, k, a, lda, x, incx)
```

Fortran 95:

```
call tbmv(a, x [,uplo] [, trans] [,diag])
```

C:

```
void cblas_stbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?tbmv routines perform one of the matrix-vector operations defined as

$$x := A^*x, \text{ or } x := A'^*x, \text{ or } x := \text{conjg}(A')^*x,$$

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is an upper or lower triangular matrix: $uplo = 'U'$ or ' u ' if $uplo = 'L'$ or ' l ', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if $trans= 'N'$ or ' n ', then $x := A^*x$; if $trans= 'T'$ or ' t ', then $x := A'^*x$; if $trans= 'C'$ or ' c ', then $x := \text{conjg}(A')^*x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if $uplo = 'U'$ or ' u ' then the matrix is unit triangular;

if $\text{diag} = \text{'N'}$ or 'n' , then the matrix is not unit triangular.

n INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.

k INTEGER. On entry with $\text{uplo} = \text{'U'}$ or 'u' specifies the number of super-diagonals of the matrix A . On entry with $\text{uplo} = \text{'L'}$ or 'l' , k specifies the number of sub-diagonals of the matrix a .

The value of k must satisfy $0 \leq k$.

a REAL for stbmv

DOUBLE PRECISION for dtbmv

COMPLEX for ctbmv

DOUBLE COMPLEX for ztbmv

Array, size (lda, n) .

Before entry with $\text{uplo} = \text{'U'}$ or 'u' , the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array a is not referenced. The following program segment transfers an upper triangular band matrix from conventional full matrix storage (matrix) to band storage (a):

```
do 20, j = 1, n
      m = k + 1 - j
      do 10, i = max( 1, j - k ), j
            a( m + i, j ) = matrix( i, j )
10          continue
20          continue
```

Before entry with $\text{uplo} = \text{'L'}$ or 'l' , the leading $(k + 1)$ by n part of the array a must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array a is not referenced. The following program segment transfers a lower triangular band matrix from conventional full matrix storage (matrix) to band storage (a):

```
do 20, j = 1, n
      m = 1 - j
      do 10, i = j, min( n, j + k )
            a( m + i, j ) = matrix( i, j )
10          continue
20          continue
```

Note that when $\text{uplo} = \text{'U'}$ or 'u' , the elements of the array a corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $(k + 1)$.

x REAL for stbmv

DOUBLE PRECISION for dtbmv
 COMPLEX for ctbmv
 DOUBLE COMPLEX for ztbmv
 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .

$incx$ INTEGER. Specifies the increment for the elements of x .
 The value of $incx$ must not be zero.

Output Parameters

x Overwritten with the transformed vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbsv` interface are the following:

a	Holds the array a of size $(k+1,n)$.
x	Holds the vector with the number of elements n .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$trans$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$diag$	Must be 'N' or 'U'. The default value is 'N'.

?tbsv

Solves a system of linear equations whose coefficients are in a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call dtbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call ctbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call ztbsv(uplo, trans, diag, n, k, a, lda, x, incx)
```

Fortran 95:

```
call tbsv(a, x [,uplo] [, trans] [,diag])
```

C:

```
void cblas_stbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
float *a, const MKL_INT lda, float *x, const MKL_INT incx);
```

```

void cblas_dtbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
double *a, const MKL_INT lda, double *x, const MKL_INT incx);

CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
void *a, const MKL_INT lda, void *x, const MKL_INT incx);

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?tbsv routines solve one of the following systems of equations:

$$A*x = b, \text{ or } A'*x = b, \text{ or } \text{conjg}(A')*x = b,$$

where:

b and *x* are *n*-element vectors,

A is an *n*-by-*n* unit, or non-unit, upper or lower triangular band matrix, with (*k* + 1) diagonals.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is an upper or lower triangular matrix: if <i>uplo</i> = 'U' or 'u' the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A')*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.

k

INTEGER. On entry with *uplo* = 'U' or 'u', *k* specifies the number of super-diagonals of the matrix *A*. On entry with *uplo* = 'L' or 'l', *k* specifies the number of sub-diagonals of the matrix *A*.

The value of *k* must satisfy $0 \leq k$.

a

REAL for stbsv
 DOUBLE PRECISION for dtbsv
 COMPLEX for ctbsv
 DOUBLE COMPLEX for ztbsv

Array, size (*lda*, *n*).

Before entry with *uplo* = 'U' or 'u', the leading $(k + 1)$ by *n* part of the array *a* must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row *k*, and so on. The top left *k* by *k* triangle of the array *a* is not referenced.

The following program segment transfers an upper triangular band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```
do 20, j = 1, n
      m = k + 1 - j
      do 10, i = max( 1, j - k ), j
            a( m + i, j ) = matrix( i, j )
10      continue
20      continue
```

Before entry with *uplo* = 'L' or 'l', the leading $(k + 1)$ by *n* part of the array *a* must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right *k* by *k* triangle of the array *a* is not referenced.

The following program segment transfers a lower triangular band matrix from conventional full matrix storage (*matrix*) to band storage (*a*):

```
do 20, j = 1, n
      m = 1 - j
      do 10, i = j, min( n, j + k )
            a( m + i, j ) = matrix( i, j )
10      continue
20      continue
```

When *diag* = 'U' or 'u', the elements of the array *a* corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k + 1)$.

x

REAL for stbsv
 DOUBLE PRECISION for dtbsv
 COMPLEX for ctbsv

DOUBLE COMPLEX for `ztbsv`
 Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element right-hand side vector b .

`incx` INTEGER. Specifies the increment for the elements of x .
 The value of `incx` must not be zero.

Output Parameters

`x` Overwritten with the solution vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbsv` interface are the following:

<code>a</code>	Holds the array a of size $(k+1,n)$.
<code>x</code>	Holds the vector with the number of elements n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?tpmv routines perform one of the matrix-vector operations defined as

$x := A^*x$, or $x := A'^*x$, or $x := \text{conjg}(A')^*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = 'U' or 'u' if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A^*x$; if <i>trans</i> = 'T' or 't', then $x := A'^*x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A')^*x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of <i>n</i> must be at least zero.
<i>ap</i>	REAL for stpmv DOUBLE PRECISION for dtpmv COMPLEX for ctpmv DOUBLE COMPLEX for ztpmv

Array, size at least $((n*(n + 1))/2)$. Before entry with $uplo = 'U'$ or ' u ', the array ap must contain the upper triangular matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1,1)$, $ap(2)$ and $ap(3)$ contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with $uplo = 'L'$ or ' l ', the array ap must contain the lower triangular matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1,1)$, $ap(2)$ and $ap(3)$ contain $a(2,1)$ and $a(3,1)$ respectively, and so on. When $diag = 'U'$ or ' u ', the diagonal elements of a are not referenced, but are assumed to be unity.

x	REAL for <code>stpmv</code> DOUBLE PRECISION for <code>dtpmv</code> COMPLEX for <code>ctpmv</code> DOUBLE COMPLEX for <code>ztpmv</code>
	Array, size at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array x must contain the n -element vector x .
$incx$	INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.

Output Parameters

x	Overwritten with the transformed vector x .
-----	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpmv` interface are the following:

ap	Holds the array ap of size $(n*(n+1)/2)$.

*x, const MKL_INT incx);

void cblas_ctpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);

void cblas_ztpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?tpsv routines solve one of the following systems of equations

$A^*x = b$, or $A'^*x = b$, or $\text{conjg}(A')^*x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

This routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = 'U' or 'u' if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A^*x = b$; if <i>trans</i> = 'T' or 't', then $A'^*x = b$;

*if trans= 'C' or 'c', then conjg(A')*x = b.*

diag CHARACTER*1. Specifies whether the matrix *A* is unit triangular:
if diag = 'U' or 'u' then the matrix is unit triangular;
if diag = 'N' or 'n' *diag = CblasNonUnit* , then the matrix is not unit triangular.

n INTEGER. Specifies the order of the matrix *A*. The value of *n* must be at least zero.

ap REAL for stpsv
 DOUBLE PRECISION for dtpsv
 COMPLEX for ctpsv
 DOUBLE COMPLEX for ztpsv
 Array, size at least $((n*(n + 1))/2)$.
 Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the triangular matrix packed sequentially, column-by-column, so that *ap*(1) contains *a*(1, 1), *ap*(2) and *ap*(3) contain *a*(1, 2) and *a*(2, 2) respectively, and so on.
 Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the triangular matrix packed sequentially, column-by-column, so that *ap*(1) contains *a*(1, 1), *ap*(2) and *ap*(3) contain *a*(2, 1) and *a*(3, 1) respectively, and so on.
 When *diag* = 'U' or 'u', the diagonal elements of *a* are not referenced, but are assumed to be unity.

x REAL for stpsv
 DOUBLE PRECISION for dtpsv
 COMPLEX for ctpsv
 DOUBLE COMPLEX for ztpsv
 Array, size at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array *x* must contain the *n*-element right-hand side vector *b*.

incx INTEGER. Specifies the increment for the elements of *x*.
 The value of *incx* must not be zero.

Output Parameters

x Overwritten with the solution vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tpsv* interface are the following:

ap Holds the array *ap* of size $(n*(n+1)/2)$.

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?trmv

Computes a matrix-vector product using a triangular matrix.

Syntax**FORTRAN 77:**

```
call strmv(uplo, trans, diag, n, a, lda, x, incx)
call dtrmv(uplo, trans, diag, n, a, lda, x, incx)
call ctrmv(uplo, trans, diag, n, a, lda, x, incx)
call ztrmv(uplo, trans, diag, n, a, lda, x, incx)
```

Fortran 95:

```
call trmv(a, x [,uplo] [, trans] [,diag])
```

C:

```
void cblas_strmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?trmv routines perform one of the following matrix-vector operations defined as

x := *A***x*, or *x* := *A'***x*, or *x* := conjg(*A'*)**x*,

where:

x is an *n*-element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: <code>uplo = 'U' or 'u'</code> <code>if uplo = 'L' or 'l', then the matrix is low triangular.</code>
<i>trans</i>	CHARACTER*1. Specifies the operation: <code>if trans= 'N' or 'n', then x := A*x;</code> <code>if trans= 'T' or 't', then x := A'*x;</code> <code>if trans= 'C' or 'c', then x := conjg(A')*x.</code>
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: <code>if diag = 'U' or 'u' then the matrix is unit triangular;</code> <code>if diag = 'N' or 'n' diag = CblasNonUnit , then the matrix is not unit triangular.</code>
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>a</i>	REAL for <code>strmv</code> DOUBLE PRECISION for <code>dtrmv</code> COMPLEX for <code>ctrmv</code> DOUBLE COMPLEX for <code>ztrmv</code> Array, size (lda, n) . Before entry with $\text{uplo} = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with $\text{uplo} = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced. When $\text{diag} = 'U'$ or $'u'$, the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	REAL for <code>strmv</code> DOUBLE PRECISION for <code>dtrmv</code> COMPLEX for <code>ctrmv</code> DOUBLE COMPLEX for <code>ztrmv</code> Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the n -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

The value of *incx* must not be zero.

Output Parameters

<i>x</i>	Overwritten with the transformed vector <i>x</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trmv` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n,n</i>).
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'.
	The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?trsv

Solves a system of linear equations whose coefficients are in a triangular matrix.

Syntax

FORTRAN 77:

```
call strsv(uplo, trans, diag, n, a, lda, x, incx)
call dtrsv(uplo, trans, diag, n, a, lda, x, incx)
call ctrsv(uplo, trans, diag, n, a, lda, x, incx)
call ztrsv(uplo, trans, diag, n, a, lda, x, incx)
```

Fortran 95:

```
call trsv(a, x [,uplo] [, trans] [,diag])
```

C:

```
void cblas_strsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *a, const

void cblas_ctrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

```
void cblas_ztrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?trsv routines solve one of the systems of equations:

$A^*x = b$, or $A'^*x = b$, or $\text{conj}(A')^*x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: <code>uplo = 'U' or 'u'</code> <code>if uplo = 'L' or 'l'</code> , then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the systems of equations: <code>if trans= 'N' or 'n'</code> , then $A^*x = b$; <code>if trans= 'T' or 't'</code> , then $A'^*x = b$; <code>if trans= 'C' or 'c'</code> , then $\text{conj}(A')^*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: <code>if diag = 'U' or 'u'</code> then the matrix is unit triangular; <code>if diag = 'N' or 'n'</code> , then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>a</i>	REAL for strsv DOUBLE PRECISION for dtrsv COMPLEX for ctrsv DOUBLE COMPLEX for ztrsv

Array, size (lda, n) . Before entry with $\text{uplo} = \text{'U'}$ or 'u' , the leading n -by- n upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with $\text{uplo} = \text{'L'}$ or 'l' , the leading n -by- n lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced.

When $\text{diag} = \text{'U'}$ or 'u' , the diagonal elements of a are not referenced either, but are assumed to be unity.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.

x REAL for strsv

DOUBLE PRECISION for dtrsv

COMPLEX for ctrsv

DOUBLE COMPLEX for ztrsv

Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element right-hand side vector b .

incx INTEGER. Specifies the increment for the elements of x .

The value of incx must not be zero.

Output Parameters

x Overwritten with the solution vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine trsv interface are the following:

a Holds the matrix a of size (n,n) .

x Holds the vector with the number of elements n .

uplo Must be 'U' or 'L' . The default value is 'U' .

trans Must be 'N' , 'C' , or 'T' .

The default value is 'N' .

diag Must be 'N' or 'U' . The default value is 'N' .

BLAS Level 3 Routines

BLAS Level 3 routines perform matrix-matrix operations. [Table "BLAS Level 3 Routine Groups and Their Data Types"](#) lists the BLAS Level 3 routine groups and the data types associated with them.

BLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
?gemm	s, d, c, z	Computes a matrix-matrix product with general matrices.
?hemm	c, z	Computes a matrix-matrix product where one input matrix is Hermitian.
?herk	c, z	Performs a Hermitian rank-k update.
?her2k	c, z	Performs a Hermitian rank-2k update.
?symm	s, d, c, z	Computes a matrix-matrix product where one input matrix is symmetric.
?syrk	s, d, c, z	Performs a symmetric rank-k update.
?syr2k	s, d, c, z	Performs a symmetric rank-2k update.
?trmm	s, d, c, z	Computes a matrix-matrix product where one input matrix is triangular.
?trsm	s, d, c, z	Solves a triangular matrix equation.

Symmetric Multiprocessing Version of Intel® MKL

Many applications spend considerable time executing BLAS routines. This time can be scaled by the number of processors available on the system through using the symmetric multiprocessing (SMP) feature built into the Intel MKL Library. The performance enhancements based on the parallel use of the processors are available without any programming effort on your part.

To enhance performance, the library uses the following methods:

- The BLAS functions are blocked where possible to restructure the code in a way that increases the localization of data reference, enhances cache memory use, and reduces the dependency on the memory bus.
- The code is distributed across the processors to maximize parallelism.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

?gemm

Computes a matrix-matrix product with general matrices.

Syntax**FORTRAN 77:**

```
call sgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call dgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?gemm routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, with general matrices. The operation is defined as

$$C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C,$$

where:

$\text{op}(X)$ is one of $\text{op}(X) = X$, or $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

See also ?gemm3m, BLAS-like extension routines, that use matrix multiplication for similar matrix-matrix operations.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>).
<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: <code>if transa = 'N' or 'n', then op(A) = A;</code> <code>if transa = 'T' or 't', then op(A) = A^T;</code> <code>if transa = 'C' or 'c', then op(A) = A^H.</code>
<i>transb</i>	CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication: <code>if transb = 'N' or 'n', then op(B) = B;</code> <code>if transb = 'T' or 't', then op(B) = B^T;</code> <code>if transb = 'C' or 'c', then op(B) = B^H.</code>
<i>m</i>	INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm, scgomm DOUBLE COMPLEX for zgemm, dzgomm Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for sgemm, scgomm DOUBLE PRECISION for dgemm, dzgomm COMPLEX for cgemm DOUBLE COMPLEX for zgemm Array, size <i>lda</i> by <i>ka</i> , where <i>ka</i> is <i>k</i> when <i>transa</i> = 'N' or 'n', and is <i>m</i> otherwise. Before entry with <i>transa</i> = 'N' or 'n', the leading <i>m</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix A , otherwise the leading <i>k</i> -by- <i>m</i> part of the array <i>a</i> must contain the matrix A .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>transa</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.

<i>b</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm, scgemm DOUBLE COMPLEX for zgemm, dzgemm Array, size ldb by kb , where kb is n when $transa = 'N'$ or ' n ', and is k otherwise. Before entry with $transa = 'N'$ or ' n ', the leading k -by- n part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading n -by- k part of the array <i>b</i> must contain the matrix <i>B</i> .
ldb	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. When $transa = 'N'$ or ' n ', then ldb must be at least $\max(1, k)$, otherwise ldb must be at least $\max(1, n)$.
<i>beta</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm, scgemm DOUBLE COMPLEX for zgemm, dzgemm Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>c</i> need not be set on input.
<i>c</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm, scgemm DOUBLE COMPLEX for zgemm, dzgemm Array, size ldc by n . Before entry, the leading m -by- n part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.
ldc	INTEGER. Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program. The value of ldc must be at least $\max(1, m)$.

Output Parameters

c Overwritten by the m -by- n matrix $(alpha * op(A) * op(B) + beta * C)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemm` interface are the following:

a Holds the matrix *A* of size (ma, ka) where
 $ka = k$ if $transa = 'N'$,
 $ka = m$ otherwise,

	<i>ma</i> = <i>m</i> if <i>transa</i> = 'N', <i>ma</i> = <i>k</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>mb,kb</i>) where <i>kb</i> = <i>n</i> if <i>transb</i> = 'N', <i>kb</i> = <i>k</i> otherwise, <i>mb</i> = <i>k</i> if <i>transb</i> = 'N', <i>mb</i> = <i>n</i> otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>transb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?hemm

Computes a matrix-matrix product where one input matrix is Hermitian.

Syntax**FORTRAN 77:**

```
call chemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call zhemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call hemm(a, b, c [,side][,uplo] [,alpha][,beta])
```

C:

```
void cblas_chemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
void cblas_zhemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?hemm routines compute a scalar-matrix-matrix product using a Hermitian matrix A and a general matrix B and add the result to a scalar-matrix product using a general matrix C . The operation is defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * B * A + \beta * C,$$

where:

α and β are scalars,

A is a Hermitian matrix,

B and C are m -by- n matrices.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

side

CHARACTER*1. Specifies whether the Hermitian matrix A appears on the left or right in the operation as follows:

```
if side = 'L' or 'l', then C :=  $\alpha * A * B + \beta * C$ ;
if side = 'R' or 'r', then C :=  $\alpha * B * A + \beta * C$ .
```

uplo

CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the Hermitian matrix A is used.

If *uplo* = 'L' or 'l', then the low triangular part of the Hermitian matrix A is used.

m

INTEGER. Specifies the number of rows of the matrix C .

The value of *m* must be at least zero.

n

INTEGER. Specifies the number of columns of the matrix C .

The value of *n* must be at least zero.

alpha

COMPLEX for `chemm`

DOUBLE COMPLEX for `zhemm`

Specifies the scalar α .

a

COMPLEX for `chemm`

DOUBLE COMPLEX for `zhemm`

Array, size (lda, ka) , where ka is m when *side* = 'L' or 'l' and is n otherwise. Before entry with *side* = 'L' or 'l', the m -by- m part of the array *a* must contain the Hermitian matrix, such that when *uplo* = 'U' or 'u', the leading m -by- m upper triangular part of the array *a* must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of *a* is not referenced, and when *uplo* = 'L' or 'l', the

leading m -by- m lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of a is not referenced.

Before entry with $\text{side} = \text{'R'}$ or 'r' , the n -by- n part of the array a must contain the Hermitian matrix, such that when $\text{uplo} = \text{'U'}$ or 'u' , the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced, and when $\text{uplo} = \text{'L'}$ or 'l' , the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of a is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

lda	INTEGER. Specifies the leading dimension of a as declared in the calling (sub) program. When $\text{side} = \text{'L'}$ or 'l' then lda must be at least $\max(1, m)$, otherwise lda must be at least $\max(1, n)$.
b	<p>COMPLEX for <code>chemm</code></p> <p>DOUBLE COMPLEX for <code>zhemm</code></p> <p>Array, size ldb by n.</p> <p>Before entry, the leading m-by-n part of the array b must contain the matrix B.</p>
ldb	INTEGER. Specifies the leading dimension of b as declared in the calling (sub)program. The value of ldb must be at least $\max(1, m)$.
β	<p>COMPLEX for <code>chemm</code></p> <p>DOUBLE COMPLEX for <code>zhemm</code></p> <p>Specifies the scalar β.</p> <p>When β is supplied as zero, then c need not be set on input.</p>
c	<p>COMPLEX for <code>chemm</code></p> <p>DOUBLE COMPLEX for <code>zhemm</code></p> <p>Array, size (c, n). Before entry, the leading m-by-n part of the array c must contain the matrix C, except when β is zero, in which case c need not be set on entry.</p>
ldc	INTEGER. Specifies the leading dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, m)$.

Output Parameters

c Overwritten by the m -by- n updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hemm` interface are the following:

<i>a</i>	Holds the matrix A of size (k,k) where $k = m$ if $\text{side} = \text{'L'}$, $k = n$ otherwise.
<i>b</i>	Holds the matrix B of size (m,n) .
<i>c</i>	Holds the matrix C of size (m,n) .
<i>side</i>	Must be 'L' or 'R' . The default value is 'L' .
<i>uplo</i>	Must be 'U' or 'L' . The default value is 'U' .
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?herk*Performs a Hermitian rank-k update.***Syntax****FORTRAN 77:**

```
call cherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc)
call zherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc)
```

Fortran 95:

```
call herk(a, c [,uplo] [, trans] [,alpha][,beta])
```

C:

```
void cblas_cherk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const

```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?herk routines perform a rank-k matrix-matrix operation using a general matrix A and a Hermitian matrix C . The operation is defined as

```
C := alpha*A*AH + beta*C,
```

or

```
C := alpha*AH*A + beta*C,
```

where:

alpha and *beta* are real scalars,

C is an n -by- n Hermitian matrix,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: <code>if trans= 'N' or 'n', then C := alpha*A*A^H + beta*C;</code> <code>if trans= 'C' or 'c', then C := alpha*A^H*A + beta*C.</code>
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. With <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i> , and with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>A</i> . The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for <code>cherk</code> DOUBLE PRECISION for <code>zherk</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for <code>cherk</code> DOUBLE COMPLEX for <code>zherk</code> Array, size (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>a</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least <code>max(1, n)</code> , otherwise <i>lda</i> must be at least <code>max(1, k)</code> .
<i>beta</i>	REAL for <code>cherk</code> DOUBLE PRECISION for <code>zherk</code> Specifies the scalar <i>beta</i> .
<i>c</i>	COMPLEX for <code>cherk</code> DOUBLE COMPLEX for <code>zherk</code> Array, size <i>ldc</i> by <i>n</i> .

Before entry with `uplo = 'U'` or `'u'`, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of c is not referenced.

Before entry with `uplo = 'L'` or `'l'`, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of c is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

`ldc`

INTEGER. Specifies the leading dimension of c as declared in the calling (sub)program. The value of `ldc` must be at least $\max(1, n)$.

Output Parameters

`c`

With `uplo = 'U'` or `'u'`, the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L'` or `'l'`, the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `herk` interface are the following:

`a`

Holds the matrix A of size (ma, ka) where
 $ka = k$ if `transa= 'N'`,
 $ka = n$ otherwise,
 $ma = n$ if `transa= 'N'`,
 $ma = k$ otherwise.

`c`

Holds the matrix C of size (n,n) .

`uplo`

Must be `'U'` or `'L'`. The default value is `'U'`.

`trans`

Must be `'N'` or `'C'`. The default value is `'N'`.

`alpha`

The default value is 1.

`beta`

The default value is 0.

?her2k

Performs a Hermitian rank- $2k$ update.

Syntax

FORTRAN 77:

```
call cher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call her2k(a, b, c [,uplo][,trans] [,alpha][,beta])
```

C:

```
void cblas_cher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *b, const MKL_INT ldb, const float beta, void *c,
const MKL_INT ldc);

void cblas_zher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *b, const MKL_INT ldb, const double beta, void *c,
const MKL_INT ldc);
```

Include Files

- Fortran 95: blas.f90
- C: mkl.h

Description

The ?her2k routines perform a rank-2k matrix-matrix operation using general matrices A and B and a Hermitian matrix C . The operation is defined as

$$C := \alpha A B^H + \text{conj}(\alpha) B A^H + \beta C,$$

or

$$C := \alpha B^H A + \text{conj}(\alpha) A^H B + \beta C,$$

where:

α is a scalar and β is a real scalar,

C is an n -by- n Hermitian matrix,

A and B are n -by- k matrices in the first case and k -by- n matrices in the second case.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

uplo

CHARACTER*1. Specifies whether the upper or lower triangular part of the array c is used.

If $uplo = 'U'$ or ' u ', then the upper triangular of the array c is used.

If $uplo = 'L'$ or ' l ', then the low triangular of the array c is used.

trans

CHARACTER*1. Specifies the operation:

If $trans= 'N'$ or ' n ', then $C:=\alpha A B^H + \alpha B A^H + \beta C;$

If $trans= 'C'$ or ' c ', then $C:=\alpha A^H B + \alpha B^H A + \beta C.$

n

INTEGER. Specifies the order of the matrix C . The value of n must be at least zero.

<i>k</i>	INTEGER. With <i>trans</i> = 'N' or 'n' specifies the number of columns of the matrix <i>A</i> , and with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>A</i> .
	The value of <i>k</i> must be at least equal to zero.
<i>alpha</i>	COMPLEX for <i>cher2k</i> DOUBLE COMPLEX for <i>zher2k</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for <i>cher2k</i> DOUBLE COMPLEX for <i>zher2k</i> Array, size (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n' <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for <i>cher2k</i> DOUBLE PRECISION for <i>zher2k</i> Specifies the scalar <i>beta</i> .
<i>b</i>	COMPLEX for <i>cher2k</i> DOUBLE COMPLEX for <i>zher2k</i> Array, size (<i>ldb</i> , <i>kb</i>), where <i>kb</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, n)$, otherwise <i>ldb</i> must be at least $\max(1, k)$.
<i>c</i>	COMPLEX for <i>cher2k</i> DOUBLE COMPLEX for <i>zher2k</i> Array, size <i>ldc</i> by <i>n</i> . Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>c</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>c</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>c</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>c</i> is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = 'L' or 'l', the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2k` interface are the following:

a Holds the matrix *A* of size (*ma,ka*) where

```
ka = k if trans = 'N',
ka = n otherwise,
ma = n if trans = 'N',
ma = k otherwise.
```

b Holds the matrix *B* of size (*mb,kb*) where

```
kb = k if trans = 'N',
kb = n otherwise,
mb = n if trans = 'N',
mb = k otherwise.
```

c Holds the matrix *C* of size (*n,n*).

uplo Must be 'U' or 'L'. The default value is 'U'.

trans Must be 'N' or 'C'. The default value is 'N'.

alpha The default value is 1.

beta The default value is 0.

?symm

Computes a matrix-matrix product where one input matrix is symmetric.

Syntax

FORTRAN 77:

```
call ssymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call dsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
```

```
call csymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call zsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call symm(a, b, c [,side] [,uplo] [,alpha] [,beta])
```

C:

```
void cblas_ssimm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const

MKL_INT ldc);

void cblas_zsymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const
MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const
MKL_INT ldc);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?symm routines compute a scalar-matrix-matrix product with one symmetric matrix and add the result to a scalar-matrix product. The operation is defined as

```
C := alpha*A*B + beta*C,
```

or

```
C := alpha*B*A + beta*C,
```

where:

alpha and *beta* are scalars,

A is a symmetric matrix,

B and *C* are *m*-by-*n* matrices.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

side

CHARACTER*1. Specifies whether the symmetric matrix *A* appears on the left or right in the operation:

```
if side = 'L' or 'l', then C := alpha*A*B + beta*C;
```

`if side = 'R' or 'r', then C := alpha*B*A + beta*C.`

`uplo`

CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is used:

`if uplo = 'U' or 'u', then the upper triangular part is used;`

`if uplo = 'L' or 'l', then the lower triangular part is used.`

`m`

INTEGER. Specifies the number of rows of the matrix C .

The value of m must be at least zero.

`n`

INTEGER. Specifies the number of columns of the matrix C .

The value of n must be at least zero.

`alpha`

REAL for ssymm

DOUBLE PRECISION for dsymm

COMPLEX for csymm

DOUBLE COMPLEX for zsymm

Specifies the scalar α .

`a`

REAL for ssymm

DOUBLE PRECISION for dsymm

COMPLEX for csymm

DOUBLE COMPLEX for zsymm

Array, size (lda, ka), where ka is m when $side = 'L'$ or ' l ' and is n otherwise.

Before entry with $side = 'L'$ or ' l ', the m -by- m part of the array a must contain the symmetric matrix, such that when $uplo = 'U'$ or ' u ', the leading m -by- m upper triangular part of the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced, and when $side = 'L'$ or ' l ', the leading m -by- m lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.

Before entry with $side = 'R'$ or ' r ', the n -by- n part of the array a must contain the symmetric matrix, such that when $uplo = 'U'$ or ' u ' the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced, and when $side = 'L'$ or ' l ', the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.

`lda`

INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. When $side = 'L'$ or ' l ' then lda must be at least $\max(1, m)$, otherwise lda must be at least $\max(1, n)$.

`b`

REAL for ssymm

DOUBLE PRECISION for dsymm

COMPLEX for `csymm`

DOUBLE COMPLEX for `zsymm`

Array, size (l_{db}, n) . Before entry, the leading m -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the leading dimension of b as declared in the calling (sub)program. The value of ldb must be at least $\max(1, m)$.

beta REAL for `ssymm`

DOUBLE PRECISION for `dsymm`

COMPLEX for `csymm`

DOUBLE COMPLEX for `zsymm`

Specifies the scalar β .

When β is set to zero, then c need not be set on input.

c REAL for `ssymm`

DOUBLE PRECISION for `dsymm`

COMPLEX for `csymm`

DOUBLE COMPLEX for `zsymm`

Array, size l_{dc} by n . Before entry, the leading m -by- n part of the array c must contain the matrix C , except when β is zero, in which case c need not be set on entry.

ldc INTEGER. Specifies the leading dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, m)$.

Output Parameters

c Overwritten by the m -by- n updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `symm` interface are the following:

a Holds the matrix A of size (k,k) where

$k = m$ if `side = 'L'`,

$k = n$ otherwise.

b Holds the matrix B of size (m,n) .

c Holds the matrix C of size (m,n) .

side Must be '`L`' or '`R`'. The default value is '`L`'.

uplo Must be '`U`' or '`L`'. The default value is '`U`'.

<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?syrk*Performs a symmetric rank-k update.***Syntax****FORTRAN 77:**

- C: mkl.h

Description

The ?syrk routines perform a rank-k matrix-matrix operation for a symmetric matrix *C* using a general matrix *A*. The operation is defined as

```
C := alpha*A*A' + beta*C,
```

or

```
C := alpha*A'*A + beta*C,
```

where:

alpha and *beta* are scalars,

C is an *n*-by-*n* symmetric matrix,

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> * <i>A</i> * <i>A</i> ' + <i>beta</i> * <i>C</i> ; if <i>trans</i> = 'T' or 't', then <i>C</i> := <i>alpha</i> * <i>A</i> '* <i>A</i> + <i>beta</i> * <i>C</i> ; if <i>trans</i> = 'C' or 'c', then <i>C</i> := <i>alpha</i> * <i>A</i> '* <i>A</i> + <i>beta</i> * <i>C</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i> , and on entry with <i>trans</i> = 'T', 't', 'C', or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i> . The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk Array, size (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk

Specifies the scalar *beta*.

c REAL for ssyrk

DOUBLE PRECISION for dsyrk

COMPLEX for csyrk

DOUBLE COMPLEX for zsydk

Array, size (*ldc*, *n*). Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *c* must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of *c* is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *c* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *c* is not referenced.

ldc INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = 'L' or 'l', the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sydk* interface are the following:

a Holds the matrix *A* of size (*ma*, *ka*) where

ka = *k* if *transa*= 'N',

ka = *n* otherwise,

ma = *n* if *transa*= 'N',

ma = *k* otherwise.

c Holds the matrix *C* of size (*n*, *n*).

uplo Must be 'U' or 'L'. The default value is 'U'.

trans Must be 'N', 'C', or 'T'.

The default value is 'N'.

alpha The default value is 1.

beta The default value is 0.

?syr2k

Performs a symmetric rank-2k update.

Description

The ?syr2k routines perform a rank-2k matrix-matrix operation for a symmetric matrix C using general matrices A and B . The operation is defined as

```
C := alpha*A*B' + alpha*B*A' + beta*C,
```

or

```
C := alpha*A'*B + alpha*B'*A + beta*C,
```

where:

α and β are scalars,

C is an n -by- n symmetric matrix,

A and B are n -by- k matrices in the first case, and k -by- n matrices in the second case.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> * <i>A</i> * <i>B</i> ' + <i>alpha</i> * <i>B</i> * <i>A</i> ' + <i>beta</i> * <i>C</i> ; if <i>trans</i> = 'T' or 't', then <i>C</i> := <i>alpha</i> * <i>A</i> '* <i>B</i> + <i>alpha</i> * <i>B</i> '* <i>A</i> + <i>beta</i> * <i>C</i> ; if <i>trans</i> = 'C' or 'c', then <i>C</i> := <i>alpha</i> * <i>A</i> '* <i>B</i> + <i>alpha</i> * <i>B</i> '* <i>A</i> + <i>beta</i> * <i>C</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrices <i>A</i> and <i>B</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrices <i>A</i> and <i>B</i> . The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyrr2k Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyrr2k Array, size (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>b</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyrr2k

Array, size ldb by kb where kb is k when $trans = 'N'$ or ' n ' and is n otherwise. Before entry with $trans = 'N'$ or ' n ', the leading n -by- k part of the array b must contain the matrix B , otherwise the leading k -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. When $trans = 'N'$ or ' n ', then ldb must be at least $\max(1, n)$, otherwise ldb must be at least $\max(1, k)$.

beta REAL for ssyr2k
DOUBLE PRECISION for dsyr2k
COMPLEX for csyr2k
DOUBLE COMPLEX for zsyrr2k
Specifies the scalar *beta*.

c REAL for ssyr2k
DOUBLE PRECISION for dsyr2k
COMPLEX for csyr2k
DOUBLE COMPLEX for zsyrr2k

Array, size (ldc, n) . Before entry with $uplo = 'U'$ or ' u ', the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of c is not referenced.

Before entry with $uplo = 'L'$ or ' l ', the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of c is not referenced.

ldc INTEGER. Specifies the leading dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, n)$.

Output Parameters

c With $uplo = 'U'$ or ' u ', the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix.
With $uplo = 'L'$ or ' l ', the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syr2k` interface are the following:

a Holds the matrix A of size (ma, ka) where
 $ka = k$ if $trans = 'N'$,
 $ka = n$ otherwise,
 $ma = n$ if $trans = 'N'$,

	$ma = k$ otherwise.
<i>b</i>	Holds the matrix B of size (mb, kb) where $kb = k$ if $trans = 'N'$, $kb = n$ otherwise, $mb = n$ if $trans = 'N'$, $mb = k$ otherwise.
<i>c</i>	Holds the matrix C of size (n, n).
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.
<i>trans</i>	Must be ' N ', ' C ', or ' T '. The default value is ' N '.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?trmm

Computes a matrix-matrix product where one input matrix is triangular.

Syntax**FORTRAN 77:**

```
call strmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call dtrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ctrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ztrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
```

Fortran 95:

```
call trmm(a, b [,side] [, uplo] [,transa] [,diag] [,alpha])
```

C:

```
void cblas_strmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const MKL_INT ldb);

void cblas_dtrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const MKL_INT ldb);

void cblas_ctrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);
```

```
void cblas_ztrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?trmm routines compute a scalar-matrix-matrix product with one triangular matrix. The operation is defined as

```
B := alpha*op(A)*B
```

or

```
B := alpha*B*op(A)
```

where:

alpha is a scalar,

B is an *m*-by-*n* matrix,

A is a unit, or non-unit, upper or lower triangular matrix

op(A) is one of *op(A) = A*, or *op(A) = A'*, or *op(A) = conjg(A')*.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (*CblasRowMajor*) or column-major (*CblasColMajor*).

side

CHARACTER*1. Specifies whether *op(A)* appears on the left or right of *B* in the operation:

```
if side = 'L' or 'l', then B := alpha*op(A)*B;
if side = 'R' or 'r', then B := alpha*B*op(A).
```

uplo

CHARACTER*1. Specifies whether the matrix *A* is upper or lower triangular:

```
uplo = 'U' or 'u'
if uplo = 'L' or 'l', then the matrix is low triangular.
```

transa

CHARACTER*1. Specifies the form of *op(A)* used in the matrix multiplication:

```
if transa= 'N' or 'n', then op(A) = A;
if transa= 'T' or 't', then op(A) = A';
if transa= 'C' or 'c', then op(A) = conjg(A').
```

diag

CHARACTER*1. Specifies whether the matrix *A* is unit triangular:

```
if diag = 'U' or 'u' then the matrix is unit triangular;
if diag = 'N' or 'n' diag = CblasNonUnit , then the matrix is not unit
triangular.
```

<i>m</i>	INTEGER. Specifies the number of rows of <i>B</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	<p>REAL for strmm</p> <p>DOUBLE PRECISION for dtrmm</p> <p>COMPLEX for ctrmm</p> <p>DOUBLE COMPLEX for ztrmm</p> <p>Specifies the scalar <i>alpha</i>.</p> <p>When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.</p>
<i>a</i>	<p>REAL for strmm</p> <p>DOUBLE PRECISION for dtrmm</p> <p>COMPLEX for ctrmm</p> <p>DOUBLE COMPLEX for ztrmm</p> <p>Array, size <i>lda</i> by <i>k</i>, where <i>k</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>k</i> by <i>k</i> upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>k</i> by <i>k</i> lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced.</p> <p>When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.</p>
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>side</i> = 'L' or 'l', then <i>lda</i> must be at least $\max(1, m)$, when <i>side</i> = 'R' or 'r', then <i>lda</i> must be at least $\max(1, n)$.
<i>b</i>	<p>REAL for strmm</p> <p>DOUBLE PRECISION for dtrmm</p> <p>COMPLEX for ctrmm</p> <p>DOUBLE COMPLEX for ztrmm</p> <p>Array, size <i>ldb</i> by <i>n</i>.</p> <p>Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p>
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.

Output Parameters

<i>b</i>	Overwritten by the transformed matrix.
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trmm` interface are the following:

<i>a</i>	Holds the matrix A of size (k,k) where $k = m$ if <i>side</i> = 'L', $k = n$ otherwise.
<i>b</i>	Holds the matrix B of size (m,n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.
<i>alpha</i>	The default value is 1.

?trsm

Solves a triangular matrix equation.

Syntax

FORTRAN 77:

```
call strsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call dtrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ctrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ztrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
```

Fortran 95:

```
call trsm(a, b [,side] [, uplo] [,transa][,diag] [,alpha])
```

C:

```
void cblas_strsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const
MKL_INT ldb);

void cblas_dtrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const
MKL_INT ldb);

void cblas_ctrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT
ldb);
```

```
void cblas_ztrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?trsm routines solve one of the following matrix equations:

```
op(A)*X = alpha*B,
```

or

```
X*op(A) = alpha*B,
```

where:

alpha is a scalar,

X and *B* are *m*-by-*n* matrices,

A is a unit, or non-unit, upper or lower triangular matrix

op(A) is one of *op(A)* = *A*, or *op(A)* = *A'*, or *op(A)* = *conjg(A')*.

The matrix *B* is overwritten by the solution matrix *X*.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (*CblasRowMajor*) or column-major (*CblasColMajor*).

side

CHARACTER*1. Specifies whether *op(A)* appears on the left or right of *X* in the equation:

```
if side = 'L' or 'l', then op(A)*X = alpha*B;
if side = 'R' or 'r', then X*op(A) = alpha*B.
```

uplo

CHARACTER*1. Specifies whether the matrix *A* is upper or lower triangular:

```
uplo = 'U' or 'u'
if uplo = 'L' or 'l', then the matrix is low triangular.
```

transa

CHARACTER*1. Specifies the form of *op(A)* used in the matrix multiplication:

```
if transa= 'N' or 'n', then op(A) = A;
if transa= 'T' or 't';
if transa= 'C' or 'c', then op(A) = conjg(A').
```

diag

CHARACTER*1. Specifies whether the matrix *A* is unit triangular:

```
if diag = 'U' or 'u' then the matrix is unit triangular;
```

if diag = 'N' or 'n' *diag = CblasNonUnit* , then the matrix is not unit triangular.

m INTEGER. Specifies the number of rows of *B*. The value of *m* must be at least zero.

n INTEGER. Specifies the number of columns of *B*. The value of *n* must be at least zero.

alpha REAL for strsm

DOUBLE PRECISION for dtrsm

COMPLEX for ctrsm

DOUBLE COMPLEX for ztrsm

Specifies the scalar *alpha*.

When *alpha* is zero, then *a* is not referenced and *b* need not be set before entry.

a REAL for strsm

DOUBLE PRECISION for dtrsm

COMPLEX for ctrsm

DOUBLE COMPLEX for ztrsm

Array, size (*lda*, *k*) , where *k* is *m* when *side* = 'L' or 'l' and is *n* when *side* = 'R' or 'r'. Before entry with *uplo* = 'U' or 'u', the leading *k* by *k* upper triangular part of the array *a* must contain the upper triangular matrix and the strictly lower triangular part of *a* is not referenced.

Before entry with *uplo* = 'L' or 'l' lower triangular part of the array *a* must contain the lower triangular matrix and the strictly upper triangular part of *a* is not referenced.

When *diag* = 'U' or 'u', the diagonal elements of *a* are not referenced either, but are assumed to be unity.

lda INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. When *side* = 'L' or 'l', then *lda* must be at least $\max(1, m)$, when *side* = 'R' or 'r', then *lda* must be at least $\max(1, n)$.

b REAL for strsm

DOUBLE PRECISION for dtrsm

COMPLEX for ctrsm

DOUBLE COMPLEX for ztrsm

Array, size (*ldb*, *n*) . Before entry, the leading *m*-by-*n* part of the array *b* must contain the right-hand side matrix *B*.

ldb INTEGER. Specifies the leading dimension of *b* as declared in the calling (sub)program. The value of *ldb* must be at least $\max(1, +m)$.

Output Parameters

b Overwritten by the solution matrix X .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsm` interface are the following:

<i>a</i>	Holds the matrix A of size (k,k) where $k = m$ if <code>side = 'L'</code> , $k = n$ otherwise.
<i>b</i>	Holds the matrix B of size (m,n) .
<i>side</i>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<i>transa</i>	Must be ' <code>N</code> ', ' <code>C</code> ', or ' <code>T</code> '.
	The default value is ' <code>N</code> '.
<i>diag</i>	Must be ' <code>N</code> ' or ' <code>U</code> '. The default value is ' <code>N</code> '.
<i>alpha</i>	The default value is 1.

Sparse BLAS Level 1 Routines

This section describes Sparse BLAS Level 1, an extension of BLAS Level 1 included in the Intel® Math Kernel Library beginning with the Intel MKL release 2.1. Sparse BLAS Level 1 is a group of routines and functions that perform a number of common vector operations on sparse vectors stored in compressed form.

Sparse vectors are those in which the majority of elements are zeros. Sparse BLAS routines and functions are specially implemented to take advantage of vector sparsity. This allows you to achieve large savings in computer time and memory. If nz is the number of non-zero vector elements, the computer time taken by Sparse BLAS operations will be $O(nz)$.

Vector Arguments

Compressed sparse vectors. Let a be a vector stored in an array, and assume that the only non-zero elements of a are the following:

```
a(k1), a(k2), a(k3) . . . a(knz),
```

where nz is the total number of non-zero elements in a .

In Sparse BLAS, this vector can be represented in compressed form by two FORTRAN arrays, x (values) and $indx$ (indices). Each array has nz elements:

```
x(1)=a(k1), x(2)=a(k2), . . . x(nz)= a(knz),
```

```
indx(1)=k1, indx(2)=k2, . . . indx(nz)= knz.
```

Thus, a sparse vector is fully determined by the triple $(nz, x, indx)$. If you pass a negative or zero value of nz to Sparse BLAS, the subroutines do not modify any arrays or variables.

Full-storage vectors. Sparse BLAS routines can also use a vector argument fully stored in a single FORTRAN array (a full-storage vector). If y is a full-storage vector, its elements must be stored contiguously: the first element in $y(1)$, the second in $y(2)$, and so on. This corresponds to an increment $incy = 1$ in BLAS Level 1. No increment value for full-storage vectors is passed as an argument to Sparse BLAS routines or functions.

Naming Conventions

Similar to BLAS, the names of Sparse BLAS subprograms have prefixes that determine the data type involved: s and d for single- and double-precision real; c and z for single- and double-precision complex respectively.

If a Sparse BLAS routine is an extension of a "dense" one, the subprogram name is formed by appending the suffix i (standing for *indexed*) to the name of the corresponding "dense" subprogram. For example, the Sparse BLAS routine `saxpyi` corresponds to the BLAS routine `saxpy`, and the Sparse BLAS function `cdotci` corresponds to the BLAS function `cdotc`.

Routines and Data Types

Routines and data types supported in the Intel MKL implementation of Sparse BLAS are listed in [Table "Sparse BLAS Routines and Their Data Types"](#).

Sparse BLAS Routines and Their Data Types

Routine/ Function	Data Types	Description
?axpyi	s, d, c, z	Scalar-vector product plus vector (routines)
?doti	s, d	Dot product (functions)
?dotci	c, z	Complex dot product conjugated (functions)
?dotui	c, z	Complex dot product unconjugated (functions)
?gthr	s, d, c, z	Gathering a full-storage sparse vector into compressed form $nz, x, indx$ (routines)
?gthrz	s, d, c, z	Gathering a full-storage sparse vector into compressed form and assigning zeros to gathered elements in the full-storage vector (routines)
?roti	s, d	Givens rotation (routines)
?sctr	s, d, c, z	Scattering a vector from compressed form to full-storage form (routines)

BLAS Level 1 Routines That Can Work With Sparse Vectors

The following BLAS Level 1 routines will give correct results when you pass to them a compressed-form array x (with the increment $incx=1$):

?asum	sum of absolute values of vector elements
?copy	copying a vector
?nrm2	Euclidean norm of a vector
?scal	scaling a vector

`i?amax` index of the element with the largest absolute value for real flavors, or the largest sum $|\operatorname{Re}(x(i))| + |\operatorname{Im}(x(i))|$ for complex flavors.

`i?amin` index of the element with the smallest absolute value for real flavors, or the smallest sum $|\operatorname{Re}(x(i))| + |\operatorname{Im}(x(i))|$ for complex flavors.

The result i returned by `i?amax` and `i?amin` should be interpreted as index in the compressed-form array, so that the largest (smallest) value is $x(i)$; the corresponding index in full-storage array is $\operatorname{indx}(i)$.

You can also call `?rotg` to compute the parameters of Givens rotation and then pass these parameters to the Sparse BLAS routines `?roti`.

?axpyi

Adds a scalar multiple of compressed sparse vector to a full-storage vector.

Syntax

FORTRAN 77:

```
call saxpyi(nz, a, x, indx, y)
call daxpyi(nz, a, x, indx, y)
call caxpyi(nz, a, x, indx, y)
call zaxpyi(nz, a, x, indx, y)
```

Fortran 95:

```
call axpyi(x, indx, y [, a])
```

C:

```
void cblas_saxpyi (const MKL_INT nz, const float a, const float *x, const MKL_INT
*indx, float *y);
void cblas_daxpyi (const MKL_INT nz, const double a, const double *x, const MKL_INT
*indx, double *y);
void cblas_caxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx,
void *y);
void cblas_zaxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx,
void *y);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The `?axpyi` routines perform a vector-vector operation defined as

```
y := a*x + y
```

where:

a is a scalar,

x is a sparse vector stored in compressed form,

y is a vector in full storage form.

The `?axpyi` routines reference or modify only the elements of y whose indices are listed in the array $indx$.

The values in $indx$ must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and $indx$.
a	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code> DOUBLE COMPLEX for <code>zaxpyi</code> Specifies the scalar a .
x	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code> DOUBLE COMPLEX for <code>zaxpyi</code> Array, size at least nz .
$indx$	INTEGER. Specifies the indices for the elements of x . Array, size at least nz .
y	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code> DOUBLE COMPLEX for <code>zaxpyi</code> Array, size at least $\max(indx(i))$.

Output Parameters

y	Contains the updated vector y .
-----	-----------------------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpyi` interface are the following:

x	Holds the vector with the number of elements nz .
$indx$	Holds the vector with the number of elements nz .
y	Holds the vector with the number of elements nz .
a	The default value is 1.

?doti

Computes the dot product of a compressed sparse real vector by a full-storage real vector.

Syntax**FORTRAN 77:**

```
res = sdoti(nz, x, indx, y)
res = ddoti(nz, x, indx, y)
```

Fortran 95:

```
res = doti(x, indx, y)
```

C:

```
float cblas_sdoti (const MKL_INT nz, const float *x, const MKL_INT *indx, const float *y);
double cblas_ddot (const MKL_INT nz, const double *x, const MKL_INT *indx, const double *y);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?doti routines return the dot product of x and y defined as

```
res = x(1)*y(indx(1)) + x(2)*y(indx(2)) + ... + x(nz)*y(indx(nz))
```

where the triple $(nz, x, indx)$ defines a sparse real vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in x and $indx$.
<i>x</i>	REAL for sdoti DOUBLE PRECISION for ddoti Array, size at least nz .
<i>indx</i>	INTEGER. Specifies the indices for the elements of x . Array, size at least nz .
<i>y</i>	REAL for sdoti DOUBLE PRECISION for ddoti Array, size at least $\max(indx(i))$.

Output Parameters

<i>res</i>	REAL for <code>sdoti</code> DOUBLE PRECISION for <code>ddot</code> Contains the dot product of <i>x</i> and <i>y</i> , if <i>nz</i> is positive. Otherwise, <i>res</i> contains 0.
------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `doti` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>nz</i> .
<i>indx</i>	Holds the vector with the number of elements <i>nz</i> .
<i>y</i>	Holds the vector with the number of elements <i>nz</i> .

?dotci

Computes the conjugated dot product of a compressed sparse complex vector with a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotci(nz, x, indx, y)
res = zdotci(nzz, x, indx, y)
```

Fortran 95:

```
res = dotci(x, indx, y)
```

C:

```
void cblas_cdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
void cblas_zdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `blas.f90`
- C: `mkl.h`

Description

The `?dotci` routines return the dot product of *x* and *y* defined as

```
conjg(x(1))*y(indx(1)) + ... + conjg(x(nz))*y(indx(nz))
```

where the triple (nz, x, indx) defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array indx . The values in indx must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and indx .
x	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, size at least nz .
indx	INTEGER. Specifies the indices for the elements of x . Array, size at least nz .
y	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, size at least $\max(\text{indx}(i))$.

Output Parameters

res	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Contains the conjugated dot product of x and y , if nz is positive. Otherwise, it contains 0.
--------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotci` interface are the following:

x	Holds the vector with the number of elements (nz).
indx	Holds the vector with the number of elements (nz).
y	Holds the vector with the number of elements (nz).

?dotui

Computes the dot product of a compressed sparse complex vector by a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotui(nz, x, indx, y )
res = zdotui(nzz, x, indx, y )
```

Fortran 95:

```
res = dotui(x, indx, y)
```

C:

```
void cblas_cdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void
*y, void *dotui);

void cblas_zdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void
*y, void *dotui);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?dotui routines return the dot product of x and y defined as

```
res = x(1)*y(indx(1)) + x(2)*y(indx(2)) +...+ x(nz)*y(indx(nz))
```

where the triple (nz , x , $indx$) defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in x and $indx$.
<i>x</i>	COMPLEX for cdotui DOUBLE COMPLEX for zdotui Array, size at least nz .
<i>indx</i>	INTEGER. Specifies the indices for the elements of x . Array, size at least nz .
<i>y</i>	COMPLEX for cdotui DOUBLE COMPLEX for zdotui Array, size at least $\max(indx(i))$.

Output Parameters

<i>res</i>	COMPLEX for cdotui DOUBLE COMPLEX for zdotui Contains the dot product of x and y , if nz is positive. Otherwise, <i>res</i> contains 0.
------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotui` interface are the following:

<i>x</i>	Holds the vector with the number of elements nz .
----------	---

<i>indx</i>	Holds the vector with the number of elements <i>nz</i> .
<i>y</i>	Holds the vector with the number of elements <i>nz</i> .

?gthr

Gathers a full-storage sparse vector's elements into compressed form.

Syntax

FORTRAN 77:

```
call sgthr(nz, y, x, indx )
call dgthr(nz, y, x, indx )
call cgthr(nz, y, x, indx )
call zgthr(nz, y, x, indx )
```

Fortran 95:

```
res = gthr(x, indx, y)
```

C:

```
void cblas_sgthr (const MKL_INT nz, const float *y, float *x, const MKL_INT *indx);
void cblas_dgthr (const MKL_INT nz, const double *y, double *x, const MKL_INT *indx);
void cblas_cgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);
void cblas_zgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?gthr routines gather the specified elements of a full-storage sparse vector *y* into compressed form(*nz*, *x*, *indx*). The routines reference only the elements of *y* whose indices are listed in the array *indx*:

x(*i*) = *y*(*indx*(*i*)), for *i*=1,2,..., *nz*.

Input Parameters

<i>nz</i>	INTEGER. The number of elements of <i>y</i> to be gathered.
<i>indx</i>	INTEGER. Specifies indices of elements to be gathered. Array, size at least <i>nz</i> .
<i>y</i>	REAL for sgthr DOUBLE PRECISION for dgthr COMPLEX for cgthr DOUBLE COMPLEX for zgthr

Array, size at least $\max(\text{indx}(i))$.

Output Parameters

<code>x</code>	REAL for sgthr DOUBLE PRECISION for dgthr COMPLEX for cgthr DOUBLE COMPLEX for zgthr Array, size at least nz . Contains the vector converted to the compressed form.
----------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gthr` interface are the following:

<code>x</code>	Holds the vector with the number of elements nz .
<code>indx</code>	Holds the vector with the number of elements nz .
<code>y</code>	Holds the vector with the number of elements nz .

?gthrz

Gathers a sparse vector's elements into compressed form, replacing them by zeros.

Syntax

FORTRAN 77:

```
call sgthrz( $nz$ ,  $y$ ,  $x$ ,  $indx$ )
call dgthrz( $nz$ ,  $y$ ,  $x$ ,  $indx$ )
call cgthrz( $nz$ ,  $y$ ,  $x$ ,  $indx$ )
call zgthrz( $nz$ ,  $y$ ,  $x$ ,  $indx$ )
```

Fortran 95:

```
res = gthrz( $x$ ,  $indx$ ,  $y$ )
```

C:

```
void cblas_sgthrz (const MKL_INT  $nz$ , float * $y$ , float * $x$ , const MKL_INT * $indx$ );
void cblas_dgthrz (const MKL_INT  $nz$ , double * $y$ , double * $x$ , const MKL_INT * $indx$ );
void cblas_cgthrz (const MKL_INT  $nz$ , void * $y$ , void * $x$ , const MKL_INT * $indx$ );
void cblas_zgthrz (const MKL_INT  $nz$ , void * $y$ , void * $x$ , const MKL_INT * $indx$ );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90

- C: mkl.h

Description

The `?gthrz` routines gather the elements with indices specified by the array *indx* from a full-storage vector *y* into compressed form (*nz*, *x*, *indx*) and overwrite the gathered elements of *y* by zeros. Other elements of *y* are not referenced or modified (see also [?gthr](#)).

Input Parameters

<i>nz</i>	INTEGER. The number of elements of <i>y</i> to be gathered.
<i>indx</i>	INTEGER. Specifies indices of elements to be gathered. Array, size at least <i>nz</i> .
<i>y</i>	REAL for sgthrz DOUBLE PRECISION for dgthrz COMPLEX for cgthrz DOUBLE COMPLEX for zgthrz Array, size at least $\max(indx(i))$.

Output Parameters

<i>x</i>	REAL for sgthrz DOUBLE PRECISION for dgthrz COMPLEX for cgthrz DOUBLE COMPLEX for zgthrz Array, size at least <i>nz</i> . Contains the vector converted to the compressed form.
<i>y</i>	The updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gthrz` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>nz</i> .
<i>indx</i>	Holds the vector with the number of elements <i>nz</i> .
<i>y</i>	Holds the vector with the number of elements <i>nz</i> .

?roti

Applies Givens rotation to sparse vectors one of which is in compressed form.

Syntax

FORTRAN 77:

```
call sroti(nz, x, indx, y, c, s)
call droti(nz, x, indx, y, c, s)
```

Fortran 95:

```
call roti(x, indx, y, c, s)
```

C:

```
void cblas_sroti (const MKL_INT nz, float *x, const MKL_INT *indx, float *y, const
float c, const float s);
void cblas_droti (const MKL_INT nz, double *x, const MKL_INT *indx, double *y, const
double c, const double s);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?roti routines apply the Givens rotation to elements of two real vectors, x (in compressed form nz , x , $indx$) and y (in full storage form):

```
x(i) = c*x(i) + s*y(indx(i))
```

```
y(indx(i)) = c*y(indx(i))- s*x(i)
```

The routines reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in x and $indx$.
<i>x</i>	REAL for sroti DOUBLE PRECISION for droti Array, size at least nz .
<i>indx</i>	INTEGER. Specifies the indices for the elements of x . Array, size at least nz .
<i>y</i>	REAL for sroti DOUBLE PRECISION for droti Array, size at least $\max(indx(i))$.
<i>c</i>	REAL for sroti DOUBLE PRECISION for droti. A scalar.
<i>s</i>	REAL for sroti

DOUBLE PRECISION **for** droti.

A scalar.

Output Parameters

<i>x</i> and <i>y</i>	The updated arrays.
-----------------------	---------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *roti* interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>nz</i> .
<i>indx</i>	Holds the vector with the number of elements <i>nz</i> .
<i>y</i>	Holds the vector with the number of elements <i>nz</i> .

?sctr

Converts compressed sparse vectors into full storage form.

Syntax

FORTRAN 77:

```
call ssctr(nz, x, indx, y )
call dsctr(nz, x, indx, y )
call csctr(nz, x, indx, y )
call zsctr(nz, x, indx, y )
```

Fortran 95:

```
call sctr(x, indx, y)
```

C:

```
void cblas_ssctr (const MKL_INT nz, const float *x, const MKL_INT *indx, float *y);
void cblas.dsctr (const MKL_INT nz, const double *x, const MKL_INT *indx, double *y);
void cblas.csctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);
void cblas_zsctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);
```

Include Files

- **Fortran:** mkl.fi
- **Fortran 95:** blas.f90
- **C:** mkl.h

Description

The ?sctr routines scatter the elements of the compressed sparse vector (*nz*, *x*, *indx*) to a full-storage vector *y*. The routines modify only the elements of *y* whose indices are listed in the array *indx*:

$y(indx(i)) = x(i)$, for $i=1, 2, \dots, nz$.

Input Parameters

nz	INTEGER. The number of elements of x to be scattered.
$indx$	INTEGER. Specifies indices of elements to be scattered. Array, size at least nz .
x	REAL for ssctr DOUBLE PRECISION for dsctr COMPLEX for csctr DOUBLE COMPLEX for zsctr Array, size at least nz . Contains the vector to be converted to full-storage form.

Output Parameters

y	REAL for ssctr DOUBLE PRECISION for dsctr COMPLEX for csctr DOUBLE COMPLEX for zsctr Array, size at least $\max(indx(i))$. Contains the vector y with updated elements.
-----	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sctr` interface are the following:

x	Holds the vector with the number of elements nz .
$indx$	Holds the vector with the number of elements nz .
y	Holds the vector with the number of elements nz .

Sparse BLAS Level 2 and Level 3 Routines

This section describes Sparse BLAS Level 2 and Level 3 routines included in the Intel® Math Kernel Library (Intel® MKL) . Sparse BLAS Level 2 is a group of routines and functions that perform operations between a sparse matrix and dense vectors. Sparse BLAS Level 3 is a group of routines and functions that perform operations between a sparse matrix and dense matrices.

The terms and concepts required to understand the use of the Intel MKL Sparse BLAS Level 2 and Level 3 routines are discussed in the [Linear Solvers Basics](#) appendix.

The Sparse BLAS routines can be useful to implement iterative methods for solving large sparse systems of equations or eigenvalue problems. For example, these routines can be considered as building blocks for [Iterative Sparse Solvers based on Reverse Communication Interface \(RCI ISS\)](#) described in the Chapter 8 of the manual.

Intel MKL provides Sparse BLAS Level 2 and Level 3 routines with typical (or conventional) interface similar to the interface used in the NIST* Sparse BLAS library [Rem05].

Some software packages and libraries (the PARDISO* Solver used in Intel MKL, Sparskit 2 [Saad94], the Compaq* Extended Math Library (CXML)[CXML01]) use different (early) variation of the compressed sparse row (CSR) format and support only Level 2 operations with simplified interfaces. Intel MKL provides an additional set of Sparse BLAS Level 2 routines with similar simplified interfaces. Each of these routines operates only on a matrix of the fixed type.

The routines described in this section support both one-based indexing and zero-based indexing of the input data (see details in the section [One-based and Zero-based Indexing](#)).

Naming Conventions in Sparse BLAS Level 2 and Level 3

Each Sparse BLAS Level 2 and Level 3 routine has a six- or eight-character base name preceded by the prefix `mkl_` or `mkl_cspblas_`.

The routines with typical (conventional) interface have six-character base names in accordance with the template:

```
mkl_<character> <data> <operation>()
```

The routines with simplified interfaces have eight-character base names in accordance with the templates:

```
mkl_<character> <data> <mtype> <operation>()
```

for routines with one-based indexing; and

```
mkl_cspblas_<character> <data> <mtype> <operation>()
```

for routines with zero-based indexing.

The `<character>` field indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

The `<data>` field indicates the sparse matrix storage format (see section [Sparse Matrix Storage Formats](#)):

coo	coordinate format
csr	compressed sparse row format and its variations
csc	compressed sparse column format and its variations
dia	diagonal format
sky	skyline storage format
bsr	block sparse row format and its variations

The `<operation>` field indicates the type of operation:

mv	matrix-vector product (Level 2)
mm	matrix-matrix product (Level 3)
sv	solving a single triangular system (Level 2)
sm	solving triangular systems with multiple right-hand sides (Level 3)

The field `<mtype>` indicates the matrix type:

ge	sparse representation of a general matrix
sy	sparse representation of the upper or lower triangle of a symmetric matrix
tr	sparse representation of a triangular matrix

Sparse Matrix Storage Formats

The current version of Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following point entry [Duff86] storage formats for sparse matrices:

- *compressed sparse row* format (CSR) and its variations;
- *compressed sparse column* format (CSC);
- *coordinate* format;
- *diagonal* format;
- *skyline* storage format;

and one block entry storage format:

- *block sparse row* format (BSR) and its variations.

For more information see "[Sparse Matrix Storage Formats](#)" in Appendix A.

Intel MKL provides auxiliary routines - [matrix converters](#) - that convert sparse matrix from one storage format to another.

Routines and Supported Operations

This section describes operations supported by the Intel MKL Sparse BLAS Level 2 and Level 3 routines. The following notations are used here:

A is a sparse matrix;
B and *C* are dense matrices;
D is a diagonal scaling matrix;
x and *y* are dense vectors;
alpha and *beta* are scalars;

op (A) is one of the possible operations:

```
op (A) = A;
op (A) = A' - transpose of A;
op (A) = conj (A') - conjugated transpose of A.
```

inv (op (A)) denotes the inverse of *op (A)*.

The Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:

```
y := alpha*op(A)*x + beta*y
```

- solving a single triangular system:

```
y := alpha*inv(op(A))*x
```

- computing a product between sparse matrix and dense matrix:

```
C := alpha*op(A)*B + beta*C
```

- solving a sparse triangular system with multiple right-hand sides:

```
C := alpha*inv(op(A))*B
```

Intel MKL provides an additional set of the Sparse BLAS Level 2 routines with *simplified interfaces*. Each of these routines operates on a matrix of the fixed type. The following operations are supported:

- computing the vector product between a sparse matrix and a dense vector (for general and symmetric matrices):

```
y := op(A) * x
```

- solving a single triangular system (for triangular matrices):

```
y := inv(op(A)) * x
```

Matrix type is indicated by the field *<mtype>* in the routine name (see section [Naming Conventions in Sparse BLAS Level 2 and Level 3](#)).

NOTE

The routines with simplified interfaces support only four sparse matrix storage formats, specifically:

CSR format in the 3-array variation accepted in the direct sparse solvers and in the CXML;
diagonal format accepted in the CXML;
coordinate format;
BSR format in the 3-array variation.

Note that routines with both typical (conventional) and simplified interfaces use the same computational kernels that work with certain internal data structures.

The Intel MKL Sparse BLAS Level 2 and Level 3 routines do not support in-place operations.

Complete list of all routines is given in the ["Sparse BLAS Level 2 and Level 3 Routines"](#).

Interface Consideration

One-Based and Zero-Based Indexing

The Intel MKL Sparse BLAS Level 2 and Level 3 routines support one-based and zero-based indexing of data arrays.

Routines with typical interfaces support zero-based indexing for the following sparse data storage formats: CSR, CSC, BSR, and COO. Routines with simplified interfaces support zero based indexing for the following sparse data storage formats: CSR, BSR, and COO. See the complete list of [Sparse BLAS Level 2 and Level 3 Routines](#).

The one-based indexing uses the convention of starting array indices at 1. The zero-based indexing uses the convention of starting array indices at 0. For example, indices of the 5-element array *x* can be presented in case of one-based indexing as follows:

Element index: 1 2 3 4 5

Element value: 1.0 5.0 7.0 8.0 9.0

and in case of zero-based indexing as follows:

Element index: 0 1 2 3 4

Element value: 1.0 5.0 7.0 8.0 9.0

The detailed descriptions of the one-based and zero-based variants of the sparse data storage formats are given in the ["Sparse Matrix Storage Formats"](#) in Appendix A.

Most parameters of the routines are identical for both one-based and zero-based indexing, but some of them have certain differences. The following table lists all these differences.

Parameter	One-based Indexing	Zero-based Indexing
<i>val</i>	Array containing non-zero elements of the matrix A , its length is $pntre(m) - pntrb(1)$.	Array containing non-zero elements of the matrix A , its length is $pntre(m-1) - pntrb(0)$.
<i>pntrb</i>	Array of length m . This array contains row indices, such that $pntrb(i) - pntrb(1)+1$ is the first index of row i in the arrays <i>val</i> and <i>indx</i>	Array of length m . This array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row i in the arrays <i>val</i> and <i>indx</i> .
<i>pntre</i>	Array of length m . This array contains row indices, such that $pntre(I) - pntrb(1)$ is the last index of row i in the arrays <i>val</i> and <i>indx</i> .	Array of length m . This array contains row indices, such that $pntre(i) - pntrb(0)-1$ is the last index of row i in the arrays <i>val</i> and <i>indx</i> .
<i>ia</i>	Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(i)$ is the index in the array <i>a</i> of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one.	Array of length $m+1$, containing indices of elements in the array <i>a</i> , such that $ia(i)$ is the index in the array <i>a</i> of the first non-zero element from the row i . The value of the last element $ia(m)$ is equal to the number of non-zeros.
<i>ldb</i>	Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>c</i> as declared in the calling (sub)program.

Difference Between Fortran and C Interfaces

Intel MKL provides both Fortran and C interfaces to all Sparse BLAS Level 2 and Level 3 routines. Parameter descriptions are common for both interfaces with the exception of data types that refer to the FORTRAN 77 standard types. Correspondence between data types specific to the Fortran and C interfaces are given below:

Fortran	C
REAL*4	float
REAL*8	double
INTEGER*4	int
INTEGER*8	long long int
CHARACTER	char

For routines with C interfaces all parameters (including scalars) must be passed by references.

Another difference is how two-dimensional arrays are represented. In Fortran the column-major order is used, and in C row-major order. This changes the meaning of the parameters *ldb* and *ldc* (see the table above).

Differences Between Intel MKL and NIST* Interfaces

The Intel MKL Sparse BLAS Level 3 routines have the following conventional interfaces:

`mkl_xyyyymm(transa, m, n, k, alpha, matdescra, arg(A), b, ldb, beta, c, ldc)`, for matrix-matrix product;

`mkl_xyyysm(transa, m, n, alpha, matdescra, arg(A), b, ldb, c, ldc)`, for triangular solvers with multiple right-hand sides.

Here `x` denotes data type, and `yyy` - sparse matrix data structure (storage format).

The analogous NIST* Sparse BLAS (NSB) library routines have the following interfaces:

`xyyymm(transa, m, n, k, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for matrix-matrix product;

`xyyyssm(transa, m, n, unitd, dv, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for triangular solvers with multiple right-hand sides.

Some similar arguments are used in both libraries. The argument `transa` indicates what operation is performed and is slightly different in the NSB library (see [Table "Parameter `transa`"](#)). The arguments `m` and `k` are the number of rows and column in the matrix `A`, respectively, `n` is the number of columns in the matrix `C`. The arguments `alpha` and `beta` are scalar `alpha` and `beta` respectively (`beta` is not used in the Intel MKL triangular solvers.) The arguments `b` and `c` are rectangular arrays with the leading dimension `ldb` and `ldc`, respectively. `arg(A)` denotes the list of arguments that describe the sparse representation of `A`.

Parameter `transa`

	MKL interface	NSB interface	Operation
data type	CHARACTER*1	INTEGER	
value	N or n	0	$\text{op}(A) = A$
	T or t	1	$\text{op}(A) = A'$
	C or c	2	$\text{op}(A) = A'$

Parameter `matdescra`

The parameter `matdescra` describes the relevant characteristic of the matrix `A`. This manual describes `matdescra` as an array of six elements in line with the NIST* implementation. However, only the first four elements of the array are used in the current versions of the Intel MKL Sparse BLAS routines. Elements `matdescra(5)` and `matdescra(6)` are reserved for future use. Note that whether `matdescra` is described in your application as an array of length 6 or 4 is of no importance because the array is declared as a pointer in the Intel MKL routines. To learn more about declaration of the `matdescra` array, see the Sparse BLAS examples located in the Intel MKL installation directory: `examples/spblasf/` for Fortran or `examples/spblasf/` for C. The table below lists elements of the parameter `matdescra`, their for Fortran values and meanings. The parameter `matdescra` corresponds to the argument `descra` from NSB library.

Possible Values of the Parameter `matdescra` (`descra`)

	MKL interface	NSB interface	Matrix characteristics	
	one-based indexing	zero-based indexing		
data type	CHARACTER	Char	INTEGER	
1st element	<code>matdescra(1)</code>	<code>matdescra(0)</code>	<code>descra(1)</code>	matrix structure
value	G	G	0	general
	S	S	1	symmetric ($A = A'$)
	H	H	2	Hermitian ($A = \text{conjg}(A')$)

	MKL interface		NSB interface	Matrix characteristics
	T	T	3	triangular
	A	A	4	skew(anti)-symmetric ($A=-A'$)
	D	D	5	diagonal
2nd element value	<i>matdescra</i> (2)	<i>matdescra</i> (1)	<i>descra</i> (2)	upper/lower triangular indicator
	L	L	1	lower
	U	U	2	upper
3rd element value	<i>matdescra</i> (3)	<i>matdescra</i> (2)	<i>descra</i> (3)	main diagonal type
	N	N	0	non-unit
	U	U	1	unit
4th element value	<i>matdescra</i> (4)	<i>matdescra</i> (3)		type of indexing
	F			one-based indexing
	C			zero-based indexing

In some cases possible element values of the parameter *matdescra* depend on the values of other elements. The [Table "Possible Combinations of Element Values of the Parameter *matdescra*"](#) lists all possible combinations of element values for both multiplication routines and triangular solvers.

Possible Combinations of Element Values of the Parameter *matdescra*

Routines	matdescra(1)	matdescra(2)	matdescra(3)	matdescra(4)
Multiplication Routines	G	ignored	ignored	F (default) or C
	S or H	L (default)	N (default)	F (default) or C
	S or H	L (default)	U	F (default) or C
	S or H	U	N (default)	F (default) or C
	S or H	U	U	F (default) or C
	A	L (default)	ignored	F (default) or C
	A	U	ignored	F (default) or C
Multiplication Routines and Triangular Solvers	T	L	U	F (default) or C
	T	L	N	F (default) or C
	T	U	U	F (default) or C
	T	U	N	F (default) or C
	D	ignored	N (default)	F (default) or C
	D	ignored	U	F (default) or C

For a matrix in the skyline format with the main diagonal declared to be a unit, diagonal elements must be stored in the sparse representation even if they are zero. In all other formats, diagonal elements can be stored (if needed) in the sparse representation if they are not zero.

Operations with Partial Matrices

One of the distinctive feature of the Intel MKL Sparse BLAS routines is a possibility to perform operations only on partial matrices composed of certain parts (triangles and the main diagonal) of the input sparse matrix. It can be done by setting properly first three elements of the parameter *matdescra*.

An arbitrary sparse matrix A can be decomposed as

$$A = L + D + U$$

where L is the strict lower triangle of A , U is the strict upper triangle of A , D is the main diagonal.

[Table "Output Matrices for Multiplication Routines"](#) shows correspondence between the output matrices and values of the parameter *matdescra* for the sparse matrix A for multiplication routines.

Output Matrices for Multiplication Routines

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
G	ignored	ignored	$\alpha * \text{op}(A) * x + \beta * y$ $\alpha * \text{op}(A) * B + \beta * C$

Sparse BLAS Level 2 and Level 3 Routines.

Table “Sparse BLAS Level 2 and Level 3 Routines” lists the sparse BLAS Level 2 and Level 3 routines described in more detail later in this section.

Sparse BLAS Level 2 and Level 3 Routines

Routine/Function	Description
Simplified interface, one-based indexing	
<code>mkl_?csrgemv</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation)
<code>mkl_?bsrgemv</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation).
<code>mkl_?coogemv</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format.
<code>mkl_?diagemv</code>	Computes matrix - vector product of a sparse general matrix in the diagonal format.
<code>mkl_?csrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation)
<code>mkl_?bsrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation).
<code>mkl_?coosymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format.
<code>mkl_?diasymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the diagonal format.
<code>mkl_?csrtrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation).

Routine/Function	Description
<code>mkl_?bsrtrs</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation).
<code>mkl_?cootrs</code>	Triangular solvers with simplified interface for a sparse matrix in the coordinate format.
<code>mkl_?diatrs</code>	Triangular solvers with simplified interface for a sparse matrix in the diagonal format.

Simplified interface, zero-based indexing

<code>mkl_cspblas_?csrgemv</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?bsrgemv</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?coogemv</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format with zero-based indexing.
<code>mkl_cspblas_?csrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) with zero-based indexing
<code>mkl_cspblas_?bsrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?coosymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format with zero-based indexing.
<code>mkl_cspblas_?csrtrs</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?bsrtrs</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?cootrs</code>	Triangular solver with simplified interface for a sparse matrix in the coordinate format with zero-based indexing.

Typical (conventional) interface, one-based and zero-based indexing

<code>mkl_?csrmv</code>	Computes matrix - vector product of a sparse matrix in the CSR format.
<code>mkl_?bsrmv</code>	Computes matrix - vector product of a sparse matrix in the BSR format.
<code>mkl_?cscmv</code>	Computes matrix - vector product for a sparse matrix in the CSC format.
<code>mkl_?coomv</code>	Computes matrix - vector product for a sparse matrix in the coordinate format.
<code>mkl_?csrs</code>	Solves a system of linear equations for a sparse matrix in the CSR format.

Routine/Function	Description
<code>mkl_?bsrsv</code>	Solves a system of linear equations for a sparse matrix in the BSR format.
<code>mkl_?cscsv</code>	Solves a system of linear equations for a sparse matrix in the CSC format.
<code>mkl_?coosv</code>	Solves a system of linear equations for a sparse matrix in the coordinate format.
<code>mkl_?csrmm</code>	Computes matrix - matrix product of a sparse matrix in the CSR format
<code>mkl_?bsrmm</code>	Computes matrix - matrix product of a sparse matrix in the BSR format.
<code>mkl_?cscmm</code>	Computes matrix - matrix product of a sparse matrix in the CSC format
<code>mkl_?coomm</code>	Computes matrix - matrix product of a sparse matrix in the coordinate format.
<code>mkl_?csrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSR format.
<code>mkl_?bsrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the BSR format.
<code>mkl_?cscsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSC format.
<code>mkl_?coosm</code>	Solves a system of linear matrix equations for a sparse matrix in the coordinate format.

Typical (conventional) interface, one-based indexing

<code>mkl_?diamv</code>	Computes matrix - vector product of a sparse matrix in the diagonal format.
<code>mkl_?skymv</code>	Computes matrix - vector product for a sparse matrix in the skyline storage format.
<code>mkl_?diasv</code>	Solves a system of linear equations for a sparse matrix in the diagonal format.
<code>mkl_?skysv</code>	Solves a system of linear equations for a sparse matrix in the skyline format.
<code>mkl_?diamm</code>	Computes matrix - matrix product of a sparse matrix in the diagonal format.
<code>mkl_?skymm</code>	Computes matrix - matrix product of a sparse matrix in the skyline storage format.
<code>mkl_?diasm</code>	Solves a system of linear matrix equations for a sparse matrix in the diagonal format.
<code>mkl_?skysm</code>	Solves a system of linear matrix equations for a sparse matrix in the skyline storage format.

Auxiliary routines

Matrix converters

Routine/Function	Description
<code>mkl_?dnsCSR</code>	Converts a sparse matrix in uncompressed representation to CSR format (3-array variation) and vice versa.
<code>mkl_?csRCOO</code>	Converts a sparse matrix in CSR format (3-array variation) to coordinate format and vice versa.
<code>mkl_?csRBsr</code>	Converts a sparse matrix in CSR format to BSR format (3-array variations) and vice versa.
<code>mkl_?csRCsc</code>	Converts a sparse matrix in CSR format to CSC format and vice versa (3-array variations).
<code>mkl_?csRDia</code>	Converts a sparse matrix in CSR format (3-array variation) to diagonal format and vice versa.
<code>mkl_?csRSky</code>	Converts a sparse matrix in CSR format (3-array variation) to sky line format and vice versa.
Operations on sparse matrices	
<code>mkl_?csRadd</code>	Computes the sum of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.
<code>mkl_?csRMultCSR</code>	Computes the product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.
<code>mkl_?csRMultD</code>	Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix.

`mkl_?csrgemv`

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrgeMV(transa, m, a, ia, ja, x, y)
call mkl_dcsrgeMV(transa, m, a, ia, ja, x, y)
call mkl_ccsrgeMV(transa, m, a, ia, ja, x, y)
call mkl_zcsrgeMV(transa, m, a, ia, ja, x, y)
```

C:

```
void mkl_scsrgeMV (char *transa, MKL_INT *m, float *a, MKL_INT *ia, MKL_INT *ja, float *x, float *y);
void mkl_dcsrgeMV (char *transa, MKL_INT *m, double *a, MKL_INT *ia, MKL_INT *ja, double *x, double *y);
void mkl_ccsrgeMV (char *transa, MKL_INT *m, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcsrgeMV (char *transa, MKL_INT *m, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrgemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := A'*x,
```

where:

x and *y* are vectors,

A is an *m*-by-*m* sparse square matrix in the CSR format (3-array variation), *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then as <i>y</i> := <i>A</i> * <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>A'</i> * <i>x</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL for <code>mkl_scsrgemv</code> . DOUBLE PRECISION for <code>mkl_dcsrgemv</code> . COMPLEX for <code>mkl_ccsrgemv</code> . DOUBLE COMPLEX for <code>mkl_zcsrgemv</code> . Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length <i>m</i> + 1, containing indices of elements in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> (<i>m</i> + 1) is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.

x

REAL for mkl_scsrgemv.
 DOUBLE PRECISION for mkl_dcsrgemv.
 COMPLEX for mkl_ccsrgemv.
 DOUBLE COMPLEX for mkl_zcsrgemv.
Array, size is m .
 On entry, the array x must contain the vector x .

Output Parameters

y

REAL for mkl_scsrgemv.
 DOUBLE PRECISION for mkl_dcsrgemv.
 COMPLEX for mkl_ccsrgemv.
 DOUBLE COMPLEX for mkl_zcsrgemv.
Array, size at least m .
 On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m
```

```
  INTEGER ia(*), ja(*)
```

```
  REAL a(*), x(*), y(*)
```

```
SUBROUTINE mkl_dcsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m
```

```
  INTEGER ia(*), ja(*)
```

```
  DOUBLE PRECISION a(*), x(*), y(*)
```

```
SUBROUTINE mkl_ccsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m
```

```
  INTEGER ia(*), ja(*)
```

```
  COMPLEX a(*), x(*), y(*)
```

```
SUBROUTINE mkl_zcsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m
  INTEGER ia(*), ja(*)
  DOUBLE COMPLEX a(*), x(*), y(*)
```

C:

```
void mkl_scsrgemv(char *transa, int *m, float *a,
int *ia, int *ja, float *x, float *y);

void mkl_dcsrgemv(char *transa, int *m, double *a,
int *ia, int *ja, double *x, double *y);

void mkl_ccsrgemv(char *transa, int *m, MKL_Complex8 *a,
int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcsrgemv(char *transa, int *m, MKL_Complex16 *a,
int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax**Fortran:**

```
call mkl_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
void mkl_sbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, float *a, MKL_INT *ia,
MKL_INT *ja, float *x, float *y);

void mkl_dbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, double *a, MKL_INT *ia,
MKL_INT *ja, double *x, double *y);

void mkl_cbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, MKL_Complex8 *a, MKL_INT *ia,
MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, MKL_Complex16 *a, MKL_INT
*ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- **Fortran:** mkl.fi
- **C:** mkl.h

Description

The `mkl_?bsrgemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := A'*x,
```

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation), A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>transa</code>	CHARACTER*1. Specifies the operation. If <code>transa</code> = ' <code>N</code> ' or ' <code>n</code> ', then the matrix-vector product is computed as <code>y := A*x</code> If <code>transa</code> = ' <code>T</code> ' or ' <code>t</code> ' or ' <code>C</code> ' or ' <code>c</code> ', then the matrix-vector product is computed as <code>y := A'*x</code> ,
<code>m</code>	INTEGER. Number of block rows of the matrix A .
<code>lb</code>	INTEGER. Size of the block in the matrix A .
<code>a</code>	REAL for <code>mkl_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_dbsrgemv</code> . COMPLEX for <code>mkl_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_zbsrgemv</code> . Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by <code>lb*lb</code> . Refer to <code>values</code> array description in BSR Format for more details.
<code>ia</code>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <code>a</code> , such that <code>ia(i)</code> is the index in the array <code>a</code> of the first non-zero element from the row i . The value of the last element <code>ia(m + 1)</code> is equal to the number of non-zero blocks plus one. Refer to <code>rowIndex</code> array description in BSR Format for more details.
<code>ja</code>	INTEGER. Array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to <code>columns</code> array description in BSR Format for more details.

x REAL for mkl_sbsrgemv.
 DOUBLE PRECISION for mkl_dbsrgemv.
 COMPLEX for mkl_cbsrgemv.
 DOUBLE COMPLEX for mkl_zbsrgemv.
 Array, size ($m \times lb$).
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for mkl_sbsrgemv.
 DOUBLE PRECISION for mkl_dbsrgemv.
 COMPLEX for mkl_cbsrgemv.
 DOUBLE COMPLEX for mkl_zbsrgemv.
 Array, size at least ($m \times lb$).
 On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m, lb
```

```
  INTEGER ia(*), ja(*)
```

```
  REAL a(*), x(*), y(*)
```

```
SUBROUTINE mkl_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m, lb
```

```
  INTEGER ia(*), ja(*)
```

```
  DOUBLE PRECISION a(*), x(*), y(*)
```

```
SUBROUTINE mkl_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

```
  CHARACTER*1 transa
```

```
  INTEGER m, lb
```

```
  INTEGER ia(*), ja(*)
```

```
  COMPLEX a(*), x(*), y(*)
```

```
SUBROUTINE mkl_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m, lb
  INTEGER ia(*), ja(*)
  DOUBLE COMPLEX a(*), x(*), y(*)
```

C:

```
void mkl_dbsrgemv(char *transa, int *m, int *lb, double *a,
int *ia, int *ja, double *x, double *y);
void mkl_sbsrgemv(char *transa, int *m, int *lb, float *a,
int *ia, int *ja, float *x, float *y);
void mkl_cbsrgemv(char *transa, int *m, int *lb, MKL_Complex8 *a,
int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zbsrgemv(char *transa, int *m, int *lb, MKL_Complex16 *a,
int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?coogemv

Computes matrix-vector product of a sparse general matrix stored in the coordinate format with one-based indexing.

Syntax**Fortran:**

```
call mkl_scoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_ccoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_zcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
void mkl_scoogemv (char *transa, MKL_INT *m, float *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, float *x, float *y);
void mkl_dcoogemv (char *transa, MKL_INT *m, double *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, double *x, double *y);
void mkl_ccoogemv (char *transa, MKL_INT *m, MKL_Complex8 *val, MKL_INT *rowind,
MKL_INT *colind, MKL_INT *nnz, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcoogemv (char *transa, MKL_INT *m, MKL_Complex16 *val, MKL_INT *rowind,
MKL_INT *colind, MKL_INT *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- **Fortran:** mkl.fi
- **C:** mkl.h

Description

The `mkl_?coogemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := A'*x,
```

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format, A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>transa</code>	CHARACTER*1. Specifies the operation. If <code>transa</code> = ' <code>N</code> ' or ' <code>n</code> ', then the matrix-vector product is computed as <code>y := A*x</code> If <code>transa</code> = ' <code>T</code> ' or ' <code>t</code> ' or ' <code>C</code> ' or ' <code>c</code> ', then the matrix-vector product is computed as <code>y := A'*x</code> ,
<code>m</code>	INTEGER. Number of rows of the matrix A .
<code>val</code>	REAL for <code>mkl_scoogemv</code> . DOUBLE PRECISION for <code>mkl_dcoogemv</code> . COMPLEX for <code>mkl_ccoogemv</code> . DOUBLE COMPLEX for <code>mkl_zcoogemv</code> . Array of length nnz , contains non-zero elements of the matrix A in the arbitrary order. Refer to <code>values</code> array description in Coordinate Format for more details.
<code>rowind</code>	INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A . Refer to <code>rows</code> array description in Coordinate Format for more details.
<code>colind</code>	INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to <code>columns</code> array description in Coordinate Format for more details.
<code>nnz</code>	INTEGER. Specifies the number of non-zero element of the matrix A . Refer to <code>nnz</code> description in Coordinate Format for more details.
<code>x</code>	REAL for <code>mkl_scoogemv</code> .

DOUBLE PRECISION **for** mkl_dcoogemv.
 COMPLEX **for** mkl_ccoogemv.
 DOUBLE COMPLEX **for** mkl_zcoogemv.
Array, size is m .
 One entry, the array x must contain the vector x .

Output Parameters

y REAL **for** mkl_scoogemv.
 DOUBLE PRECISION **for** mkl_dcoogemv.
 COMPLEX **for** mkl_ccoogemv.
 DOUBLE COMPLEX **for** mkl_zcoogemv.
Array, size at least m .
 On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

int *colind, int *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?diagemv

Computes matrix - vector product of a sparse general matrix stored in the diagonal format with one-based indexing.

Syntax**Fortran:**

```
call mkl_sdiagemv(transa, m, val, lval, iddiag, ndiag, x, y)
call mkl_ddiagemv(transa, m, val, lval, iddiag, ndiag, x, y)
call mkl_cdiagemv(transa, m, val, lval, iddiag, ndiag, x, y)
call mkl_zdiagemv(transa, m, val, lval, iddiag, ndiag, x, y)
```

C:

```
void mkl_sdiagemv (char *transa, MKL_INT *m, float *val, MKL_INT *lval, MKL_INT *iddiag,
MKL_INT *ndiag, float *x, float *y);
void mkl_ddiagemv (char *transa, MKL_INT *m, double *val, MKL_INT *lval, MKL_INT
*iddiag, MKL_INT *ndiag, double *x, double *y);
void mkl_cdiagemv (char *transa, MKL_INT *m, MKL_Complex8 *val, MKL_INT *lval, MKL_INT
*iddiag, MKL_INT *ndiag, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zdiagemv (char *transa, MKL_INT *m, MKL_Complex16 *val, MKL_INT *lval, MKL_INT
*iddiag, MKL_INT *ndiag, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The mkl_?diagemv routine performs a matrix-vector operation defined as

$y := A \cdot x$

or

$y := A' \cdot x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the diagonal storage format, A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for mkl_sdiagemv. DOUBLE PRECISION for mkl_ddiagemv. COMPLEX for mkl_ccsrgemv. DOUBLE COMPLEX for mkl_zdiagemv. Two-dimensional array of size <i>lval</i> * <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix A .
<i>x</i>	REAL for mkl_sdiagemv. DOUBLE PRECISION for mkl_ddiagemv. COMPLEX for mkl_ccsrgemv. DOUBLE COMPLEX for mkl_zdiagemv. Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector x .

Output Parameters

<i>y</i>	REAL for mkl_sdiagemv. DOUBLE PRECISION for mkl_ddiagemv. COMPLEX for mkl_ccsrgemv.
----------	---

DOUBLE COMPLEX for mkl_zdiagemv.
Array, size at least m .
 On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```

```

```
  INTEGER iddiag(*)
```

```
  DOUBLE COMPLEX val(lval,*), x(*), y(*)
```

C:

```
void mkl_sdiagemv(char *transa, int *m, float *val, int *lval,
int *iddiag, int *ndiag, float *x, float *y);

void mkl_ddiagemv(char *transa, int *m, double *val, int *lval,
int *iddiag, int *ndiag, double *x, double *y);

void mkl_cdiagemv(char *transa, int *m, MKL_Complex8 *val, int *lval,
int *iddiag, int *ndiag, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zdiagemv(char *transa, int *m, MKL_Complex16 *val, int *lval,
int *iddiag, int *ndiag, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?csrsymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_dcsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_ccsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_zcsrsymv(uplo, m, a, ia, ja, x, y)
```

C:

```
void mkl_scsrsymv (char *uplo, MKL_INT *m, float *a, MKL_INT *ia, MKL_INT *ja, float *x, float *y);
void mkl_dcsrsymv (char *uplo, MKL_INT *m, double *a, MKL_INT *ia, MKL_INT *ja, double *x, double *y);
void mkl_ccsrsymv (char *uplo, MKL_INT *m, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcsrsymv (char *uplo, MKL_INT *m, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrsymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

`x` and `y` are vectors,

`A` is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation).

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <code>A</code> is used. If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangle of the matrix <code>A</code> is used.
-------------------	--

If `uplo = 'L'` or `'l'`, then the low triangle of the matrix A is used.

`m`

INTEGER. Number of rows of the matrix A .

`a`

REAL **for** `mkl_scsrsymv`.

DOUBLE PRECISION **for** `mkl_dcsrsymv`.

COMPLEX **for** `mkl_ccsrsymv`.

DOUBLE COMPLEX **for** `mkl_zcsrsymv`.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

`ia`

INTEGER. Array of length $m + 1$, containing indices of elements in the array `a`, such that `ia(i)` is the index in the array `a` of the first non-zero element from the row i . The value of the last element `ia(m + 1)` is equal to the number of non-zeros plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`ja`

INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array `a`. Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

`x`

REAL **for** `mkl_scsrsymv`.

DOUBLE PRECISION **for** `mkl_dcsrsymv`.

COMPLEX **for** `mkl_ccsrsymv`.

DOUBLE COMPLEX **for** `mkl_zcsrsymv`.

Array, size is m .

On entry, the array `x` must contain the vector x .

Output Parameters

`y`

REAL **for** `mkl_scsrsymv`.

DOUBLE PRECISION **for** `mkl_dcsrsymv`.

COMPLEX **for** `mkl_ccsrsymv`.

DOUBLE COMPLEX **for** `mkl_zcsrsymv`.

Array, size at least m .

On exit, the array `y` must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrsymv(uplo, m, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER m
  INTEGER ia(*), ja(*)
  REAL a(*), x(*), y(*)

SUBROUTINE mkl_dcsrsymv(uplo, m, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER m
  INTEGER ia(*), ja(*)
  DOUBLE PRECISION a(*), x(*), y(*)

SUBROUTINE mkl_ccsrsymv(uplo, m, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER m
  INTEGER ia(*), ja(*)
  COMPLEX a(*), x(*), y(*)

SUBROUTINE mkl_zcsrsymv(uplo, m, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER m
  INTEGER ia(*), ja(*)
  DOUBLE COMPLEX a(*), x(*), y(*)
```

C:

```
void mkl_scsrsymv(char *uplo, int *m, float *a,
  int *ia, int *ja, float *x, float *y);

void mkl_dcsrsymv(char *uplo, int *m, double *a,
  int *ia, int *ja, double *x, double *y);

void mkl_ccsrsymv(char *uplo, int *m, MKL_Complex8 *a,
  int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcsrsymv(char *uplo, int *m, MKL_Complex16 *a,
  int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?bsrsymv

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_sbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_zbsrsymv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
void mkl_sbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, float *a, MKL_INT *ia, MKL_INT *ja, float *x, float *y);
void mkl_dbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, double *a, MKL_INT *ia, MKL_INT *ja, double *x, double *y);
void mkl_cbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?bsrsymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation).

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <code>uplo = 'U'</code> or ' <code>u</code> ', then the upper triangle of the matrix A is used.
-------------------	---

If $uplo = 'L'$ or $'l'$, then the low triangle of the matrix A is used.

m

INTEGER. Number of block rows of the matrix A .

lb

INTEGER. Size of the block in the matrix A .

a

REAL **for** mkl_sbsrsymv.

DOUBLE PRECISION **for** mkl_dbsrsymv.

COMPLEX **for** mkl_cbsrsymv.

DOUBLE COMPLEX **for** mkl_zcsrgemv.

Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to *values* array description in [BSR Format](#) for more details.

ia

INTEGER. Array of length $(m + 1)$, containing indices of block in the array *a*, such that $ia(i)$ is the index in the array *a* of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja

INTEGER. Array containing the column indices for each non-zero block in the matrix A .

Its length is equal to the number of non-zero blocks of the matrix A . Refer to *columns* array description in [BSR Format](#) for more details.

x

REAL **for** mkl_sbsrsymv.

DOUBLE PRECISION **for** mkl_dbsrsymv.

COMPLEX **for** mkl_cbsrsymv.

DOUBLE COMPLEX **for** mkl_zcsrgemv.

Array, size $(m * lb)$.

On entry, the array *x* must contain the vector *x*.

Output Parameters

y

REAL **for** mkl_sbsrsymv.

DOUBLE PRECISION **for** mkl_dbsrsymv.

COMPLEX **for** mkl_cbsrsymv.

DOUBLE COMPLEX **for** mkl_zcsrgemv.

Array, size at least $(m * lb)$.

On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_sbsrsymv(uplo, m, lb, a, ia, ja, x, y)

float *a, int *ia, int *ja, float *x, float *y);

void mkl_dbsrsymv(char *uplo, int *m, int *lb,
double *a, int *ia, int *ja, double *x, double *y);

void mkl_cbsrsymv(char *uplo, int *m, int *lb,
MKL_Complex8 *a, int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zbsrsymv(char *uplo, int *m, int *lb,
MKL_Complex16 *a, int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_scoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_ccoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_zcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
void mkl_scoosymv (char *uplo, MKL_INT *m, float *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, float *x, float *y);

void mkl_dcoosymv (char *uplo, MKL_INT *m, double *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, double *x, double *y);

void mkl_ccoosymv (char *uplo, MKL_INT *m, MKL_Complex8 *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcoosymv (char *uplo, MKL_INT *m, MKL_Complex16 *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The mkl_?coosymv routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and *y* are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

uplo CHARACTER*1. Specifies whether the upper or low triangle of the matrix *A* is used.

If *uplo* = 'U' or 'u', then the upper triangle of the matrix *A* is used.

If `uplo` = 'L' or 'l', then the low triangle of the matrix A is used.

`m` INTEGER. Number of rows of the matrix A .

`val` REAL for `mkl_scoosymv`.

DOUBLE PRECISION for `mkl_dcoosymv`.

COMPLEX for `mkl_ccoosymv`.

DOUBLE COMPLEX for `mkl_zcoosymv`.

Array of length `nnz`, contains non-zero elements of the matrix A in the arbitrary order.

Refer to `values` array description in [Coordinate Format](#) for more details.

`rowind` INTEGER. Array of length `nnz`, contains the row indices for each non-zero element of the matrix A .

Refer to `rows` array description in [Coordinate Format](#) for more details.

`colind` INTEGER. Array of length `nnz`, contains the column indices for each non-zero element of the matrix A . Refer to `columns` array description in [Coordinate Format](#) for more details.

`nnz` INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to `nnz` description in [Coordinate Format](#) for more details.

`x` REAL for `mkl_scoosymv`.

DOUBLE PRECISION for `mkl_dcoosymv`.

COMPLEX for `mkl_ccoosymv`.

DOUBLE COMPLEX for `mkl_zcoosymv`.

Array, size is `m`.

On entry, the array `x` must contain the vector x .

Output Parameters

`y` REAL for `mkl_scoosymv`.

DOUBLE PRECISION for `mkl_dcoosymv`.

COMPLEX for `mkl_ccoosymv`.

DOUBLE COMPLEX for `mkl_zcoosymv`.

Array, size at least `m`.

On exit, the array `y` must contain the vector y .

Interfaces

```

mkl_?diasymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
call mkl_ddiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
call mkl_cdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
call mkl_zdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
```

C:

```
void mkl_sdiasymv (char *uplo, MKL_INT *m, float *val, MKL_INT *lval, MKL_INT *iddiag,
MKL_INT *ndiag, float *x, float *y);

void mkl_ddiasymv (char *uplo, MKL_INT *m, double *val, MKL_INT *lval, MKL_INT *iddiag,
MKL_INT *ndiag, double *x, double *y);

void mkl_cdiasymv (char *uplo, MKL_INT *m, MKL_Complex8 *val, MKL_INT *lval, MKL_INT
*iddiag, MKL_INT *ndiag, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zdiasymv (char *uplo, MKL_INT *m, MKL_Complex16 *val, MKL_INT *lval, MKL_INT
*iddiag, MKL_INT *ndiag, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The mkl_?diasymv routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and *y* are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

uplo CHARACTER*1. Specifies whether the upper or low triangle of the matrix *A* is used.

If *uplo* = 'U' or 'u', then the upper triangle of the matrix *A* is used.

If `uplo` = 'L' or 'l', then the low triangle of the matrix A is used.

`m` INTEGER. Number of rows of the matrix A .

`val` REAL for `mkl_sdiasymv`.

DOUBLE PRECISION for `mkl_ddiasymv`.

COMPLEX for `mkl_cdiasymv`.

DOUBLE COMPLEX for `mkl_zdiasymv`.

Two-dimensional array of size `lval` by `ndiag`, contains non-zero diagonals of the matrix A . Refer to `values` array description in [Diagonal Storage Scheme](#) for more details.

`lval` INTEGER. Leading dimension of `val`, $lval \geq m$. Refer to `lval` description in [Diagonal Storage Scheme](#) for more details.

`idiag` INTEGER. Array of length `ndiag`, contains the distances between main diagonal and each non-zero diagonals in the matrix A .

Refer to `distance` array description in [Diagonal Storage Scheme](#) for more details.

`ndiag` INTEGER. Specifies the number of non-zero diagonals of the matrix A .

`x` REAL for `mkl_sdiasymv`.

DOUBLE PRECISION for `mkl_ddiasymv`.

COMPLEX for `mkl_cdiasymv`.

DOUBLE COMPLEX for `mkl_zdiasymv`.

Array, size is m .

On entry, the array `x` must contain the vector x .

Output Parameters

`y` REAL for `mkl_sdiasymv`.

DOUBLE PRECISION for `mkl_ddiasymv`.

COMPLEX for `mkl_cdiasymv`.

DOUBLE COMPLEX for `mkl_zdiasymv`.

Array, size at least m .

On exit, the array `y` must contain the vector y .

Interfaces

void mkl_zdiasymv(char *uplo, int *m, MKL_Complex16 *val, int *lval,
int *idiag, int *ndiag, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?csrtrs

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_dcsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_ccsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_zcsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
void mkl_scsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, float *a, MKL_INT
*ia, MKL_INT *ja, float *x, float *y);

void mkl_dcsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, double *a,
MKL_INT *ia, MKL_INT *ja, double *x, double *y);

void mkl_ccsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex8 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex16 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrtrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3 array variation):

$A^*y = x$

or

$A'^*y = x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If $uplo = 'U'$ or ' u ', then the upper triangle of the matrix A is used. If $uplo = 'L'$ or ' l ', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If $transa = 'N'$ or ' n ', then $A^*y = x$ If $transa = 'T'$ or ' t ' or ' C ' or ' c ', then $A'^*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If $diag = 'U'$ or ' u ', then A is a unit triangular. If $diag = 'N'$ or ' n ', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL for mkl_scsrtrmv. DOUBLE PRECISION for mkl_dcsrtrmv. COMPLEX for mkl_ccsrtrmv. DOUBLE COMPLEX for mkl_zcsrtrmv. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(i)$ is the index in the array <i>a</i> of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
-----------	---

<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
-----------	--

NOTE

Column indices must be sorted in increasing order for each row.

<i>x</i>	REAL for mkl_scsrtrmv. DOUBLE PRECISION for mkl_dcsrtrmv.
----------	--

COMPLEX for mkl_ccsrtrmv.
 DOUBLE COMPLEX for mkl_zcsrtrmv.
Array, size is m .
 On entry, the array x must contain the vector x .

Output Parameters

y
 REAL for mkl_scsrtrmv.
 DOUBLE PRECISION for mkl_dcsrtrmv.
 COMPLEX for mkl_ccsrtrmv.
 DOUBLE COMPLEX for mkl_zcsrtrmv.
Array, size at least m .
 Contains the vector y .

MKL_Complex16 *a, int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?bsrtrs

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax**Fortran:**

```
call mkl_sbsrtrs(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_dbsrtrs(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_cbsrtrs(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_zbsrtrs(uplo, transa, diag, m, lb, a, ia, ja, x, y)
```

C:

```
void mkl_sbsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_INT *lb,
float *a, MKL_INT *ia, MKL_INT *ja, float *x, float *y);

void mkl_dbsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_INT *lb,
double *a, MKL_INT *ia, MKL_INT *ja, double *x, double *y);

void mkl_cbsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_INT *lb,
MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zbsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_INT *lb,
MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The mkl_?bsrtrs routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) :

$y := A \cdot x$

or

$y := A' \cdot x,$

where:

x and *y* are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as <i>y</i> := <i>A</i> * <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as <i>y</i> := <i>A'</i> * <i>x</i> .
<i>diag</i>	CHARACTER*1. Specifies whether <i>A</i> is a unit triangular matrix. If <i>diag</i> = 'U' or 'u', then <i>A</i> is a unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not a unit triangular.
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>a</i>	REAL for mkl_sbsrtrsv. DOUBLE PRECISION for mkl_dbsrtrsv. COMPLEX for mkl_cbsrtrsv. DOUBLE COMPLEX for mkl_zbsrtrsv. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb</i> * <i>lb</i> . Refer to <i>values</i> array description in BSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for mkl_sbsrtrs v. DOUBLE PRECISION for mkl_dbsrtrs v. COMPLEX for mkl_cbsrtrs v. DOUBLE COMPLEX for mkl_zbsrtrs v. Array, size $(m * lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for mkl_sbsrtrs v. DOUBLE PRECISION for mkl_dbsrtrs v. COMPLEX for mkl_cbsrtrs v. DOUBLE COMPLEX for mkl_zbsrtrs v. Array, size at least $(m * lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> .
----------	--

```

mkl_?cootrv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with one-based indexing.

Syntax**Fortran:**

```
call mkl_scootrv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_dcootrv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_ccootrv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_zcootrv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
```

C:

```
void mkl_scootrv (char *uplo, char *transa, char *diag, MKL_INT *m, float *val,
MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, float *x, float *y);
void mkl_dcootrv (char *uplo, char *transa, char *diag, MKL_INT *m, double *val,
MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, double *x, double *y);
void mkl_ccootrv (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex8 *val,
MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, MKL_Complex8 *x, MKL_Complex8 *y);
```

```
void mkl_zcootrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex16
*val, MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, MKL_Complex16 *x, MKL_Complex16
*y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?cootrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format:

$A^*y = x$

or

$A'^*y = x$,

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A^*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'^*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_scootrs</code> . DOUBLE PRECISION for <code>mkl_dcootrs</code> . COMPLEX for <code>mkl_ccootrs</code> . DOUBLE COMPLEX for <code>mkl_zcootrs</code> .

Array of length nnz , contains non-zero elements of the matrix A in the arbitrary order.

Refer to $values$ array description in [Coordinate Format](#) for more details.

$rowind$

INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A .

Refer to $rows$ array description in [Coordinate Format](#) for more details.

$colind$

INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to $columns$ array description in [Coordinate Format](#) for more details.

nnz

INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to nnz description in [Coordinate Format](#) for more details.

x

REAL **for** mkl_scootrs.

DOUBLE PRECISION **for** mkl_dcootrs.

COMPLEX **for** mkl_ccootrs.

DOUBLE COMPLEX **for** mkl_zcootrs.

Array, size is m .

On entry, the array x must contain the vector x .

Output Parameters

y

REAL **for** mkl_scootrs.

DOUBLE PRECISION **for** mkl_dcootrs.

COMPLEX **for** mkl_ccootrs.

DOUBLE COMPLEX **for** mkl_zcootrs.

Array, size at least m .

Contains the vector y .

```

[mkl_?diatrs](#)

Triangular solvers with simplified interface for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiatrsv(uplo, transa, diag, m, val, lval, iddiag, ndiag, x, y)
call mkl_ddiatrsv(uplo, transa, diag, m, val, lval, iddiag, ndiag, x, y)
call mkl_cdiatrsv(uplo, transa, diag, m, val, lval, iddiag, ndiag, x, y)
call mkl_zdiatrsv(uplo, transa, diag, m, val, lval, iddiag, ndiag, x, y)
```

C:

```
void mkl_sdiatrs (char *uplo, char *transa, char *diag, MKL_INT *m, float *val,
MKL_INT *lval, MKL_INT *idiag, MKL_INT *ndiag, float *x, float *y);
void mkl_ddiatrs (char *uplo, char *transa, char *diag, MKL_INT *m, double *val,
MKL_INT *lval, MKL_INT *idiag, MKL_INT *ndiag, double *x, double *y);
void mkl_cdiatrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex8 *val,
MKL_INT *lval, MKL_INT *idiag, MKL_INT *ndiag, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zdiatrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_Complex16
*val, MKL_INT *lval, MKL_INT *idiag, MKL_INT *ndiag, MKL_Complex16 *x, MKL_Complex16
*y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?diatrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$A^*y = x$

or

$A'^*y = x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <code>uplo</code> = 'U' or 'u', then the upper triangle of the matrix A is used. If <code>uplo</code> = 'L' or 'l', then the low triangle of the matrix A is used.
<code>transa</code>	CHARACTER*1. Specifies the system of linear equations. If <code>transa</code> = 'N' or 'n', then $A^*y = x$ If <code>transa</code> = 'T' or 't' or 'C' or 'c', then $A'^*y = x$,
<code>diag</code>	CHARACTER*1. Specifies whether A is unit triangular. If <code>diag</code> = 'U' or 'u', then A is unit triangular. If <code>diag</code> = 'N' or 'n', then A is not unit triangular.

<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	<p>REAL for mkl_sdiatrv.</p> <p>DOUBLE PRECISION for mkl_ddiatrv.</p> <p>COMPLEX for mkl_cdiatrv.</p> <p>DOUBLE COMPLEX for mkl_zdiatrv.</p>
	Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> .

NOTE

All elements of this array must be sorted in increasing order.

	Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	<p>REAL for mkl_sdiatrv.</p> <p>DOUBLE PRECISION for mkl_ddiatrv.</p> <p>COMPLEX for mkl_cdiatrv.</p> <p>DOUBLE COMPLEX for mkl_zdiatrv.</p>
	Array, size is <i>m</i> .
	On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	<p>REAL for mkl_sdiatrv.</p> <p>DOUBLE PRECISION for mkl_ddiatrv.</p> <p>COMPLEX for mkl_cdiatrv.</p> <p>DOUBLE COMPLEX for mkl_zdiatrv.</p>
	Array, size at least <i>m</i> .

Contains the vector *y*.

*val, int *lval, int *idiag, int *ndiag, float *x, float *y);
```

```
void mkl_ddiatrsv(char *uplo, char *transa, char *diag, int *m, double
```

```
*val, int *lval, int *idiag, int *ndiag, double *x, double *y);
```

```
void mkl_cdiatrsv(char *uplo, char *transa, char *diag, int *m, MKL_Complex8
```

```
*val, int *lval, int *idiag, int *ndiag, MKL_Complex8 *x, MKL_Complex8 *y);
```

```
void mkl_zdiatrsv(char *uplo, char *transa, char *diag, int *m, MKL_Complex16
```

```
*val, int *lval, int *idiag, int *ndiag, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_cspblas_?csrgemv

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrgemv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_dcsrgemv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_ccsrgemv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_zcsrgemv(transa, m, a, ia, ja, x, y)
```

C:

```
void mkl_cspblas_scsrgemv (char *transa, MKL_INT *m, float *a, MKL_INT *ia, MKL_INT
*ja, float *x, float *y);

void mkl_cspblas_dcsrgemv (char *transa, MKL_INT *m, double *a, MKL_INT *ia, MKL_INT
*ja, double *x, double *y);

void mkl_cspblas_ccsrgemv (char *transa, MKL_INT *m, MKL_Complex8 *a, MKL_INT *ia,
MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcsrgemv (char *transa, MKL_INT *m, MKL_Complex16 *a, MKL_INT *ia,
MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?csrgemv` routine performs a matrix-vector operation defined as

$y := A^*x$

or

$y := A'^*x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

`transa` CHARACTER*1. Specifies the operation.

If $\text{transa} = \text{'N'}$ or 'n' , then the matrix-vector product is computed as
 $y := A^*x$

If $\text{transa} = \text{'T'}$ or 't' or 'C' or 'c' , then the matrix-vector product is computed as $y := A'^*x$,

m

INTEGER. Number of rows of the matrix A .

a

REAL **for** mkl_cspblas_scsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dcsrgemv.

COMPLEX **for** mkl_cspblas_ccsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcsrgemv.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ia

INTEGER. Array of length $m + 1$, containing indices of elements in the array *a*, such that $\text{ia}(I)$ is the index in the array *a* of the first non-zero element from the row I . The value of the last element $\text{ia}(m)$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

ja

INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

x

REAL **for** mkl_cspblas_scsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dcsrgemv.

COMPLEX **for** mkl_cspblas_ccsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcsrgemv.

Array, size is *m*.

One entry, the array *x* must contain the vector *x*.

Output Parameters

y

REAL **for** mkl_cspblas_scsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dcsrgemv.

COMPLEX **for** mkl_cspblas_ccsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcsrgemv.

Array, size at least *m*.

On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_scsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m
  INTEGER ia(*), ja(*)
  REAL a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_dcsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m
  INTEGER ia(*), ja(*)
  DOUBLE PRECISION a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_ccsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m
  INTEGER ia(*), ja(*)
  COMPLEX a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_zcsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m
  INTEGER ia(*), ja(*)
  DOUBLE COMPLEX a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_scsrgemv(char *transa, int *m, float *a,
                           int *ia, int *ja, float *x, float *y);

void mkl_cspblas_dcsrgemv(char *transa, int *m, double *a,
                           int *ia, int *ja, double *x, double *y);

void mkl_cspblas_ccsrgemv(char *transa, int *m, MKL_Complex8 *a,
                           int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcsrgemv(char *transa, int *m, MKL_Complex16 *a,
                           int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_cspblas_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
void mkl_cspblas_sbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, float *a, MKL_INT
*ia, MKL_INT *ja, float *x, float *y);
void mkl_cspblas_dbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, double *a, MKL_INT
*ia, MKL_INT *ja, double *x, double *y);
void mkl_cspblas_cbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, MKL_Complex8 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zbsrgemv (char *transa, MKL_INT *m, MKL_INT *lb, MKL_Complex16 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?bsrgemv` routine performs a matrix-vector operation defined as

$y := A^*x$

or

$y := A'^*x,$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

`transa` CHARACTER*1. Specifies the operation.

If $\text{transa} = \text{'N'}$ or 'n' , then the matrix-vector product is computed as
 $y := A^*x$

If $\text{transa} = \text{'T'}$ or 't' or 'C' or 'c' , then the matrix-vector product is computed as $y := A'^*x$,

m

INTEGER. Number of block rows of the matrix A .

lb

INTEGER. Size of the block in the matrix A .

a

REAL **for** mkl_cspblas_sbsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrgemv.

COMPLEX **for** mkl_cspblas_cbsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrgemv.

Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to *values* array description in [BSR Format](#) for more details.

ia

INTEGER. Array of length $(m + 1)$, containing indices of block in the array *a*, such that $ia(i)$ is the index in the array *a* of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja

INTEGER. Array containing the column indices for each non-zero block in the matrix A .

Its length is equal to the number of non-zero blocks of the matrix A . Refer to *columns* array description in [BSR Format](#) for more details.

x

REAL **for** mkl_cspblas_sbsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrgemv.

COMPLEX **for** mkl_cspblas_cbsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrgemv.

Array, size $(m * lb)$.

On entry, the array *x* must contain the vector *x*.

Output Parameters

y

REAL **for** mkl_cspblas_sbsrgemv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrgemv.

COMPLEX **for** mkl_cspblas_cbsrgemv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrgemv.

Array, size at least $(m * lb)$.

On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m, lb
  INTEGER ia(*), ja(*)
  REAL a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m, lb
  INTEGER ia(*), ja(*)
  DOUBLE PRECISION a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m, lb
  INTEGER ia(*), ja(*)
  COMPLEX a(*), x(*), y(*)

SUBROUTINE mkl_cspblas_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER m, lb
  INTEGER ia(*), ja(*)
  DOUBLE COMPLEX a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_sbsrgemv(char *transa, int *m, int *lb,
                           float *a, int *ia, int *ja, float *x, float *y);

void mkl_cspblas_dbsrgemv(char *transa, int *m, int *lb,
                           double *a, int *ia, int *ja, double *x, double *y);

void mkl_cspblas_cbsrgemv(char *transa, int *m, int *lb,
                           MKL_Complex8 *a, int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zbsrgemv(char *transa, int *m, int *lb,
                           MKL_Complex16 *a, int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_cspblas_?coogemv

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_ccoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_zcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
void mkl_cspblas_scoogemv (char *transa, MKL_INT *m, float *val, MKL_INT *rowind,
                            MKL_INT *colind, MKL_INT *nnz, float *x, float *y);
void mkl_cspblas_dcoogemv (char *transa, MKL_INT *m, double *val, MKL_INT *rowind,
                           MKL_INT *colind, MKL_INT *nnz, double *x, double *y);
void mkl_cspblas_ccoogemv (char *transa, MKL_INT *m, MKL_Complex8 *val, MKL_INT
                           *rowind, MKL_INT *colind, MKL_INT *nnz, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zcoogemv (char *transa, MKL_INT *m, MKL_Complex16 *val, MKL_INT
                           *rowind, MKL_INT *colind, MKL_INT *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_dcoogemv` routine performs a matrix-vector operation defined as

$y := A^*x$

or

$y := A'^*x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format with zero-based indexing, A' is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>transa</code>	CHARACTER*1. Specifies the operation.
---------------------	---------------------------------------

If $\text{transa} = \text{'N'}$ or 'n' , then the matrix-vector product is computed as

$y := A^*x$

If $\text{transa} = \text{'T'}$ or 't' or 'C' or 'c' , then the matrix-vector product is computed as $y := A'^*x$.

m

INTEGER. Number of rows of the matrix A .

val

REAL **for** mkl_cspblas_scoogemv.

DOUBLE PRECISION **for** mkl_cspblas_dcoogemv.

COMPLEX **for** mkl_cspblas_ccoogemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcoogemv.

Array of length nnz , contains non-zero elements of the matrix A in the arbitrary order.

Refer to *values* array description in [Coordinate Format](#) for more details.

rowind

INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A .

Refer to *rows* array description in [Coordinate Format](#) for more details.

colind

INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to *columns* array description in [Coordinate Format](#) for more details.

nnz

INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to *nnz* description in [Coordinate Format](#) for more details.

x

REAL **for** mkl_cspblas_scoogemv.

DOUBLE PRECISION **for** mkl_cspblas_dcoogemv.

COMPLEX **for** mkl_cspblas_ccoogemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcoogemv.

Array, size is m .

On entry, the array *x* must contain the vector x .

Output Parameters

y

REAL **for** mkl_cspblas_scoogemv.

DOUBLE PRECISION **for** mkl_cspblas_dcoogemv.

COMPLEX **for** mkl_cspblas_ccoogemv.

DOUBLE COMPLEX **for** mkl_cspblas_zcoogemv.

Array, size at least m .

On exit, the array *y* must contain the vector y .

Interfaces

FORTRAN 77:

```

```

```
void mkl_cspblas_ccoogemv(char *transa, int *m, MKL_Complex8 *val, int *rowind,
int *colind, int *nnz, MKL_Complex8 *x, MKL_Complex8 *y);
```

```
void mkl_cspblas_zcoogemv(char *transa, int *m, MKL_Complex16 *val, int *rowind,
int *colind, int *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_cspblas_?csrsymv

Computes matrix-vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_cspblas_dcsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_cspblas_ccsrsymv(uplo, m, a, ia, ja, x, y)
call mkl_cspblas_zcsrsymv(uplo, m, a, ia, ja, x, y)
```

C:

```
void mkl_cspblas_scsrsymv (char *uplo, MKL_INT *m, float *a, MKL_INT *ia, MKL_INT *ja,
float *x, float *y);

void mkl_cspblas_dcsrsymv (char *uplo, MKL_INT *m, double *a, MKL_INT *ia, MKL_INT *ja,
double *x, double *y);

void mkl_cspblas_ccsrsymv (char *uplo, MKL_INT *m, MKL_Complex8 *a, MKL_INT *ia,
MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcsrsymv (char *uplo, MKL_INT *m, MKL_Complex16 *a, MKL_INT *ia,
MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?csrsymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation) with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.
-------------------	---

If $uplo = 'U'$ or ' u ', then the upper triangle of the matrix A is used.

If $uplo = 'L'$ or ' l ', then the low triangle of the matrix A is used.

m

INTEGER. Number of rows of the matrix A .

a

REAL for `mkl_cspblas_scsrsymv`.

DOUBLE PRECISION for `mkl_cspblas_dcsrsymv`.

COMPLEX for `mkl_cspblas_ccsrsymv`.

DOUBLE COMPLEX for `mkl_cspblas_zcsrsymv`.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

ia

INTEGER. Array of length $m + 1$, containing indices of elements in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

ja

INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array a . Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

x

REAL for `mkl_cspblas_scsrsymv`.

DOUBLE PRECISION for `mkl_cspblas_dcsrsymv`.

COMPLEX for `mkl_cspblas_ccsrsymv`.

DOUBLE COMPLEX for `mkl_cspblas_zcsrsymv`.

Array, size is m .

On entry, the array x must contain the vector x .

Output Parameters

y

REAL for `mkl_cspblas_scsrsymv`.

DOUBLE PRECISION for `mkl_cspblas_dcsrsymv`.

COMPLEX for `mkl_cspblas_ccsrsymv`.

DOUBLE COMPLEX for `mkl_cspblas_zcsrsymv`.

Array, size at least m .

On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_scsrsymv(uplo, m, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER m
  INTEGER ia(*), ja(*)
  REAL a(*), x(*), y(*)

```

C:

```
void mkl_cspblas_scsrsymv(char *uplo, int *m, float *a,
                           int *ia, int *ja, float *x, float *y);

void mkl_cspblas_dcsrsymv(char *uplo, int *m, double *a,
                           int *ia, int *ja, double *x, double *y);

void mkl_cspblas_ccsrsymv(char *uplo, int *m, MKL_Complex8 *a,
                           int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcsrsymv(char *uplo, int *m, MKL_Complex16 *a,
                           int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_cspblas_?bsrsymv

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-arrays variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_sbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_cbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_zbsrsymv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
void mkl_cspblas_sbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, float *a, MKL_INT *ia,
MKL_INT *ja, float *x, float *y);
void mkl_cspblas_dbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, double *a, MKL_INT *ia,
MKL_INT *ja, double *x, double *y);
void mkl_cspblas_cbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, MKL_Complex8 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zbsrsymv (char *uplo, MKL_INT *m, MKL_INT *lb, MKL_Complex16 *a,
MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?bsrsymv` routine performs a matrix-vector operation defined as

$y := A^*x$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation) with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.
-------------------	---

If $uplo = 'U'$ or ' u ', then the upper triangle of the matrix A is used.

If $uplo = 'L'$ or ' l ', then the low triangle of the matrix A is used.

m

INTEGER. Number of block rows of the matrix A .

lb

INTEGER. Size of the block in the matrix A .

a

REAL **for** mkl_cspblas_sbsrsymv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrsymv.

COMPLEX **for** mkl_cspblas_cbsrsymv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrsymv.

Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to *values* array description in [BSR Format](#) for more details.

ia

INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja

INTEGER. Array containing the column indices for each non-zero block in the matrix A .

Its length is equal to the number of non-zero blocks of the matrix A . Refer to *columns* array description in [BSR Format](#) for more details.

x

REAL **for** mkl_cspblas_sbsrsymv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrsymv.

COMPLEX **for** mkl_cspblas_cbsrsymv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrsymv.

Array, size $(m * lb)$.

On entry, the array x must contain the vector x .

Output Parameters

y

REAL **for** mkl_cspblas_sbsrsymv.

DOUBLE PRECISION **for** mkl_cspblas_dbsrsymv.

COMPLEX **for** mkl_cspblas_cbsrsymv.

DOUBLE COMPLEX **for** mkl_cspblas_zbsrsymv.

Array, size at least $(m * lb)$.

On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```

mkl_cspblas_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with zero-based indexing .

Syntax

Fortran:

```
call mkl_cspblas_scoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_ccoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_zcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
void mkl_cspblas_scoosymv (char *uplo, MKL_INT *m, float *val, MKL_INT *rowind, MKL_INT
*colind, MKL_INT *nnz, float *x, float *y);

void mkl_cspblas_dcoosymv (char *uplo, MKL_INT *m, double *val, MKL_INT *rowind,
MKL_INT *colind, MKL_INT *nnz, double *x, double *y);

void mkl_cspblas_ccoosymv (char *uplo, MKL_INT *m, MKL_Complex8 *val, MKL_INT *rowind,
MKL_INT *colind, MKL_INT *nnz, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcoosymv (char *uplo, MKL_INT *m, MKL_Complex16 *val, MKL_INT *rowind,
MKL_INT *colind, MKL_INT *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?coosymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and *y* are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used.
-------------	--

If $uplo = 'L'$ or ' l ', then the low triangle of the matrix A is used.

m INTEGER. Number of rows of the matrix A .

val REAL for mkl_cspblas_scoosymv.
 DOUBLE PRECISION for mkl_cspblas_dcoosymv.
 COMPLEX for mkl_cspblas_ccoosymv.
 DOUBLE COMPLEX for mkl_cspblas_zcoosymv.

Array of length nnz , contains non-zero elements of the matrix A in the arbitrary order.

Refer to $values$ array description in [Coordinate Format](#) for more details.

$rowind$ INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A .

Refer to $rows$ array description in [Coordinate Format](#) for more details.

$colind$ INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to $columns$ array description in [Coordinate Format](#) for more details.

nnz INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to nnz description in [Coordinate Format](#) for more details.

x REAL for mkl_cspblas_scoosymv.
 DOUBLE PRECISION for mkl_cspblas_dcoosymv.
 COMPLEX for mkl_cspblas_ccoosymv.
 DOUBLE COMPLEX for mkl_cspblas_zcoosymv.

Array, size is m .

On entry, the array x must contain the vector x .

Output Parameters

y REAL for mkl_cspblas_scoosymv.
 DOUBLE PRECISION for mkl_cspblas_dcoosymv.
 COMPLEX for mkl_cspblas_ccoosymv.
 DOUBLE COMPLEX for mkl_cspblas_zcoosymv.

Array, size at least m .

On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```

mkl_cspblas_?csrtrs

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_dcsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_ccsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_zcsrtrs(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
void mkl_cspblas_scsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, float *a,
                           MKL_INT *ia, MKL_INT *ja, float *x, float *y);
void mkl_cspblas_dcsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, double *a,
                           MKL_INT *ia, MKL_INT *ja, double *x, double *y);
void mkl_cspblas_ccsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m,
                           MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zcsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m,
                           MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?csrtrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3-array variation) with zero-based indexing:

$A^*y = x$

or

$A'^*y = x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>A</i> * <i>y</i> = <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>A</i> '* <i>y</i> = <i>x</i> ,
<i>diag</i>	CHARACTER*1. Specifies whether matrix <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL for mkl_cspblas_scsrtrsv. DOUBLE PRECISION for mkl_cspblas_dcsrtrsv. COMPLEX for mkl_cspblas_ccsrtrsv. DOUBLE COMPLEX for mkl_cspblas_zcsrtrsv. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>ia</i>	INTEGER. Array of length <i>m</i> +1, containing indices of elements in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> (<i>m</i>) is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
-----------	--

<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
-----------	---

NOTE

Column indices must be sorted in increasing order for each row.

<i>x</i>	REAL for mkl_cspblas_scsrtrsv. DOUBLE PRECISION for mkl_cspblas_dcsrtrsv.
----------	--

COMPLEX for `mkl_cspblas_ccsrtrsv`.
 DOUBLE COMPLEX for `mkl_cspblas_zcsrtrsv`.
Array, size is m .
 On entry, the array x must contain the vector x .

Output Parameters

y
 REAL for `mkl_cspblas_scsrtrsv`.
 DOUBLE PRECISION for `mkl_cspblas_dcsrtrsv`.
 COMPLEX for `mkl_cspblas_ccsrtrsv`.
 DOUBLE COMPLEX for `mkl_cspblas_zcsrtrsv`.
Array, size at least m .
 Contains the vector y .

void mkl_cspblas_zbsrtrs (char *uplo, char *transa, char *diag, MKL_INT *m, MKL_INT
*lb, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_cspblas_?bsrtrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing:

`y := A*x`

or

`y := A'*x,`

where:

x and *y* are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as <i>y</i> := <i>A</i> * <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as <i>y</i> := <i>A'</i> * <i>x</i> .
<i>diag</i>	CHARACTER*1. Specifies whether matrix <i>A</i> is unit triangular or not. If <i>diag</i> = 'U' or 'u', <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>a</i>	REAL for mkl_cspblas_sbsrtrsv. DOUBLE PRECISION for mkl_cspblas_dbsrtrsv. COMPLEX for mkl_cspblas_cbsrtrsv. DOUBLE COMPLEX for mkl_cspblas_zbsrtrsv. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb</i> * <i>lb</i> . Refer to <i>values</i> array description in BSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_cspblas_sbsrtrsv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrtrsv</code> . COMPLEX for <code>mkl_cspblas_cbsrtrsv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrtrsv</code> . Array, size $(m * lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_cspblas_sbsrtrsv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrtrsv</code> . COMPLEX for <code>mkl_cspblas_cbsrtrsv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrtrsv</code> . Array, size at least $(m * lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> .
----------	--

Description

The `mkl_cspblas_?cootrs` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format with zero-based indexing:

$A^*y = x$

or

$A'^*y = x$,

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A^*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'^*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_cspblas_scootrs</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcootrs</code> . COMPLEX for <code>mkl_cspblas_ccootrs</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcootrs</code> .

Array of length nnz , contains non-zero elements of the matrix A in the arbitrary order.

Refer to *values* array description in [Coordinate Format](#) for more details.

rowind

INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A .

Refer to *rows* array description in [Coordinate Format](#) for more details.

colind

INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to *columns* array description in [Coordinate Format](#) for more details.

nnz

INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to *nnz* description in [Coordinate Format](#) for more details.

x

REAL **for** mkl_cspblas_scootrs.

DOUBLE PRECISION **for** mkl_cspblas_dcootrs.

COMPLEX **for** mkl_cspblas_ccootrs.

DOUBLE COMPLEX **for** mkl_cspblas_zcootrs.

Array, size is m .

On entry, the array *x* must contain the vector *x*.

Output Parameters

y

REAL **for** mkl_cspblas_scootrs.

DOUBLE PRECISION **for** mkl_cspblas_dcootrs.

COMPLEX **for** mkl_cspblas_ccootrs.

DOUBLE COMPLEX **for** mkl_cspblas_zcootrs.

Array, size at least m .

Contains the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_scootrs(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)

  INTEGER m, nnz
  INTEGER rowind(*), colind(*)
  DOUBLE COMPLEX val(*), x(*), y(*)
```

C:

```
void mkl_cspblas_scootrv(char *uplo, char *transa, char *diag, int *m,
float *val, int *rowind, int *colind, int *nnz, float *x, float *y);

void mkl_cspblas_dcootrv(char *uplo, char *transa, char *diag, int *m,
double *val, int *rowind, int *colind, int *nnz, double *x, double *y);

void mkl_cspblas_ccootrv(char *uplo, char *transa, char *diag, int *m,
MKL_Complex8 *val, int *rowind, int *colind, int *nnz, MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcootrv(char *uplo, char *transa, char *diag, int *m,
MKL_Complex16 *val, int *rowind, int *colind, int *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?csrmv

Computes matrix - vector product of a sparse matrix stored in the CSR format.

Syntax**Fortran:**

```
call mkl_scsrsv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x, beta, y)
call mkl_dcsrsv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x, beta, y)
call mkl_ccsrsv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x, beta, y)
call mkl_zcsrsv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x, beta, y)
```

C:

```

void mkl_scsrmv (char *transa, MKL_INT *m, MKL_INT *k, float *alpha, char *matdescra,
float *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, float *x, float *beta,
float *y);

void mkl_dcsrmv (char *transa, MKL_INT *m, MKL_INT *k, double *alpha, char *matdescra,
double *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, double *x, double *beta,
double *y);

void mkl_ccsrmv (char *transa, MKL_INT *m, MKL_INT *k, MKL_Complex8 *alpha, char
*matdescra, MKL_Complex8 *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre,
MKL_Complex8 *x, MKL_Complex8 *beta, MKL_Complex8 *y);

void mkl_zcsrmv (char *transa, MKL_INT *m, MKL_INT *k, MKL_Complex16 *alpha, char
*matdescra, MKL_Complex16 *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre,
MKL_Complex16 *x, MKL_Complex16 *beta, MKL_Complex16 *y);

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrmv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in the CSR format, *A'* is the transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation.
	If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> * <i>A</i> * <i>x</i> + <i>beta</i> * <i>y</i>
	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> * <i>A'</i> * <i>x</i> + <i>beta</i> * <i>y</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for <code>mkl_scsrmv</code> .
	DOUBLE PRECISION for <code>mkl_dcsrmv</code> .

COMPLEX for `mkl_ccsrmv`.
 DOUBLE COMPLEX for `mkl_zcsrmv`.
 Specifies the scalar *alpha*.

matdescra
 CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in [Table "Possible Values of the Parameter *matdescra* \(*descra*\)"](#). Possible combinations of element values of this parameter are given in [Table "Possible Combinations of Element Values of the Parameter *matdescra*"](#).

val
 REAL for `mkl_scsrmv`.
 DOUBLE PRECISION for `mkl_dcsrmv`.
 COMPLEX for `mkl_ccsrmv`.
 DOUBLE COMPLEX for `mkl_zcsrmv`.
 Array containing non-zero elements of the matrix *A*.
 For one-based indexing its length is $pntre(m) - pntrb(1)$.
 For zero-based indexing its length is $pntre(m-1) - pntrb(0)$.
 Refer to *values* array description in [CSR Format](#) for more details.

indx
 INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.
 Refer to *columns* array description in [CSR Format](#) for more details.

pntrb
 INTEGER. Array of length *m*.
 For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row *i* in the arrays *val* and *indx*.
 For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row *i* in the arrays *val* and *indx*. Refer to *pointerb* array description in [CSR Format](#) for more details.

pntre
 INTEGER. Array of length *m*.
 For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of row *i* in the arrays *val* and *indx*.
 For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0)-1$ is the last index of row *i* in the arrays *val* and *indx*. Refer to *pointerE* array description in [CSR Format](#) for more details.

x
 REAL for `mkl_scsrmv`.
 DOUBLE PRECISION for `mkl_dcsrmv`.
 COMPLEX for `mkl_ccsrmv`.
 DOUBLE COMPLEX for `mkl_zcsrmv`.
 Array, size at least *k* if *transa* = 'N' or 'n' and at least *m* otherwise. On entry, the array *x* must contain the vector *x*.

beta
 REAL for `mkl_scsrmv`.

DOUBLE PRECISION for mkl_dcsrmv.
 COMPLEX for mkl_ccsrmv.
 DOUBLE COMPLEX for mkl_zcsrmv.
Specifies the scalar *beta*.

y REAL for mkl_scsrmv.
 DOUBLE PRECISION for mkl_dcsrmv.
 COMPLEX for mkl_ccsrmv.
 DOUBLE COMPLEX for mkl_zcsrmv.
 Array, size at least *m* if *transa* = 'N' or 'n' and at least *k* otherwise. On entry, the array *y* must contain the vector *y*.

Output Parameters

y Overwritten by the updated vector *y*.

Interfaces

FORTRAN 77:

*pntre, MKL_Complex16 *x, MKL_Complex16 *beta, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?bsrmv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* block sparse matrix in the BSR format, *A'* is the transpose of *A*.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as <i>y</i> := <i>alpha</i> * <i>A</i> * <i>x</i> + <i>beta</i> * <i>y</i>
---------------	--

If $\text{transa} = \text{'T'}$ or 't' or 'C' or 'c' , then the matrix-vector product is computed as $y := \alpha A^*x + \beta y$,

<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sbsrmv. DOUBLE PRECISION for mkl_dbsrmv. COMPLEX for mkl_cbsrmv. DOUBLE COMPLEX for mkl_zbsrmv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_sbsrmv. DOUBLE PRECISION for mkl_dbsrmv. COMPLEX for mkl_cbsrmv. DOUBLE COMPLEX for mkl_zbsrmv. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb * lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i> . For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>m</i> . For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i> . For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i> .

Refer to *pointerE* array description in [BSR Format](#) for more details.

x

REAL for mkl_sbsrmv.
 DOUBLE PRECISION for mkl_dbsrmv.
 COMPLEX for mkl_cbsrmv.
 DOUBLE COMPLEX for mkl_zbsrmv.
 Array, size at least ($k * lb$) if *transa* = 'N' or 'n', and at least ($m * lb$) otherwise. On entry, the array *x* must contain the vector *x*.

beta

REAL for mkl_sbsrmv.
 DOUBLE PRECISION for mkl_dbsrmv.
 COMPLEX for mkl_cbsrmv.
 DOUBLE COMPLEX for mkl_zbsrmv.
 Specifies the scalar *beta*.

y

REAL for mkl_sbsrmv.
 DOUBLE PRECISION for mkl_dbsrmv.
 COMPLEX for mkl_cbsrmv.
 DOUBLE COMPLEX for mkl_zbsrmv.
 Array, size at least ($m * lb$) if *transa* = 'N' or 'n', and at least ($k * lb$) otherwise. On entry, the array *y* must contain the vector *y*.

Output Parameters

y Overwritten by the updated vector *y*.

MKL_Complex16 *x, MKL_Complex16 *beta, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?cscmv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in compressed sparse column (CSC) format, *A'* is the transpose of *A*.

NOTE

This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A^T x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv. DOUBLE COMPLEX for mkl_zcscmv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv. DOUBLE COMPLEX for mkl_zcscmv. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is $\text{pntrb}(k) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrb}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSC Format for more details.
<i>indx</i>	INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>k</i> . For one-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(1) + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> .

For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column i in the arrays `val` and `indx`.

Refer to `pointerb` array description in [CSC Format](#) for more details.

`pntre`

INTEGER. Array of length k .

For one-based indexing this array contains column indices, such that $pntre(i) - pntre(1)$ is the last index of column i in the arrays `val` and `indx`.

For zero-based indexing this array contains column indices, such that $pntre(i) - pntre(1) - 1$ is the last index of column i in the arrays `val` and `indx`.

Refer to `pointerE` array description in [CSC Format](#) for more details.

`x`

REAL **for** `mkl_scscmv`.

DOUBLE PRECISION **for** `mkl_dcscmv`.

COMPLEX **for** `mkl_ccscmv`.

DOUBLE COMPLEX **for** `mkl_zcscmv`.

Array, size at least k if $transa = 'N'$ or ' n ' and at least m otherwise. On entry, the array `x` must contain the vector x .

`beta`

REAL **for** `mkl_scscmv`.

DOUBLE PRECISION **for** `mkl_dcscmv`.

COMPLEX **for** `mkl_ccscmv`.

DOUBLE COMPLEX **for** `mkl_zcscmv`.

Specifies the scalar `beta`.

`y`

REAL **for** `mkl_scscmv`.

DOUBLE PRECISION **for** `mkl_dcscmv`.

COMPLEX **for** `mkl_ccscmv`.

DOUBLE COMPLEX **for** `mkl_zcscmv`.

Array, size at least m if $transa = 'N'$ or ' n ' and at least k otherwise. On entry, the array `y` must contain the vector y .

Output Parameters

`y`

Overwritten by the updated vector y .

Description

The `mkl_?coomv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in compressed coordinate format, *A'* is the transpose of *A*.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A' x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for <code>mkl_scoomv</code> . DOUBLE PRECISION for <code>mkl_dcoomv</code> . COMPLEX for <code>mkl_ccoomv</code> . DOUBLE COMPLEX for <code>mkl_zcoomv</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for <code>mkl_scoomv</code> . DOUBLE PRECISION for <code>mkl_dcoomv</code> . COMPLEX for <code>mkl_ccoomv</code> . DOUBLE COMPLEX for <code>mkl_zcoomv</code> . Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order.

Refer to `values` array description in [Coordinate Format](#) for more details.

`rowind`

INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A .

Refer to `rows` array description in [Coordinate Format](#) for more details.

`colind`

INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to `columns` array description in [Coordinate Format](#) for more details.

`nnz`

INTEGER. Specifies the number of non-zero element of the matrix A .

Refer to `nnz` description in [Coordinate Format](#) for more details.

`x`

REAL for `mkl_scoomv`.

DOUBLE PRECISION for `mkl_dcoomv`.

COMPLEX for `mkl_ccoomv`.

DOUBLE COMPLEX for `mkl_zcoomv`.

Array, size at least k if $transa = 'N'$ or ' n ' and at least m otherwise. On entry, the array x must contain the vector x .

`beta`

REAL for `mkl_scoomv`.

DOUBLE PRECISION for `mkl_dcoomv`.

COMPLEX for `mkl_ccoomv`.

DOUBLE COMPLEX for `mkl_zcoomv`.

Specifies the scalar β .

`y`

REAL for `mkl_scoomv`.

DOUBLE PRECISION for `mkl_dcoomv`.

COMPLEX for `mkl_ccoomv`.

DOUBLE COMPLEX for `mkl_zcoomv`.

Array, size at least m if $transa = 'N'$ or ' n ' and at least k otherwise. On entry, the array y must contain the vector y .

Output Parameters

`y`

Overwritten by the updated vector y .

Interfaces

MKL_Complex16 *y);
```

mkl_?csrv

Solves a system of linear equations for a sparse matrix in the CSR format.

Syntax

Fortran:

```
call mkl_scsrsv(transa, m, alpha, matdescra, val, indx, pntrb, pntre, x, y)
call mkl_dcsrsv(transa, m, alpha, matdescra, val, indx, pntrb, pntre, x, y)
call mkl_ccsrsv(transa, m, alpha, matdescra, val, indx, pntrb, pntre, x, y)
call mkl_zcsrsv(transa, m, alpha, matdescra, val, indx, pntrb, pntre, x, y)
```

C:

```
void mkl_scsrsv (char *transa, MKL_INT *m, float *alpha, char *matdescra, float *val,
MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, float *x, float *y);
void mkl_dcsrsv (char *transa, MKL_INT *m, double *alpha, char *matdescra, double *val,
MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, double *x, double *y);
void mkl_ccsrsv (char *transa, MKL_INT *m, MKL_Complex8 *alpha, char *matdescra,

MKL_Complex16 *y);
```

Include Files

- **Fortran:** mkl.fi
- **C:** mkl.h

Description

The `mkl_?csrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSR format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')*x,
```

where:

`alpha` is scalar, `x` and `y` are vectors, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha^{-1}(A)x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha^{-1}(A^T)x$,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_scsrsv. DOUBLE PRECISION for mkl_dcsrsv. COMPLEX for mkl_ccsrsv. DOUBLE COMPLEX for mkl_zcsrsv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scsrsv. DOUBLE PRECISION for mkl_dcsrsv. COMPLEX for mkl_ccsrsv. DOUBLE COMPLEX for mkl_zcsrsv. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is $pntre(m) - pntrb(1)$. For zero-based indexing its length is $pntre(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

NOTE

Column indices must be sorted in increasing order for each row.

pntrb

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row i in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row i in the arrays *val* and *indx*. Refer to *pointerb* array description in [CSR Format](#) for more details.

pntre

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of row i in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of row i in the arrays *val* and *indx*. Refer to *pointerE* array description in [CSR Format](#) for more details.

x

REAL **for** mkl_scsrsv.

DOUBLE PRECISION **for** mkl_dcsrsv.

COMPLEX **for** mkl_ccsrsv.

DOUBLE COMPLEX **for** mkl_zcsrsv.

Array, size at least m .

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y

REAL **for** mkl_scsrsv.

DOUBLE PRECISION **for** mkl_dcsrsv.

COMPLEX **for** mkl_ccsrsv.

DOUBLE COMPLEX **for** mkl_zcsrsv.

Array, size at least m .

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y

Contains solution vector *x*.

Description

The mkl_?bsrsv routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the BSR format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')* x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> *inv(<i>A</i>)* <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>x</i> ,
<i>m</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sbsrv. DOUBLE PRECISION for mkl_dbsrv. COMPLEX for mkl_cbsrv. DOUBLE COMPLEX for mkl_zbsrv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_sbsrv. DOUBLE PRECISION for mkl_dbsrv. COMPLEX for mkl_cbsrv. DOUBLE COMPLEX for mkl_zbsrv. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb</i> * <i>lb</i> . Refer to the <i>values</i> array description in BSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks in the matrix A .
	Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length m .
	For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row i in the array <i>indx</i> .
	For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row i in the array <i>indx</i>
	Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntre</i>	INTEGER. Array of length m .
	For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of block row i in the array <i>indx</i> .
	For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of block row i in the array <i>indx</i> .
	Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_sbsrsv</code> . DOUBLE PRECISION for <code>mkl_dbsrsv</code> . COMPLEX for <code>mkl_cbsrsv</code> . DOUBLE COMPLEX for <code>mkl_zbsrsv</code> . Array, size at least $(m * lb)$. On entry, the array <i>x</i> must contain the vector x . The elements are accessed with unit increment.
<i>y</i>	REAL for <code>mkl_sbsrsv</code> . DOUBLE PRECISION for <code>mkl_dbsrsv</code> . COMPLEX for <code>mkl_cbsrsv</code> . DOUBLE COMPLEX for <code>mkl_zbsrsv</code> . Array, size at least $(m * lb)$. On entry, the array <i>y</i> must contain the vector y . The elements are accessed with unit increment.

Output Parameters

<i>y</i>	Contains solution vector x .

Description

The `mkl_?cscsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSC format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')* x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> *inv(<i>A</i>)* <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>x</i> ,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_scscsv. DOUBLE PRECISION for mkl_dcscsv. COMPLEX for mkl_ccscsv. DOUBLE COMPLEX for mkl_zcscsv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scscsv. DOUBLE PRECISION for mkl_dcscsv. COMPLEX for mkl_ccscsv. DOUBLE COMPLEX for mkl_zcscsv. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is <i>pntre(m)</i> - <i>pntrb(1)</i> . For zero-based indexing its length is <i>pntre(m-1)</i> - <i>pntrb(0)</i> . Refer to <i>values</i> array description in CSC Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx INTEGER. Array containing the row indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.
 Refer to *columns* array description in [CSC Format](#) for more details.

NOTE

Row indices must be sorted in increasing order for each column.

pntrb INTEGER. Array of length *m*.
 For one-based indexing this array contains column indices, such that *pntrb*(*i*) - *pntrb*(1) + 1 is the first index of column *i* in the arrays *val* and *indx*.
 For zero-based indexing this array contains column indices, such that *pntrb*(*i*) - *pntrb*(0) is the first index of column *i* in the arrays *val* and *indx*.
 Refer to *pointerb* array description in [CSC Format](#) for more details.

pntre INTEGER. Array of length *m*.
 For one-based indexing this array contains column indices, such that *pntre*(*i*) - *pntrb*(1) is the last index of column *i* in the arrays *val* and *indx*.
 For zero-based indexing this array contains column indices, such that *pntre*(*i*) - *pntrb*(1) - 1 is the last index of column *i* in the arrays *val* and *indx*.
 Refer to *pointerE* array description in [CSC Format](#) for more details.

x REAL for *mkl_scscsv*.
 DOUBLE PRECISION for *mkl_dcscsv*.
 COMPLEX for *mkl_ccscsv*.
 DOUBLE COMPLEX for *mkl_zcscsv*.
 Array, size at least *m*.
 On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y REAL for *mkl_scscsv*.
 DOUBLE PRECISION for *mkl_dcscsv*.
 COMPLEX for *mkl_ccscsv*.
 DOUBLE COMPLEX for *mkl_zcscsv*.
 Array, size at least *m*.
 On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains the solution vector *x*.

Description

The `mkl_?coosv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the coordinate format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')*x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> *inv(<i>A</i>)* <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>x</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_scoosv. DOUBLE PRECISION for mkl_dcoosv. COMPLEX for mkl_ccoosv. DOUBLE COMPLEX for mkl_zcoosv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scoosv. DOUBLE PRECISION for mkl_dcoosv. COMPLEX for mkl_ccoosv. DOUBLE COMPLEX for mkl_zcoosv. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.

nnz INTEGER. Specifies the number of non-zero element of the matrix *A*.

Refer to *nnz* description in [Coordinate Format](#) for more details.

x REAL for mkl_scoosv.

DOUBLE PRECISION for mkl_dcoosv.

COMPLEX for mkl_ccoosv.

DOUBLE COMPLEX for mkl_zcoosv.

Array, size at least *m*.

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y REAL for mkl_scoosv.

DOUBLE PRECISION for mkl_dcoosv.

COMPLEX for mkl_ccoosv.

DOUBLE COMPLEX for mkl_zcoosv.

Array, size at least *m*.

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains solution vector *x*.

Interfaces

MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?csrmm

Computes matrix - matrix product of a sparse matrix stored in the CSR format.

Syntax

Fortran:

```
call mkl_scsrmm(transa, m, n, k, alpha, matdescra, val, indx, pntrb, pntre, b, ldb,
beta, c, ldc)

call mkl_dcsrmm(transa, m, n, k, alpha, matdescra, val, indx, pntrb, pntre, b, ldb,
beta, c, ldc)

call mkl_ccsrmm(transa, m, n, k, alpha, matdescra, val, indx, pntrb, pntre, b, ldb,
beta, c, ldc)

call mkl_zcsrmm(transa, m, n, k, alpha, matdescra, val, indx, pntrb, pntre, b, ldb,
beta, c, ldc)
```

C:

```
void mkl_scsrmm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *alpha, char
*matdescra, float *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, float *b,
MKL_INT *ldb, float *beta, float *c, MKL_INT *ldc);

void mkl_dcsrmm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *alpha, char
*matdescra, double *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre, double *b,
MKL_INT *ldb, double *beta, double *c, MKL_INT *ldc);

void mkl_ccsrmm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *alpha,
char *matdescra, MKL_Complex8 *val, MKL_INT *indx, MKL_INT *pntrb, MKL_INT *pntre,

*pntre, MKL_Complex16 *b, MKL_INT *ldb, MKL_Complex16 *beta, MKL_Complex16 *c, MKL_INT
*ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrmm` routine performs a matrix-matrix operation defined as

```
C := alpha*A*B + beta*C
```

or

```
C := alpha*A'*B + beta*C,
```

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse row (CSR) format, *A'* is the transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha A^T B + \beta C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha A^* B + \beta C$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_scsrmm. DOUBLE PRECISION for mkl_dcsrmm. COMPLEX for mkl_ccsrmm. DOUBLE COMPLEX for mkl_zcsrmm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scsrmm. DOUBLE PRECISION for mkl_dcsrmm. COMPLEX for mkl_ccsrmm. DOUBLE COMPLEX for mkl_zcsrmm. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is <i>pntrc(m)</i> - <i>pntrb(1)</i> . For zero-based indexing its length is <i>pntrc(-1)</i> - <i>pntrb(0)</i> . Refer to <i>values</i> array description in CSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.

*pntrb*INTEGER. Array of length m .For one-based indexing this array contains row indices, such that $pntrb(I) - pntrb(1) + 1$ is the first index of row I in the arrays *val* and *indx*.For zero-based indexing this array contains row indices, such that $pntrb(I) - pntrb(0)$ is the first index of row I in the arrays *val* and *indx*.Refer to *pointerb* array description in [CSR Format](#) for more details.*pntre*INTEGER. Array of length m .For one-based indexing this array contains row indices, such that $pntre(I) - pntrb(1)$ is the last index of row I in the arrays *val* and *indx*.For zero-based indexing this array contains row indices, such that $pntre(I) - pntrb(0) - 1$ is the last index of row I in the arrays *val* and *indx*.Refer to *pointerE* array description in [CSR Format](#) for more details.*b*REAL **for** mkl_scsrmm.DOUBLE PRECISION **for** mkl_dcsrmm.COMPLEX **for** mkl_ccsrmm.DOUBLE COMPLEX **for** mkl_zcsrmm.Array, size ldb by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, ldb) for zero-based indexing.On entry with *transa*= 'N' or 'n', the leading k -by- n part of the array *b* must contain the matrix B , otherwise the leading m -by- n part of the array *b* must contain the matrix B .*ldb*INTEGER. Specifies the leading dimension of *b* for one-based indexing, and the second dimension of *b* for zero-based indexing, as declared in the calling (sub)program.*beta*REAL **for** mkl_scsrmm.DOUBLE PRECISION **for** mkl_dcsrmm.COMPLEX **for** mkl_ccsrmm.DOUBLE COMPLEX **for** mkl_zcsrmm.Specifies the scalar *beta*.*c*REAL **for** mkl_scsrmm.DOUBLE PRECISION **for** mkl_dcsrmm.COMPLEX **for** mkl_ccsrmm.DOUBLE COMPLEX **for** mkl_zcsrmm.Array, size ldc by n for one-based indexing, and (m , ldc) for zero-based indexing.On entry, the leading m -by- n part of the array *c* must contain the matrix C , otherwise the leading k -by- n part of the array *c* must contain the matrix C .

ldc INTEGER. Specifies the leading dimension of *c* for one-based indexing, and the second dimension of *c* for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

Description

The `mkl_?bsrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha A^* B + \beta C$$

or

$$C := \alpha A'^* B + \beta C,$$

where:

`alpha` and `beta` are scalars,

`B` and `C` are dense matrices, `A` is an m -by- k sparse matrix in block sparse row (BSR) format, `A'` is the transpose of `A`.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>transa</code>	CHARACTER*1. Specifies the operation. If <code>transa = 'N'</code> or <code>'n'</code> , then the matrix-matrix product is computed as $C := \alpha A^* B + \beta C$ If <code>transa = 'T'</code> or <code>'t'</code> or <code>'C'</code> or <code>'c'</code> , then the matrix-vector product is computed as $C := \alpha A'^* B + \beta C,$
<code>m</code>	INTEGER. Number of block rows of the matrix <code>A</code> .
<code>n</code>	INTEGER. Number of columns of the matrix <code>C</code> .

<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_sbsrmm.</p> <p>DOUBLE PRECISION for mkl_dbsrmm.</p> <p>COMPLEX for mkl_cbsrmm.</p> <p>DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	<p>REAL for mkl_sbsrmm.</p> <p>DOUBLE PRECISION for mkl_dbsrmm.</p> <p>COMPLEX for mkl_cbsrmm.</p> <p>DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Array containing elements of non-zero blocks of the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb</i>*<i>lb</i>. Refer to the <i>values</i> array description in BSR Format for more details.</p>
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	<p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing: this array contains row indices, such that <i>pntrb</i>(<i>I</i>) - <i>pntrb</i>(1) + 1 is the first index of block row <i>I</i> in the array <i>indx</i>.</p> <p>For zero-based indexing: this array contains row indices, such that <i>pntrb</i>(<i>I</i>) - <i>pntrb</i>(0) is the first index of block row <i>I</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerB</i> array description in BSR Format for more details.</p>
<i>pntre</i>	<p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing this array contains row indices, such that <i>pntre</i>(<i>I</i>) - <i>pntrb</i>(1) is the last index of block row <i>I</i> in the array <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that <i>pntre</i>(<i>I</i>) - <i>pntrb</i>(0) - 1 is the last index of block row <i>I</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in BSR Format for more details.</p>
<i>b</i>	<p>REAL for mkl_sbsrmm.</p> <p>DOUBLE PRECISION for mkl_dbsrmm.</p> <p>COMPLEX for mkl_cbsrmm.</p>

DOUBLE COMPLEX for `mkl_zbsrmm`.

Array, size l_{db} by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, l_{db}) for zero-based indexing.

On entry with $\text{transa} = \text{'N'}$ or ' n ', the leading n -by- k block part of the array b must contain the matrix B , otherwise the leading m -by- n block part of the array b must contain the matrix B .

l_{db} INTEGER. Specifies the leading dimension (in blocks) of b as declared in the calling (sub)program.

β REAL for `mkl_sbsrmm`.

DOUBLE PRECISION for `mkl_dbsrmm`.

COMPLEX for `mkl_cbsrmm`.

DOUBLE COMPLEX for `mkl_zbsrmm`.

Specifies the scalar β .

c REAL for `mkl_sbsrmm`.

DOUBLE PRECISION for `mkl_dbsrmm`.

COMPLEX for `mkl_cbsrmm`.

DOUBLE COMPLEX for `mkl_zbsrmm`.

Array, size (l_{dc}, n) for one-based indexing, size (k, l_{dc}) for zero-based indexing.

On entry, the leading m -by- n block part of the array c must contain the matrix C , otherwise the leading n -by- k block part of the array c must contain the matrix C .

l_{dc} INTEGER. Specifies the leading dimension (in blocks) of c as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

Description

The `mkl_?cscmm` routine performs a matrix-matrix operation defined as

```
C := alpha*A*B + beta*C
```

or

```
C := alpha*A'*B + beta*C,
```

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse column (CSC) format, *A'* is the transpose of *A*.

NOTE

This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha A^* B + \beta C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha A'^* B + \beta C$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for <code>mkl_scscmm</code> . DOUBLE PRECISION for <code>mkl_dcscmm</code> . COMPLEX for <code>mkl_ccscmm</code> . DOUBLE COMPLEX for <code>mkl_zcscmm</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for <code>mkl_scscmm</code> .

DOUBLE PRECISION **for** mkl_dcscmm.

COMPLEX **for** mkl_ccscmm.

DOUBLE COMPLEX **for** mkl_zcscmm.

Array containing non-zero elements of the matrix A .

For one-based indexing its length is $pntrb(k) - pntrb(1)$.

For zero-based indexing its length is $pntrb(m-1) - pntrb(0)$.

Refer to *values* array description in [CSC Format](#) for more details.

indx

INTEGER. Array containing the row indices for each non-zero element of the matrix A . Its length is equal to length of the *val* array.

Refer to *rows* array description in [CSC Format](#) for more details.

pntrb

INTEGER. Array of length k .

For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of column i in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column i in the arrays *val* and *indx*.

Refer to *pointerb* array description in [CSC Format](#) for more details.

pntre

INTEGER. Array of length k .

For one-based indexing this array contains column indices, such that $pntre(i) - pntrb(1)$ is the last index of column i in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntre(i) - pntrb(1) - 1$ is the last index of column i in the arrays *val* and *indx*.

Refer to *pointerE* array description in [CSC Format](#) for more details.

b

REAL **for** mkl_scscmm.

DOUBLE PRECISION **for** mkl_dcscmm.

COMPLEX **for** mkl_ccscmm.

DOUBLE COMPLEX **for** mkl_zcscmm.

Array, size ldb by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, ldb) for zero-based indexing.

On entry with $transa = 'N'$ or ' n ', the leading k -by- n part of the array *b* must contain the matrix B , otherwise the leading m -by- n part of the array *b* must contain the matrix B .

ldb

INTEGER. Specifies the leading dimension of *b* for one-based indexing, and the second dimension of *b* for zero-based indexing, as declared in the calling (sub)program.

<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>c</i>	REAL for mkl_scscmm. DOUBLE PRECISION for mkl_dcscmm. COMPLEX for mkl_ccscmm. DOUBLE COMPLEX for mkl_zcscmm.
	Array, size <i>lrc</i> by <i>n</i> for one-based indexing, and (<i>m</i> , <i>lrc</i>) for zero-based indexing.
	On entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> .
<i>lrc</i>	INTEGER. Specifies the leading dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix (<i>alpha</i> * <i>A</i> * <i>B</i> + <i>beta</i> * <i>C</i>) or (<i>alpha</i> * <i>A'</i> * <i>B</i> + <i>beta</i> * <i>C</i>).

int *pntrb, int *pntre, MKL_Complex16 *b, int *ldb,
MKL_Complex16 *beta, MKL_Complex16 *c, int *ldc);

```

mkl_?coomm

Computes matrix-matrix product of a sparse matrix stored in the coordinate format.

Syntax

Fortran:

```
call mkl_scoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz, b, ldb,
beta, c, ldc)

call mkl_dcoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz, b, ldb,
beta, c, ldc)

call mkl_ccoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz, b, ldb,
beta, c, ldc)

call mkl_zcoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz, b, ldb,
beta, c, ldc)
```

C:

```
void mkl_scoomm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *alpha, char
*matdescra, float *val, MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, float *b,
MKL_INT *ldb, float *beta, float *c, MKL_INT *ldc);

void mkl_dcoomm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *alpha, char
*matdescra, double *val, MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz, double *b,
MKL_INT *ldb, double *beta, double *c, MKL_INT *ldc);

void mkl_ccoomm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *alpha,
char *matdescra, MKL_Complex8 *val, MKL_INT *rowind, MKL_INT *colind, MKL_INT *nnz,
MKL_Complex8 *b, MKL_INT *ldb, MKL_Complex8 *beta, MKL_Complex8 *c, MKL_INT *ldc);

void mkl_zcoomm (char *transa, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16
*alpha, char *matdescra, MKL_Complex16 *val, MKL_INT *rowind, MKL_INT *colind, MKL_INT
*nnz, MKL_Complex16 *b, MKL_INT *ldb, MKL_Complex16 *beta, MKL_Complex16 *c, MKL_INT
*ldc);
```

Include Files

Description

The `mkl_?coomm` routine performs a matrix-matrix operation defined as

```
C := alpha*A*B + beta*C
```

or

```
C := alpha*A'*B + beta*C,
```

where:

`alpha` and `beta` are scalars,

`B` and `C` are dense matrices, `A` is an m -by- k sparse matrix in the coordinate format, A' is the transpose of A .

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha A^T B + \beta C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha A^H B + \beta C$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for mkl_scoomm. DOUBLE PRECISION for mkl_dcoomm. COMPLEX for mkl_ccoomm. DOUBLE COMPLEX for mkl_zcoomm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scoomm. DOUBLE PRECISION for mkl_dcoomm. COMPLEX for mkl_ccoomm. DOUBLE COMPLEX for mkl_zcoomm. Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix A . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix A . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>b</i>	REAL for mkl_scoomm.

DOUBLE PRECISION for mkl_dcoomm.

COMPLEX for mkl_ccoomm.

DOUBLE COMPLEX for mkl_zcoomm.

Array, size ldb by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, ldb) for zero-based indexing.

On entry with $transa = 'N'$ or ' n ', the leading k -by- n part of the array b must contain the matrix B , otherwise the leading m -by- n part of the array b must contain the matrix B .

ldb

INTEGER. Specifies the leading dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

β

REAL for mkl_scoomm.

DOUBLE PRECISION for mkl_dcoomm.

COMPLEX for mkl_ccoomm.

DOUBLE COMPLEX for mkl_zcoomm.

Specifies the scalar β .

c

REAL for mkl_scoomm.

DOUBLE PRECISION for mkl_dcoomm.

COMPLEX for mkl_ccoomm.

DOUBLE COMPLEX for mkl_zcoomm.

Array, size ldc by n for one-based indexing, and (m , ldc) for zero-based indexing.

On entry, the leading m -by- n part of the array c must contain the matrix C , otherwise the leading k -by- n part of the array c must contain the matrix C .

ldc

INTEGER. Specifies the leading dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c

Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

MKL_Complex16 *b, MKL_INT *ldb, MKL_Complex16 *c, MKL_INT *ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?csrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSR format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(A')*B,
```

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> *inv(<i>A</i>)* <i>B</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>C</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>B</i> ,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for <code>mkl_scsrsm</code> . DOUBLE PRECISION for <code>mkl_dcsrsm</code> . COMPLEX for <code>mkl_ccsrsm</code> . DOUBLE COMPLEX for <code>mkl_zcsrsm</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for <code>mkl_scsrsm</code> . DOUBLE PRECISION for <code>mkl_dcsrsm</code> . COMPLEX for <code>mkl_ccsrsm</code> .

DOUBLE COMPLEX for `mkl_zcsrsm`.

Array containing non-zero elements of the matrix A .

For one-based indexing its length is $pntre(m) - pntrb(1)$.

For zero-based indexing its length is $pntre(m-1) - pntrb(0)$.

Refer to `values` array description in [CSR Format](#) for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx

INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to length of the `val` array.

Refer to `columns` array description in [CSR Format](#) for more details.

NOTE

Column indices must be sorted in increasing order for each row.

pntrb

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row i in the arrays `val` and `indx`.

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row i in the arrays `val` and `indx`. Refer to `pointerb` array description in [CSR Format](#) for more details.

pntre

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of row i in the arrays `val` and `indx`.

For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of row i in the arrays `val` and `indx`. Refer to `pointerE` array description in [CSR Format](#) for more details.

b

REAL for `mkl_scsrsm`.

DOUBLE PRECISION for `mkl_dcsrsm`.

COMPLEX for `mkl_ccsrsm`.

DOUBLE COMPLEX for `mkl_zcsrsm`.

Array, size (l_{db}, n) for one-based indexing, and (m, l_{db}) for zero-based indexing.

On entry the leading m -by- n part of the array *b* must contain the matrix B .

ldb

INTEGER. Specifies the leading dimension of *b* for one-based indexing, and the second dimension of *b* for zero-based indexing, as declared in the calling (sub)program.

ldc INTEGER. Specifies the leading dimension of *c* for one-based indexing, and the second dimension of *c* for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c REAL*8.
Array, size *ldc* by *n* for one-based indexing, and (*m*, *ldc*) for zero-based indexing.
The leading *m*-by-*n* part of the array *c* contains the output matrix *C*.

Interfaces

FORTRAN 77:

Description

The `mkl_?cscsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSC format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(A')*B,
```

where:

`alpha` is scalar, `B` and `C` are dense matrices, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>transa</code>	CHARACTER*1. Specifies the system of equations. If <code>transa = 'N'</code> or <code>'n'</code> , then <code>C := alpha*inv(A)*B</code> If <code>transa = 'T'</code> or <code>'t'</code> or <code>'C'</code> or <code>'c'</code> , then <code>C := alpha*inv(A')*B,</code>
<code>m</code>	INTEGER. Number of columns of the matrix <code>A</code> .
<code>n</code>	INTEGER. Number of columns of the matrix <code>C</code> .
<code>alpha</code>	REAL for <code>mkl_scscsm</code> . DOUBLE PRECISION for <code>mkl_dcscsm</code> . COMPLEX for <code>mkl_ccscsm</code> .

DOUBLE COMPLEX for `mkl_zcscsm`.

Specifies the scalar *alpha*.

matdescra

CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in [Table "Possible Values of the Parameter *matdescra* \(*descra*\)"](#). Possible combinations of element values of this parameter are given in [Table "Possible Combinations of Element Values of the Parameter *matdescra*"](#).

val

REAL for `mkl_scscsm`.

DOUBLE PRECISION for `mkl_dcscsm`.

COMPLEX for `mkl_ccscsm`.

DOUBLE COMPLEX for `mkl_zcscsm`.

Array containing non-zero elements of the matrix *A*.

For one-based indexing its length is $pntre(k) - pntrb(1)$.

For zero-based indexing its length is $pntre(m-1) - pntrb(0)$.

Refer to *values* array description in [CSC Format](#) for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx

INTEGER. Array containing the row indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.

Refer to *rows* array description in [CSC Format](#) for more details.

NOTE

Row indices must be sorted in increasing order for each column.

pntrb

INTEGER. Array of length *m*.

For one-based indexing this array contains column indices, such that $pntrb(I) - pntrb(1) + 1$ is the first index of column *I* in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntrb(I) - pntrb(0)$ is the first index of column *I* in the arrays *val* and *indx*.

Refer to *pointerb* array description in [CSC Format](#) for more details.

pntre

INTEGER. Array of length *m*.

For one-based indexing this array contains column indices, such that $pntre(I) - pntre(1)$ is the last index of column *I* in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntre(I) - pntrb(1)-1$ is the last index of column I in the arrays `val` and `indx`.

Refer to `pointerE` array description in [CSC Format](#) for more details.

b

REAL for `mkl_scscsm`.

DOUBLE PRECISION for `mkl_dcscsm`.

COMPLEX for `mkl_ccscsm`.

DOUBLE COMPLEX for `mkl_zcscsm`.

Array, size ldb by n for one-based indexing, and (m, ldb) for zero-based indexing.

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb

INTEGER. Specifies the leading dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

ldc

INTEGER. Specifies the leading dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c

REAL for `mkl_scscsm`.

DOUBLE PRECISION for `mkl_dcscsm`.

COMPLEX for `mkl_ccscsm`.

DOUBLE COMPLEX for `mkl_zcscsm`.

Array, size ldc by n for one-based indexing, and (m, ldc) for zero-based indexing.

The leading m -by- n part of the array c contains the output matrix C .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scscsm(transa, m, n, alpha, matdescra, val, indx,
pntrb, pntre, b, ldb, c, ldc)

CHARACTER*1 transa
CHARACTER matdescra(*)
INTEGER m, n, ldb, ldc
INTEGER indx(*), pntrb(m), pntre(m)

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?coasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the coordinate format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(A')*B,
```

where:

`alpha` is scalar, `B` and `C` are dense matrices, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> .

Refer to *nnz* description in [Coordinate Format](#) for more details.

<i>b</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Array, size <i>ldb</i> by <i>n</i> for one-based indexing, and (<i>m</i> , <i>ldb</i>) for zero-based indexing. Before entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the leading dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Array, size <i>ldc</i> by <i>n</i> for one-based indexing, and (<i>m</i> , <i>ldc</i>) for zero-based indexing. The leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> contains the output matrix <i>C</i> .

*pntre, MKL_Complex16 *b, MKL_INT *ldb, MKL_Complex16 *c, MKL_INT *ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?bsrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the BSR format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(A')*B,
```

where:

`alpha` is scalar, `B` and `C` are dense matrices, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$. If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A') * B$.
<i>m</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sbsrsm. DOUBLE PRECISION for mkl_dbsrsm. COMPLEX for mkl_cbsrsm. DOUBLE COMPLEX for mkl_zbsrsm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra" .
<i>val</i>	REAL for mkl_sbsrsm. DOUBLE PRECISION for mkl_dbsrsm. COMPLEX for mkl_cbsrsm. DOUBLE COMPLEX for mkl_zbsrsm. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the <i>ABAB</i> number <i>ABAB</i> of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb</i> * <i>lb</i> . Refer to the <i>values</i> array description in BSR Format for more details.
<hr/>	
NOTE	
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).	
No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.	
<hr/>	
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing: this array contains row indices, such that <i>pntrb</i> (<i>i</i>) - <i>pntrb</i> (1) + 1 is the first index of block row <i>i</i> in the array <i>indx</i> .

For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row i in the array $indx$.

Refer to [pointerB](#) array description in [BSR Format](#) for more details.

$pntrc$

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntrc(i) - pntrb(1)$ is the last index of block row i in the array $indx$.

For zero-based indexing this array contains row indices, such that $pntrc(i) - pntrb(0) - 1$ is the last index of block row i in the array $indx$.

Refer to [pointerE](#) array description in [BSR Format](#) for more details.

b

REAL for `mkl_sbsrsm`.

DOUBLE PRECISION for `mkl_dbsrsm`.

COMPLEX for `mkl_cbsrsm`.

DOUBLE COMPLEX for `mkl_zbsrsm`.

Array, size (ldb, n) for one-based indexing, size (m, ldb) for zero-based indexing.

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb

INTEGER. Specifies the leading dimension (in blocks) of b as declared in the calling (sub)program.

ldc

INTEGER. Specifies the leading dimension (in blocks) of c as declared in the calling (sub)program.

Output Parameters

c

REAL for `mkl_sbsrsm`.

DOUBLE PRECISION for `mkl_dbsrsm`.

COMPLEX for `mkl_cbsrsm`.

DOUBLE COMPLEX for `mkl_zbsrsm`.

Array, size (ldc, n) for one-based indexing, size (m, ldc) for zero-based indexing.

The leading m -by- n part of the array c contains the output matrix C .

mkl_?diamv

*Computes matrix - vector product for a sparse matrix
in the diagonal format with one-based indexing.*

Syntax

Fortran:

```
call mkl_sdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x, beta, y)
call mkl_ddiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x, beta, y)
call mkl_cdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x, beta, y)
call mkl_zdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x, beta, y)
```

C:

```
void mkl_sdiamv (char *transa, MKL_INT *m, MKL_INT *k, float *alpha, char *matdescra,
float *val, MKL_INT *lval, MKL_INT *iddiag, MKL_INT *ndiag, float *x, float *beta,
float *y);

void mkl_ddiamv (char *transa, MKL_INT *m, MKL_INT *k, double *alpha, char *matdescra,
double *val, MKL_INT *lval, MKL_INT *iddiag, MKL_INT *ndiag, double *x, double *beta,
double *y);

void mkl_cdiamv (char *transa, MKL_INT *m, MKL_INT *k, MKL_Complex8 *alpha, char
*matdescra, MKL_Complex8 *val, MKL_INT *lval, MKL_INT *iddiag, MKL_INT *ndiag,
MKL_Complex8 *x, MKL_Complex8 *beta, MKL_Complex8 *y);

void mkl_zdiamv (char *transa, MKL_INT *m, MKL_INT *k, MKL_Complex16 *alpha, char
*matdescra, MKL_Complex16 *val, MKL_INT *lval, MKL_INT *iddiag, MKL_INT *ndiag,
MKL_Complex16 *x, MKL_Complex16 *beta, MKL_Complex16 *y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?diamv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix stored in the diagonal format, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation.
---------------	---------------------------------------

If $\text{transa} = \text{'N'}$ or 'n' , then $y := \alpha * A * x + \beta * y$,
 If $\text{transa} = \text{'T'}$ or 't' or 'C' or 'c' , then $y := \alpha * A' * x + \beta * y$.

m INTEGER. Number of rows of the matrix *A*.

k INTEGER. Number of columns of the matrix *A*.

alpha REAL for mkl_sdiamp.

DOUBLE PRECISION for mkl_ddiamv.

COMPLEX for mkl_cdiamp.

DOUBLE COMPLEX for mkl_zdiamp.

Specifies the scalar *alpha*.

matdescra CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in [Table "Possible Values of the Parameter matdescra \(descra\)"](#). Possible combinations of element values of this parameter are given in [Table "Possible Combinations of Element Values of the Parameter matdescra"](#).

val REAL for mkl_sdiamp.

DOUBLE PRECISION for mkl_ddiamv.

COMPLEX for mkl_cdiamp.

DOUBLE COMPLEX for mkl_zdiamp.

Two-dimensional array of size *lval* by *ndiag*, contains non-zero diagonals of the matrix *A*. Refer to *values* array description in [Diagonal Storage Scheme](#) for more details.

lval INTEGER. Leading dimension of *val*, $lval \geq m$. Refer to *lval* description in [Diagonal Storage Scheme](#) for more details.

idiag INTEGER. Array of length *ndiag*, contains the distances between main diagonal and each non-zero diagonals in the matrix *A*.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix *A*.

x REAL for mkl_sdiamp.

DOUBLE PRECISION for mkl_ddiamv.

COMPLEX for mkl_cdiamp.

DOUBLE COMPLEX for mkl_zdiamp.

Array, size at least *k* if $\text{transa} = \text{'N'}$ or 'n' , and at least *m* otherwise. On entry, the array *x* must contain the vector *x*.

beta REAL for mkl_sdiamp.

DOUBLE PRECISION for mkl_ddiamv.

COMPLEX for mkl_cdiamv.
 DOUBLE COMPLEX for mkl_zdiamv.
 Specifies the scalar *beta*.

y
 REAL for mkl_sdiamv.
 DOUBLE PRECISION for mkl_ddiamv.
 COMPLEX for mkl_cdiamv.
 DOUBLE COMPLEX for mkl_zdiamv.
 Array, size at least *m* if *transa* = 'N' or 'n', and at least *k* otherwise. On entry, the array *y* must contain the vector *y*.

Output Parameters

y Overwritten by the updated vector *y*.

Interfaces

Description

The `mkl_?skymv` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix stored using the skyline storage scheme, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation.
	If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> * <i>A</i> * <i>x</i> + <i>beta</i> * <i>y</i>
	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> * <i>A'</i> * <i>x</i> + <i>beta</i> * <i>y</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .

<i>alpha</i>	REAL for mkl_sskymv. DOUBLE PRECISION for mkl_dskymv. COMPLEX for mkl_cskymv. DOUBLE COMPLEX for mkl_zskymv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra" .
<hr/>	
	NOTE
	General matrices (<i>matdescra</i> (1) = 'G') is not supported.
<hr/>	
<i>val</i>	REAL for mkl_sskymv. DOUBLE PRECISION for mkl_dskymv. COMPLEX for mkl_cskymv. DOUBLE COMPLEX for mkl_zskymv. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i> (2) = 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescrsa</i> (2) = 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <i>val</i> the positions of the first element in each row (column) of the matrix <i>A</i> . Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.
<i>x</i>	REAL for mkl_sskymv. DOUBLE PRECISION for mkl_dskymv. COMPLEX for mkl_cskymv. DOUBLE COMPLEX for mkl_zskymv. Array, size at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL for mkl_sskymv. DOUBLE PRECISION for mkl_dskymv.

COMPLEX for mkl_cskymv.
 DOUBLE COMPLEX for mkl_zskymv.
 Specifies the scalar *beta*.

y
 REAL for mkl_sskymv.
 DOUBLE PRECISION for mkl_dskymv.
 COMPLEX for mkl_cskymv.
 DOUBLE COMPLEX for mkl_zskymv.
 Array, size at least *m* if *transa* = 'N' or 'n' and at least *k* otherwise. On entry, the array *y* must contain the vector *y*.

Output Parameters

y Overwritten by the updated vector *y*.

Description

The `mkl_?diasv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')* x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> *inv(<i>A</i>)* <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>x</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	REAL for <code>mkl_sdiasv</code> . DOUBLE PRECISION for <code>mkl_ddiasv</code> . COMPLEX for <code>mkl_cdiasv</code> . DOUBLE COMPLEX for <code>mkl_zdiasv</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for <code>mkl_sdiasv</code> . DOUBLE PRECISION for <code>mkl_ddiasv</code> . COMPLEX for <code>mkl_cdiasv</code> . DOUBLE COMPLEX for <code>mkl_zdiasv</code> .

Two-dimensional array of size $lval$ by $ndiag$, contains non-zero diagonals of the matrix A. Refer to *values* array description in [Diagonal Storage Scheme](#) for more details.

lval INTEGER. Leading dimension of *val*, $lval \geq m$. Refer to *lval* description in [Diagonal Storage Scheme](#) for more details.

idiag INTEGER. Array of length $ndiag$, contains the distances between main diagonal and each non-zero diagonals in the matrix A.

NOTE

All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix A.

x REAL for `mkl_sdiasv`.

DOUBLE PRECISION for `mkl_ddiasv`.

COMPLEX for `mkl_cdiasv`.

DOUBLE COMPLEX for `mkl_zdiasv`.

Array, size at least m .

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y REAL for `mkl_sdiasv`.

DOUBLE PRECISION for `mkl_ddiasv`.

COMPLEX for `mkl_cdiasv`.

DOUBLE COMPLEX for `mkl_zdiasv`.

Array, size at least m .

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains solution vector *x*.

Description

The `mkl_?skysv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the skyline storage format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(A')*x,
```

where:

`alpha` is scalar, `x` and `y` are vectors, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>y</i> := <i>alpha</i> *inv(<i>A</i>)* <i>x</i> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>y</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>x</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sskysv. DOUBLE PRECISION for mkl_dskysv. COMPLEX for mkl_cskysv. DOUBLE COMPLEX for mkl_zskysv. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .

NOTE

General matrices (*matdescra*(1)='G') is not supported.

<i>val</i>	REAL for mkl_sskysv. DOUBLE PRECISION for mkl_dskysv. COMPLEX for mkl_cskysv. DOUBLE COMPLEX for mkl_zskysv. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescra</i> (2)= 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescra</i> (2)= 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <i>val</i> the positions of the first element in each row (column) of the matrix <i>A</i> . Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.

x REAL for mkl_sskysv.
 DOUBLE PRECISION for mkl_dskysv.
 COMPLEX for mkl_cskysv.
 DOUBLE COMPLEX for mkl_zskysv.
 Array, size at least m .
 On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y REAL for mkl_sskysv.
 DOUBLE PRECISION for mkl_dskysv.
 COMPLEX for mkl_cskysv.
 DOUBLE COMPLEX for mkl_zskysv.
 Array, size at least m .
 On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains solution vector *x*.

Interfaces

Description

The `mkl_?diamm` routine performs a matrix-matrix operation defined as

$$C := \alpha A^* B + \beta C$$

or

$$C := \alpha A'^* B + \beta C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the diagonal format, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha A^* B + \beta C$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha A'^* B + \beta C$.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .

<i>alpha</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , <i>lval</i> \geq <i>m</i> . Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>b</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Array, size (<i>ldb</i> , <i>n</i>). On entry with <i>transa</i> = 'N' or 'n', the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program.
<i>beta</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm.

Specifies the scalar *beta*.

c REAL for mkl_sdiamm.

DOUBLE PRECISION for mkl_ddiamm.

COMPLEX for mkl_cdiamm.

DOUBLE COMPLEX for mkl_zdiamm.

Array, size *ldc* by *n*.

On entry, the leading *m*-by-*n* part of the array *c* must contain the matrix *C*, otherwise the leading *k*-by-*n* part of the array *c* must contain the matrix *C*.

ldc INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix (*alpha***A***B* + *beta***C*) or (*alpha***A*'**B* + *beta***C*).

Interfaces

FORTRAN 77:

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?skymm` routine performs a matrix-matrix operation defined as

```
C := alpha*A*B + beta*C
```

or

```
C := alpha*A'*B + beta*C,
```

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the skyline storage format, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation.
	If <i>transa</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> * <i>A</i> * <i>B</i> + <i>beta</i> * <i>C</i> ,
	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>C</i> := <i>alpha</i> * <i>A'</i> * <i>B</i> + <i>beta</i> * <i>C</i> ,

<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sskymm. DOUBLE PRECISION for mkl_dskymm. COMPLEX for mkl_cskymm. DOUBLE COMPLEX for mkl_zskymm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .

NOTE

General matrices (*matdescra* (1)='G') is not supported.

<i>val</i>	REAL for mkl_sskymm. DOUBLE PRECISION for mkl_dskymm. COMPLEX for mkl_cskymm. DOUBLE COMPLEX for mkl_zskymm. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i> (2)= 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescrsa</i> (2)= 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <i>val</i> the positions of the first element in each row (column) of the matrix <i>A</i> . Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.
<i>b</i>	REAL for mkl_sskymm. DOUBLE PRECISION for mkl_dskymm. COMPLEX for mkl_cskymm. DOUBLE COMPLEX for mkl_zskymm.

Array, size (*ldb*, *n*).

On entry with *transa* = 'N' or 'n', the leading *k*-by-*n* part of the array *b* must contain the matrix *B*, otherwise the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

ldb INTEGER. Specifies the leading dimension of *b* as declared in the calling (sub)program.

beta REAL for mkl_ssksymm.

DOUBLE PRECISION for mkl_dskymm.

COMPLEX for mkl_cskymm.

DOUBLE COMPLEX for mkl_zskymm.

Specifies the scalar *beta*.

c REAL for mkl_ssksymm.

DOUBLE PRECISION for mkl_dskymm.

COMPLEX for mkl_cskymm.

DOUBLE COMPLEX for mkl_zskymm.

Array, size *ldc* by *n*.

On entry, the leading *m*-by-*n* part of the array *c* must contain the matrix *C*, otherwise the leading *k*-by-*n* part of the array *c* must contain the matrix *C*.

ldc INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix (*alpha***A***B* + *beta***C*) or (*alpha***A*'**B* + *beta***C*).

Description

The `mkl_?diasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the diagonal format:

$C := \alpha \cdot \text{inv}(A) \cdot B$

or

$C := \alpha \cdot \text{inv}(A') \cdot B,$

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> *inv(<i>A</i>)* <i>B</i> , If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>C</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>B</i> .
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_sdiasm. DOUBLE PRECISION for mkl_ddiasm. COMPLEX for mkl_cdiasm. DOUBLE COMPLEX for mkl_zdiasm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .
<i>val</i>	REAL for mkl_sdiasm. DOUBLE PRECISION for mkl_ddiasm. COMPLEX for mkl_cdiasm. DOUBLE COMPLEX for mkl_zdiasm. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , <i>lval</i> $\geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> .

NOTE

All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix *A*.

b REAL for mkl_sdiasm.

DOUBLE PRECISION for mkl_ddiasm.

COMPLEX for mkl_cdiasm.

DOUBLE COMPLEX for mkl_zdiasm.

Array, size (*ldb*, *n*).

On entry the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

ldb INTEGER. Specifies the leading dimension of *b* as declared in the calling (sub)program.

ldc INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program.

Output Parameters

c REAL for mkl_sdiasm.

DOUBLE PRECISION for mkl_ddiasm.

COMPLEX for mkl_cdiasm.

DOUBLE COMPLEX for mkl_zdiasm.

Array, size *ldc* by *n*.

The leading *m*-by-*n* part of the array *c* contains the matrix *C*.

```

mkl_?skysm

Solves a system of linear matrix equations for a sparse matrix stored using the skyline storage scheme with one-based indexing.

Syntax

Fortran:

```
call mkl_sskysm(transa, m, n, alpha, matdescra, val, pptr, b, ldb, c, ldc)
call mkl_dskysm(transa, m, n, alpha, matdescra, val, pptr, b, ldb, c, ldc)
call mkl_cskysm(transa, m, n, alpha, matdescra, val, pptr, b, ldb, c, ldc)
call mkl_zskysm(transa, m, n, alpha, matdescra, val, pptr, b, ldb, c, ldc)
```

C:

```
void mkl_sskysm (char *transa, MKL_INT *m, MKL_INT *n, float *alpha, char *matdescra,
float *val, MKL_INT *pptr, float *b, MKL_INT *ldb, float *c, MKL_INT *ldc);
void mkl_dskysm (char *transa, MKL_INT *m, MKL_INT *n, double *alpha, char *matdescra,
double *val, MKL_INT *pptr, double *b, MKL_INT *ldb, double *c, MKL_INT *ldc);
void mkl_cskysm (char *transa, MKL_INT *m, MKL_INT *n, MKL_Complex8 *alpha, char
*matdescra, MKL_Complex8 *val, MKL_INT *pptr, MKL_Complex8 *b, MKL_INT *ldb,
MKL_Complex8 *c, MKL_INT *ldc);
void mkl_zskysm (char *transa, MKL_INT *m, MKL_INT *n, MKL_Complex16 *alpha, char
*matdescra, MKL_Complex16 *val, MKL_INT *pptr, MKL_Complex16 *b, MKL_INT *ldb,
MKL_Complex16 *c, MKL_INT *ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?skysm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the skyline storage format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(A')*B,
```

where:

`alpha` is scalar, `B` and `C` are dense matrices, `A` is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, `A'` is the transpose of `A`.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> *inv(<i>A</i>)* <i>B</i> , If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <i>C</i> := <i>alpha</i> *inv(<i>A'</i>)* <i>B</i> ,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_sskysm. DOUBLE PRECISION for mkl_dskysm. COMPLEX for mkl_cskysm. DOUBLE COMPLEX for mkl_zskysm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" .

NOTE

General matrices (*matdescra*(1)='G') is not supported.

<i>val</i>	REAL for mkl_sskysm. DOUBLE PRECISION for mkl_dskysm. COMPLEX for mkl_cskysm. DOUBLE COMPLEX for mkl_zskysm. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i> (2) = 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescrsa</i> (2) = 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length $(m+m)$. It contains the indices specifying in the <i>val</i> the positions of the first non-zero element of each <i>i</i> -row (column) of the matrix <i>A</i> such that <i>pointers</i> (<i>i</i>) - <i>pointers</i> (1) + 1. Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.

b

REAL for mkl_sskysm.
 DOUBLE PRECISION for mkl_dskysm.
 COMPLEX for mkl_cskysm.
 DOUBLE COMPLEX for mkl_zskysm.
 Array, size (*ldb*, *n*).

On entry the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

ldb

INTEGER. Specifies the leading dimension of *b* as declared in the calling (sub)program.

ldc

INTEGER. Specifies the leading dimension of *c* as declared in the calling (sub)program.

Output Parameters

c

REAL for mkl_sskysm.
 DOUBLE PRECISION for mkl_dskysm.
 COMPLEX for mkl_cskysm.
 DOUBLE COMPLEX for mkl_zskysm.
 Array, size *ldc* by *n*.

The leading *m*-by-*n* part of the array *c* contains the matrix *C*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_sskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
```

```
  CHARACTER*1 transa
```

```

```

mkl_?dnsCSR

Convert a sparse matrix in uncompressed representation to the CSR format and vice versa.

Syntax**Fortran:**

```
call mkl_sdnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
call mkl_ddnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
call mkl_cdnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
call mkl_zdnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
```

C:

```
void mkl_sdnscsr (MKL_INT *job, MKL_INT *m, MKL_INT *n, float *adns, MKL_INT *lda,
float *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *info);
```

```
void mkl_ddnscsr (MKL_INT *job, MKL_INT *m, MKL_INT *n, double *adns, MKL_INT *lda,
double *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *info);

void mkl_cdnscsr (MKL_INT *job, MKL_INT *m, MKL_INT *n, MKL_Complex8 *adns, MKL_INT
*lda, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *info);

void mkl_zdnscsr (MKL_INT *job, MKL_INT *m, MKL_INT *n, MKL_Complex16 *adns, MKL_INT
*lda, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *info);
```

Include Files

- C: `mkl.h`

Description

This routine converts a sparse matrix A between formats: stored as a rectangular array (dense representation) and stored using compressed sparse row (CSR) format (3-array variation).

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>job</i>	INTEGER
Array, contains the following conversion parameters:	
<i>job(1)</i>	If $job(1)=0$, the rectangular matrix A is converted to the CSR format; if $job(1)=1$, the rectangular matrix A is restored from the CSR format.
<i>job(2)</i>	If $job(2)=0$, zero-based indexing for the rectangular matrix A is used; if $job(2)=1$, one-based indexing for the rectangular matrix A is used.
<i>job(3)</i>	If $job(3)=0$, zero-based indexing for the matrix in CSR format is used; if $job(3)=1$, one-based indexing for the matrix in CSR format is used.
<i>job(4)</i>	If $job(4)=0$, $adns$ is a lower triangular part of matrix A ; If $job(4)=1$, $adns$ is an upper triangular part of matrix A ; If $job(4)=2$, $adns$ is a whole matrix A .
<i>job(5)</i>	$job(5)=nzmax$ - maximum number of the non-zero elements allowed if $job(1)=0$.
<i>job(6)</i>	- job indicator for conversion to CSR format. If $job(6)=0$, only array ia is generated for the output storage. If $job(6)>0$, arrays $acsr$, ia , ja are generated for the output storage.
<i>m</i>	INTEGER. Number of rows of the matrix A .

<i>n</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>adns</i>	(input/output) REAL for mkl_sdnscsr. DOUBLE PRECISION for mkl_ddnscsr. COMPLEX for mkl_cdnscsr. DOUBLE COMPLEX for mkl_zdnscsr. If <i>job</i> (1)=0, on input <i>adns</i> contains an uncompressed (dense) representation of matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>adns</i> as declared in the calling (sub)program. For <i>job</i> (2)=0 (zero-based indexing of <i>A</i>), <i>lda</i> must be at least $\max(1, n)$. For <i>job</i> (2)=1 (one-based indexing of <i>A</i>), <i>lda</i> must be at least $\max(1, m)$.
<i>acsr</i>	(input/output) REAL for mkl_sdnscsr. DOUBLE PRECISION for mkl_ddnscsr. COMPLEX for mkl_cdnscsr. DOUBLE COMPLEX for mkl_zdnscsr. If <i>job</i> (1)=1, on input <i>acsr</i> contains the non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	(input/output) INTEGER. If <i>job</i> (1)=1, on input <i>ja</i> contains the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	(input/output) INTEGER. Array of length $m + 1$. If <i>job</i> (1)=1, on input <i>ia</i> contains indices of elements in the array <i>acsr</i> , such that <i>ia</i> (<i>I</i>) is the index in the array <i>acsr</i> of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia</i> ($m + 1$) is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.

Output Parameters

<i>adns</i>	If <i>job</i> (1)=1, on output <i>adns</i> contains the uncompressed (dense) representation of matrix <i>A</i> .
<i>acsr, ja, ia</i>	If <i>job</i> (1)=0, on output <i>acsr</i> , <i>ja</i> , and <i>ia</i> contain the compressed sparse row (CSR) format (3-array variation) of matrix <i>A</i> (see Sparse Matrix Storage Formats for a description of the storage format).
<i>info</i>	INTEGER. Integer info indicator only for restoring the matrix <i>A</i> from the CSR format.

If $info=0$, the execution is successful.

If $info=i$, the routine is interrupted processing the i -th row because there is no space in the arrays $acsr$ and ja according to the value $nzmax$.

Interfaces

```

```
int *lda, MKL_Complex16 *acsr, int *ja, int *ia, int *info);
```

mkl_?csrcoo

Converts a sparse matrix in the CSR format to the coordinate format and vice versa.

Syntax

Fortran:

```
call mkl_scsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
call mkl_dcsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
call mkl_ccsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
call mkl_zcsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
```

C:

```
void mkl_dcsrcoo (MKL_INT *job, MKL_INT *n, double *acsr, MKL_INT *ja, MKL_INT *ia,
MKL_INT *nnz, double *aco, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
void mkl_scsrcoo (MKL_INT *job, MKL_INT *n, float *acsr, MKL_INT *ja, MKL_INT *ia,
MKL_INT *nnz, float *aco, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
void mkl_ccsrcoo (MKL_INT *job, MKL_INT *n, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_INT *nnz, MKL_Complex8 *aco, MKL_INT *rowind, MKL_INT *colind, MKL_INT
*info);
void mkl_zcsrcoo (MKL_INT *job, MKL_INT *n, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_INT *nnz, MKL_Complex16 *aco, MKL_INT *rowind, MKL_INT *colind, MKL_INT
*info);
```

Include Files

- C: mkl.h

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to coordinate format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>job</i>	INTEGER
	Array, contains the following conversion parameters:
<i>job</i> (1)	If <i>job</i> (1)=0, the matrix in the CSR format is converted to the coordinate format;
	if <i>job</i> (1)=1, the matrix in the coordinate format is converted to the CSR format.
	if <i>job</i> (1)=2, the matrix in the coordinate format is converted to the CSR format, and the column indices in CSR representation are sorted in the increasing order within each row.

job(2)
 If *job*(2)=0, zero-based indexing for the matrix in CSR format is used;
 if *job*(2)=1, one-based indexing for the matrix in CSR format is used.

job(3)
 If *job*(3)=0, zero-based indexing for the matrix in coordinate format is used;
 if *job*(3)=1, one-based indexing for the matrix in coordinate format is used.

job(5)
job(5)=*nzmax* - maximum number of the non-zero elements allowed if *job*(1)=0.
job(5)=*nnz* - sets number of the non-zero elements of the matrix *A* if *job*(1)=1.

job(6) - job indicator.

For conversion to the coordinate format:

If *job*(6)=1, only array *rowind* is filled in for the output storage.
 If *job*(6)=2, arrays *rowind*, *colind* are filled in for the output storage.
 If *job*(6)=3, all arrays *rowind*, *colind*, *acoo* are filled in for the output storage.

For conversion to the CSR format:

If *job*(6)=0, all arrays *acsr*, *ja*, *ia* are filled in for the output storage.
 If *job*(6)=1, only array *ia* is filled in for the output storage.
 If *job*(6)=2, then it is assumed that the routine already has been called with the *job*(6)=1, and the user allocated the required space for storing the output arrays *acsr* and *ja*.

n INTEGER. Dimension of the matrix *A*.

acsr (input/output)

REAL for mkl_scsrcoo.
 DOUBLE PRECISION for mkl_dcsrcoo.
 COMPLEX for mkl_ccsrcoo.
 DOUBLE COMPLEX for mkl_zcsrcoo.

Array containing non-zero elements of the matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja (input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix *A*.

Its length is equal to the length of the array *acsr*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

<i>ia</i>	(input/output) INTEGER. Array of length $n + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia(I)$ is the index in the array <i>acsr</i> of the first non-zero element from the row I . The value of the last element $ia(n + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>acoo</i>	(input/output) REAL for mkl_sscsrcoo. DOUBLE PRECISION for mkl_dscsrcoo. COMPLEX for mkl_ccscsrcoo. DOUBLE COMPLEX for mkl_zscsrcoo. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>rowind</i>	(input/output) INTEGER. Array of length nnz , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	(input/output) INTEGER. Array of length nnz , contains the column indices for each non-zero element of the matrix A . Refer to <i>columns</i> array description in Coordinate Format for more details.

Output Parameters

<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix A . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>info</i>	INTEGER. Integer info indicator only for converting the matrix A from the CSR format. If $info=0$, the execution is successful. If $info=1$, the routine is interrupted because there is no space in the arrays <i>acoo</i> , <i>rowind</i> , <i>colind</i> according to the value <i>nzmax</i> .

Interfaces

FORTRAN 77:

MKL_INT *iab, MKL_INT *info);

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the block sparse row (BSR) format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>job</code> <code>job(1)</code> <code>job(2)</code> <code>job(3)</code> <code>job(4)</code> <code>job(6)</code> - job indicator. For conversion to the BSR format: <code>If job(6)=0, only arrays jab, iab are generated for the output storage.</code>	<code>INTEGER</code> Array, contains the following conversion parameters: <code>job(1)</code> If <code>job(1)=0</code> , the matrix in the CSR format is converted to the BSR format; if <code>job(1)=1</code> , the matrix in the BSR format is converted to the CSR format. <code>job(2)</code> If <code>job(2)=0</code> , zero-based indexing for the matrix in CSR format is used; if <code>job(2)=1</code> , one-based indexing for the matrix in CSR format is used. <code>job(3)</code> If <code>job(3)=0</code> , zero-based indexing for the matrix in the BSR format is used; if <code>job(3)=1</code> , one-based indexing for the matrix in the BSR format is used. <code>job(4)</code> is only used for conversion to CSR format. By default, the converter saves the blocks without checking whether an element is zero or not. If <code>job(4)=1</code> , then the converter only saves non-zero elements in blocks.
---	--

If $job(6) > 0$, all output arrays $absr$, jab , and iab are filled in for the output storage.

If $job(6) = -1$, $iab(1)$ returns the number of non-zero blocks.

For conversion to the CSR format:

If $job(6) = 0$, only arrays ja , ia are generated for the output storage.

m

INTEGER. Actual row dimension of the matrix A for convert to the BSR format; block row dimension of the matrix A for convert to the CSR format.

$mblk$

INTEGER. Size of the block in the matrix A .

$ldabsr$

INTEGER. Leading dimension of the array $absr$ as declared in the calling program. $ldabsr$ must be greater than or equal to $mblk * mblk$.

$acsr$

(input/output)

REAL for `mkl_scsrbsr`.

DOUBLE PRECISION for `mkl_dcsrbsr`.

COMPLEX for `mkl_ccsrbsr`.

DOUBLE COMPLEX for `mkl_zcsrbsr`.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja

(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array $acsr$. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia

(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia(I)$ is the index in the array $acsr$ of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

$absr$

(input/output)

REAL for `mkl_scsrbsr`.

DOUBLE PRECISION for `mkl_dcsrbsr`.

COMPLEX for `mkl_ccsrbsr`.

DOUBLE COMPLEX for `mkl_zcsrbsr`.

Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $mblk * mblk$. Refer to *values* array description in [BSR Format](#) for more details.

jab

(input/output) INTEGER. Array containing the column indices for each non-zero block of the matrix A .

Its length is equal to the number of non-zero blocks of the matrix A . Refer to [columns](#) array description in [BSR Format](#) for more details.

iab (input/output) INTEGER. Array of length $(m + 1)$, containing indices of blocks in the array *absr*, such that *iab*(*i*) is the index in the array *absr* of the first non-zero element from the *i*-th row . The value of the last element *iab*($m + 1$) is equal to the number of non-zero blocks plus one. Refer to [rowIndex](#) array description in [BSR Format](#) for more details.

Output Parameters

info INTEGER. Integer info indicator only for converting the matrix A from the CSR format.
 If *info*=0, the execution is successful.
 If *info*=1, it means that *mblk* is equal to 0.
 If *info*=2, it means that *ldabsr* is less than *mblk*mblk* and there is no space for all blocks.

int *ia, MKL_Complex16 *absr, int *jab, int *iab, int *info);
```

mkl_?csrcsc

Converts a square sparse matrix in the CSR format to the CSC format and vice versa.

Syntax**Fortran:**

```
call mkl_sscrcsc(job, m, acsr, ja, ia, acsc, jal, ial, info)
call mkl_dscrcsc(job, m, acsr, ja, ia, acsc, jal, ial, info)
call mkl_ccrcsc(job, m, acsr, ja, ia, acsc, jal, ial, info)
call mkl_zscrcsc(job, m, acsr, ja, ia, acsc, jal, ial, info)
```

C:

```
void mkl_sscrcsc (MKL_INT *job, MKL_INT *m, float *acsr, MKL_INT *ja, MKL_INT *ia,
float *acsc, MKL_INT *jal, MKL_INT *ial, MKL_INT *info);
void mkl_dscrcsc (MKL_INT *job, MKL_INT *m, double *acsr, MKL_INT *ja, MKL_INT *ia,
double *acsc, MKL_INT *jal, MKL_INT *ial, MKL_INT *info);
void mkl_ccrcsc (MKL_INT *job, MKL_INT *m, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_Complex8 *acsc, MKL_INT *jal, MKL_INT *ial, MKL_INT *info);
void mkl_zscrcsc (MKL_INT *job, MKL_INT *m, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_Complex16 *acsc, MKL_INT *jal, MKL_INT *ial, MKL_INT *info);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine converts a square sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the compressed sparse column (CSC) format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

job

INTEGER

Array, contains the following conversion parameters:

job(1)If *job*(1)=0, the matrix in the CSR format is converted to the CSC format;
if *job*(1)=1, the matrix in the CSC format is converted to the CSR format.*job*(2)If *job*(2)=0, zero-based indexing for the matrix in CSR format is used;
if *job*(2)=1, one-based indexing for the matrix in CSR format is used.*job*(3)If *job*(3)=0, zero-based indexing for the matrix in the CSC format is used;
if *job*(3)=1, one-based indexing for the matrix in the CSC format is used.*job*(6) - job indicator.

For conversion to the CSC format:

If *job*(6)=0, only arrays *ja1*, *ia1* are filled in for the output storage.If *job*(6)≠0, all output arrays *acsc*, *ja1*, and *ia1* are filled in for the output storage.

For conversion to the CSR format:

If *job*(6)=0, only arrays *ja*, *ia* are filled in for the output storage.If *job*(6)≠0, all output arrays *acsr*, *ja*, and *ia* are filled in for the output storage.*m*INTEGER. Dimension of the square matrix *A*.*acsr*

(input/output)

REAL for mkl_scsrcsc.

DOUBLE PRECISION for mkl_dscrcsc.

COMPLEX for mkl_ccsrcsc.

DOUBLE COMPLEX for mkl_zscrcsc.

Array containing non-zero elements of the square matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.*ja*(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix *A*.Its length is equal to the length of the array *acsr*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.*ia*(input/output) INTEGER. Array of length *m* + 1, containing indices of elements in the array *acsr*, such that *ia*(*I*) is the index in the array *acsr* of the first non-zero element from the row *I*. The value of the last element *ia*(*m* + 1) is equal to the number of non-zeros plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

acsc (input/output)
 REAL for mkl_scsrcsc.
 DOUBLE PRECISION for mkl_dcsrcsc.
 COMPLEX for mkl_ccsrcsc.
 DOUBLE COMPLEX for mkl_zcsrcsc.

Array containing non-zero elements of the square matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja1 (input/output) INTEGER. Array containing the row indices for each non-zero element of the matrix A .
 Its length is equal to the length of the array *acsc*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ial (input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array *acsc*, such that *ial*(I) is the index in the array *acsc* of the first non-zero element from the column I . The value of the last element *ial*($m + 1$) is equal to the number of non-zeros plus one. Refer to *RowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

Output Parameters

info INTEGER. This parameter is not used now.

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the diagonal format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<code>job</code> <code>job(1)</code> <code>job(2)</code> <code>job(3)</code> <code>job(6)</code> - job indicator. For conversion to the diagonal format: If <code>job(6)=0</code> , diagonals are not selected internally, and <code>acsr_rem</code> , <code>ja_rem</code> , <code>ia_rem</code> are not filled in for the output storage. If <code>job(6)=1</code> , diagonals are not selected internally, and <code>acsr_rem</code> , <code>ja_rem</code> , <code>ia_rem</code> are filled in for the output storage. If <code>job(6)=10</code> , diagonals are selected internally, and <code>acsr_rem</code> , <code>ja_rem</code> , <code>ia_rem</code> are not filled in for the output storage. If <code>job(6)=11</code> , diagonals are selected internally, and <code>csr_rem</code> , <code>ja_rem</code> , <code>ia_rem</code> are filled in for the output storage. For conversion to the CSR format: If <code>job(6)=0</code> , each entry in the array <code>adia</code> is checked whether it is zero. Zero entries are not included in the array <code>acsr</code> .

If $job(6) \neq 0$, each entry in the array $adia$ is not checked whether it is zero.

m

INTEGER. Dimension of the matrix A .

$acsr$

(input/output)

REAL for mkl_scsrdia.

DOUBLE PRECISION for mkl_dcsrdia.

COMPLEX for mkl_ccsrdia.

DOUBLE COMPLEX for mkl_zcsrdia.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to $values$ array description in [Sparse Matrix Storage Formats](#) for more details.

ja

(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array $acsr$. Refer to $columns$ array description in [Sparse Matrix Storage Formats](#) for more details.

ia

(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia(I)$ is the index in the array $acsr$ of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to $rowIndex$ array description in [Sparse Matrix Storage Formats](#) for more details.

$adia$

(input/output)

REAL for mkl_scsrdia.

DOUBLE PRECISION for mkl_dcsrdia.

COMPLEX for mkl_ccsrdia.

DOUBLE COMPLEX for mkl_zcsrdia.

Array of size $(ndiag \times iddiag)$ containing diagonals of the matrix A .

The key point of the storage is that each element in the array $adia$ retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom.

$ndiag$

INTEGER.

Specifies the leading dimension of the array $adia$ as declared in the calling (sub)program, must be at least $\max(1, m)$.

$distance$

INTEGER.

Array of length $iddiag$, containing the distances between the main diagonal and each non-zero diagonal to be extracted. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

$iddiag$

INTEGER.

Number of diagonals to be extracted. For conversion to diagonal format on return this parameter may be modified.

acsr_rem, *ja_rem*, *ia_rem* Remainder of the matrix in the CSR format if it is needed for conversion to the diagonal format.

Output Parameters

info INTEGER. This parameter is not used now.

Interfaces

FORTRAN 77:

int *idiag, MKL_Complex16 *acsr_rem, int *ja_rem, int *ia_rem, int *info);

```

mkl_?csrsky

Converts a sparse matrix in CSR format to the skyline format and vice versa.

Syntax

Fortran:

```

call mkl_scsrsky(job, m, acsr, ja, ia, asky, pointers, info)
call mkl_dcsrsky(job, m, acsr, ja, ia, asky, pointers, info)
call mkl_ccsrsky(job, m, acsr, ja, ia, asky, pointers, info)
call mkl_zcsrsky(job, m, acsr, ja, ia, asky, pointers, info)

```

C:

```

void mkl_dcsrsky (MKL_INT *job, MKL_INT *m, double *acsr, MKL_INT *ja, MKL_INT *ia,
double *asky, MKL_INT *pointers, MKL_INT *info);

void mkl_scsrsky (MKL_INT *job, MKL_INT *m, float *acsr, MKL_INT *ja, MKL_INT *ia,
float *asky, MKL_INT *pointers, MKL_INT *info);

void mkl_ccsrsky (MKL_INT *job, MKL_INT *m, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_Complex8 *asky, MKL_INT *pointers, MKL_INT *info);

void mkl_zcsrsky (MKL_INT *job, MKL_INT *m, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT
*ia, MKL_Complex16 *asky, MKL_INT *pointers, MKL_INT *info);

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the skyline format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

job	INTEGER
-----	---------

Array, contains the following conversion parameters:

job(1)

If *job*(1)=0, the matrix in the CSR format is converted to the skyline format;

if *job*(1)=1, the matrix in the skyline format is converted to the CSR format.

job(2)

If *job*(2)=0, zero-based indexing for the matrix in CSR format is used;

if *job*(2)=1, one-based indexing for the matrix in CSR format is used.

job(3)

If *job*(3)=0, zero-based indexing for the matrix in the skyline format is used;

if *job*(3)=1, one-based indexing for the matrix in the skyline format is used.

job(4)

For conversion to the skyline format:

If *job*(4)=0, the upper part of the matrix A in the CSR format is converted.

If *job*(4)=1, the lower part of the matrix A in the CSR format is converted.

For conversion to the CSR format:

If *job*(4)=0, the matrix is converted to the upper part of the matrix A in the CSR format.

If *job*(4)=1, the matrix is converted to the lower part of the matrix A in the CSR format.

job(5)

job(5)=*nzmax* - maximum number of the non-zero elements of the matrix A if *job*(1)=0.

job(6) - job indicator.

Only for conversion to the skyline format:

If *job*(6)=0, only arrays *pointers* is filled in for the output storage.

If *job*(6)=1, all output arrays *asky* and *pointers* are filled in for the output storage.

m

INTEGER. Dimension of the matrix A.

acsr

(input/output)

REAL for mkl_scsrsky.

DOUBLE PRECISION for mkl_dcsrsky.

COMPLEX for mkl_ccsrsky.

DOUBLE COMPLEX for mkl_zcsrsky.

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja

(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array *acsrr*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia

(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array *acsrr*, such that $ia(I)$ is the index in the array *acsrr* of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

asky

(input/output)

REAL for mkl_scsrsky.

DOUBLE PRECISION for mkl_dcsrsky.

COMPLEX for mkl_ccsrsky.

DOUBLE COMPLEX for mkl_zcsrsky.

Array, for a lower triangular part of A it contains the set of elements from each row starting from the first none-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets. Refer to *values* array description in [Skyline Storage Format](#) for more details.

pointers

(input/output) INTEGER.

Array with dimension $(m+1)$, where m is number of rows for lower triangle (columns for upper triangle), $pointers(I) - pointers(1) + 1$ gives the index of element in the array *asky* that is first non-zero element in row (column) I . The value of $pointers(m + 1)$ is set to $nnz + pointers(1)$, where nnz is the number of elements in the array *asky*. Refer to *pointers* array description in [Skyline Storage Format](#) for more details

Output Parameters

info

INTEGER. Integer info indicator only for converting the matrix A from the CSR format.

If $info=0$, the execution is successful.

If $info=1$, the routine is interrupted because there is no space in the array *asky* according to the value *nzmax*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrsky(job, m, acsr, ja, ia, asky, pointers, info)
    INTEGER      job(8)
    INTEGER      m, info
    INTEGER      ja(*), ia(m+1), pointers(m+1)
    REAL         acsr(*), asky(*)

SUBROUTINE mkl_dcsrsky(job, m, acsr, ja, ia, asky, pointers, info)
    INTEGER      job(8)
    INTEGER      m, info
    INTEGER      ja(*), ia(m+1), pointers(m+1)
    DOUBLE PRECISION      acsr(*), asky(*)

SUBROUTINE mkl_ccsrsky(job, m, acsr, ja, ia, asky, pointers, info)
    INTEGER      job(8)
    INTEGER      m, info
    INTEGER      ja(*), ia(m+1), pointers(m+1)
    COMPLEX      acsr(*), asky(*)

SUBROUTINE mkl_zcsrsky(job, m, acsr, ja, ia, asky, pointers, info)
    INTEGER      job(8)
    INTEGER      m, info
    INTEGER      ja(*), ia(m+1), pointers(m+1)
    DOUBLE COMPLEX      acsr(*), asky(*)
```

C:

```
void mkl_scsrsky(int *job, int *m, float *acsr, int *ja,
                  int *ia, float *asky, int *pointers, int *info);

void mkl_dcsrsky(int *job, int *m, double *acsr, int *ja,
                  int *ia, double *asky, int *pointers, int *info);

void mkl_ccsrsky(int *job, int *m, MKL_COMPLEX8 *acsr, int *ja,
                  int *ia, MKL_COMPLEX8 *asky, int *pointers, int *info);

void mkl_zcsrsky(int *job, int *m, MKL_COMPLEX16 *acsr, int *ja,
                  int *ia, MKL_COMPLEX16 *asky, int *pointers, int *info);
```

mkl_?csradd

Computes the sum of two matrices stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c, jc, ic,
nzmax, info)

call mkl_dcsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c, jc, ic,
nzmax, info)

call mkl_ccsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c, jc, ic,
nzmax, info)

call mkl_zcsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c, jc, ic,
nzmax, info)
```

C:

```
void mkl_scsradd (char *trans, MKL_INT *request, MKL_INT *sort, MKL_INT *m, MKL_INT *n,
float *a, MKL_INT *ja, MKL_INT *ia, float *beta, float *b, MKL_INT *jb, MKL_INT *ib,
float *c, MKL_INT *jc, MKL_INT *ic, MKL_INT *nzmax, MKL_INT *info);

void mkl_dcsradd (char *trans, MKL_INT *request, MKL_INT *sort, MKL_INT *m, MKL_INT *n,
double *a, MKL_INT *ja, MKL_INT *ia, double *beta, double *b, MKL_INT *jb, MKL_INT

Description

The `mkl_?csradd` routine performs a matrix-matrix operation defined as

$$C := A + \beta \operatorname{op}(B)$$

where:

A, B, C are the sparse matrices in the CSR format (3-array variation).

$\operatorname{op}(B)$ is one of $\operatorname{op}(B) = B$, or $\operatorname{op}(B) = B'$, or $\operatorname{op}(A) = \operatorname{conjg}(B')$

β is a scalar.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>trans</i>	CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A + \beta * B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A + \beta * B^T$.
<i>request</i>	INTEGER. If <i>request</i> =0, the routine performs addition. The memory for the output arrays <i>ic</i> , <i>jc</i> , <i>c</i> must be allocated beforehand. If <i>request</i> =1, the routine only computes the values of the array <i>ic</i> of length $m + 1$. The memory for the <i>ic</i> array must be allocated beforehand. On exit the value $ic(m+1) - 1$ is the actual number of the elements in the arrays <i>c</i> and <i>jc</i> . If <i>request</i> =2, after the routine is called previously with the parameter <i>request</i> =1 and after the output arrays <i>jc</i> and <i>c</i> are allocated in the calling program with length at least $ic(m+1) - 1$, the routine performs addition.
<i>sort</i>	INTEGER. Specifies the type of reordering. If this parameter is not set (default), the routine does not perform reordering. If <i>sort</i> =1, the routine arranges the column indices <i>ja</i> for each row in the increasing order and reorders the corresponding values of the matrix <i>A</i> in the array <i>a</i> . If <i>sort</i> =2, the routine arranges the column indices <i>jb</i> for each row in the increasing order and reorders the corresponding values of the matrix <i>B</i> in the array <i>b</i> . If <i>sort</i> =3, the routine performs reordering for both input matrices <i>A</i> and <i>B</i> .
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>a</i>	REAL for mkl_scsradd. DOUBLE PRECISION for mkl_dcsradd. COMPLEX for mkl_ccsradd. DOUBLE COMPLEX for mkl_zcsradd. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array a . Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia INTEGER. Array of length $m + 1$, containing indices of elements in the array a , such that $ia(I)$ is the index in the array a of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

beta REAL **for** mkl_scsradd.
DOUBLE PRECISION **for** mkl_dcsradd.
COMPLEX **for** mkl_ccsradd.
DOUBLE COMPLEX **for** mkl_zcsradd.
Specifies the scalar *beta*.

b REAL **for** mkl_scsradd.
DOUBLE PRECISION **for** mkl_dcsradd.
COMPLEX **for** mkl_ccsradd.
DOUBLE COMPLEX **for** mkl_zcsradd.
Array containing non-zero elements of the matrix B . Its length is equal to the number of non-zero elements in the matrix B . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

jb INTEGER. Array containing the column indices for each non-zero element of the matrix B . For each row the column indices must be arranged in the increasing order.
The length of this array is equal to the length of the array *b*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ib INTEGER. Array of length $m + 1$ when *trans* = 'N' or 'n', or $n + 1$ otherwise.
This array contains indices of elements in the array *b*, such that $ib(I)$ is the index in the array *b* of the first non-zero element from the row I . The value of the last element $ib(m + 1)$ or $ib(n + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

nzmax INTEGER. The length of the arrays *c* and *jc*.
This parameter is used only if *request*=0. The routine stops calculation if the number of elements in the result matrix *C* exceeds the specified value of *nzmax*.

Output Parameters

c REAL **for** mkl_scsradd.
DOUBLE PRECISION **for** mkl_dcsradd.

COMPLEX for `mkl_ccsradd`.

DOUBLE COMPLEX for `mkl_zcsradd`.

Array containing non-zero elements of the result matrix C . Its length is equal to the number of non-zero elements in the matrix C . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

`jc`

INTEGER. Array containing the column indices for each non-zero element of the matrix C .

The length of this array is equal to the length of the array `c`. Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

`ic`

INTEGER. Array of length $m + 1$, containing indices of elements in the array `c`, such that $ic(I)$ is the index in the array `c` of the first non-zero element from the row I . The value of the last element $ic(m + 1)$ is equal to the number of non-zero elements of the matrix C plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`info`

INTEGER.

If $info=0$, the execution is successful.

If $info=I>0$, the routine stops calculation in the I -th row of the matrix C because number of elements in C exceeds `nzmax`.

If $info=-1$, the routine calculates only the size of the arrays `c` and `jc` and returns this value plus 1 as the last element of the array `ic`.

Description

The `mkl_?csrmultcsr` routine performs a matrix-matrix operation defined as

$C := \text{op}(A) * B$

where:

A, B, C are the sparse matrices in the CSR format (3-array variation);

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

You can use the parameter `sort` to perform or not perform reordering of non-zero entries in input and output sparse matrices. The purpose of reordering is to rearrange non-zero entries in compressed sparse row matrix so that column indices in compressed sparse representation are sorted in the increasing order for each row.

The following table shows correspondence between the value of the parameter `sort` and the type of reordering performed by this routine for each sparse matrix involved:

Value of the parameter <code>sort</code>	Reordering of A (arrays a, ja, ia)	Reordering of B (arrays b, ja, ib)	Reordering of C (arrays c, jc, ic)
1	yes	no	yes
2	no	yes	yes
3	yes	yes	yes
4	yes	no	no
5	no	yes	no
6	yes	yes	no
7	no	no	no
arbitrary value not equal to 1, 2,..., 7	no	no	yes

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>trans</i>	CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A \times B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A^T \times B$.
<i>request</i>	INTEGER. If <i>request</i> =0, the routine performs multiplication, the memory for the output arrays <i>ic</i> , <i>jc</i> , <i>c</i> must be allocated beforehand. If <i>request</i> =1, the routine computes only values of the array <i>ic</i> of length $m + 1$, the memory for this array must be allocated beforehand. On exit the value $ic(m+1) - 1$ is the actual number of the elements in the arrays <i>c</i> and <i>jc</i> . If <i>request</i> =2, the routine has been called previously with the parameter <i>request</i> =1, the output arrays <i>jc</i> and <i>c</i> are allocated in the calling program and they are of the length $ic(m+1) - 1$ at least.
<i>sort</i>	INTEGER. Specifies whether the routine performs reordering of non-zeros entries in input and/or output sparse matrices (see table above).
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>B</i> .
<i>a</i>	REAL for mkl_scsrmultcsr. DOUBLE PRECISION for mkl_dcsrmultcsr. COMPLEX for mkl_ccsrmultcsr. DOUBLE COMPLEX for mkl_zcsrmultcsr. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$.

This array contains indices of elements in the array a , such that $ia(I)$ is the index in the array a of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zero elements of the matrix A plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

b REAL **for** `mkl_scsrmultcsr`.

DOUBLE PRECISION **for** `mkl_dcsrmultcsr`.

COMPLEX **for** `mkl_ccsrmultcsr`.

DOUBLE COMPLEX **for** `mkl_zcsrmultcsr`.

Array containing non-zero elements of the matrix B . Its length is equal to the number of non-zero elements in the matrix B . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

jb INTEGER. Array containing the column indices for each non-zero element of the matrix B . For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array b . Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

ib INTEGER. Array of length $n + 1$ when $trans = 'N'$ or ' n ', or $m + 1$ otherwise.

This array contains indices of elements in the array b , such that $ib(I)$ is the index in the array b of the first non-zero element from the row I . The value of the last element $ib(n + 1)$ or $ib(m + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

$nzmax$ INTEGER. The length of the arrays c and jc .

This parameter is used only if $request=0$. The routine stops calculation if the number of elements in the result matrix C exceeds the specified value of $nzmax$.

Output Parameters

c REAL **for** `mkl_scsrmultcsr`.

DOUBLE PRECISION **for** `mkl_dcsrmultcsr`.

COMPLEX **for** `mkl_ccsrmultcsr`.

DOUBLE COMPLEX **for** `mkl_zcsrmultcsr`.

Array containing non-zero elements of the result matrix C . Its length is equal to the number of non-zero elements in the matrix C . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

jc INTEGER. Array containing the column indices for each non-zero element of the matrix C .

The length of this array is equal to the length of the array c . Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ic INTEGER. Array of length $m + 1$ when $trans = 'N'$ or ' n ', or $n + 1$ otherwise.

This array contains indices of elements in the array c , such that $ic(I)$ is the index in the array c of the first non-zero element from the row I . The value of the last element $ic(m + 1)$ or $ic(n + 1)$ is equal to the number of non-zero elements of the matrix C plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

info INTEGER.

If $info=0$, the execution is successful.

If $info=I>0$, the routine stops calculation in the I -th row of the matrix C because number of elements in C exceeds $nzmax$.

If $info=-1$, the routine calculates only the size of the arrays c and jc and returns this value plus 1 as the last element of the array ic .

Description

The `mkl_?csrmultd` routine performs a matrix-matrix operation defined as

$$C := \text{op}(A) * B$$

where:

A, B are the sparse matrices in the CSR format (3-array variation), C is dense matrix;

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>trans</i>	CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A * B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A' * B$.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix B .
<i>a</i>	REAL for <code>mkl_scsrmultd</code> . DOUBLE PRECISION for <code>mkl_dcsrmultd</code> . COMPLEX for <code>mkl_ccsrmultd</code> . DOUBLE COMPLEX for <code>mkl_zcsrmultd</code> . Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <code>values</code> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix A . For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>a</i> . Refer to <code>columns</code> array description in Sparse Matrix Storage Formats for more details.

ia INTEGER. Array of length $m + 1$ when $\text{trans} = \text{'N'}$ or 'n' , or $n + 1$ otherwise.

This array contains indices of elements in the array *a*, such that $\text{ia}(I)$ is the index in the array *a* of the first non-zero element from the row I . The value of the last element $\text{ia}(m + 1)$ or $\text{ia}(n + 1)$ is equal to the number of non-zero elements of the matrix *A* plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

b REAL for `mkl_scsrmultd`.

DOUBLE PRECISION for `mkl_dcsrmultd`.

COMPLEX for `mkl_ccsrmultd`.

DOUBLE COMPLEX for `mkl_zcsrmultd`.

Array containing non-zero elements of the matrix *B*. Its length is equal to the number of non-zero elements in the matrix *B*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

jb INTEGER. Array containing the column indices for each non-zero element of the matrix *B*. For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array *b*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ib INTEGER. Array of length $m + 1$.

This array contains indices of elements in the array *b*, such that $\text{ib}(I)$ is the index in the array *b* of the first non-zero element from the row I . The value of the last element $\text{ib}(m + 1)$ is equal to the number of non-zero elements of the matrix *B* plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

Output Parameters

c REAL for `mkl_scsrmultd`.

DOUBLE PRECISION for `mkl_dcsrmultd`.

COMPLEX for `mkl_ccsrmultd`.

DOUBLE COMPLEX for `mkl_zcsrmultd`.

Array containing non-zero elements of the result matrix *C*.

ldc INTEGER. Specifies the leading dimension of the dense matrix *C* as declared in the calling (sub)program. Must be at least $\max(m, 1)$ when $\text{trans} = \text{'N'}$ or 'n' , or $\max(1, n)$ otherwise.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrmultd( trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
```

```
    CHARACTER*1 trans
```

```
    INTEGER m, n, k, ldc
```

```
    INTEGER ja(*), jb(*), ia(*), ib(*)
```

```
    REAL a(*), b(*), c(ldc, *)
```

```
SUBROUTINE mkl_dcsrmultd( trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
```

```
    CHARACTER*1 trans
```

```
    INTEGER m, n, k, ldc
```

```
    INTEGER ja(*), jb(*), ia(*), ib(*)
```

```
    DOUBLE PRECISION a(*), b(*), c(ldc, *)
```

```
SUBROUTINE mkl_ccsrmultd( trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
```

```
    CHARACTER*1 trans
```

```
    INTEGER m, n, k, ldc
```

```
    INTEGER ja(*), jb(*), ia(*), ib(*)
```

```
    COMPLEX a(*), b(*), c(ldc, *)
```

```
SUBROUTINE mkl_zcsrmultd( trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
```

```
    CHARACTER*1 trans
```

```
    INTEGER m, n, k, ldc
```

```
    INTEGER ja(*), jb(*), ia(*), ib(*)
```

```
    DOUBLE COMPLEX a(*), b(*), c(ldc, *)
```

C:

```
void mkl_scsrmultd(char *trans, int *m, int *n, int *k,
float *a, int *ja, int *ia, float *b, int *jb, int *ib, float *c, int *ldc);
```

```
void mkl_dcsrmultd(char *trans, int *m, int *n, int *k,
double *a, int *ja, int *ia, double *b, int *jb, int *ib, double *c, int *ldc);
```

```
void mkl_ccsrmultd(char *trans, int *m, int *n, int *k,
MKL_Complex8 *a, int *ja, int *ia, MKL_Complex8 *b, int *jb, int *ib,
MKL_Complex8 *c, int *ldc);
```

```
void mkl_zcsrmultd(char *trans, int *m, int *n, int *k,
MKL_Complex16 *a, int *ja, int *ia, MKL_Complex16 *b, int *jb, int *ib,
MKL_Complex16 *c, int *ldc);
```

BLAS-like Extensions

Intel MKL provides C and Fortran routines to extend the functionality of the BLAS routines. These include routines to compute vector products, matrix-vector products, and matrix-matrix products.

Intel MKL also provides routines to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations. Transposition operations are Copy As Is, Conjugate transpose, Transpose, and Conjugate. Each routine adds the possibility of scaling during the transposition operation by giving some *alpha* and/or *beta* parameters. Each routine supports both row-major orderings and column-major orderings.

Table “BLAS-like Extensions” lists these routines.

The <?> symbol in the routine short names is a precision prefix that indicates the data type:

<i>s</i>	REAL for Fortran interface, or float for C interface .
<i>d</i>	DOUBLE PRECISION for Fortran interface, or double for C interface .
<i>c</i>	COMPLEX for Fortran interface, or MKL_Complex8 for C interface .
<i>z</i>	DOUBLE COMPLEX for Fortran interface, or MKL_Complex16 for C interface .

BLAS-like Extensions

Routine	Data Types	Description
?axpby ?axpby	<i>s, d, c, z</i>	Scales two vectors, adds them to one another and stores result in the vector (routines)
?gem2vu	<i>s, d</i>	Two matrix-vector products using a general matrix, real data
?gem2vc	<i>c, z</i>	Two matrix-vector products using a general matrix, complex data
?gemm3m	<i>c, z</i>	Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.
mkl_?imatcopy	<i>s, d, c, z</i>	Performs scaling and in-place transposition/copying of matrices.
mkl_?omatcopy	<i>s, d, c, z</i>	Performs scaling and out-of-place transposition/copying of matrices.
mkl_?omatcopy2	<i>s, d, c, z</i>	Performs two-strided scaling and out-of-place transposition/copying of matrices.
mkl_?omatadd	<i>s, d, c, z</i>	Performs scaling and sum of two matrices including their out-of-place transposition/copying.

?axpby

Scales two vectors, adds them to one another and stores result in the vector.

Syntax

FORTRAN 77:

```
call saxpby(n, a, x, incx, b, y, incy)
call daxpby(n, a, x, incx, b, y, incy)
call caxpby(n, a, x, incx, b, y, incy)
call zaxpby(n, a, x, incx, b, y, incy)
```

Fortran 95:

```
call axpby(x, y [,a] [,b])
```

C:

```
void cblas_saxpby (const MKL_INT n, const float a, const float *x, const MKL_INT incx,
const float b, float *y, const MKL_INT incy);

void cblas_daxpby (const MKL_INT n, const double a, const double *x, const MKL_INT incx,
const double b, double *y, const MKL_INT incy);

void cblas_caxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,
const void *b, void *y, const MKL_INT incy);

void cblas_zaxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,
const void *b, void *y, const MKL_INT incy);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?axpby routines perform a vector-vector operation defined as

$$y := a*x + b*y$$

where:

a and *b* are scalars

x and *y* are vectors each with *n* elements.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>a</i>	REAL for saxpby DOUBLE PRECISION for daxpby COMPLEX for caxpby DOUBLE COMPLEX for zaxpby Specifies the scalar <i>a</i> .
<i>x</i>	REAL for saxpby DOUBLE PRECISION for daxpby COMPLEX for caxpby DOUBLE COMPLEX for zaxpby Array, size at least $(1 + (n-1) * \text{abs}(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>b</i>	REAL for saxpby DOUBLE PRECISION for daxpby COMPLEX for caxpby DOUBLE COMPLEX for zaxpby

Specifies the scalar b .

y REAL for saxpby
 DOUBLE PRECISION for daxpby
 COMPLEX for caxpby
 DOUBLE COMPLEX for zaxpby
 Array, size at least $(1 + (n-1) * \text{abs}(incy))$.

$incy$ INTEGER. Specifies the increment for the elements of y .

Output Parameters

y Contains the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpby` interface are the following:

x	Holds the array of size n .
y	Holds the array of size n .
a	The default value is 1.
b	The default value is 1.

?gem2vu

Computes two matrix-vector products using a general matrix (real data)

Syntax

FORTRAN 77:

```
call sgem2vu(m, n, alpha, a, lda, x1, incx1, x2, incx2, beta, y1, incy1, y2, incy2)
call dgem2vu(m, n, alpha, a, lda, x1, incx1, x2, incx2, beta, y1, incy1, y2, incy2)
```

Fortran 95:

```
call gem2vu(a, x1, x2, y1, y2 [,alpha] [,beta] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90

Description

The ?gem2vu routines perform two matrix-vector operations defined as

$y1 := \alpha * A * x1 + \beta * y1$,

and

```
y2 := alpha*A'*x2 + beta*y2,
```

where:

alpha and *beta* are scalars,
x1, *x2*, *y1*, and *y2* are vectors,
A is an *m*-by-*n* matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sgem2vu DOUBLE PRECISION for dgem2vu Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for sgem2vu DOUBLE PRECISION for dgem2vu Array, size (<i>lda</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.
<i>x1</i>	REAL for sgem2vu DOUBLE PRECISION for dgem2vu Array, size at least $(1 + (n - 1) * \text{abs}(incx1))$. Before entry, the incremented array <i>x1</i> must contain the vector <i>x1</i> .
<i>incx1</i>	INTEGER. Specifies the increment for the elements of <i>x1</i> . The value of <i>incx1</i> must not be zero.
<i>x2</i>	REAL for sgem2vu DOUBLE PRECISION for dgem2vu Array, size at least $(1 + (m - 1) * \text{abs}(incx2))$. Before entry, the incremented array <i>x2</i> must contain the vector <i>x2</i> .
<i>incx2</i>	INTEGER. Specifies the increment for the elements of <i>x2</i> . The value of <i>incx2</i> must not be zero.
<i>beta</i>	REAL for sgem2vu DOUBLE PRECISION for dgem2vu Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>y1</i> and <i>y2</i> need not be set on input.
<i>y1</i>	REAL for sgem2vu

DOUBLE PRECISION for dgem2vu

Array, size at least $(1 + (m - 1) * \text{abs}(incy1))$. Before entry with non-zero *beta*, the incremented array *y1* must contain the vector *y1*.

incy1

INTEGER. Specifies the increment for the elements of *y1*.

The value of *incy1* must not be zero.

y

REAL for sgem2vu

DOUBLE PRECISION for dgem2vu

Array, size at least $(1 + (n - 1) * \text{abs}(incy2))$. Before entry with non-zero *beta*, the incremented array *y2* must contain the vector *y2*.

incy2

INTEGER. Specifies the increment for the elements of *y2*.

The value of *incy2* must not be zero.

Output Parameters

y1 Updated vector *y1*.

y2 Updated vector *y2*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gem2vu` interface are the following:

a Holds the matrix *A* of size (m, n) .

x1 Holds the vector with the number of elements *rx1* where $rx1 = n$.

x2 Holds the vector with the number of elements *rx2* where $rx2 = m$.

y1 Holds the vector with the number of elements *ry1* where $ry1 = m$.

y2 Holds the vector with the number of elements *ry2* where $ry2 = n$.

alpha The default value is 1.

beta The default value is 0.

?gem2vc

Computes two matrix-vector products using a general matrix (complex data)

Syntax

FORTRAN 77:

```
call cgem2vc(m, n, alpha, a, lda, x1, incx1, x2, incx2, beta, y1, incy1, y2, incy2)
call zgem2vc(m, n, alpha, a, lda, x1, incx1, x2, incx2, beta, y1, incy1, y2, incy2)
```

Fortran 95:

```
call gem2vc(a, x1, x2, y1, y2 [,alpha] [,beta] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90

Description

The ?gem2vc routines perform two matrix-vector operations defined as

$y1 := \alpha * A * x1 + \beta * y1,$

and

$y2 := \alpha * \text{conjg}(A') * x2 + \beta * y2,$

where:

α and β are scalars,

$x1, x2, y1$, and $y2$ are vectors,

A is an m -by- n matrix.

Input Parameters

m INTEGER. Specifies the number of rows of the matrix A . The value of m must be at least zero.

n INTEGER. Specifies the number of columns of the matrix A . The value of n must be at least zero.

α COMPLEX for cgem2vc
DOUBLE COMPLEX for zgem2vc

Specifies the scalar α .

a COMPLEX for cgem2vc
DOUBLE COMPLEX for zgem2vc

Array, size (lda, n). Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of $lدا$ must be at least $\max(1, m)$.

$x1$ COMPLEX for cgem2vc
DOUBLE COMPLEX for zgem2vc
Array, size at least $(1 + (n - 1) * \text{abs}(incx1))$. Before entry, the incremented array $x1$ must contain the vector $x1$.

$incx1$ INTEGER. Specifies the increment for the elements of $x1$.
The value of $incx1$ must not be zero.

$x2$ COMPLEX for cgem2vc
DOUBLE COMPLEX for zgem2vc

Array, size at least $(1 + (m-1) * \text{abs}(incx2))$. Before entry, the incremented array $x2$ must contain the vector $x2$.

incx2 INTEGER. Specifies the increment for the elements of $x2$.

The value of *incx2* must not be zero.

beta COMPLEX for `cgem2vc`

DOUBLE COMPLEX for `zgem2vc`

Specifies the scalar *beta*. When *beta* is set to zero, then $y1$ and $y2$ need not be set on input.

y1 COMPLEX for `cgem2vc`

DOUBLE COMPLEX for `zgem2vc`

Array, size at least $(1 + (m-1) * \text{abs}(incy1))$. Before entry with non-zero *beta*, the incremented array $y1$ must contain the vector $y1$.

incy1 INTEGER. Specifies the increment for the elements of $y1$.

The value of *incy1* must not be zero.

y2 COMPLEX for `cgem2vc`

DOUBLE COMPLEX for `zgem2vc`

Array, size at least $(1 + (n-1) * \text{abs}(incy2))$. Before entry with non-zero *beta*, the incremented array $y2$ must contain the vector $y2$.

incy2 INTEGER. Specifies the increment for the elements of $y2$.

The value of *incy* must not be zero.

INTEGER. Specifies the increment for the elements of y .

Output Parameters

y1 Updated vector $y1$.

y2 Updated vector $y2$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gem2vc` interface are the following:

a Holds the matrix A of size (m, n) .

x1 Holds the vector with the number of elements $rx1$ where $rx1 = n$.

x2 Holds the vector with the number of elements $rx2$ where $rx2 = m$.

y1 Holds the vector with the number of elements $ry1$ where $ry1 = m$.

y2 Holds the vector with the number of elements $ry2$ where $ry2 = n$.

<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?gemm3m

Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call cgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call gemm3m(a, b, c [,transa] [,transb] [,alpha] [,beta])
```

C:

```
void cblas_cgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);

void cblas_zgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: blas.f90
- C: mkl.h

Description

The ?gemm3m routines perform a matrix-matrix operation with general complex matrices. These routines are similar to the ?gemm routines, but they use matrix multiplications(see *Application Notes* below).

The operation is defined as

$$C := \alpha \operatorname{op}(A) \operatorname{op}(B) + \beta C,$$

where:

$\operatorname{op}(x)$ is one of $\operatorname{op}(x) = x$, or $\operatorname{op}(x) = x'$, or $\operatorname{op}(x) = \operatorname{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\operatorname{op}(A)$ is an m -by- k matrix,

$\operatorname{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

Input Parameters

<i>Layout</i>	Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>).
<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: <code>if transa = 'N' or 'n', then op(A) = A;</code> <code>if transa = 'T' or 't', then op(A) = A';</code> <code>if transa = 'C' or 'c', then op(A) = conjg(A').</code>
<i>transb</i>	CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication: <code>if transb = 'N' or 'n', then op(B) = B;</code> <code>if transb = 'T' or 't', then op(B) = B';</code> <code>if transb = 'C' or 'c', then op(B) = conjg(B').</code>
<i>m</i>	INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.
<i>alpha</i>	COMPLEX for <code>cgemm3m</code> DOUBLE COMPLEX for <code>zgemm3m</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for <code>cgemm3m</code> DOUBLE COMPLEX for <code>zgemm3m</code> Array, size (lda, ka) , where ka is <i>k</i> when $\text{transa} = 'N'$ or ' <i>n</i> ', and is <i>m</i> otherwise. Before entry with $\text{transa} = 'N'$ or ' <i>n</i> ', the leading <i>m</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When $\text{transa} = 'N'$ or ' <i>n</i> ', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>b</i>	COMPLEX for <code>cgemm3m</code> DOUBLE COMPLEX for <code>zgemm3m</code>

Array, size ldb by kb , where kb is n when $transb = 'N'$ or ' n ', and is k otherwise. Before entry with $transb = 'N'$ or ' n ', the leading k -by- n part of the array b must contain the matrix B , otherwise the leading n -by- k part of the array b must contain the matrix B .

ldb INTEGER. Specifies the leading dimension of b as declared in the calling (sub)program. When $transb = 'N'$ or ' n ', then ldb must be at least $\max(1, k)$, otherwise ldb must be at least $\max(1, n)$.

$beta$ COMPLEX for $cgemm3m$
DOUBLE COMPLEX for $zgemm3m$

Specifies the scalar $beta$.

When $beta$ is equal to zero, then c need not be set on input.

c COMPLEX for $cgemm3m$
DOUBLE COMPLEX for $zgemm3m$
Array, size ldc by n .

Before entry, the leading m -by- n part of the array c must contain the matrix C , except when $beta$ is equal to zero, in which case c need not be set on entry.

ldc INTEGER. Specifies the leading dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, m)$.

Output Parameters

c Overwritten by the m -by- n matrix $(alpha * op(A) * op(B) + beta * C)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine $gemm3m$ interface are the following:

a Holds the matrix A of size (ma, ka) where
 $ka = k$ if $transa = 'N'$,
 $ka = m$ otherwise,
 $ma = m$ if $transa = 'N'$,
 $ma = k$ otherwise.

b Holds the matrix B of size (mb, kb) where
 $kb = n$ if $transb = 'N'$,
 $kb = k$ otherwise,
 $mb = k$ if $transb = 'N'$,
 $mb = n$ otherwise.

c Holds the matrix C of size (m, n) .

<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>transb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

Application Notes

These routines perform the complex multiplication by forming the real and imaginary parts of the input matrices. It allows to use three real matrix multiplications and five real matrix additions, instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications only gives a 25% reduction of time in matrix operations. This can result in significant savings in computing time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

$$f1(x \text{ op } y) = (x \text{ op } y)(1+\delta), |\delta| \leq u, \text{ op}=\times, /, f1(x \pm y) = x(1+\alpha) \pm y(1+\beta), |\alpha|, |\beta| \leq u$$

then for n -by- n matrix $\hat{C} = f1(C_1 + iC_2) = f1((A_1 + iA_2)(B_1 + iB_2)) = \hat{C}_1 + i\hat{C}_2$ the following estimations are correct

$$\|\hat{C}_1 - C_1\| \leq 2(n+1)u\|A\|_\infty\|B\|_\infty + O(u^2),$$

$$\|\hat{C}_2 - C_2\| \leq 4(n+4)u\|A\|_\infty\|B\|_\infty + O(u^2),$$

where $\|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty)$, and $\|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty)$.

and hence the matrix multiplications are stable.

mkl_?imatcopy

Performs scaling and in-place transposition/copying of matrices.

Syntax

Fortran:

```
call mkl_simatcopy(ordering, trans, rows, cols, alpha, ab, lda, ldb)
call mkl_dimatcopy(ordering, trans, rows, cols, alpha, ab, lda, ldb)
call mkl_cimatcopy(ordering, trans, rows, cols, alpha, ab, lda, ldb)
call mkl_zimatcopy(ordering, trans, rows, cols, alpha, ab, lda, ldb)
```

C:

```
void mkl_simatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const float alpha, float * AB, size_t lda, size_t ldb);

void mkl_dimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const double alpha, double * AB, size_t lda, size_t ldb);

void mkl_cimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const MKL_Complex8 alpha, MKL_Complex8 * AB, size_t lda, size_t ldb);

void mkl_zimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const MKL_Complex16 alpha, MKL_Complex16 * AB, size_t lda, size_t ldb);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?imatcopy` routine performs scaling and in-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$AB := \alpha * op(AB)$.

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

NOTE

Different arrays must not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $op(AB) = AB$ and the matrix AB is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that AB should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that AB should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that AB should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of rows in matrix AB before the transpose operation.
<i>cols</i>	INTEGER. The number of columns in matrix AB before the transpose operation.
<i>ab</i>	REAL for <code>mkl_simatcopy</code> . DOUBLE PRECISION for <code>mkl_dimatcopy</code> . COMPLEX for <code>mkl_cimatcopy</code> . DOUBLE COMPLEX for <code>mkl_zimatcopy</code> . Array, size $ab(lda, *)$.
<i>alpha</i>	REAL for <code>mkl_simatcopy</code> . DOUBLE PRECISION for <code>mkl_dimatcopy</code> .

COMPLEX for `mkl_cimatcopy`.

DOUBLE COMPLEX for `mkl_zimatcopy`.

This parameter scales the input matrix by *alpha*.

lda

INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.

This parameter must be at least *rows* if *ordering* = 'C' or 'c', and $\max(1, \text{cols})$ otherwise.

ldb

INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.

To determine the minimum value of *ldb* on output, consider the following guideline:

If *ordering* = 'C' or 'c', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{cols})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{rows})$

If *ordering* = 'R' or 'r', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{rows})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{cols})$

Output Parameters

ab

REAL for `mkl_simatcopy`.

DOUBLE PRECISION for `mkl_dimatcopy`.

COMPLEX for `mkl_cimatcopy`.

DOUBLE COMPLEX for `mkl_zimatcopy`.

Array, size *ab*(*ldb*, *).

Contains the matrix *AB*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_simatcopy ( ordering, trans, rows, cols, alpha, ab, lda, ldb )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld

```

```
SUBROUTINE mkl_zimatcopy ( ordering, trans, rows, cols, alpha, ab, lda, ldb )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld
  DOUBLE COMPLEX ab(*), alpha*
```

mkl_?omatcopy

Performs scaling and out-place transposition/copying of matrices.

Syntax

Fortran:

```
call mkl_somatcopy(ordering, trans, rows, cols, alpha, a, lda, b, ldb)
call mkl_domatcopy(ordering, trans, rows, cols, alpha, a, lda, b, ldb)
call mkl_comatcopy(ordering, trans, rows, cols, alpha, a, lda, b, ldb)
call mkl_zomatcopy(ordering, trans, rows, cols, alpha, a, lda, b, ldb)
```

C:

```
void mkl_somatcopy (char ordering, char trans, size_t rows, size_t cols, const float
alpha, const float * A, size_t lda, float * B, size_t ldb);
void mkl_domatcopy (char ordering, char trans, size_t rows, size_t cols, const double
alpha, const double * A, size_t lda, double * B, size_t ldb);
void mkl_comatcopy (char ordering, char trans, size_t rows, size_t cols, const
MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, MKL_Complex8 * B, size_t ldb);
void mkl_zomatcopy (char ordering, char trans, size_t rows, size_t cols, const
MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, MKL_Complex16 * B, size_t
ldb);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?omatcopy` routine performs scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$B := \alpha * \text{op}(A)$$

The routine parameter descriptions are common for all implemented interfaces with the exception of data types that mostly refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

NOTE

Different arrays must not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $\text{op}(A)=A$ and the matrix A is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that A should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that A should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that A should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of rows in the source matrix.
<i>cols</i>	INTEGER. The number of columns in the source matrix.
<i>alpha</i>	REAL for mkl_somatcopy. DOUBLE PRECISION for mkl_domatcopy. COMPLEX for mkl_comatcopy. DOUBLE COMPLEX for mkl_zomatcopy. This parameter scales the input matrix by <i>alpha</i> .
<i>a</i>	REAL for mkl_somatcopy. DOUBLE PRECISION for mkl_domatcopy. COMPLEX for mkl_comatcopy. DOUBLE COMPLEX for mkl_zomatcopy. Array, size <i>a</i> (<i>lda</i> , *).
<i>lda</i>	INTEGER. (Fortran interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements. This parameter must be at least $\max(1, \text{rows})$ if <i>ordering</i> = 'C' or 'c', and $\max(1, \text{cols})$ otherwise.
<i>b</i>	REAL for mkl_somatcopy. DOUBLE PRECISION for mkl_domatcopy. COMPLEX for mkl_comatcopy. DOUBLE COMPLEX for mkl_zomatcopy. Array, size <i>b</i> (<i>ldb</i> , *).

ldb

INTEGER. (Fortran interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.

To determine the minimum value of *ldb* on output, consider the following guideline:

If *ordering* = 'C' or 'c', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{cols})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{rows})$

If *ordering* = 'R' or 'r', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{rows})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{cols})$

Output Parameters

b

REAL for mkl_somatcopy.

DOUBLE PRECISION for mkl_damatcopy.

COMPLEX for mkl_comatcopy.

DOUBLE COMPLEX for mkl_zomatcopy.

Array, size at least *m*.

Contains the destination matrix.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_somatcopy ( ordering, trans, rows, cols, alpha, a, lda, b, ldb )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, lda, ldb

  DOUBLE COMPLEX alpha, b(ldb,*), a(lda,*)
```

mkl_?omatcopy2

Performs two-strided scaling and out-of-place transposition/copying of matrices.

Syntax

Fortran:

```
call mkl_somatcopy2(ordering, trans, rows, cols, alpha, a, lda, stridea, b, ldb,
strideb)

call mkl_domatcopy2(ordering, trans, rows, cols, alpha, a, lda, stridea, b, ldb,
strideb)

call mkl_comatcopy2(ordering, trans, rows, cols, alpha, a, lda, stridea, b, ldb,
strideb)

call mkl_zomatcopy2(ordering, trans, rows, cols, alpha, a, lda, stridea, b, ldb,
strideb)
```

C:

```
void mkl_somatcopy2 (char ordering, char trans, size_t rows, size_t cols, const float
alpha, const float * A, size_t lda, size_t stridea, float * B, size_t ldb, size_t
strideb);

void mkl_domatcopy2 (char ordering, char trans, size_t rows, size_t cols, const double
alpha, const double * A, size_t lda, size_t stridea, double * B, size_t ldb, size_t
strideb);

void mkl_comatcopy2 (char ordering, char trans, size_t rows, size_t cols, const
MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, size_t stridea, MKL_Complex8 *
B, size_t ldb, size_t strideb);

void mkl_zomatcopy2 (char ordering, char trans, size_t rows, size_t cols, const
MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, size_t stridea, MKL_Complex16
* B, size_t ldb, size_t strideb);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?omatcopy2` routine performs two-strided scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$B := \text{alpha}^*\text{op}(A)$$

Normally, matrices in the BLAS or LAPACK are specified by a single stride index. For instance, in the column-major order, $A(2,1)$ is stored in memory one element away from $A(1,1)$, but $A(1,2)$ is a leading dimension away. The leading dimension in this case is the single stride. If a matrix has two strides, then both $A(2,1)$ and $A(1,2)$ may be an arbitrary distance from $A(1,1)$.

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

NOTE

Different arrays must not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $\text{op}(A) = A$ and the matrix A is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that A should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that A should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that A should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of matrix rows.
<i>cols</i>	INTEGER. The number of matrix columns.
<i>alpha</i>	REAL for mkl_somatcopy2. DOUBLE PRECISION for mkl_domatcopy2. COMPLEX for mkl_comatcopy2. DOUBLE COMPLEX for mkl_zomatcopy2. This parameter scales the input matrix by <i>alpha</i> .
<i>a</i>	REAL for mkl_somatcopy2. DOUBLE PRECISION for mkl_domatcopy2. COMPLEX for mkl_comatcopy2. DOUBLE COMPLEX for mkl_zomatcopy2. Array, size <i>a</i> (*).
<i>lda</i>	INTEGER. Distance between the first elements in adjacent rows in the source matrix; measured in the number of elements. This parameter must be at least $\max(1, \text{rows})$ if <i>ordering</i> = 'C' or 'c', and $\max(1, \text{cols})$ otherwise.
<i>stridea</i>	INTEGER. Distance between the first elements in adjacent columns (for row-major layout) or between the first elements in adjacent rows (for column-major layout) in the source matrix; measured in the number of elements. This parameter must be at least $\max(1, \text{cols})$.

b

REAL for mkl_somatcopy2.
 DOUBLE PRECISION for mkl_domatcopy2.
 COMPLEX for mkl_comatcopy2.
 DOUBLE COMPLEX for mkl_zomatcopy2.
 Array, size *b*(*).

ldb
 INTEGER. Distance between the first elements in adjacent rows in the destination matrix; measured in the number of elements.

To determine the minimum value of *ldb* on output, consider the following guideline:

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{rows})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{cols})$

strideb
 INTEGER. Distance between the first elements in adjacent columns in the destination matrix; measured in the number of elements.

To determine the minimum value of *strideb* on output, consider the following guideline:

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{cols})$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{rows})$

Output Parameters

b

REAL for mkl_somatcopy2.
 DOUBLE PRECISION for mkl_domatcopy2.
 COMPLEX for mkl_comatcopy2.
 DOUBLE COMPLEX for mkl_zomatcopy2.
 Array, size at least *m*.

Contains the destination matrix.

[mkl_?omatadd](#)

Performs scaling and sum of two matrices including their out-of-place transposition/copying.

Syntax

Fortran:

```
call mkl_somatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b, ldb, c, ldc)
call mkl_domatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b, ldb, c, ldc)
call mkl_comatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b, ldb, c, ldc)
call mkl_zomatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b, ldb, c, ldc)
```

C:

```
void mkl_somatadd (char ordering, char transa, char transb, size_t m, size_t n, const
float alpha, const float * A, size_t lda, const float beta, const float * B, size_t
ldb, float * C, size_t ldc);

void mkl_domatadd (char ordering, char transa, char transb, size_t m, size_t n, const
double alpha, const double * A, size_t lda, const double beta, const double * B,
size_t ldb, double * C, size_t ldc);

void mkl_comatadd (char ordering, char transa, char transb, size_t m, size_t n, const
MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, const MKL_Complex8 beta, const
MKL_Complex8 * B, size_t ldb, MKL_Complex8 * C, size_t ldc);

void mkl_zomatadd (char ordering, char transa, char transb, size_t m, size_t n, const
MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, const MKL_Complex16 beta,
const MKL_Complex16 * B, size_t ldb, MKL_Complex16 * C, size_t ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `mkl_?omatadd` routine scaling and sum of two matrices including their out-of-place transposition/copying. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The following out-of-place memory movement is done:

$$C := \alpha \cdot op(A) + \beta \cdot op(B)$$

`op(A)` is either transpose, conjugate-transpose, or leave alone depending on `transa`. If no transposition of the source matrices is required, `m` is the number of rows and `n` is the number of columns in the source matrices `A` and `B`. In this case, the output matrix `C` is `m`-by-`n`.

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

NOTE

Note that different arrays must not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>transa</i>	CHARACTER*1. Parameter that specifies the operation type on matrix A. If <i>transa</i> = 'N' or 'n', $\text{op}(A)=A$ and the matrix A is assumed unchanged on input. If <i>transa</i> = 'T' or 't', it is assumed that A should be transposed. If <i>transa</i> = 'C' or 'c', it is assumed that A should be conjugate transposed. If <i>transa</i> = 'R' or 'r', it is assumed that A should be only conjugated. If the data is real, then <i>transa</i> = 'R' is the same as <i>transa</i> = 'N', and <i>transa</i> = 'C' is the same as <i>transa</i> = 'T'.
<i>transb</i>	CHARACTER*1. Parameter that specifies the operation type on matrix B. If <i>transb</i> = 'N' or 'n', $\text{op}(B)=B$ and the matrix B is assumed unchanged on input. If <i>transb</i> = 'T' or 't', it is assumed that B should be transposed. If <i>transb</i> = 'C' or 'c', it is assumed that B should be conjugate transposed. If <i>transb</i> = 'R' or 'r', it is assumed that B should be only conjugated. If the data is real, then <i>transb</i> = 'R' is the same as <i>transb</i> = 'N', and <i>transb</i> = 'C' is the same as <i>transb</i> = 'T'.
<i>m</i>	INTEGER. The number of matrix rows.
<i>n</i>	INTEGER. The number of matrix columns.
<i>alpha</i>	REAL for mkl_somatadd. DOUBLE PRECISION for mkl_domatadd. COMPLEX for mkl_comatadd. DOUBLE COMPLEX for mkl_zomatadd. This parameter scales the input matrix by <i>alpha</i> .
<i>a</i>	REAL for mkl_somatadd. DOUBLE PRECISION for mkl_domatadd.

COMPLEX **for** mkl_comatadd.

DOUBLE COMPLEX **for** mkl_zomatadd.

Array, size $a(1da, *)$.

lda INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix A ; measured in the number of elements.

This parameter must be at least $\max(1, \text{rows})$ if $\text{ordering} = 'C'$ or ' c ', and $\max(1, \text{cols})$ otherwise.

beta REAL **for** mkl_somatadd.

DOUBLE PRECISION **for** mkl_domatadd.

COMPLEX **for** mkl_comatadd.

DOUBLE COMPLEX **for** mkl_zomatadd.

This parameter scales the input matrix by *beta*.

b REAL **for** mkl_somatadd.

DOUBLE PRECISION **for** mkl_domatadd.

COMPLEX **for** mkl_comatadd.

DOUBLE COMPLEX **for** mkl_zomatadd.

Array, size $b(1db, *)$.

ldb INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix B ; measured in the number of elements.

This parameter must be at least $\max(1, \text{rows})$ if $\text{ordering} = 'C'$ or ' c ', and $\max(1, \text{cols})$ otherwise.

Output Parameters

c REAL **for** mkl_somatadd.

DOUBLE PRECISION **for** mkl_domatadd.

COMPLEX **for** mkl_comatadd.

DOUBLE COMPLEX **for** mkl_zomatadd.

Array, size $c(1dc, *)$.

ldc INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix C ; measured in the number of elements.

To determine the minimum value of *ldc*, consider the following guideline:

If $\text{ordering} = 'C'$ or ' c ', then

- If transa or $\text{transb} = 'T'$ or ' t ' or ' C ' or ' c ', this parameter must be at least $\max(1, \text{cols})$
- If transa or $\text{transb} = 'N'$ or ' n ' or ' R ' or ' r ', this parameter must be at least $\max(1, \text{rows})$

If *ordering* = 'R' or 'r', then

- If *transa* or *transb* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{rows})$
- If *transa* or *transb* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{cols})$

LAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving systems of linear equations, linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. The library includes LAPACK routines for both real and complex data. Routines are supported for systems of equations with the following types of matrices:

- general
- banded
- symmetric or Hermitian positive-definite (full, packed, and rectangular full packed (RFP) storage)
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian indefinite (both full and packed storage)
- symmetric or Hermitian indefinite banded
- triangular (full, packed, and RFP storage)
- triangular banded
- tridiagonal
- diagonally dominant tridiagonal.

NOTE

Different arrays used as parameters to Intel MKL LAPACK routines must not overlap.

WARNING

LAPACK routines assume that input matrices do not contain IEEE 754 special values such as `INF` or `NaN` values. Using these special values may cause LAPACK to return unexpected results or become unstable.

Intel MKL supports the Fortran 95 interface, which uses simplified routine calls with shorter argument lists, in addition to the FORTRAN 77 interface to LAPACK computational and driver routines. The syntax section of the routine description gives the calling sequence for the Fortran 95 interface, where available, immediately after the FORTRAN 77 calls.

Routine Naming Conventions

To call one of the routines from a FORTRAN 77 program, you can use the LAPACK name.

LAPACK names have the structure `?yyzzz` or `?yyzz`, where the initial symbol `?` indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

Some routines can have combined character codes, such as `ds` or `zc`.

The Fortran 95 interfaces to the LAPACK computational and driver routines are the same as the FORTRAN 77 names but without the first letter that indicates the data type. For example, the name of the routine that performs a triangular factorization of general real matrices in Fortran 95 is `getrf`. Different data types are handled through the definition of a specific internal parameter that refers to a module block with named constants for single and double precision.

C Interface Conventions

The C interfaces are implemented for most of the Intel MKL LAPACK driver and computational routines.

The arguments of the C interfaces for the Intel MKL LAPACK functions comply with the following rules:

- Scalar input arguments are passed by value.
- Array arguments are passed by reference.
- Array input arguments are declared with the `const` modifier.
- Function arguments are passed by pointer.
- An integer return value replaces the `info` output parameter. The return value equal to 0 means the function operation is completed successfully. See also [special error codes](#) below.

Function Prototypes

Some Intel MKL functions differ in data types they support and vary in the parameters they take.

Each function type has a unique prototype defined. Use this prototype when you call the function from your application program. In most cases, Intel MKL supports four distinct floating-point precisions. Each corresponding prototype looks similar, usually differing only in the data type. To avoid listing all the prototypes in every supported precision, a generic prototype template is provided.

`<?>` denotes precision and is `s`, `d`, `c`, or `z`:

- `s` for real, single precision
- `d` for real, double precision
- `c` for complex, single precision
- `z` for complex, double precision

`<datatype>` stands for a respective data type: `float`, `double`, `lapack_complex_float`, or `lapack_complex_double`.

For example, the C prototype template for the `?pptrs` function that solves a system of linear equations with a packed Cholesky-factored symmetric (Hermitian) positive-definite matrix looks as follows:

```
lapack_int LAPACKE_<?>pptrs(int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
                           const <datatype>* ap, <datatype>* b, lapack_int ldb);
```

To obtain the function name and parameter list that corresponds to a specific precision, replace the `<?>` symbol with `s`, `d`, `c`, or `z` and the `<datatype>` field with the corresponding data type (`float`, `double`, `lapack_complex_float`, or `lapack_complex_double` respectively).

A specific example follows. To solve a system of linear equations with a packed Cholesky-factored Hermitian positive-definite matrix with complex precision, use the following:

```
lapack_int LAPACKE_cpptrs(int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
                           const lapack_complex_float* ap, lapack_complex_float* b, lapack_int ldb);
```

NOTE

For the `select` parameter, the respective values of the `<datatype>` field for `s`, `d`, `c`, or `z` are as follows: `LAPACK_S_SELECT3`, `LAPACK_D_SELECT3`, `LAPACK_C_SELECT2`, and `LAPACK_Z_SELECT2`.

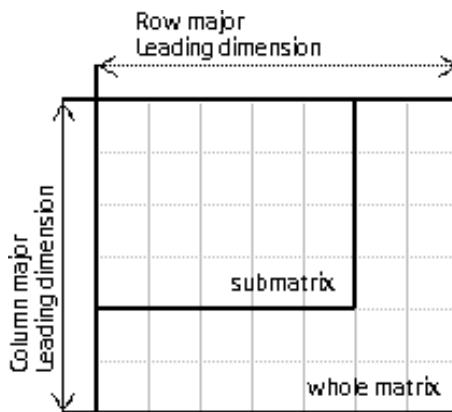

Matrix Layout

Most of the LAPACK C interfaces have an additional parameter `matrix_layout` of type `int` as their first argument. This parameter specifies whether the two-dimensional arrays are row-major (`LAPACK_ROW_MAJOR`) or column-major (`LAPACK_COL_MAJOR`).

In general the leading dimension `lда` is equal to the number of elements in the major dimension. It is also equal to the distance in elements between two neighboring elements in a line in the minor dimension. If there are no extra elements in a matrix with m rows and n columns, then

- For row-major ordering: the number of elements in a row is n , and row i is stored in memory right after row $i-1$. Therefore `lда` is n .
- For column-major ordering: the number of elements in a column is m , and column i is stored in memory right after column $i-1$. Therefore `lда` is m .

To refer to a submatrix with dimensions k by l , use the number of elements in the major dimension of the whole matrix (as above) as the leading dimension and k and l in the subroutine's input parameters to describe the size of the submatrix.

Workspace Arrays

In general, the LAPACK C interface omits workspace parameters because workspace is allocated during runtime and released upon completion of the function operation.

For some functions, `work` arrays contain valuable information on exit. In such cases, the interface contains an additional argument or arguments, namely:

- `?gesvx` and `?gbsvx` contain `rpivot`
- `?gesvd` contains `superb`
- `?gejsv` and `?gesvj` contain `istat` and `stat`, respectively.

If you prefer to allocate workspace functions yourself, the LAPACK C interface provides alternate interfaces with `work` parameters. The name of the alternate interface is the same as the LAPACK C interface with `_work` appended. For example, the syntax for the singular value decomposition of a real bidiagonal matrix is:

FORTRAN 77: `call sbdsdc (uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)`

C LAPACK interface: `lapack_int LAPACKE_sbdsdc (int matrix_layout, char uplo, char compq, lapack_int n, float* d, float* e, float* u, lapack_int ldu, float* vt, lapack_int ldvt, float* q, lapack_int* iq);`

Alternate C LAPACK interface with *work* parameters:

```
lapack_int LAPACKE_sbdsdc_work( int matrix_layout, char uplo,
                                char compq, lapack_int n, float* d, float* e, float* u,
                                lapack_int ldu, float* vt, lapack_int ldvt, float* q, lapack_int* iq,
                                float* work, lapack_int* iwork );
```

Function Types

The function types are used in non-symmetric eigenproblem functions only.

```
typedef lapack_logical (*LAPACK_S_SELECT2) (const float*, const float*);
typedef lapack_logical (*LAPACK_S_SELECT3) (const float*, const float*, const float*);
typedef lapack_logical (*LAPACK_D_SELECT2) (const double*, const double*);
typedef lapack_logical (*LAPACK_D_SELECT3) (const double*, const double*, const double*);

typedef lapack_logical (*LAPACK_C_SELECT1) (const lapack_complex_float*);
typedef lapack_logical (*LAPACK_C_SELECT2) (const lapack_complex_float*, const lapack_complex_float*);
typedef lapack_logical (*LAPACK_Z_SELECT1) (const lapack_complex_double*);
typedef lapack_logical (*LAPACK_Z_SELECT2) (const lapack_complex_double*, const lapack_complex_double*);
```

Mapping FORTRAN Data Types against C Data Types

FORTRAN Data Types vs. C Data Types

FORTRAN	C
INTEGER	lapack_int
LOGICAL	lapack_logical
REAL	float
DOUBLE PRECISION	double
COMPLEX	lapack_complex_float
COMPLEX*16/DOUBLE COMPLEX	lapack_complex_double
CHARACTER	char

C Type Definitions

```
#ifndef lapack_int
#define lapack_int MKL_INT
#endif

#ifndef lapack_logical
#define lapack_logical lapack_int
#endif
```

Complex Type Definitions

Complex type for single precision:

```
#ifndef lapack_complex_float
#define lapack_complex_float MKL_Complex8
#endif
```

Complex type for double precision:

```
#ifndef lapack_complex_double
#define lapack_complex_double MKL_Complex16
#endif
```

Matrix Order Definitions

```
#define LAPACK_ROW_MAJOR 101
#define LAPACK_COL_MAJOR 102
```

See [Matrix Order](#) for an explanation of row-major order and column-major order storage.

Error Code Definitions

```
#define LAPACK_WORK_MEMORY_ERROR -1010 /* Failed to allocate memory
                                         for a working array */
#define LAPACK_TRANSPOSE_MEMORY_ERROR -1011 /* Failed to allocate memory
                                         for transposed matrix */
```

If the return value is `-i`, the `-i`-th parameter has an invalid value.

Fortran 95 Interface Conventions

Intel® MKL implements the Fortran 95 interface to LAPACK through wrappers that call respective FORTRAN 77 routines. This interface uses such Fortran 95 features as assumed-shape arrays and optional arguments to provide simplified calls to LAPACK routines with fewer arguments.

NOTE

For LAPACK, Intel MKL offers two types of the Fortran 95 interfaces:

- using `mkl_lapack.fi` only through the `include 'mkl_lapack.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
- using `lapack.f90` that includes improved interfaces. This file is used to generate the module files `lapack95.mod` and `f95_precision.mod`. See also the section "Fortran 95 interfaces and wrappers to LAPACK and BLAS" of the *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the LAPACK interface: `use lapack95` and `use f95_precision`.

The main conventions for the Fortran 95 interface are as follows:

- The names of arguments used in Fortran 95 call are typically the same as for the respective generic (FORTRAN 77) interface. In rare cases, formal argument names may be different. For instance, `select` instead of `selctg`.
- Input arguments such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.

Another type of generic arguments that are skipped in the Fortran 95 interface are arguments that represent workspace arrays (such as `work`, `rwork`, and so on). The only exception are cases when workspace arrays return significant information on output.

An argument can also be skipped if its value is completely defined by the presence or absence of another argument in the calling sequence, and the restored value is the only meaningful value for the skipped argument.

- Some generic arguments are declared as optional in the Fortran 95 interface and may or may not be present in the calling sequence. An argument can be declared optional if it meets one of the following conditions:
 - If an argument value is completely defined by the presence or absence of another argument in the calling sequence, it can be declared optional. The difference from the skipped argument in this case is that the optional argument can have some meaningful values that are distinct from the value reconstructed by default. For example, if some argument (like `jobz`) can take only two values and one of these values directly implies the use of another argument, then the value of `jobz` can be uniquely reconstructed from the actual presence or absence of this second argument, and `jobz` can be omitted.

- If an input argument can take only a few possible values, it can be declared as optional. The default value of such argument is typically set as the first value in the list and all exceptions to this rule are explicitly stated in the routine description.
- If an input argument has a natural default value, it can be declared as optional. The default value of such optional argument is set to its natural default value.
- Argument *info* is declared as optional in the Fortran 95 interface. If it is present in the calling sequence, the value assigned to *info* is interpreted as follows:
 - If this value is more than -1000, its meaning is the same as in the FORTRAN 77 routine.
 - If this value is equal to -1000, it means that there is not enough work memory.
 - If this value is equal to -1001, incompatible arguments are present in the calling sequence.
 - If this value is equal to *i*, the *i*th parameter (counting parameters in the FORTRAN 77 interface, not the Fortran 95 interface) had an illegal value.
- Optional arguments are given in square brackets in the Fortran 95 call syntax.

The "Fortran 95 Notes" subsection at the end of the topic describing each routine details concrete rules for reconstructing the values of the omitted optional parameters.

Intel® MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation

The following list presents general digressions of the Intel MKL LAPACK95 implementation from the Netlib analog:

- The Intel MKL Fortran 95 interfaces are provided for pure procedures.
- Names of interfaces do not contain the `LA_` prefix.
- An optional array argument always has the `target` attribute.
- Functionality of the Intel MKL LAPACK95 wrapper is close to the FORTRAN 77 original implementation in the `getrf`, `gbtrf`, and `potrf` interfaces.
- If `jobz` argument value specifies presence or absence of `z` argument, then `z` is always declared as optional and `jobz` is restored depending on whether `z` is present or not. It is not always so in the Netlib version (see "[Modified Netlib Interfaces](#)" in Appendix E).
- To avoid double error checking, processing of the *info* argument is limited to checking of the allocated memory and disarranging of optional arguments.
- If an argument that is present in the list of arguments completely defines another argument, the latter is always declared as optional.

You can transform an application that uses the Netlib LAPACK interfaces to ensure its work with the Intel MKL interfaces providing that:

- a. The application is correct, that is, unambiguous, compiler-independent, and contains no errors.
- b. Each routine name denotes only one specific routine. If any routine name in the application coincides with a name of the original Netlib routine (for example, after removing the `LA_` prefix) but denotes a routine different from the Netlib original routine, this name should be modified through context name replacement.

You should transform your application in the following cases (see Appendix E for specific differences of individual interfaces):

- When using the Netlib routines that differ from the Intel MKL routines only by the `LA_` prefix or in the array attribute `target`. The only transformation required in this case is context name replacement. See "[Interfaces Identical to Netlib](#)" in Appendix E for details.
- When using Netlib routines that differ from the Intel MKL routines by the `LA_` prefix, the `target` array attribute, and the names of formal arguments. In the case of positional passing of arguments, no additional transformation except context name replacement is required. In the case of the keywords passing of arguments, in addition to the context name replacement the names of mismatching keywords should also be modified. See "[Interfaces with Replaced Argument Names](#)" in Appendix E for details.
- When using the Netlib routines that differ from the respective Intel MKL routines by the `LA_` prefix, the `target` array attribute, sequence of the arguments, arguments missing in Intel MKL but present in Netlib and, vice versa, present in Intel MKL but missing in Netlib. Remove the differences in the sequence and range of the arguments in process of all the transformations when you use the Netlib routines specified by this bullet and the preceding bullet. See "[Modified Netlib Interfaces](#)" in Appendix E for details.

- When using the `getrf`, `gbtrf`, and `potrf` interfaces, that is, new functionality implemented in Intel MKL but unavailable in the Netlib source. To override the differences, build the desired functionality explicitly with the Intel MKL means or create a new subroutine with the new functionality, using specific MKL interfaces corresponding to LAPACK 77 routines. You can call the LAPACK 77 routines directly but using the new Intel MKL interfaces is preferable. See "[Interfaces Absent From Netlib](#)" and "[Interfaces of New Functionality](#)" in Appendix E for details. Note that if the transformed application calls `getrf`, `gbtrf` or `potrf` without controlling arguments `rcond` and `norm`, just context name replacement is enough in modifying the calls into the Intel MKL interfaces, as described in the first bullet above. The Netlib functionality is preserved in such cases.
- When using the Netlib auxiliary routines. In this case, call a corresponding subroutine directly, using the Intel MKL LAPACK 77 interfaces.

Transform your application as follows:

1. Make sure conditions a. and b. are met.
2. Select Netlib LAPACK 95 calls. For each call, do the following:
 - Select the type of digression and do the required transformations.
 - Revise results to eliminate unneeded code or data, which may appear after several identical calls.
3. Make sure the transformations are correct and complete.

Matrix Storage Schemes

LAPACK routines use the following matrix storage schemes:

- Full storage:** an m -by- n matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} ($i = 1..m$ $j = 1..n$), and stored in the array element $a(i, j)$.
- Packed storage** scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- Band storage:** an m -by- n band matrix with k_l sub-diagonals and k_u superdiagonals is stored compactly in a two-dimensional array ab with k_l+k_u+1 rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.
- Rectangular Full Packed (RFP) storage:** the upper or lower triangle of the matrix is packed combining the full and packed storage schemes. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.

Generally in LAPACK routines, arrays that hold matrices in packed storage have names ending in *p*; arrays with matrices in band storage have names ending in *b*; arrays with matrices in the RFP storage have names ending in *fp*.

For more information on matrix storage schemes, see "[Matrix Arguments](#)" in Appendix B.

Mathematical Notation

Descriptions of LAPACK routines use the following notation:

$Ax = b$	A system of linear equations with an n -by- n matrix $A = \{a_{ij}\}$, a right-hand side vector $b = \{b_i\}$, and an unknown vector $x = \{x_i\}$.
$AX = B$	A set of systems with a common matrix A and multiple right-hand sides. The columns of B are individual right-hand sides, and the columns of X are the corresponding solutions.
$ x $	the vector with elements $ x_i $ (absolute values of x_i).
$ A $	the matrix with elements $ a_{ij} $ (absolute values of a_{ij}).
$\ x\ _\infty = \max_i x_i $	The <i>infinity-norm</i> of the vector x .

$\ A\ _\infty = \max_i \sum_j a_{ij} $	The <i>infinity-norm</i> of the matrix A .
$\ A\ _1 = \max_j \sum_i a_{ij} $	The <i>one-norm</i> of the matrix A . $\ A\ _1 = \ A^T\ _\infty = \ A^H\ _\infty$
$\ x\ _2$	The <i>2-norm</i> of the vector x : $\ x\ _2 = (\sum_i x_i ^2)^{1/2} = \ x\ _E$.
$\ A\ _2$	The <i>2-norm (or spectral norm)</i> of the matrix A .
$\ A\ _2 = \max_i \sigma_i$, $\ A\ _2^2 = \max_{\ x\ =1} (Ax \cdot Ax)$.	
$\ A\ _E$	The <i>Euclidean norm</i> of the matrix A : $\ A\ _E^2 = \sum_i \sum_j a_{ij} ^2$ (for vectors, the Euclidean norm and the 2-norm are equal: $\ x\ _E = \ x\ _2$).
$\kappa(A) = \ A\ _1 \ A^{-1}\ _1$	The <i>condition number</i> of the matrix A .
λ_i	<i>Eigenvalues</i> of the matrix A (for the definition of eigenvalues, see Eigenvalue Problems).
σ_i	<i>Singular values</i> of the matrix A . They are equal to square roots of the eigenvalues of $A^H A$. (For more information, see Singular Value Decomposition).
$q(x, y)$	The <i>acute angle between vectors</i> x and y :
	$\cos q(x, y) = x \cdot y / (\ x\ _2 \ y\ _2)$.

Error Analysis

In practice, most computations are performed with rounding errors. Besides, you often need to solve a system $Ax = b$, where the data (the elements of A and b) are not known exactly. Therefore, it is important to understand how the data errors and rounding errors can affect the solution x .

Data perturbations. If x is the exact solution of $Ax = b$, and $x + \delta x$ is the exact solution of a perturbed problem $(A + \delta A)x = (b + \delta b)$, then

where

$$\kappa(A) = \|A\| \|A^{-1}\|.$$

In other words, relative errors in A or b may be amplified in the solution vector x by a factor $\kappa(A) = \|A\| \|A^{-1}\|$ called the *condition number* of A .

Rounding errors have the same effect as relative perturbations $c(n)\varepsilon$ in the original data. Here ε is the *machine precision*, and $c(n)$ is a modest function of the matrix order n . The corresponding solution error is $\|\delta x\| / \|x\| \leq c(n)\kappa(A)\varepsilon$. (The value of $c(n)$ is seldom greater than $10n$.)

Thus, if your matrix A is *ill-conditioned* (that is, its condition number $\kappa(A)$ is very large), then the error in the solution x is also large; you may even encounter a complete loss of precision. LAPACK provides routines that allow you to estimate $\kappa(A)$ (see [Routines for Estimating the Condition Number](#)) and also give you a more precise estimate for the actual solution error (see [Refining the Solution and Estimating Its Error](#)).

Linear Equation Routines

This section describes routines for performing the following computations:

- factoring the matrix (except for triangular matrices)
- equilibrating the matrix (except for RFP matrices)
- solving a system of linear equations
- estimating the condition number of a matrix (except for RFP matrices)
- refining the solution of linear equations and computing its error bounds (except for RFP matrices)
- inverting the matrix.

To solve a particular problem, you can call two or more [computational routines](#) or call a corresponding [driver routine](#) that combines several tasks in one call. For example, to solve a system of linear equations with a general matrix, call `?getrf` (*LU* factorization) and then `?getrs` (computing the solution). Then, call `?gerfs` to refine the solution and get the error bounds. Alternatively, use the driver routine `?gesvx` that performs all these tasks in one call.

Computational Routines

[Table "Computational Routines for Systems of Equations with Real Matrices"](#) lists the LAPACK computational routines (FORTRAN 77 and Fortran 95 interfaces) for factorizing, equilibrating, and inverting *real* matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error. [Table "Computational Routines for Systems of Equations with Complex Matrices"](#) lists similar routines for *complex* matrices. Respective routine names in the Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

In the table above, ? stands for c (single precision complex) or z (double precision complex) for FORTRAN 77 interface.

Routines for Matrix Factorization

This section describes the LAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization
- Cholesky factorization of real symmetric positive-definite matrices
- Cholesky factorization of real symmetric positive-definite matrices with pivoting
- Cholesky factorization of Hermitian positive-definite matrices
- Cholesky factorization of Hermitian positive-definite matrices with pivoting
- Bunch-Kaufman factorization of real and complex symmetric matrices
- Bunch-Kaufman factorization of Hermitian matrices.

You can compute:

- the LU factorization using full and band storage of matrices
- the Cholesky factorization using full, packed, RFP, and band storage
- the Bunch-Kaufman factorization using full and packed storage.

?getrf

Computes the LU factorization of a general m-by-n matrix.

Syntax

FORTRAN 77:

```
call sgetrf( m, n, a, lda, ipiv, info )
call dgetrf( m, n, a, lda, ipiv, info )
call cgetrf( m, n, a, lda, ipiv, info )
call zgetrf( m, n, a, lda, ipiv, info )
```

Fortran 95:

```
call getrf( a [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>getrf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the *LU* factorization of a general m -by- n matrix A as

$$A = P \cdot L \cdot U,$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ; $n \geq 0$.
<i>a</i>	REAL for sgetrf DOUBLE PRECISION for dgetrf COMPLEX for cgetrf DOUBLE COMPLEX for zgetrf. Array, DIMENSION (<i>lda</i> , *). Contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of array <i>a</i> .

Output Parameters

a Overwritten by *L* and *U*. The unit diagonal elements of *L* are not stored.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row *i* was interchanged with row *ipiv(i)*.

info INTEGER. If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, u_{ii} is 0. The factorization has been completed, but *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrf` interface are as follows:

a Holds the matrix *A* of size (*m*, *n*).

ipiv Holds the vector of length $\min(m, n)$.

Application Notes

The computed *L* and *U* are the exact factors of a perturbed matrix *A* + *E*, where

$$\|E\| \leq c(\min(m, n))\epsilon \|A\| \|U\|$$

c(n) is a modest linear function of *n*, and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(2/3)n^3 \quad \text{If } m = n,$$

$$(1/3)n^2(3m-n) \quad \text{If } m > n,$$

$$(1/3)m^2(3n-m) \quad \text{If } m < n.$$

The number of operations for complex flavors is four times greater.

After calling this routine with *m* = *n*, you can call the following:

?getrs to solve $A^*x = B$ or $A^T x = B$ or $A^H x = B$

?gecon to estimate the condition number of *A*

?getri to compute the inverse of *A*.

See Also

[mkl_progress](#)

?gbtrf

Computes the LU factorization of a general m-by-n band matrix.

Syntax**FORTRAN 77:**

```
call sgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
```

Fortran 95:

```

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the *LU* factorization of a general m -by- n band matrix A with kl non-zero subdiagonals and ku non-zero superdiagonals, that is,

$$A = P \cdot L \cdot U,$$

where P is a permutation matrix; L is lower triangular with unit diagonal elements and at most kl non-zero elements in each column; U is an upper triangular band matrix with $kl + ku$ superdiagonals. The routine uses partial pivoting, with row interchanges (which creates the additional kl superdiagonals in U).

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in matrix A ; $m \geq 0$.
<i>n</i>	INTEGER. The number of columns in matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>ab</i>	REAL for sgbtrf DOUBLE PRECISION for dgbtrf

COMPLEX for `cgbtrf`

DOUBLE COMPLEX for `zgbtrf`.

Array, DIMENSION ($l\text{dab}, *$). The array ab contains the matrix A in band storage, in rows $k_1 + 1$ to $2*k_1 + k_u + 1$; rows 1 to k_1 of the array need not be set. The j -th column of A is stored in the j -th column of the array ab as follows:

$ab(k_1 + k_u + 1 + i - j, j) = a(i, j)$ for $\max(1, j-k_u) \leq i \leq \min(m, j+k_1)$.

$l\text{dab}$

INTEGER. The leading dimension of the array ab . ($l\text{dab} \geq 2*k_1 + k_u + 1$)

Output Parameters

ab

Overwritten by L and U . U is stored as an upper triangular band matrix with $k_1 + k_u$ superdiagonals in rows 1 to $k_1 + k_u + 1$, and the multipliers used during the factorization are stored in rows $k_1 + k_u + 2$ to $2*k_1 + k_u + 1$. See Application Notes below for further details.

$ipiv$

INTEGER.
Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row $ipiv(i)$.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbtrf` interface are as follows:

ab

Holds the array A of size $(2*k_1+k_u+1, n)$.

$ipiv$

Holds the vector of length $\min(m, n)$.

k_1

If omitted, assumed $k_1 = k_u$.

k_u

Restored as $k_u = l\text{da}-2*k_1-1$.

m

If omitted, assumed $m = n$.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(k_1+k_u+1) \cdot \epsilon \cdot P |L| |U|$$

$c(k)$ is a modest linear function of k , and ϵ is the machine precision.

The total number of floating-point operations for real flavors varies between approximately $2n(ku+1)k_1$ and $2n(k_1+ku+1)k_1$. The number of operations for complex flavors is four times greater. All these estimates assume that k_1 and ku are much less than $\min(m, n)$.

The band storage scheme is illustrated by the following example, when $m = n = 6$, $k_1 = 2$, $ku = 1$:

on entry							on exit						
$\begin{bmatrix} * & * & * & + & + & + \\ * & * & + & + & + & + \\ * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$							$\begin{bmatrix} * & * & * & u_{14} & u_{25} & u_{36} \\ * & * & u_{13} & u_{24} & u_{35} & u_{46} \\ * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$						

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

After calling this routine with $m = n$, you can call the following routines:

[gbtrs](#) to solve $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$

[gbcon](#) to estimate the condition number of A .

```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`

- C: mkl.h

Description

The routine computes the *LU* factorization of a real or complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L^*U,$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>d1, d, du</i>	REAL for sgttrf DOUBLE PRECISION for dgttrf COMPLEX for cgttrf DOUBLE COMPLEX for zgttrf. Arrays containing elements of A . The array <i>d1</i> of dimension $(n - 1)$ contains the subdiagonal elements of A . The array <i>d</i> of dimension n contains the diagonal elements of A . The array <i>du</i> of dimension $(n - 1)$ contains the superdiagonal elements of A .
<i>dl</i>	Overwritten by the $(n-1)$ multipliers that define the matrix L from the <i>LU</i> factorization of A . The matrix L has unit diagonal elements, and the $(n-1)$ elements of <i>dl</i> form the subdiagonal. All other elements of L are zero.
<i>d</i>	Overwritten by the n diagonal elements of the upper triangular matrix U from the <i>LU</i> factorization of A .
<i>du</i>	Overwritten by the $(n-1)$ elements of the first superdiagonal of U .
<i>du2</i>	REAL for sgttrf DOUBLE PRECISION for dgttrf COMPLEX for cgttrf DOUBLE COMPLEX for zgttrf. Array, dimension $(n - 2)$. On exit, <i>du2</i> contains $(n-2)$ elements of the second superdiagonal of U .
<i>ipiv</i>	INTEGER.

Output Parameters

<i>dl</i>	Overwritten by the $(n-1)$ multipliers that define the matrix L from the <i>LU</i> factorization of A . The matrix L has unit diagonal elements, and the $(n-1)$ elements of <i>dl</i> form the subdiagonal. All other elements of L are zero.
<i>d</i>	Overwritten by the n diagonal elements of the upper triangular matrix U from the <i>LU</i> factorization of A .
<i>du</i>	Overwritten by the $(n-1)$ elements of the first superdiagonal of U .
<i>du2</i>	REAL for sgttrf DOUBLE PRECISION for dgttrf COMPLEX for cgttrf DOUBLE COMPLEX for zgttrf. Array, dimension $(n - 2)$. On exit, <i>du2</i> contains $(n-2)$ elements of the second superdiagonal of U .
<i>ipiv</i>	INTEGER.

Array, dimension (n). The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$. $ipiv(i)$ is always i or $i+1$; $ipiv(i) = i$ indicates a row interchange was not required.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gttrf` interface are as follows:

<i>dl</i>	Holds the vector of length ($n-1$).
<i>d</i>	Holds the vector of length n .
<i>du</i>	Holds the vector of length ($n-1$).
<i>du2</i>	Holds the vector of length ($n-2$).
<i>ipiv</i>	Holds the vector of length n .

Application Notes

?gbtrs	to solve $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$
?gbcon	to estimate the condition number of A .

?dttrfb

Computes the factorization of a diagonally dominant tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sdttrfb( n, dl, d, du, info )
call ddttrfb( n, dl, d, du, info )
call cdttrfb( n, dl, d, du, info )
call zdttrfb( n, dl, d, du, info )
```

Fortran 95:

```
call dttrfb( dl, d, du [, info] )
```

C:

MKL_Complex16 * du , MKL_INT * info );

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The ?dttrfb routine computes the factorization of a real or complex tridiagonal matrix A with the BABE (Burning At Both Ends) algorithm without pivoting. The factorization has the form

$$A = L_1 * U * L_2$$

where

- L_1 and L_2 are unit lower bidiagonal with k and $n - k - 1$ subdiagonal elements, respectively, where $k = n/2$, and
- U is an upper bidiagonal matrix with nonzeros in only the main diagonal and first superdiagonal.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>dl, d, du</i>	REAL for sdttrfb DOUBLE PRECISION for ddttrfb COMPLEX for cdttrfb DOUBLE COMPLEX for zdttrfb. Arrays containing elements of A . The array <i>dl</i> of dimension $(n - 1)$ contains the subdiagonal elements of A . The array <i>d</i> of dimension <i>n</i> contains the diagonal elements of A . The array <i>du</i> of dimension $(n - 1)$ contains the superdiagonal elements of A .
<i>info</i>	None

Output Parameters

<i>dl</i>	Overwritten by the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A .
<i>d</i>	Overwritten by the <i>n</i> diagonal element reciprocals of the upper triangular matrix U from the factorization of A .
<i>du</i>	Overwritten by the $(n-1)$ elements of the superdiagonal of U .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any i :

$1 < i < n$, and $|d_1| > |du_1|$, $|d_n| > |dl_{n-1}|$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems are free from the numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see [?gttrf](#)). The diagonally dominant systems are much faster than the canonical systems.

NOTE

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
 - Applying the [?dttrfb](#) factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.
-

?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrf( uplo, n, a, lda, info )
call dpotrf( uplo, n, a, lda, info )
call cpotrf( uplo, n, a, lda, info )
call zpotrf( uplo, n, a, lda, info )
```

Fortran 95:

```
call potrf( a [, uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>potrf( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A :

$A = U^T * U$ for real data, $A = U^H * U$ for complex data if $uplo='U'$
 $A = L * L^T$ for real data, $A = L * L^H$ for complex data if $uplo='L'$
 where L is a lower triangular matrix and U is upper triangular.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = ' <i>U</i> ', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = ' <i>L</i> ', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	REAL for <i>spotrf</i> DOUBLE PRECISION for <i>dpotrf</i> COMPLEX for <i>cpotrf</i> DOUBLE COMPLEX for <i>zpotrf</i> . Array, DIMENSION (<i>lda</i> , *). The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor U or L , as specified by <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *potrf* interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

If $uplo = \text{'U'}$, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = \text{'L'}$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

?potrs	to solve $A^*X = B$
?pocon	to estimate the condition number of A
?potri	to compute the inverse of A .

lapack_int LAPACKE_cpstrf( int matrix_layout, char uplo, lapack_int n,
                           lapack_complex_float* a, lapack_int lda, lapack_int* piv, lapack_int* rank, float tol );
lapack_int LAPACKE_zpstrf( int matrix_layout, char uplo, lapack_int n,
                           lapack_complex_double* a, lapack_int lda, lapack_int* piv, lapack_int* rank, double tol );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix. The form of the factorization is:

$$\begin{aligned} P^T * A * P &= U^T * U, \text{ if } \text{uplo} = 'U' \text{ for real flavors,} \\ P^H * A * P &= U^H * U, \text{ if } \text{uplo} = 'U' \text{ for complex flavors,} \\ P^T * A * P &= L * L^T, \text{ if } \text{uplo} = 'L' \text{ for real flavors,} \\ P^H * A * P &= L * L^H, \text{ if } \text{uplo} = 'L' \text{ for complex flavors,} \end{aligned}$$

where P is stored as vector piv , ' U ' and ' L ' are upper and lower triangular matrices respectively.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' U ' or ' L '.
	Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced. If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for spstrf DOUBLE PRECISION for dpstrf COMPLEX for cpstrf DOUBLE COMPLEX for zpstrf. Array a , DIMENSION ($lda, *$). The array a contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of a must be at least $\max(1, n)$. $work(*)$ is a workspace array. The dimension of $work$ is at least $\max(1, 2*n)$.
<i>tol</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

User defined tolerance. If $tol < 0$, then $n*U*\max(a(k,k))$ will be used. The algorithm terminates at the $(k-1)$ -th step, if the pivot $\leq tol$.

*lda*INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

*a*If $info = 0$, the factor *U* or *L* from the Cholesky factorization is as described in *Description*.*piv*

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *piv* is such that the nonzero entries are $p(piv(k), k) = 1$.*rank*

INTEGER.

The rank of *a* given by the number of steps the algorithm completed.*info*INTEGER. If $info = 0$, the execution is successful.If $info = -k$, the k -th argument had an illegal value.If $info > 0$, the matrix *A* is either rank deficient with a computed rank as returned in *rank*, or is indefinite.

?pftrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using the Rectangular Full Packed (RFP) format .

Syntax

FORTRAN 77:

```
call spftrf( transr, uplo, n, a, info )
call dpftrf( transr, uplo, n, a, info )
call cpftrf( transr, uplo, n, a, info )
call zpftrf( transr, uplo, n, a, info )
```

C:

```
lapack_int LAPACKE_<?>pftrf( int matrix_layout, char transr, char uplo, lapack_int n,
<datatype>* a );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, a Hermitian positive-definite matrix *A*:

$A = U^T * U$ for real data, $A = U^H * U$ for complex data	if $uplo='U'$
$A = L * L^T$ for real data, $A = L * L^H$ for complex data	if $uplo='L'$

where L is a lower triangular matrix and U is upper triangular.

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for <i>spftrf</i> DOUBLE PRECISION for <i>dpftrf</i> COMPLEX for <i>cpftrf</i> DOUBLE COMPLEX for <i>zpftrf</i> . Array, DIMENSION ($n * (n+1) / 2$). The array <i>a</i> contains the matrix A in the RFP format.

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor U or L , as specified by <i>info</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = i , the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

?pptrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using packed storage.

Syntax**FORTRAN 77:**

```
call spptrf( uplo, n, ap, info )
call dpptrf( uplo, n, ap, info )
call cpptrf( uplo, n, ap, info )
call zpptrf( uplo, n, ap, info )
```

Fortran 95:

```
call pptrf( ap [, uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>pptrf( int matrix_layout, char uplo, lapack_int n, <datatype>* ap );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite packed matrix A :

$$\begin{aligned} A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo='U' \\ A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo='L' \end{aligned}$$

where L is a lower triangular matrix and U is upper triangular.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

`uplo`

CHARACTER*1. Must be '`U`' or '`L`'.

Indicates whether the upper or lower triangular part of A is packed in the array `ap`, and how A is factored:

If `uplo = 'U'`, the array `ap` stores the upper triangular part of the matrix A , and A is factored as $U^H * U$.

If `uplo = 'L'`, the array `ap` stores the lower triangular part of the matrix A ; A is factored as $L * L^H$.

n INTEGER. The order of matrix A ; $n \geq 0$.

ap REAL for `spptrf`
DOUBLE PRECISION for `dpptrf`
COMPLEX for `cpptrf`
DOUBLE COMPLEX for `zpptrf`.
Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array *ap* contains either the upper or the lower triangular part of the matrix A (as specified by *uplo*) in packed storage (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by *uplo*.

info INTEGER. If *info*=0, the execution is successful.
If *info* = $-i$, the *i*-th parameter had an illegal value.
If *info* = i , the leading minor of order *i* (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrf` interface are as follows:

<i>ap</i>	Holds the array A of size $(n^*(n+1)/2)$.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

If *uplo* = '`U`', the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for *uplo* = '`L`'.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

? <code>pptrs</code>	to solve $A^*X = B$
? <code>ppcon</code>	to estimate the condition number of A

<datatype>* ab, lapack_int ldab );
```

Include Files

- Fortran: mkl.fi
 - Fortran 95: lapack.f90
 - C: mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix A :

$A = U^T * U$ for real data, $A = U^H * U$ for complex data if $\text{uplo} = 'U'$
 $A = L * L^T$ for real data, $A = L * L^H$ for complex data if $\text{uplo} = 'L'$

where L is a lower triangular matrix and U is upper triangular.

NOTE

NOTE This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored in the array ab , and how A is factored:

	If $uplo = 'U'$, the upper triangle of A is stored.
	If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
kd	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
ab	REAL for <code>s pbtrf</code> DOUBLE PRECISION for <code>d pbtrf</code> COMPLEX for <code>c pbtrf</code> DOUBLE COMPLEX for <code>z pbtrf</code> . Array, DIMENSION $(*, *)$. The array ab contains either the upper or the lower triangular part of the matrix A (as specified by $uplo$) in band storage (see Matrix Storage Schemes). The second dimension of ab must be at least $\max(1, n)$.
$ldab$	INTEGER. The leading dimension of the array ab . ($ldab \geq kd + 1$)

Output Parameters

ab	The upper or lower triangular part of A (in band storage) is overwritten by the Cholesky factor U or L , as specified by $uplo$.
$info$	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbtrf` interface are as follows:

ab	Holds the array A of size $(kd+1, n)$.
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

If $uplo = 'U'$, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(kd + 1)\varepsilon |U^H| |U|, |e_{ij}| \leq c(kd + 1)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

The total number of floating-point operations for real flavors is approximately $n(kd+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kd is much less than n .

After calling this routine, you can call the following routines:

?pbtrs	to solve $A^*X = B$
?pbcon	to estimate the condition number of A .

lapack_int LAPACKE_zpttrf( lapack_int n, double* d, lapack_complex_double* e );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite tridiagonal matrix A :

$A = L^*D*L^T$ for real flavors, or

$A = L^*D*L^H$ for complex flavors,

where D is diagonal and L is unit lower bidiagonal. The factorization may also be regarded as having the form $A = U^T*D*U$ for real flavors, or $A = U^H*D*U$ for complex flavors, where U is unit upper bidiagonal.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>d</i>	REAL for <code>spttrf</code> , <code>cpttrf</code> DOUBLE PRECISION for <code>dpttrf</code> , <code>zpttrf</code> . Array, dimension (n). Contains the diagonal elements of A .
<i>e</i>	REAL for <code>spttrf</code> DOUBLE PRECISION for <code>dpttrf</code> COMPLEX for <code>cpttrf</code> DOUBLE COMPLEX for <code>zpttrf</code> . Array, dimension ($n - 1$). Contains the subdiagonal elements of A .

Output Parameters

<i>d</i>	Overwritten by the n diagonal elements of the diagonal matrix D from the L^*D*L^T (for real flavors) or L^*D*L^H (for complex flavors) factorization of A .
<i>e</i>	Overwritten by the $(n - 1)$ off-diagonal elements of the unit bidiagonal factor L or U from the factorization of A .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite; if $i < n$, the factorization could not be completed, while if $i = n$, the factorization was completed, but $d(n) \leq 0$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrf` interface are as follows:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length $(n-1)$.

?sytrf

Computes the Bunch-Kaufman factorization of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call dsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call csytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call zsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call sytrf( a [, uplo] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sytrf( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda, lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

```
if uplo='U',  $A = P \cdot U \cdot D \cdot U^T \cdot P^T$   
if uplo='L',  $A = P \cdot L \cdot D \cdot L^T \cdot P^T$ ,
```

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Routine](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A , and A is factored as $P \cdot U \cdot D \cdot U^T \cdot P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A , and A is factored as $P \cdot L \cdot D \cdot L^T \cdot P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	REAL for ssytrf DOUBLE PRECISION for dsytrf COMPLEX for csytrf DOUBLE COMPLEX for zsytrf. Array, DIMENSION (<i>lda</i> , *). The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

work Same type as *a*. A workspace array, dimension at least $\max(1, lwork)$.

lwork INTEGER. The size of the *work* array (*lwork* $\geq n$).

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.

See [Application Notes](#) for the suggested value of *lwork*.

Output Parameters

a The upper or lower triangular part of *a* is overwritten by details of the block-diagonal matrix *D* and the multipliers used to obtain the factor *U* (or *L*).

work(1) If *info*=0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of *D*. If *ipiv*(*i*) = *k* > 0, then d_{ii} is a 1-by-1 block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.

If *uplo* = 'U' and *ipiv*(*i*) = *ipiv*(*i*-1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*-1, and (*i*-1)-th row and column of *A* was interchanged with the *m*-th row and column.

If *uplo* = 'L' and *ipiv*(*i*) = *ipiv*(*i*+1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*+1, and (*i*+1)-th row and column of *A* was interchanged with the *m*-th row and column.

info INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, d_{ii} is 0. The factorization has been completed, but *D* is exactly singular. Division by 0 will occur if you use *D* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrf` interface are as follows:

a holds the matrix *A* of size (*n*, *n*)

ipiv holds the vector of length *n*

*uplo*must be '`U`' or '`L`'. The default value is '`U`'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array *a*, but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array *a*.

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |P| |U| |D| |U^T| |P^T|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

?sytrs	to solve $A^*X = B$
?sycon	to estimate the condition number of A
?sytri	to compute the inverse of A .

If $uplo = 'U'$, then $A = U^*D^*U'$, where

$$U = P(n)*U(n)* \dots *P(k)*U(k)* \dots ,$$

that is, U is a product of terms $P(k)*U(k)$, where

- k decreases from n to 1 in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by $ipiv(k)$.
- $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

$$\begin{matrix} k-s & s & n-k \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$ and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $uplo = 'L'$, then $A = L^*D^*L'$, where

$L = P(1)^*L(1)^* \dots ^*P(k)^*L(k)^* \dots$

that is, L is a product of terms $P(k)^*L(k)$, where

- k increases from 1 to n in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by $ipiv(k)$.
- $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & v & I \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

$$\begin{matrix} k-1 & s & n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

call sytrf_rook( a [, uplo] [,ipiv] [,info] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is:

```
if uplo='U',  $A = U*D*U^T$ 
if uplo='L',  $A = L*D*L^T$ ,
```

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored and how A is factored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A , and A is factored as $U*D*U^T$.
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A , and A is factored as $L*D*L^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	REAL for ssytrf_rook DOUBLE PRECISION for dsytrf_rook COMPLEX for csytrf_rook DOUBLE COMPLEX for zsytrf_rook. Array, size (<i>lda</i> , *). The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>work</i>	Same type as <i>a</i> . A workspace array, dimension at least $\max(1, lwork)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> $\geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See ?sytrf Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>).
<i>work(1)</i>	If <i>info</i> =0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>ipiv</i>	INTEGER. Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> . If <i>ipiv(k) > 0</i> , then rows and columns <i>k</i> and <i>ipiv(k)</i> were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block. If <i>uplo = 'U'</i> and <i>ipiv(k) < 0</i> and <i>ipiv(k - 1) < 0</i> , then rows and columns <i>k</i> and $-ipiv(k)$ were interchanged, rows and columns <i>k - 1</i> and $-ipiv(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block. If <i>uplo = 'L'</i> and <i>ipiv(k) < 0</i> and <i>ipiv(k + 1) < 0</i> , then rows and columns <i>k</i> and $-ipiv(k)$ were interchanged, rows and columns <i>k + 1</i> and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , D_{ii} is 0. The factorization has been completed, but <i>D</i> is exactly singular. Division by 0 will occur if you use <i>D</i> for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrf_rook` interface are as follows:

<i>a</i>	holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>)
<i>ipiv</i>	holds the vector of length <i>n</i>
<i>uplo</i>	must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.

Application Notes

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?sytrs_rook</code>	to solve $A^*X = B$
<code>?sycon_rook</code>	to estimate the condition number of <i>A</i>

[?sytri_rook](#)to compute the inverse of A .

If $uplo = 'U'$, then $A = U^*D^*U'$, where

$$U = P(n)*U(n)* \dots *P(k)*U(k)* \dots ,$$

that is, U is a product of terms $P(k)*U(k)$, where

- k decreases from n to 1 in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by $ipiv(k)$.
- $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix}_{\begin{array}{c} k-s \\ s \\ n-k \end{array}}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$ and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $uplo = 'L'$, then $A = L^*D^*L'$, where

$$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots ,$$

that is, L is a product of terms $P(k)*L(k)$, where

- k increases from 1 to n in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by $ipiv(k)$.
- $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & v & I \end{pmatrix}_{\begin{array}{c} k-1 \\ s \\ n-k-s+1 \end{array}}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

Description

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

```
if uplo='U', A = P*U*D*UH*PT
if uplo='L', A = P*L*D*LH*PT,
```

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Routine](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be '`U`' or '`L`'.

Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and A is factored as $P*U*D*U^H*P^T$.

If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and A is factored as $P*L*D*L^H*P^T$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

<i>a, work</i>	COMPLEX for chetrf DOUBLE COMPLEX for zhetrf. Arrays, DIMENSION $a(1:\text{lda}, :)$, $\text{work}(1:\text{lwork})$. The array <i>a</i> contains the upper or the lower triangular part of the matrix <i>A</i> (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array of dimension at least $\max(1, \text{lwork})$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($\text{lwork} \geq n$). If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> . If <i>ipiv</i> (<i>i</i>) = <i>k</i> > 0, then d_{ii} is a 1-by-1 block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column. If <i>uplo</i> = 'U' and <i>ipiv</i> (<i>i</i>) = <i>ipiv</i> (<i>i</i> -1) = <i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i> -1, and the (<i>i</i> -1)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column. If <i>uplo</i> = 'L' and <i>ipiv</i> (<i>i</i>) = <i>ipiv</i> (<i>i</i> +1) = <i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i> +1, and the (<i>i</i> +1)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , d_{ii} is 0. The factorization has been completed, but <i>D</i> is exactly singular. Division by 0 will occur if you use <i>D</i> for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrf` interface are as follows:

<code>a</code>	holds the matrix A of size (n, n)
<code>ipiv</code>	holds the vector of length n
<code>uplo</code>	must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

This routine is suitable for Hermitian matrices that are not known to be positive-definite. If A is in fact positive-definite, the routine does not perform interchanges, and no 2-by-2 diagonal blocks occur in D .

For better performance, try using $\text{lwork} = n * \text{blocksize}$, where blocksize is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of lwork for the first run or set $\text{lwork} = -1$.

If you choose the first option and set any of admissible lwork sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $\text{lwork} = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set lwork to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array `a`, but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $\text{ipiv}(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array `a`.

If $\text{uplo} = \text{'U'}$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$\|E\| \leq c(n)\varepsilon \|P\| \|U\| \|D\| \|U^T\| \|P^T\|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for the computed L and D when $\text{uplo} = \text{'L'}$.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

<code>?hetrs</code>	to solve $A^T X = B$
<code>?hecon</code>	to estimate the condition number of A
<code>?hetri</code>	to compute the inverse of A .

`mkl_progress`

`?hetrf_rook`

Computes the bounded Bunch-Kaufman factorization of a complex Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetrf_rook( uplo, n, a, lda, ipiv, work, lwork, info )
call zhetrf_rook( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call hetrf_rook( a [, uplo] [,ipiv] [,info] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman diagonal pivoting method:

```
if uplo='U', A = U*D*UH
if uplo='L', A = L*D*LH,
```

where A is the input matrix, U (or L) is a product of permutation and unit upper (or lower) triangular matrices, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A .
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i> , <i>work</i>	COMPLEX for chetrf_rook COMPLEX*16 for zhetrf_rook. Arrays, size (<i>lda</i> ,*), <i>work</i> (*).
	The array <i>a</i> contains the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A , and the strictly upper triangular part of <i>a</i> is not referenced. <i>work</i> (*) is a workspace array of dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> $\geq n$).

The length of `work`. $lwork \geq 1$. For best performance $lwork \geq n*nb$, where nb is the block size returned by `ilaenv`.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`.

Output Parameters

`a`

The block diagonal matrix D and the multipliers used to obtain the factor U or L (see Application Notes for further details).

`work(1)`

If $info = 0$, on exit `work(1)` contains the minimum value of `lwork` required for optimum performance. Use this `lwork` for subsequent runs.

`ipiv`

INTEGER.

Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D .

- If $uplo = 'U'$:

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged and rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, $D_{k-1:k,k-1:k}$ is a 2-by-2 diagonal block.

- If $uplo = 'L'$:

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged and rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, $D_{k:k+1,k:k+1}$ is a 2-by-2 diagonal block.

`info`

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, D_{ii} is exactly 0. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrf_rook` interface are as follows:

`a`

holds the matrix A of size (n, n)

<i>ipiv</i>	holds the vector of length <i>n</i>
<i>uplo</i>	must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *uplo* = 'U', then $A = U^*D*U^H$, where

$$U = P(n)*U(n)* \dots *P(k)U(k)* \dots,$$

i.e., U is a product of terms $P(k)*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by *ipiv*(k), and $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$U(k) =$	$\begin{pmatrix} I & v & 0 & \dots \\ 0 & I & 0 & \dots \\ 0 & 0 & I & \dots \\ k-s & s & n-k & \dots \end{pmatrix}$	$k-s$
		s
		$n-k$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If *uplo* = 'L', then $A = L^*D*L^H$, where

$$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by *ipiv*(k), and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$L(k) =$	$\begin{pmatrix} I & 0 & 0 & \dots \\ 0 & I & 0 & \dots \\ 0 & v & I & \dots \\ k-1 & s & n-k-s+1 & \dots \end{pmatrix}$	$k-1$
		s
		$n-k-s+1$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix A stored in the packed format using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

```
if uplo='U',  $A = P \cdot U \cdot D \cdot U^T \cdot P^T$   
if uplo='L',  $A = P \cdot L \cdot D \cdot L^T \cdot P^T$ ,
```

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. ```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
if uplo='U', A = P*U*D*UH*PT
if uplo='L', A = P*L*D*LH*PT,
```

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo	CHARACTER*1. Must be 'U' or 'L'.
------	----------------------------------

Indicates whether the upper or lower triangular part of A is packed and how A is factored:

If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as $P^*U*D*U^H*P^T$.

If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A , and A is factored as $P*L*D*L^H*P^T$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

ap

COMPLEX for chptrf

DOUBLE COMPLEX for zhpstrf.

Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in *packed storage* (see [Matrix Storage Schemes](#)).

Output Parameters

ap

The upper or lower triangle of A (as specified by $uplo$) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and the $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and the $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrf` interface are as follows:

ap

Holds the array A of size $(n*(n+1)/2)$.

$ipiv$

Holds the vector of length n .

`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of $U(L)$ are stored explicitly in the corresponding elements of the array a .

If $\text{uplo} = \text{'U'}$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n) \varepsilon P |U| |D| |U^T| P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for the computed L and D when `uplo = 'L'`.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

?hpcon to estimate the cost.

?hptri to compute the inverse of A .

Routines for Solving Systems of Linear Equations

This section describes the LAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

sgetrs dgetrs cgetrs zgetrs Reference

Solves a system of linear equations with an LU-factored square matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call dgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call cgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call zgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call getrs( a, ipiv, b [, trans] [, info] )
```

C:

```
lapack_int LAPACKE_<?>getrs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const <datatype>* a, lapack_int lda, const lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations:

$$\begin{aligned} A^*X &= B && \text{if } trans = 'N', \\ A^T*X &= B && \text{if } trans = 'T', \\ A^H*X &= B && \text{if } trans = 'C' \text{ (for complex matrices only).} \end{aligned}$$

Before calling this routine, you must call [?getrf](#) to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
	Indicates the form of the equations:
	If <i>trans</i> = 'N', then $A^*X = B$ is solved for X .
	If <i>trans</i> = 'T', then $A^T*X = B$ is solved for X .
	If <i>trans</i> = 'C', then $A^H*X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A ; the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a</i> , <i>b</i>	REAL for sgetrs DOUBLE PRECISION for dgetrs COMPLEX for cgetrs DOUBLE COMPLEX for zgetrs. Arrays: $a(1:da, :)$, $b(1:db, :)$. The array <i>a</i> contains LU factorization of matrix A resulting from the call of ?getrf . The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$, the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER.

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?getrf](#).

Output Parameters

b Overwritten by the solution matrix X .
info INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrs` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, nrhs) .
<i>ipiv</i>	Holds the vector of length n .
<i>trans</i>	Must be ' <code>N</code> ', ' <code>C</code> ', or ' <code>T</code> '. The default value is ' <code>N</code> '.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n) \varepsilon P |L| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

.....

where $\text{cond}(A, x) = \|A^{-1}\| |A| \|x\|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?gecon](#).

To refine the solution and estimate the error, call `?gerfs`.

?gbtrs

Solves a system of linear equations with an LU-factored band matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbtrs( ab, b, ipiv, [, kl] [, trans] [, info] )
```

C:

```
lapack_int LAPACKE_<?>gbtrs( int matrix_layout, char trans, lapack_int n, lapack_int
kl, lapack_int ku, lapack_int nrhs, const <datatype>* ab, lapack_int ldab,
const lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations:

$$\begin{aligned} A^*X = B && \text{if } trans='N', \\ A^T*X = B && \text{if } trans='T', \\ A^H*X = B && \text{if } trans='C' \text{ (for complex matrices only).} \end{aligned}$$

Here A is an LU -factored general band matrix of order n with kl non-zero subdiagonals and ku nonzero superdiagonals. Before calling this routine, call [?gbtrf](#) to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
<i>n</i>	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab</i> , <i>b</i>	REAL for sgbtrs DOUBLE PRECISION for dgbtrs COMPLEX for cgbtrs

DOUBLE COMPLEX for zgbtrs.

Arrays: $ab(1dab, *)$, $b(1db, *)$.

The array ab contains the matrix A in *band storage* (see [Matrix Storage Schemes](#)).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The second dimension of ab must be at least $\max(1, n)$, and the second dimension of b at least $\max(1, nrhs)$.

$1dab$

INTEGER. The leading dimension of the array ab ; $1dab \geq 2*kl + ku + 1$.

$1db$

INTEGER. The leading dimension of b ; $1db \geq \max(1, n)$.

$ipiv$

INTEGER. Array, DIMENSION at least $\max(1, n)$. The $ipiv$ array, as returned by [?gbtrf](#).

Output Parameters

b

Overwritten by the solution matrix X .

$info$

INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbtrs` interface are as follows:

ab

Holds the array A of size $(2*kl+ku+1, n)$.

b

Holds the matrix B of size $(n, nrhs)$.

$ipiv$

Holds the vector of length $\min(m, n)$.

kl

If omitted, assumed $kl = ku$.

ku

Restored as $1da-2*kl-1$.

$trans$

Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kl + ku + 1)\varepsilon P|L||U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\begin{array}{ccccccccc} & | & \dots & : & : & : & : & : & : \\ \dots & | & \dots \\ & | & \dots & : & : & : & : & : & : \end{array}$$

where $\text{cond}(A, x) = |||A^{-1}||A||x||_{\infty} / ||x||_{\infty} \leq ||A^{-1}||_{\infty} ||A||_{\infty} = \kappa_{\infty}(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector is $2n(ku + 2kl)$ for real flavors. The number of operations for complex flavors is 4 times greater. All these estimates assume that kl and ku are much less than $\min(m,n)$.

To estimate the condition number $\kappa_{\infty}(A)$, call [?gbcon](#).

To refine the solution and estimate the error, call [?gbrfs](#).

[?gttrs](#)

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by [?gttrf](#).

Syntax

FORTRAN 77:

```
call sgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call dgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call cgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call zgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
```

Fortran 95:

```
call gttrs( dl, d, du, du2, b, ipiv [, trans] [,info] )
```

C:

```
lapack_int LAPACKE_<?>gttrs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs,
const <datatype>* dl, const <datatype>* d, const <datatype>* du,
const <datatype>* du2, const lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations with multiple right hand sides:

$$\begin{aligned} A^*X = B && \text{if } trans='N', \\ A^T*X = B && \text{if } trans='T', \\ A^H*X = B && \text{if } trans='C' \text{ (for complex matrices only).} \end{aligned}$$

Before calling this routine, you must call [?gttrf](#) to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A^X = B$ is solved for X . If <i>trans</i> = 'T', then $A^T X = B$ is solved for X . If <i>trans</i> = 'C', then $A^H X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns in B ; $nrhs \geq 0$.
<i>dl, d, du, du2, b</i>	REAL for <code>sgttrs</code> DOUBLE PRECISION for <code>dgttrs</code> COMPLEX for <code>cgttrs</code> DOUBLE COMPLEX for <code>zgttrs</code> . Arrays: $dl(n - 1), d(n), du(n - 1), du2(n - 2), b(ldb, nrhs)$. The array <i>dl</i> contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . The array <i>d</i> contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array <i>du</i> contains the $(n - 1)$ elements of the first superdiagonal of U . The array <i>du2</i> contains the $(n - 2)$ elements of the second superdiagonal of U . The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). The <i>ipiv</i> array, as returned by <code>?gttrf</code> .

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gttrs` interface are as follows:

<code>dl</code>	Holds the vector of length $(n-1)$.
<code>d</code>	Holds the vector of length n .
<code>du</code>	Holds the vector of length $(n-1)$.
<code>du2</code>	Holds the vector of length $(n-2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>trans</code>	Must be ' <code>N</code> ', ' <code>C</code> ', or ' <code>T</code> '. The default value is ' <code>N</code> '.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon P|L||U|$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\begin{array}{ccccccccc} & & | & . & : & : & : & : & \\ & & | & . & : & : & : & : & \\ \dots & \dots & | & . & : & : & : & : & \dots \\ & & | & . & : & : & : & : & \end{array}$$

where $\text{cond}(A, x) = ||A^{-1}||A||x||_{\infty}/||x||_{\infty} \leq ||A^{-1}||_{\infty} ||A||_{\infty} = \kappa_{\infty}(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $7n$ (including n divisions) for real flavors and $34n$ (including $2n$ divisions) for complex flavors.

To estimate the condition number $\kappa_{\infty}(A)$, call `?gtcon`.

To refine the solution and estimate the error, call `?gtrfs`.

?dttrsbs

Solves a system of linear equations with a diagonally dominant tridiagonal matrix using the LU factorization computed by `?dttrfb`.

Syntax

FORTRAN 77:

```
call sdtrrsb( trans, n, nrhs, dl, d, du, b, ldb, info )
call ddtrrsb( trans, n, nrhs, dl, d, du, b, ldb, info )
```

```
call cdttrsbs( trans, n, nrhs, dl, d, du, b, ldb, info )
call zdttrsbs( trans, n, nrhs, dl, d, du, b, ldb, info )
```

Fortran 95:

```
call dttrsbs( dl, d, du, b [, trans] [, info] )
```

C:

```
void sdttrsbs (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const float
* dl, const float * d, const float * du, float * b, const MKL_INT * ldb, MKL_INT *
info );
void ddttrsbs (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const double
* dl, const double * d, const double * du, double * b, const MKL_INT * ldb, MKL_INT *
info );
void cdttrsbs (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const
MKL_Complex8 * dl, const MKL_Complex8 * d, const MKL_Complex8 * du, MKL_Complex8 * b,
const MKL_INT * ldb, MKL_INT * info );
void zdttrsbs (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const
MKL_Complex16 * dl, const MKL_Complex16 * d, const MKL_Complex16 * du, MKL_Complex16 *
b, const MKL_INT * ldb, MKL_INT * info );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The ?dttrsbs routine solves the following systems of linear equations with multiple right hand sides for X :

$$\begin{aligned} A^*X = B & \quad \text{if } \text{trans} = 'N', \\ A^T*X = B & \quad \text{if } \text{trans} = 'T', \\ A^H*X = B & \quad \text{if } \text{trans} = 'C' \text{ (for complex matrices only).} \end{aligned}$$

Before calling this routine, call [?dttrfb](#) to compute the factorization of A .

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations solved for X :	
If <i>trans</i> = 'N', then $A^*X = B$.	
If <i>trans</i> = 'T', then $A^T*X = B$.	
If <i>trans</i> = 'C', then $A^H*X = B$.	
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns in B ; $nrhs \geq 0$.
<i>dl, d, du, b</i>	REAL for sdttrsbs

DOUBLE PRECISION for ddttrsbs

COMPLEX for cdttrsbs

DOUBLE COMPLEX for zdttrsbs.

Arrays: $d_1(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, nrhs)$.

The array d_1 contains the $(n - 1)$ multipliers that define the matrices L_1, L_2 from the factorization of A .

The array d contains the n diagonal elements of the upper triangular matrix U from the factorization of A .

The array du contains the $(n - 1)$ elements of the superdiagonal of U .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b

Overwritten by the solution matrix X .

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?potrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call dpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call cpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call zpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call potrs( a, b [,uplo] [, info] )
```

C:

```
lapack_int LAPACKE_<?>potrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const <datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the system of linear equations $A^*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$$\begin{array}{ll} A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\ A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L' \end{array}$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [potrf](#) to compute the Cholesky factorization of A .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Indicates how the input matrix A has been factored:
	If <code>uplo</code> = ' <code>U</code> ', the upper triangle of A is stored.
	If <code>uplo</code> = ' <code>L</code> ', the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<code>a, b</code>	REAL for <code>sputrs</code> DOUBLE PRECISION for <code>dputrs</code> COMPLEX for <code>cputrs</code> DOUBLE COMPLEX for <code>zputrs</code> . Arrays: $a(1da, *)$, $b(1db, *)$. The array a contains the factor U or L (see <code>uplo</code>). The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.
<code>lda</code>	INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<code>b</code>	Overwritten by the solution matrix X .
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potrs` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

If $uplo = 'U'$, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\left| \begin{array}{c} | \\ | \\ \dots & \dots & \dots & \dots & \dots \\ | & | \end{array} \right|$$

where $\text{cond}(A, x) = |||A^{-1}|||A|||x|||_\infty / |||x|||_\infty \leq |||A^{-1}|||_\infty |||A|||_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$. The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?pocon](#).

To refine the solution and estimate the error, call [?porfs](#).

?pftrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite matrix using the Rectangular Full Packed (RFP) format.

Syntax

FORTRAN 77:

```
call spftrs( transr, uplo, n, nrhs, a, b, ldb, info )
call dpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
call cpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
call zpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
```

C:

```
lapack_int LAPACKE_<?>pftrs( int matrix_layout, char transr, char uplo, lapack_int n,
lapack_int nrhs, const <datatype>* a, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`

- C: mkl.h

Description

The routine solves a system of linear equations $A \cdot X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization of A :

$$\begin{array}{ll} A = U^T \cdot U \text{ for real data, } A = U^H \cdot U \text{ for complex data} & \text{if } \text{uplo} = 'U' \\ A = L \cdot L^T \text{ for real data, } A = L \cdot L^H \text{ for complex data} & \text{if } \text{uplo} = 'L' \end{array}$$

computed by [?pftrf](#). L stands for a lower triangular matrix and U - for an upper triangular matrix.

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of the RFP matrix A is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>a, b</i>	REAL for <i>sfptrs</i> DOUBLE PRECISION for <i>dpftrs</i> COMPLEX for <i>cpftrs</i> DOUBLE COMPLEX for <i>zpftrs</i> . Arrays: $a(n \cdot (n+1)/2)$, $b(ldb, nrhs)$. The array <i>a</i> contains the matrix A in the RFP format. The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	The solution matrix X .
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

?pptrs

Solves a system of linear equations with a packed Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spptrs( uplo, n, nrhs, ap, b, ldb, info )
call dpptrs( uplo, n, nrhs, ap, b, ldb, info )
call cpptrs( uplo, n, nrhs, ap, b, ldb, info )
call zpptrs( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call pptrs( ap, b [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>pptrs( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, const <datatype>* ap, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the system of linear equations $A^*X = B$ with a packed symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$$\begin{array}{ll} A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo='U' \\ A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo='L' \end{array}$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call `?pptrf` to compute the Cholesky factorization of A .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored:
-------------	---

	If $uplo = 'U'$, the upper triangle of A is stored.
	If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
ap, b	REAL for spptrs DOUBLE PRECISION for dpptrs COMPLEX for cpptrs DOUBLE COMPLEX for zpptrs. Arrays: $ap(*)$, $b(ldb,*)$
	The dimension of ap must be at least $\max(1, n(n+1)/2)$.
	The array ap contains the factor U or L , as specified by $uplo$, in packed storage (see Matrix Storage Schemes).
	The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
ldb	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b	Overwritten by the solution matrix X .
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrs` interface are as follows:

ap	Holds the array A of size $(n*(n+1)/2)$.
b	Holds the matrix B of size $(n, nrhs)$.
$uplo$	Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

If $uplo = 'U'$, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\begin{array}{ccccccccc} & & | & \dots & | & \dots & : & : & : \\ & & | & \dots & | & \dots & . & . & . \end{array}$$

where $\text{cond}(A, x) = |||A^{-1}|||A|||x|||_\infty / |||x|||_\infty \leq |||A^{-1}|||_\infty |||A|||_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?ppcon](#).

To refine the solution and estimate the error, call [?pprfs](#).

?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbtrs( ab, b [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>pbtrs( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
lapack_int nrhs, const <datatype>* ab, lapack_int ldab, <datatype>* b, lapack_int
ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for real data a system of linear equations $A \cdot X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite *band* matrix A , given the Cholesky factorization of A :

$$\begin{array}{ll} A = U^T \cdot U \text{ for real data, } A = U^H \cdot U \text{ for complex data} & \text{if } \text{uplo} = 'U' \\ A = L \cdot L^T \text{ for real data, } A = L \cdot L^H \text{ for complex data} & \text{if } \text{uplo} = 'L' \end{array}$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [?pbtrf](#) to compute the Cholesky factorization of A in the band storage form.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix <i>A</i> has been factored:
	If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> .
	If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for spbtrs DOUBLE PRECISION for dpbtrs COMPLEX for cpbtrs DOUBLE COMPLEX for zpbtrs. Arrays: <i>ab</i> (<i>ldab</i> , *), <i>b</i> (<i>ldb</i> , *). The array <i>ab</i> contains the Cholesky factor, as returned by the factorization routine, in <i>band storage</i> form. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>ab</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbtrs` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size (<i>kd</i> +1, <i>n</i>).
-----------	--

<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kd + 1)\epsilon P|U^H||U| \text{ or } |E| \leq c(kd + 1)\epsilon P|L^H||L|$$

$c(k)$ is a modest linear function of k , and ϵ is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kd + 1) \operatorname{cond}(A, x)\epsilon$$

where $\operatorname{cond}(A, x) = |||A^{-1}||A||x||_\infty / ||x||_\infty \leq ||A^{-1}||_\infty ||A||_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $4n*kd$ for real flavors and $16n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?pbcon](#).

To refine the solution and estimate the error, call [?pbrfs](#).

?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix using the factorization computed by [?pttrf](#).

Syntax

FORTRAN 77:

```
call spttrs( n, nrhs, d, e, b, ldb, info )
call dpttrs( n, nrhs, d, e, b, ldb, info )
call cpttrs( uplo, n, nrhs, d, e, b, ldb, info )
call zpttrs( uplo, n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call pttrs( d, e, b [,info] )
call pttrs( d, e, b [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_spttrs( int matrix_layout, lapack_int n, lapack_int nrhs,
                           const float* d, const float* e, float* b, lapack_int ldb );
lapack_int LAPACKE_dpttrs( int matrix_layout, lapack_int n, lapack_int nrhs,
                           const double* d, const double* e, double* b, lapack_int ldb );
```

```
lapack_int LAPACKE_cpttrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const float* d, const lapack_complex_float* e, lapack_complex_float* b, lapack_int ldb );

lapack_int LAPACKE_zpttrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const double* d, const lapack_complex_double* e, lapack_complex_double* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive-definite tridiagonal matrix A . Before calling this routine, call [?pttrf](#) to compute the $L \cdot D \cdot L'$ for real data and the $L \cdot D \cdot L'$ or $U' \cdot D \cdot U$ factorization of A for complex data.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Used for cpttrs/zpttrs only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>e</i> stores the superdiagonal of A , and A is factored as $U' \cdot D \cdot U$. If <i>uplo</i> = 'L', the array <i>e</i> stores the subdiagonal of A , and A is factored as $L \cdot D \cdot L'$.
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>d</i>	REAL for spttrs, cpttrs DOUBLE PRECISION for dpttrs, zpttrs. Array, dimension (<i>n</i>). Contains the diagonal elements of the diagonal matrix D from the factorization computed by ?pttrf .
<i>e, b</i>	REAL for spttrs DOUBLE PRECISION for dpttrs COMPLEX for cpttrs DOUBLE COMPLEX for zpttrs. Arrays: $e(n - 1)$, $b(lsb, nrhs)$. The array <i>e</i> contains the (<i>n</i> - 1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ?pttrf (see <i>uplo</i>).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix X .

$info$ INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrs` interface are as follows:

d Holds the vector of length n .

e Holds the vector of length $(n-1)$.

b Holds the matrix B of size $(n, nrhs)$.

$uplo$ Used in complex flavors only. Must be '`U`' or '`L`'. The default value is '`U`'.

?sytrs

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call dsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call csytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call zsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call sytrs( a, b, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sytrs( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, const <datatype>* a, lapack_int lda, const lapack_int* ipiv, <datatype>* b,
lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine solves for X the system of linear equations $A^T X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

```
if uplo='U',           A = P*U*D*U^T*P^T
if uplo='L',           A = P*L*D*L^T*P^T,
```

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array $ipiv$ returned by the factorization routine [?sytrf](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor U of the factorization $A = P*U*D*U^T*P^T$.
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor L of the factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf .
<i>a, b</i>	REAL for ssytrs DOUBLE PRECISION for dsytrs COMPLEX for csytrs DOUBLE COMPLEX for zsytrs. Arrays: <i>a</i> (<i>lda</i> , *), <i>b</i> (<i>ldb</i> , *). The array <i>a</i> contains the factor U or L (see <i>uplo</i>). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> $\geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; <i>ldb</i> $\geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrs` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\epsilon P|L||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x)\epsilon$$

where $\operatorname{cond}(A, x) = |||A^{-1}|||A|||x|||_\infty / |||x|||_\infty \leq |||A^{-1}|||_\infty |||A|||_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?sycon](#).

To refine the solution and estimate the error, call [?syrfs](#).

?sytrs_rook

Solves a system of linear equations with a UDU- or LDL-factored symmetric coefficient matrix.

Syntax

FORTRAN 77:

```
call ssytrs_rook( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

```
call dsytrs_rook( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

?sytrs2

Solves a system of linear equations with a UDU - or LDL -factored symmetric matrix computed by `?sytrf` and converted by `?syconv`.

Syntax

FORTRAN 77:

```
call ssytrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
call dsytrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
call csytrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
call zsytrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
```

Fortran 95:

```
call sytrs2( a,b,ipiv[,uplo][,info] )
```

C:

```
lapack_int LAPACKE_<?>sytrs2( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, const <datatype>* a, lapack_int lda, const lapack_int* ipiv, <datatype>* b,
lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine solves a system of linear equations $A \cdot X = B$ with a symmetric matrix A using the factorization of A :

```
if uplo='U',           A = U*D*UT
if uplo='L',           A = L*D*LT
```

where

- U and L are upper and lower triangular matrices with unit diagonal
- D is a symmetric block-diagonal matrix.

The factorization is computed by `?sytrf` and converted by `?syconv`.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '.
	Indicates how the input matrix <i>A</i> has been factored:
	If <i>uplo</i> = ' <i>U</i> ', the array <i>a</i> stores the upper triangular factor <i>U</i> of the factorization $A = U*D*U^T$.
	If <i>uplo</i> = ' <i>L</i> ', the array <i>a</i> stores the lower triangular factor <i>L</i> of the factorization $A = L*D*L^T$.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a, b</i>	REAL for <code>ssytrs2</code> DOUBLE PRECISION for <code>dsytrs2</code> COMPLEX for <code>csytrs2</code> DOUBLE COMPLEX for <code>zsytrs2</code> Arrays: <i>a</i> (<i>lda</i> ,*), <i>b</i> (<i>ldb</i> ,*).
	The array <i>a</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by <code>?sytrf</code> .
	The array <i>b</i> contains the right-hand side matrix <i>B</i> .
	The second dimension of <i>a</i> must be at least <code>max(1, n)</code> , and the second dimension of <i>b</i> at least <code>max(1, nrhs)</code> .
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array of DIMENSION <i>n</i> . The <i>ipiv</i> array contains details of the interchanges and the block structure of <i>D</i> as determined by <code>?sytrf</code> .
<i>work</i>	REAL for <code>ssytrs2</code> DOUBLE PRECISION for <code>dsytrs2</code> COMPLEX for <code>csytrs2</code> DOUBLE COMPLEX for <code>zsytrs2</code> Workspace array, DIMENSION <i>n</i> .

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrs2` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Indicates how the input matrix A has been factored. Must be ' <code>U</code> ' or ' <code>L</code> '.

[?sytrf](#)
[?syconv](#)

?hetrs2

Solves a system of linear equations with a UDU - or LDL -factored Hermitian matrix computed by `?hetrf` and converted by `?syconv`.

Syntax

FORTRAN 77:

```
call chetrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
call zhetrs2( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, info )
```

Fortran 95:

```
call hetrs2( a, b, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>hetrs2( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, const <datatype>* a, lapack_int lda, const lapack_int* ipiv, <datatype>* b,
lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine solves a system of linear equations $A^*X = B$ with a complex Hermitian matrix A using the factorization of A :

```
if uplo='U',           A = U*D*UH
if uplo='L',           A = L*D*LH
```

where

- U and L are upper and lower triangular matrices with unit diagonal
- D is a Hermitian block-diagonal matrix.

The factorization is computed by `?hetrf` and converted by `?syconv`.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Indicates how the input matrix A has been factored:
	If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U \cdot D \cdot U^H$.
	If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L \cdot D \cdot L^H$.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>a, b</code>	COMPLEX for <code>chetrs2</code> DOUBLE COMPLEX for <code>zhetrs2</code> Arrays: $a(1:da, :)$, $b(1:db, :)$.
	The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?hetrf</code> .
	The array b contains the right-hand side matrix B .
	The second dimension of a must be at least $\max(1, n)$, and the second dimension of b at least $\max(1, nrhs)$.
<code>lda</code>	INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.
<code>ipiv</code>	INTEGER. Array of DIMENSION n . The $ipiv$ array contains details of the interchanges and the block structure of D as determined by <code>?hetrf</code> .
<code>work</code>	COMPLEX for <code>chetrs2</code> DOUBLE COMPLEX for <code>zhetrs2</code> Workspace array, DIMENSION n .

Output Parameters

<code>b</code>	Overwritten by the solution matrix X .
<code>info</code>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrs2` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

See Also

[?hetrf](#)

[?syconv](#)

[?sptrs](#)

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call dsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call csptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call sptrs( ap, b, ipiv [, uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sptrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const <datatype>* ap, const lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine solves for X the system of linear equations $A^T X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

`if uplo='U',` $A = PUDU^TP^T$

`if uplo='L',` $A = PLDL^TP^T,$

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply the factor U (or L) and the array $ipiv$ returned by the factorization routine [?sptrf](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the array <i>ap</i> stores the packed factor U of the factorization $A = P^*U^*D^*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the packed factor L of the factorization $A = P^*L^*D^*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sptrf .
<i>ap, b</i>	REAL for ssptrs DOUBLE PRECISION for dsptrs COMPLEX for csptrs DOUBLE COMPLEX for zsptrs. Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*).
	The dimension of <i>ap</i> must be at least $\max(1,n(n+1)/2)$. The array <i>ap</i> contains the factor U or L , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptrs` interface are as follows:

<code>ap</code>	Holds the array A of size $(n^*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x)\varepsilon$$

where $\operatorname{cond}(A, x) = |||A^{-1}||A||x||||_\infty / ||x||_\infty \leq ||A^{-1}||_\infty ||A||_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?spcon](#).

To refine the solution and estimate the error, call [?sprfs](#).

?hptrs

Solves a system of linear equations with a UDU- or LDL-factored Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hptrs( ap, b, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>hptrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const <datatype>* ap, const lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`

- C: mkl.h

Description

The routine solves for X the system of linear equations $A^*X = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

```
if uplo='U',           A = P*U*D*UH*PT
if uplo='L',           A = P*L*D*LH*PT,
```

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

You must supply to this routine the arrays ap (containing U or L) and $ipiv$ in the form returned by the factorization routine [?hptrf](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the array ap stores the packed factor U of the factorization $A = P*U*D*UH*PT$. If <i>uplo</i> = 'L', the array ap stores the packed factor L of the factorization $A = P*L*D*LH*PT$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hptrf .
<i>ap, b</i>	COMPLEX for chptrs DOUBLE COMPLEX for zhptrs. Arrays: $ap(*)$, $b(ldb, *)$.
	The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrs` interface are as follows:

<code>ap</code>	Holds the array A of size $(n^*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^H|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^H|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x)\varepsilon$$

where $\operatorname{cond}(A, x) = |||A^{-1}|||A|||x|||_\infty / |||x|||_\infty \leq |||A^{-1}|||_\infty |||A|||_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?hpcon](#).

To refine the solution and estimate the error, call [?hprfs](#).

?trtrs

Solves a system of linear equations with a triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call strtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call dtrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ctrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ztrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call trtrs( a, b [,uplo] [, trans] [,diag] [,info] )
```

C:

```
lapack_int LAPACKE_<?>trtrs( int matrix_layout, char uplo, char trans, char diag,
lapack_int n, lapack_int nrhs, const <datatype>* a, lapack_int lda, <datatype>* b,
lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations with a triangular matrix A , with multiple right-hand sides stored in B :

$$\begin{aligned} A^*X = B && \text{if } \text{trans} = 'N', \\ A^T X = B && \text{if } \text{trans} = 'T', \\ A^H X = B && \text{if } \text{trans} = 'C' \text{ (for complex matrices only).} \end{aligned}$$

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <code>uplo</code> = 'U', then A is upper triangular. If <code>uplo</code> = 'L', then A is lower triangular.
<code>trans</code>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If <code>trans</code> = 'N', then $A^*X = B$ is solved for X . If <code>trans</code> = 'T', then $A^T X = B$ is solved for X . If <code>trans</code> = 'C', then $A^H X = B$ is solved for X .
<code>diag</code>	CHARACTER*1. Must be 'N' or 'U'. If <code>diag</code> = 'N', then A is not a unit triangular matrix. If <code>diag</code> = 'U', then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <code>a</code> .
<code>n</code>	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>a, b</code>	REAL for strtrs DOUBLE PRECISION for dtrtrs COMPLEX for ctrtrs

DOUBLE COMPLEX for ztrtrs.

Arrays: $a(1da, *)$, $b(1db, *)$.

The array a contains the matrix A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldb INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix X .

$info$ INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtrs` interface are as follows:

a Stands for argument `ap` in FORTRAN 77 interface. Holds the matrix A of size $(n * (n+1) / 2)$.

b Holds the matrix B of size $(n, nrhs)$.

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

$trans$ Must be '`N`', '`C`', or '`T`'. The default value is '`N`'.

$diag$ Must be '`N`' or '`U`'. The default value is '`N`'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x)\varepsilon \text{ provided } c(n) \operatorname{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = |||A^{-1}|||A|||x|||_\infty / |||x|||_\infty \leq |||A^{-1}|||_\infty |||A|||_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?trcon](#).

To estimate the error in the solution, call [?trrfs](#).

[?tptrs](#)

Solves a system of linear equations with a packed triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call dptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call cptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call zptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call tptrs( ap, b [,uplo] [, trans] [,diag] [,info] )
```

C:

```
lapack_int LAPACKE_<?>tptrs( int matrix_layout, char uplo, char trans, char diag,
lapack_int n, lapack_int nrhs, const <datatype>* ap, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations with a packed triangular matrix A , with multiple right-hand sides stored in B :

$$\begin{aligned} A^*X &= B && \text{if } \text{trans} = 'N', \\ A^T X &= B && \text{if } \text{trans} = 'T', \\ A^H X &= B && \text{if } \text{trans} = 'C' \text{ (for complex matrices only).} \end{aligned}$$

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

`uplo` CHARACTER*1. Must be 'U' or 'L'.

Indicates whether A is upper or lower triangular:

	If <i>uplo</i> = 'U', then <i>A</i> is upper triangular.
	If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
	If <i>trans</i> = 'N', then <i>A</i> * <i>X</i> = <i>B</i> is solved for <i>X</i> .
	If <i>trans</i> = 'T', then <i>A</i> ^T * <i>X</i> = <i>B</i> is solved for <i>X</i> .
	If <i>trans</i> = 'C', then <i>A</i> ^H * <i>X</i> = <i>B</i> is solved for <i>X</i> .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.
	If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix.
	If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of <i>A</i> ; the number of rows in <i>B</i> ; <i>n</i> ≥ 0.
<i>nrhs</i>	INTEGER. The number of right-hand sides; <i>nrhs</i> ≥ 0.
<i>ap, b</i>	REAL for stptrs DOUBLE PRECISION for dtptrs COMPLEX for ctptrs DOUBLE COMPLEX for ztptrs. Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*).
	The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes).
	The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; <i>ldb</i> ≥ $\max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tptrs` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.

<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon |A|$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\begin{array}{ccccccccc} & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \\ & | & \dots & : & : & : & : & : & : \end{array}$$

where $\text{cond}(A, x) = ||A^{-1}||\|A\| \|x\|_\infty / \|x\|_\infty \leq ||A^{-1}||_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tpcon](#).

To estimate the error in the solution, call [?tprrfs](#).

?tbtrs

Solves a system of linear equations with a band triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call dtbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call ctbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call ztbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call tbtrs( ab, b [, uplo] [, trans] [, diag] [, info] )
```

C:

```
lapack_int LAPACKE_<?>tbtrs( int matrix_layout, char uplo, char trans, char diag,
lapack_int n, lapack_int kd, lapack_int nrhs, const <datatype>* ab, lapack_int ldab,
<datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the following systems of linear equations with a band triangular matrix A , with multiple right-hand sides stored in B :

$$\begin{aligned} A^*X = B & \quad \text{if } trans='N', \\ A^T*X = B & \quad \text{if } trans='T', \\ A^H*X = B & \quad \text{if } trans='C' \text{ (for complex matrices only).} \end{aligned}$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', then $A^*X = B$ is solved for X . If <i>trans</i> = 'T', then $A^T*X = B$ is solved for X . If <i>trans</i> = 'C', then $A^H*X = B$ is solved for X .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ab</i> .
<i>n</i>	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for stbtrs DOUBLE PRECISION for dtbtrs COMPLEX for ctbtrs DOUBLE COMPLEX for ztbtrs. Arrays: <i>ab</i> (<i>ldab</i> , *), <i>b</i> (<i>ldb</i> , *).

The array ab contains the matrix A in *band storage form*.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The second dimension of ab must be at least $\max(1, n)$, the second dimension of b at least $\max(1, \text{nrhs})$.

1dab

INTEGER. The leading dimension of ab ; $ldab \geq kd + 1$.

1db

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b

Overwritten by the solution matrix X .

info

INTEGER. If *info*=0, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbtrs` interface are as follows:

ab

Holds the array A of size $(kd+1, n)$

b

Holds the matrix B of size (n, nrhs) .

uplo

Must be 'U' or 'L'. The default value is 'U'.

trans

Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n) s |\Lambda|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

.....

where $\text{cond}(A, x) = \|\|A^{-1}\|A\| |x|\|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n*kd$ for real flavors and $8n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tbcon](#).

To estimate the error in the solution, call [?tbrfs](#).

Routines for Estimating the Condition Number

This section describes the LAPACK routines for estimating the *condition number* of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations (see [Error Analysis](#)). Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

[?gecon](#)

Estimates the reciprocal of the condition number of a general matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call dgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call cgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
call zgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call gecon( a, anorm, rcond [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_sgecon( int matrix_layout, char norm, lapack_int n, const float* a,
                            lapack_int lda, float anorm, float* rcond );
lapack_int LAPACKE_dgecon( int matrix_layout, char norm, lapack_int n, const double* a,
                            lapack_int lda, double anorm, double* rcond );
lapack_int LAPACKE_cgecon( int matrix_layout, char norm, lapack_int n,
                           const lapack_complex_float* a, lapack_int lda, float anorm, float* rcond );
lapack_int LAPACKE_zgecon( int matrix_layout, char norm, lapack_int n,
                           const lapack_complex_double* a, lapack_int lda, double anorm, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a general matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute anorm (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?getrf](#) to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i> , <i>work</i>	REAL for sgecon DOUBLE PRECISION for dgecon COMPLEX for cgecon DOUBLE COMPLEX for zgecon. Arrays: <i>a</i> (<i>lda</i> , *), <i>work</i> (*). The array <i>a</i> contains the LU -factored matrix A , as returned by ?getrf . The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 4*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the original matrix A (see Description).
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cgecon DOUBLE PRECISION for zgecon. Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gecon` interface are as follows:

`a` Holds the matrix A of size (n, n) .

`norm` Must be '`1`', '`0`', or '`I`'. The default value is '`1`'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$ or $A^{H*}x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n^2$ floating-point operations for real flavors and $8*n^2$ for complex flavors.

?gbcon

Estimates the reciprocal of the condition number of a band matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info )
call dgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info )
call cgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info )
call zgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call gbcon( ab, ipiv, anorm, rcond [,kl] [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_sgbcon( int matrix_layout, char norm, lapack_int n, lapack_int kl,
                           lapack_int ku, const float* ab, lapack_int ldab, const lapack_int* ipiv, float anorm,
                           float* rcond );
lapack_int LAPACKE_dgbcon( int matrix_layout, char norm, lapack_int n, lapack_int kl,
                           lapack_int ku, const double* ab, lapack_int ldab, const lapack_int* ipiv, double
                           anorm, double* rcond );
lapack_int LAPACKE_cgbcon( int matrix_layout, char norm, lapack_int n, lapack_int kl,
                           lapack_int ku, const lapack_complex_float* ab, lapack_int ldab, const lapack_int* ipiv,
                           float anorm, float* rcond );
lapack_int LAPACKE_zgbcon( int matrix_layout, char norm, lapack_int n, lapack_int kl,
                           lapack_int ku, const lapack_complex_double* ab, lapack_int ldab, const lapack_int*
                           ipiv, double anorm, double* rcond );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a general band matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = ||A||_1 ||A^{-1}||_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = ||A||_\infty ||A^{-1}||_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute anorm (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call [?gbtrf](#) to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'.
	If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm.
	If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>k1</i>	INTEGER. The number of subdiagonals within the band of A ; $k1 \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . ($ldab \geq 2*k1 + ku + 1$).
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf .
<i>ab, work</i>	REAL for sgbccon DOUBLE PRECISION for dgbccon COMPLEX for cgbccon DOUBLE COMPLEX for zgbccon. Arrays: <i>ab</i> (<i>ldab, *</i>), <i>work</i> (*).
	The array <i>ab</i> contains the factored band matrix A , as returned by ?gbtrf .
	The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine.
	The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see [Description](#)).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork

REAL for cgbcon

DOUBLE PRECISION for zgbcon .

Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

rcond

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets *rcond* = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info

INTEGER. If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine gbcon interface are as follows:

ab

Holds the array A of size $(2*k1+ku+1, n)$.

ipiv

Holds the vector of length n .

norm

Must be '1', 'O', or 'I'. The default value is '1'.

k1

If omitted, assumed $k1 = ku$.

ku

Restored as $ku = lda - 2*k1 - 1$.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$ or $A^{H*}x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n(ku + 2k1)$ floating-point operations for real flavors and $8n(ku + 2k1)$ for complex flavors.

?gtcon

Estimates the reciprocal of the condition number of a tridiagonal matrix using the factorization computed by [?gttrf](#).

Syntax

FORTRAN 77:

```
call sgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info )
call dgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info )
call cgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
call zgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call gtcon( dl, d, du, du2, ipiv, anorm, rcond [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_sgtcon( char norm, lapack_int n, const float* dl, const float* d,
                           const float* du, const float* du2, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_dgtcon( char norm, lapack_int n, const double* dl, const double* d,
                           const double* du, const double* du2, const lapack_int* ipiv, double anorm, double* rcond );
lapack_int LAPACKE_cgtcon( char norm, lapack_int n, const lapack_complex_float* dl,
                           const lapack_complex_float* d, const lapack_complex_float* du,
                           const lapack_complex_float* du2, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_zgtcon( char norm, lapack_int n, const lapack_complex_double* dl,
                           const lapack_complex_double* d, const lapack_complex_double* du,
                           const lapack_complex_double* du2, const lapack_int* ipiv, double anorm, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a real or complex tridiagonal matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = ||A||_1 ||A^{-1}||_1$$

$$\kappa_\infty(A) = ||A||_\infty ||A^{-1}||_\infty$$

An estimate is obtained for $||A^{-1}||$, and the reciprocal of the condition number is computed as $rcond = 1 / (||A|| \cdot ||A^{-1}||)$.

Before calling this routine:

- compute $anorm$ (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call `?gttrf` to compute the LU factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

norm

CHARACTER*1. Must be '1' or 'O' or 'I'.

If $norm = '1'$ or ' ∞ ', then the routine estimates the condition number of matrix A in 1-norm.

If $norm = 'I'$, then the routine estimates the condition number of matrix A in infinity-norm.

n

INTEGER. The order of the matrix A ; $n \geq 0$.

$dl, d, du, du2$

REAL for sgtcon

DOUBLE PRECISION for dgtcon

COMPLEX for cgtcon

DOUBLE COMPLEX for zgtcon.

Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $du2(n - 2)$.

The array dl contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A as computed by [?gttrf](#).

The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

The array du contains the $(n - 1)$ elements of the first superdiagonal of U .

The array $du2$ contains the $(n - 2)$ elements of the second superdiagonal of U .

$ipiv$

INTEGER.

Array, DIMENSION (n) . The array of pivot indices, as returned by [?gttrf](#).

$anorm$

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

$work$

REAL for sgtcon

DOUBLE PRECISION for dgtcon

COMPLEX for cgtcon

DOUBLE COMPLEX for zgtcon.

Workspace array, DIMENSION $(2*n)$.

$iwork$

INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.

Output Parameters

$rcond$

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond=0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

<i>d1</i>	Holds the vector of length (<i>n</i> -1).
<i>d</i>	Holds the vector of length <i>n</i> .
<i>du</i>	Holds the vector of length (<i>n</i> -1).
<i>du2</i>	Holds the vector of length (<i>n</i> -2).
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pocon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call dpocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call cpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
call zpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pocon( a, anorm, rcond [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_spocon( int matrix_layout, char uplo, lapack_int n, const float* a,
                           lapack_int lda, float anorm, float* rcond );
lapack_int LAPACKE_dpocon( int matrix_layout, char uplo, lapack_int n, const double* a,
                           lapack_int lda, double anorm, double* rcond );
lapack_int LAPACKE_cpocon( int matrix_layout, char uplo, lapack_int n,
                           const lapack_complex_float* a, lapack_int lda, float anorm, float* rcond );
```

```
lapack_int LAPACKE_zpocon( int matrix_layout, char uplo, lapack_int n,
const lapack_complex_double* a, lapack_int lda, double anorm, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is symmetric or Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute anorm (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call [?potrf](#) to compute the Cholesky factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i> , <i>work</i>	REAL for <i>sopocon</i> DOUBLE PRECISION for <i>dpocon</i> COMPLEX for <i>cpocon</i> DOUBLE COMPLEX for <i>zpocon</i> . Arrays: <i>a</i> (<i>lda</i> , *), <i>work</i> (*). The array <i>a</i> contains the factored matrix A , as returned by ?potrf . The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $\text{lda} \geq \max(1, n)$.
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pocon` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?ppcon

Estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```

call sppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call dppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call cppcon( uplo, n, ap, anorm, rcond, work, rwork, info )
call zppcon( uplo, n, ap, anorm, rcond, work, rwork, info )

```

Fortran 95:

```
call ppcon( ap, anorm, rcond [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_sppcon( int matrix_layout, char uplo, lapack_int n, const float* ap,
float anorm, float* rcond );

lapack_int LAPACKE_dppcon( int matrix_layout, char uplo, lapack_int n, const double* ap,
double anorm, double* rcond );

lapack_int LAPACKE_cppcon( int matrix_layout, char uplo, lapack_int n,
const lapack_complex_float* ap, float anorm, float* rcond );

lapack_int LAPACKE_zppcon( int matrix_layout, char uplo, lapack_int n,
const lapack_complex_double* ap, double anorm, double* rcond );
```

Description

The routine estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = ||A||_1 \ ||A^{-1}||_1 \ (\text{since } A \text{ is symmetric or Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute anorm (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call [?ptrf](#) to compute the Cholesky factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap, work</i>	REAL for sppcon DOUBLE PRECISION for dppcon COMPLEX for cppcon DOUBLE COMPLEX for zppcon. Arrays: <i>ap</i> (*), <i>work</i> (*).
	The array <i>ap</i> contains the packed factored matrix A , as returned by ?ptrf . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for *cpbcon*

DOUBLE PRECISION for *zpbcon*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets *rcond* = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ppbcon* interface are as follows:

ap Holds the array A of size $(n * (n+1) / 2)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pbcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call dpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call cpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
call zpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pbcon( ab, anorm, rcond [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_spbcon( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
                           const float* ab, lapack_int ldab, float anorm, float* rcond );

Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix A :

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is symmetric or Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute anorm (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call [?pbtrf](#) to compute the Cholesky factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> .
	If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . ($ldab \geq kd + 1$).
<i>ab, work</i>	REAL for spbcon DOUBLE PRECISION for dpbcon COMPLEX for cpbcon DOUBLE COMPLEX for zpbcon.

Arrays: $ab(1:dab, \cdot)$, $work(\cdot)$.

The array *ab* contains the factored matrix *A* in band form, as returned by [?pbtrf](#). The second dimension of *ab* must be at least $\max(1, n)$.

The array `work` is a workspace for the routine. The dimension of `work` must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

anorm

`REAL` for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork

REAL for cpbcon

DOUBLE PRECISION for zpbcon.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info

INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbcon` interface are as follows:

ab

Holds the array A of size $(kd+1, n)$.

uplo

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n(kd + 1)$ floating-point operations for real flavors and $16*n(kd + 1)$ for complex flavors.

?ptcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax**FORTRAN 77:**

```
call sptcon( n, d, e, anorm, rcond, work, info )
call dptcon( n, d, e, anorm, rcond, work, info )
call cptcon( n, d, e, anorm, rcond, work, info )
call zptcon( n, d, e, anorm, rcond, work, info )
```

Fortran 95:

```
call ptcon( d, e, anorm, rcond [,info] )
```

C:

```
lapack_int LAPACKE_sptcon( lapack_int n, const float* d, const float* e, float anorm,
float* rcond );

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the reciprocal of the condition number (in the 1-norm) of a real symmetric or complex Hermitian positive-definite tridiagonal matrix using the factorization $A = L*D*L^T$ for real flavors and $A = L*D*L^H$ for complex flavors or $A = U^T*D*U$ for real flavors and $A = U^H*D*U$ for complex flavors computed by [?pttrf](#) :

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is symmetric or Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

The norm $||A^{-1}||$ is computed by a direct method, and the reciprocal of the condition number is computed as $rcond = 1 / (||A|| \cdot ||A^{-1}||)$.

Before calling this routine:

- compute *anorm* as $||A||_1 = \max_j \sum_i |a_{ij}|$
- call [?pttrf](#) to compute the factorization of *A*.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>d, work</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, dimension (n). The array d contains the n diagonal elements of the diagonal matrix D from the factorization of A , as computed by ?pttrf ; $work$ is a workspace array.
<i>e</i>	REAL for $sptcon$ DOUBLE PRECISION for $dptcon$ COMPLEX for $cptcon$ DOUBLE COMPLEX for $zptcon$. Array, DIMENSION ($n - 1$). Contains off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ?pttrf .
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The 1- norm of the <i>original</i> matrix A (see <i>Description</i>).

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length ($n-1$).

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n(kd + 1)$ floating-point operations for real flavors and $16*n(kd + 1)$ for complex flavors.

?sycon

Estimates the reciprocal of the condition number of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssycon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call dsycon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call csycon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zsycon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call sycon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_ssycon( int matrix_layout, char uplo, lapack_int n, const float* a,
                            lapack_int lda, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_dsycon( int matrix_layout, char uplo, lapack_int n, const double* a,
                            lapack_int lda, const lapack_int* ipiv, double anorm, double* rcond );

Description

The routine estimates the reciprocal of the condition number of a symmetric matrix A :

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is symmetric}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute $anorm$ (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call `?sytrf_rook` to compute the factorization of A .

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
-------------------	--

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U*D*U^T$.

If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L*D*L^T$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

$a, work$

REAL for ssycon_rook

DOUBLE PRECISION for dsycon_rook

COMPLEX for csycon_rook

DOUBLE COMPLEX for zsycon_rook.

Arrays: $a(1:n, :)$, $work(*)$.

The array a contains the factored matrix A , as returned by [?sytrf_rook](#). The second dimension of a must be at least $\max(1, n)$.

The array $work$ is a workspace for the routine.

The dimension of $work$ must be at least $\max(1, 2*n)$.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

$ipiv$

INTEGER. Array, size at least $\max(1, n)$.

The array $ipiv$, as returned by [?sytrf_rook](#).

$anorm$

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

$iwork$

INTEGER. Workspace array, size at least $\max(1, n)$.

Output Parameters

$rcond$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sycon_rook` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine estimates the reciprocal of the condition number of a Hermitian matrix A :

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute $anorm$ (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call `?hetrf` to compute the factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = P^*U*D*U^H*P^T$.

If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = P^*L*D*L^H*P^T$.

*n*INTEGER. The order of matrix A ; $n \geq 0$.*a, work*

COMPLEX for checon

DOUBLE COMPLEX for zhecon.

Arrays: $a(1da, *)$, $work(*)$.

The array a contains the factored matrix A , as returned by [?hetrf](#).
The second dimension of a must be at least $\max(1, n)$.

The array $work$ is a workspace for the routine.

The dimension of $work$ must be at least $\max(1, 2*n)$.

*lda*INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.*ipiv*INTEGER. Array, DIMENSION at least $\max(1, n)$.

The array $ipiv$, as returned by [?hetrf](#).

anorm

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

Output Parameters

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

*info*INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hecon` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?hecon_rook

Estimates the reciprocal of the condition number of a Hermitian matrix using factorization obtained with one of the bounded diagonal pivoting methods (max 2 interchanges).

Syntax

FORTRAN 77:

```
call checon_rook( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zhecon_rook( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hecon_rook( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine estimates the reciprocal of the condition number of a Hermitian matrix A using the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ computed by [?hetrf_rook](#).

An estimate is obtained for $\text{norm}(A^{-1})$, and the reciprocal of the condition number is computed as $rcond = 1/(anorm*\text{norm}(A^{-1}))$.

Input Parameters

`uplo` CHARACTER*1. Must be '`U`' or '`L`'.

Indicates how the input matrix A has been factored:

If `uplo` = '`U`', the array `a` stores the upper triangular factor U of the factorization $A = U^*D^*U^H$.

If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L \cdot D \cdot L^H$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

a, work

COMPLEX for checon_rook

COMPLEX*16 for zhecon_rook.

Arrays: $a(1:n, 1:n)$, $work(1:n)$.

The array a contains the factored matrix A , as returned by [?hetrf_rook](#). The second dimension of a must be at least $\max(1, n)$.

The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 2*n)$.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ipiv

INTEGER. Array, size at least $\max(1, n)$.

The array $ipiv$, as returned by [?hetrf_rook](#).

anorm

REAL for checon_rook

DOUBLE PRECISION for zhecon_rook.

The 1-norm of the original matrix A (see *Description*).

Output Parameters

rcond

REAL for checon_rook

DOUBLE PRECISION for zhecon_rook.

The reciprocal of the condition number of the matrix A , computed as $rcond = 1/(anorm * ainvnm)$, where $ainvnm$ is an estimate of the 1-norm of A^{-1} computed in this routine.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hecon_rook` interface are as follows:

a

Holds the matrix A of size (n, n) .

ipiv

Holds the vector of length n .

uplo

Must be '`U`' or '`L`'. The default value is '`U`'.

Description

The routine estimates the reciprocal of the condition number of a packed symmetric matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute anorm (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?sptrf` to compute the factorization of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array ap stores the packed upper triangular factor U of the factorization $A = P^*U^*D^*U^T*P^T$.

If $uplo = 'L'$, the array ap stores the packed lower triangular factor L of the factorization $A = P^T L D L^T P$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

ap, work

REAL for sspcon

DOUBLE PRECISION for dspcon

COMPLEX for cspcon

DOUBLE COMPLEX for zspcon.

Arrays: $ap(*)$, $work(*)$.

The array ap contains the packed factored matrix A , as returned by [?sptrf](#). The dimension of ap must be at least $\max(1, n(n+1)/2)$.

The array $work$ is a workspace for the routine.

The dimension of $work$ must be at least $\max(1, 2*n)$.

ipiv

INTEGER. Array, DIMENSION at least $\max(1, n)$.

The array $ipiv$, as returned by [?sptrf](#).

anorm

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spcon` interface are as follows:

ap

Holds the array A of size $(n*(n+1)/2)$.

ipiv

Holds the vector of length n .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?hpcon

Estimates the reciprocal of the condition number of a packed Hermitian matrix.

Syntax

FORTRAN 77:

```
call chpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
call zhpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hpcon( ap, ipiv, anorm, rcond [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_chpcon( int matrix_layout, char uplo, lapack_int n,
                           const lapack_complex_float* ap, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_zhpcon( int matrix_layout, char uplo, lapack_int n,
                           const lapack_complex_double* ap, const lapack_int* ipiv, double anorm, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90

Description

The routine estimates the reciprocal of the condition number of a Hermitian matrix *A*:

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1 \quad (\text{since } A \text{ is Hermitian}, \kappa_\infty(A) = \kappa_1(A)).$$

Before calling this routine:

- compute *anorm* (either $||A||_1 = \max_j \sum_i |a_{ij}|$ or $||A||_\infty = \max_i \sum_j |a_{ij}|$)
- call ?hptrf to compute the factorization of *A*.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo CHARACTER*1. Must be 'U' or 'L'.

Indicates how the input matrix *A* has been factored:

If *uplo* = 'U', the array *ap* stores the packed upper triangular factor *U* of the factorization $A = P^*U^*D^*U^T*P^T$.

If $uplo = 'L'$, the array ap stores the packed lower triangular factor L of the factorization $A = P^T L D L^T P$.

n INTEGER. The order of matrix A ; $n \geq 0$.

$ap, work$ COMPLEX for chpcon

DOUBLE COMPLEX for zhpcon.

Arrays: $ap(*)$, $work(*)$.

The array ap contains the packed factored matrix A , as returned by [?hptrf](#). The dimension of ap must be at least $\max(1, n(n+1)/2)$.

The array $work$ is a workspace for the routine.

The dimension of $work$ must be at least $\max(1, 2*n)$.

$ipiv$ INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$, as returned by [?hptrf](#).

$anorm$ REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix A (see *Description*).

Output Parameters

$rcond$ REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

$info$ INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbcon` interface are as follows:

ap Holds the array A of size $(n*(n+1)/2)$.

$ipiv$ Holds the vector of length n .

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?trcon

Estimates the reciprocal of the condition number of a triangular matrix.

Syntax

FORTRAN 77:

```
call strcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call dtrcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call ctrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
call ztrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
```

Fortran 95:

```
call trcon( a, rcond [,uplo] [,diag] [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_strcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const float* a, lapack_int lda, float* rcond );
lapack_int LAPACKE_dtrcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const double* a, lapack_int lda, double* rcond );
lapack_int LAPACKE_ctrcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const lapack_complex_float* a, lapack_int lda, float* rcond );
lapack_int LAPACKE_ztrcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const lapack_complex_double* a, lapack_int lda, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a triangular matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

norm

CHARACTER*1. Must be '1' or 'O' or 'I'.

If $norm = '1'$ or ' ∞ ', then the routine estimates the condition number of matrix A in 1-norm.

If $norm = 'I'$, then the routine estimates the condition number of matrix A in infinity-norm.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether A is upper or lower triangular:

If $uplo = 'U'$, the array a stores the upper triangle of A , other array elements are not referenced.

If $uplo = 'L'$, the array a stores the lower triangle of A , other array elements are not referenced.

diag

CHARACTER*1. Must be 'N' or 'U'.

If $diag = 'N'$, then A is not a unit triangular matrix.

If $diag = 'U'$, then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array a .

n

INTEGER. The order of the matrix A ; $n \geq 0$.

a, work

REAL for strcon

DOUBLE PRECISION for dtrcon

COMPLEX for ctrcon

DOUBLE COMPLEX for ztrcon.

Arrays: $a(1:n, :)$, $work(1:n)$.

The array a contains the matrix A . The second dimension of a must be at least $\max(1, n)$.

The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork

REAL for ctrcon

DOUBLE PRECISION for ztrcon.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trcon` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations *A***x* = *b*; the number is usually 4 or 5 and never more than 11. Each solution requires approximately *n*² floating-point operations for real flavors and 4*n*² operations for complex flavors.

?tpcon

Estimates the reciprocal of the condition number of a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call dtpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call ctpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
call ztpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
```

Fortran 95:

```
call tpcon( ap, rcond [,uplo] [,diag] [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_stpcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const float* ap, float* rcond );
lapack_int LAPACKE_dtpcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const double* ap, double* rcond );
lapack_int LAPACKE_ctpcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const lapack_complex_float* ap, float* rcond );
lapack_int LAPACKE_ztpcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, const lapack_complex_double* ap, double* rcond );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine estimates the reciprocal of the condition number of a packed triangular matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of A in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of A in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap, work</i>	REAL for stpcon DOUBLE PRECISION for dtpcon COMPLEX for ctpcon DOUBLE COMPLEX for ztpcon. Arrays: <i>ap(*)</i> , <i>work(*)</i> . The array <i>ap</i> contains the packed matrix A . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctpcon</i> DOUBLE PRECISION for <i>ztpcon</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.
	An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tpcon* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

?tbcon

Estimates the reciprocal of the condition number of a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call dtbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call ctbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
call ztbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
```

Fortran 95:

```
call tbcon( ab, rcond [,uplo] [,diag] [,norm] [,info] )
```

C:

```
lapack_int LAPACKE_stbcon( int matrix_layout, char norm, char uplo, char diag,
                           lapack_int n, lapack_int kd, const float* ab, lapack_int ldab, float* rcond );
lapack_int LAPACKE_dtbcon( int matrix_layout, char norm, char uplo, char diag,

Description

The routine estimates the reciprocal of the condition number of a triangular band matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of A in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of A in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix.

If $diag = 'U'$, then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array ab .

n

INTEGER. The order of the matrix A ; $n \geq 0$.

kd

INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.

ab, work

REAL for `stbcon`

DOUBLE PRECISION for `dtbcon`

COMPLEX for `ctbcon`

DOUBLE COMPLEX for `ztbcon`.

Arrays: $ab(1:dab, *)$, $work(*)$.

The array ab contains the band matrix A . The second dimension of ab must be at least $\max(1, n)$. The array $work$ is a workspace for the routine.

The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldab

INTEGER. The leading dimension of the array ab . ($ldab \geq kd + 1$).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork

REAL for `ctbcon`

DOUBLE PRECISION for `ztbcon`.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbccon` interface are as follows:

ab

Holds the array A of size $(kd+1, n)$.

<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n(kd + 1)$ floating-point operations for real flavors and $8*n(kd + 1)$ operations for complex flavors.

Refining the Solution and Estimating Its Error

This section describes the LAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Routines for Solving Systems of Linear Equations](#)).

?gerfs

Refines the solution of a system of linear equations with a general matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work,
iwork, info )
call dgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work,
iwork, info )
call cgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work,
rwork, info )
call zgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work,
rwork, info )
```

Fortran 95:

```
call gerfs( a, af, ipiv, b, x [,trans] [,ferr] [,berr] [,info] )
```

C:

```
lapack_int LAPACKE_sgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const float* a, lapack_int lda, const float* af, lapack_int ldaf,
const lapack_int* ipiv, const float* b, lapack_int ldb, float* x, lapack_int ldx,
float* ferr, float* berr );
lapack_int LAPACKE_dgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const double* a, lapack_int lda, const double* af, lapack_int ldaf,
const lapack_int* ipiv, const double* b, lapack_int ldb, double* x, lapack_int ldx,
double* ferr, double* berr );
lapack_int LAPACKE_cgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* af,
lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* x, lapack_int ldx, float* ferr, float* berr );
```

```
lapack_int LAPACKE_zgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* af,
lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_double* b, lapack_int
ldb, lapack_complex_double* x, lapack_int ldx, double* ferr, double* berr );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^T X = B$ or $A^H X = B$ with a general matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?getrf](#)
- call the solver routine [?getrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^T X = B$. If <i>trans</i> = 'T', the system has the form $A^H X = B$. If <i>trans</i> = 'C', the system has the form $A^T X = B$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	REAL for sgerfs DOUBLE PRECISION for dgerfs COMPLEX for cgerfs DOUBLE COMPLEX for zgerfs. Arrays: <i>a</i> (<i>lda</i> ,*) contains the original matrix A , as supplied to ?getrf . <i>af</i> (<i>ldaf</i> ,*) contains the factored matrix A , as returned by ?getrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix B .

`x(1:dx, *)` contains the solution matrix X .

`work(*)` is a workspace array.

The second dimension of `a` and `af` must be at least $\max(1, n)$; the second dimension of `b` and `x` must be at least $\max(1, nrhs)$; the dimension of `work` must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<code>lda</code>	INTEGER. The leading dimension of <code>a</code> ; $lda \geq \max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of <code>af</code> ; $ldaf \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The leading dimension of <code>b</code> ; $ldb \geq \max(1, n)$.
<code>ldx</code>	INTEGER. The leading dimension of <code>x</code> ; $ldx \geq \max(1, n)$.
<code>ipiv</code>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?getrf .
<code>iwork</code>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<code>rwork</code>	REAL for <code>cgerfs</code> DOUBLE PRECISION for <code>zgerfs</code> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<code>x</code>	The refined solution matrix X .
<code>ferr, berr</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gerfs` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>af</code>	Holds the matrix AF of size (n, n) .

<i>ipiv</i>	Holds the vector of length n .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gerfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a general matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x, idx,
rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork,
info )
call dgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x, idx,
rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork,
info )
call cgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x, idx,

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed`, `r`, and `c` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>trans</code>	CHARACTER*1. Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form $A^*X = B$ (No transpose). If <code>trans</code> = 'T', the system has the form $A^{**}T^*X = B$ (Transpose). If <code>trans</code> = 'C', the system has the form $A^{***}H^*X = B$ (Conjugate transpose = Transpose).
<code>equed</code>	CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. Specifies the form of equilibration that was done to A before calling this routine.

If $\text{equed} = \text{'N'}$, no equilibration was done.

If $\text{equed} = \text{'R'}$, row equilibration was done, that is, A has been premultiplied by $\text{diag}(r)$.

If $\text{equed} = \text{'C'}$, column equilibration was done, that is, A has been postmultiplied by $\text{diag}(c)$.

If $\text{equed} = \text{'B'}$, both row and column equilibration was done, that is, A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$. The right-hand side B has been changed accordingly.

n

INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

a, af, b, work

REAL for sgerfsx

DOUBLE PRECISION for dgerfsx

COMPLEX for cgerfsx

DOUBLE COMPLEX for zgerfsx.

Arrays: $a(1da, *)$, $af(1daf, *)$, $b(1db, *)$, $work(*)$.

The array a contains the original n -by- n matrix A .

The array af contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = P * L * U$ as computed by [?getrf](#).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4 * n)$ for real flavors, and at least $\max(1, 2 * n)$ for complex flavors.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldaf

INTEGER. The leading dimension of af ; $ldaf \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices as computed by [?getrf](#); for row $1 \leq i \leq n$, row i of the matrix was interchanged with row $ipiv(i)$.

r, c

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: $r(n)$, $c(n)$. The array r contains the row scale factors for A , and the array c contains the column scale factors for A .

$\text{equed} = \text{'R'}$ or 'B' , A is multiplied on the left by $\text{diag}(r)$; if $\text{equed} = \text{'N'}$ or 'C' , r is not accessed.

If $\text{equed} = \text{'R'}$ or 'B' , each element of r must be positive.

If $\text{equed} = \text{'C'}$ or 'B' , A is multiplied on the right by $\text{diag}(c)$; if $\text{equed} = \text{'N'}$ or 'R' , c is not accessed.

If $\text{equed} = \text{'C'}$ or 'B' , each element of c must be positive.

Each element of r or c should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

x

REAL for sgerfsx

DOUBLE PRECISION for dgerfsx

COMPLEX for cgerfsx

DOUBLE COMPLEX for zgerfsx .

Array, DIMENSION ($l_{\text{dx}}, *$).

The solution matrix X as computed by [?getrs](#)

l_{dx}

INTEGER. The leading dimension of the output array x ; $l_{\text{dx}} \geq \max(1, n)$.

$n_{\text{err_bnds}}$

INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in *Output Arguments* section below.

n_{params}

INTEGER. Specifies the number of parameters set in params . If ≤ 0 , the params array is never referenced and default values are used.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION n_{params} . Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to n_{params} are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $n_{\text{params}} = 0$, which prevents the source code from accessing the params argument.

$\text{params}(\text{la_linrx_itref_i} = 1)$: Whether to perform iterative refinement or not. Default: 1.0

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.

(Other values are reserved for future use.)

$\text{params}(\text{la_linrx_ithresh_i} = 2)$: Maximum number of residual computations allowed for refinement.

Default

10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params(la_linrx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for `sgerfsx`

DOUBLE PRECISION for `dgerfsx`

COMPLEX for `cgerfsx`

DOUBLE COMPLEX for `zgerfsx`.

The improved solution matrix *X*.

rcond REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector *x(j)*, that is, the smallest relative change in any element of *A* or *B* that makes *x(j)* an exact solution.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z .

Let $z = s^*a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (`nrhs, n_err_bnds`). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then err_bnds_comp is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in $\text{err_bnds_comp}(i, :)$ corresponds to the i -th right-hand side.

The second index in $\text{err_bnds_comp}(:, \text{err})$ contains the following three fields:

$\text{err}=1$ "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

$\text{err}=2$ "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

$\text{err}=3$ Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Output parameter only if the input contains erroneous values, namely, in $\text{params}(1)$, $\text{params}(2)$, $\text{params}(3)$. In such a case, the corresponding elements of params are filled with default values on output.

info

INTEGER. If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$). See the definition of $\text{err_bnds_norm}(:, 1)$ and $\text{err_bnds_comp}(:, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?gbrfs

Refines the solution of a system of linear equations with a general band matrix and estimates its error.

Syntax

FORTRAN 77:

```

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gbtrf](#)
- call the solver routine [?gbtrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T*X = B$. If <i>trans</i> = 'C', the system has the form $A^H*X = B$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for sgbrfs DOUBLE PRECISION for dgbrfs COMPLEX for cgbrfs DOUBLE COMPLEX for zgbrfs. Arrays:

ab(*ldab*, *) contains the original band matrix *A*, as supplied to [?gbtrf](#), but stored in rows from 1 to *kl* + *ku* + 1.

afb(*ldafb*, *) contains the factored band matrix *A*, as returned by [?gbtrf](#).

b(*ldb*, *) contains the right-hand side matrix *B*.

x(*ldx*, *) contains the solution matrix *X*.

work(*) is a workspace array.

The second dimension of *ab* and *afb* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldab

INTEGER. The leading dimension of *ab*.

ldafb

INTEGER. The leading dimension of *afb*.

ldb

INTEGER. The leading dimension of *b*; *ldb* $\geq \max(1, n)$.

ldx

INTEGER. The leading dimension of *x*; *ldx* $\geq \max(1, n)$.

ipiv

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?gbtrf](#).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork

REAL for *cgbtrfs*

DOUBLE PRECISION for *zgbtrfs*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x

The refined solution matrix *X*.

ferr, *berr*

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbrfs* interface are as follows:

<i>ab</i>	Holds the array A of size $(kl+ku+1, n)$.
<i>afb</i>	Holds the array AF of size $(2*kl*ku+1, n)$.
<i>ipiv</i>	Holds the vector of length n .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda - kl - 1$.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n(kl + ku)$ floating-point operations (for real flavors) or $16n(kl + ku)$ operations (for complex flavors). In addition, each step of iterative refinement involves $2n(4kl + 3ku)$ operations (for real flavors) or $8n(4kl + 3ku)$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gbrfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a banded matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sgbrfsx( trans, equed, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, r, c, b, ldb,
x, ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparms, params, work,
iwork, info )

 - C: mkl.h

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed*, *r*, and *c* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

trans CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If $trans = 'N'$, the system has the form A^*x

If $\text{trans} = \text{'T'}$, the system has the form $A^{**} T^* X = B$ (Transpose).

If $\text{trans} = \text{'C'}$, the system has the form $A^{**} H^* X = B$ (Conjugate transpose = Transpose).

equed

CHARACTER*1. Must be 'N', 'R', 'C', or 'B'.

Specifies the form of equilibration that was done to A before calling this routine.

If $\text{equed} = \text{'N'}$, no equilibration was done.

If $\text{equed} = \text{'R'}$, row equilibration was done, that is, A has been premultiplied by $\text{diag}(r)$.

If $\text{equed} = \text{'C'}$, column equilibration was done, that is, A has been postmultiplied by $\text{diag}(c)$.

If $\text{equed} = \text{'B'}$, both row and column equilibration was done, that is, A has been replaced by $\text{diag}(r)^* A^* \text{diag}(c)$. The right-hand side B has been changed accordingly.

n

INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

k1

INTEGER. The number of subdiagonals within the band of A ; $k1 \geq 0$.

ku

INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.

nrhs

INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

ab, afb, b, work

REAL for sgbrfsx

DOUBLE PRECISION for dgbrfsx

COMPLEX for cgbrfsx

DOUBLE COMPLEX for zgbrfsx.

Arrays: $ab(1dab, *)$, $afb(1dafb, *)$, $b(1db, *)$, $work(*)$.

The array ab contains the original matrix A in band storage, in rows 1 to $k1 + ku + 1$. The j -th column of A is stored in the j -th column of the array ab as follows:

$ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+k1)$.

The array afb contains details of the LU factorization of the banded matrix A as computed by [?gbtrf](#). U is stored as an upper triangular banded matrix with $k1 + ku$ superdiagonals in rows 1 to $k1 + ku + 1$. The multipliers used during the factorization are stored in rows $k1 + ku + 2$ to $2*k1 + ku + 1$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

1dab

INTEGER. The leading dimension of the array ab ; $1dab \geq k1 + ku + 1$.

1dafb

INTEGER. The leading dimension of the array afb ; $1dafb \geq 2*k1 + ku + 1$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices as computed by [?gbtrf](#); for row $1 \leq i \leq n$, row i of the matrix was interchanged with row $ipiv(i)$.

r, c

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: $r(n)$, $c(n)$. The array r contains the row scale factors for A , and the array c contains the column scale factors for A .

If $equed = 'R'$ or $'B'$, A is multiplied on the left by $diag(r)$; if $equed = 'N'$ or $'C'$, r is not accessed.

If $equed = 'R'$ or $'B'$, each element of r must be positive.

If $equed = 'C'$ or $'B'$, A is multiplied on the right by $diag(c)$; if $equed = 'N'$ or $'R'$, c is not accessed.

If $equed = 'C'$ or $'B'$, each element of c must be positive.

Each element of r or c should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

*ldb*INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.*x*

REAL for sgbrfsx

DOUBLE PRECISION for dgbrfsx

COMPLEX for cgbrfsx

DOUBLE COMPLEX for zgbrfsx.

Array, DIMENSION ($lidx, *$).

The solution matrix X as computed by [sgbtrs/dgbtrs](#) for real flavors or [cgbtrs/zgbtrs](#) for complex flavors.

*lidx*INTEGER. The leading dimension of the output array x ; $lidx \geq \max(1, n)$.*n_err_bnds*

INTEGER. Number of error bounds to return for each right-hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in *Output Arguments* section below.

nparams

INTEGER. Specifies the number of parameters set in $params$. If ≤ 0 , the $params$ array is never referenced and default values are used.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used

for higher-numbered parameters. If defaults are acceptable, you can pass `nparams = 0`, which prevents the source code from accessing the `params` argument.

`params(la_linrx_itref_i = 1)` : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.
------	--

(Other values are reserved for future use.)

`params(la_linrx_ithresh_i = 2)` : Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <code>err_bnds_norm</code> and <code>err_bnds_comp</code> may no longer be trustworthy.
------------	---

`params(la_linrx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

`iwork` INTEGER. Workspace array, DIMENSION at least `max(1, n)`; used in real flavors only.

`rwork` REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least `max(1, 3*n)`; used in complex flavors only.

Output Parameters

`x` REAL for sgbrfsx
DOUBLE PRECISION for dgbrfsx
COMPLEX for cgbrfsx
DOUBLE COMPLEX for zgbrfsx.
The improved solution matrix X.

`rcond` REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $(nrhs, n_err_bnds)$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in $err_bnds_norm(i, :)$ corresponds to the i -th right-hand side.

The second index in $err_bnds_norm(:, err)$ contains the following three fields:

err=1

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors.

err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is

"guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION ($\text{nrhs}, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision

flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s^*(\alpha * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $\alpha * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

<i>params</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Output parameter only if the input contains erroneous values, namely, in <i>params</i> (1), <i>params</i> (2), <i>params</i> (3). In such a case, the corresponding elements of <i>params</i> are filled with default values on output.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = $n+j$: The solution corresponding to the <i>j</i> -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides <i>k</i> with <i>k</i> > <i>j</i> may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested <i>params</i> (3) = 0.0, then the <i>j</i> -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest <i>j</i> such that <i>err_bnds_norm(j, 1)</i> = 0.0 or <i>err_bnds_comp(j, 1)</i> = 0.0. See the definition of <i>err_bnds_norm(, 1)</i> and <i>err_bnds_comp(, 1)</i> . To get information about all of the right-hand sides, check <i>err_bnds_norm</i> or <i>err_bnds_comp</i> .

?gtrfs

Refines the solution of a system of linear equations with a tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^T X = B$ or $A^H X = B$ with a tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| / |a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| / |b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gttrf](#)
- call the solver routine [?gttrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

trans

CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If $\text{trans} = \text{'N'}$, the system has the form $A*X = B$.

If $\text{trans} = \text{'T'}$, the system has the form $A^T*X = B$.

If $\text{trans} = \text{'C'}$, the system has the form $A^H*X = B$.

n

INTEGER. The order of the matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.

dl,d,du,dlf,

df,duf,du2,

b,x,work

REAL for sgtrfs

DOUBLE PRECISION for dgtrfs

COMPLEX for cgtrfs

DOUBLE COMPLEX for zgtrfs.

Arrays:

dl, dimension $(n - 1)$, contains the subdiagonal elements of A .

d, dimension (n) , contains the diagonal elements of A .

du, dimension $(n - 1)$, contains the superdiagonal elements of A .

dlf, dimension $(n - 1)$, contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A as computed by [?gttrf](#).

df, dimension (n) , contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

duf, dimension $(n - 1)$, contains the $(n - 1)$ elements of the first superdiagonal of U .

du2, dimension $(n - 2)$, contains the $(n - 2)$ elements of the second superdiagonal of U .

b(1:db, nrhs) contains the right-hand side matrix B .

x(1:dx, nrhs) contains the solution matrix X , as computed by [?gttrs](#).

work()* is a workspace array; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb

INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ldx

INTEGER. The leading dimension of *x*; $ldx \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?gttrf](#).

iwork

INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.

rwork

REAL for cgtrfs

DOUBLE PRECISION for zgtrfs.

Workspace array, DIMENSION (n) . Used for complex flavors only.

Output Parameters

<i>x</i>	The refined solution matrix X .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.
	Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtrfs` interface are as follows:

<i>d1</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length n .
<i>du</i>	Holds the vector of length $(n-1)$.
<i>d1f</i>	Holds the vector of length $(n-1)$.
<i>df</i>	Holds the vector of length n .
<i>duf</i>	Holds the vector of length $(n-1)$.
<i>du2</i>	Holds the vector of length $(n-2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

?porfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```

call sporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr, work, iwork,

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?potrf](#)
- call the solver routine [?potrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; <i>n</i> \geq 0.
<i>nrhs</i>	INTEGER. The number of right-hand sides; <i>nrhs</i> \geq 0.
<i>a,af,b,x,work</i>	REAL for <i>sporfs</i> DOUBLE PRECISION for <i>dporfs</i> COMPLEX for <i>cporfs</i> DOUBLE COMPLEX for <i>zporfs</i> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the original matrix <i>A</i> , as supplied to ?potrf . <i>af</i> (<i>ldaf</i> ,*) contains the factored matrix <i>A</i> , as returned by ?potrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>idx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> $\geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> ; <i>ldaf</i> $\geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; <i>ldb</i> $\geq \max(1, n)$.
<i>idx</i>	INTEGER. The leading dimension of <i>x</i> ; <i>idx</i> $\geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cporfs</i> DOUBLE PRECISION for <i>zporfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `porfs` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?porfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric/Hermitian positive-definite matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sporfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, s, b, ldb, x, idx, rcond, berr,
n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork, info )

- **C:** mkl.h

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed* and *s* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of *A* is stored:

If $uplo = 'U'$, the upper triangle of A is stored.

If $uplo = 'L'$, the lower triangle of A is stored.

$equed$

CHARACTER*1. Must be ' N ' or ' Y '.

Specifies the form of equilibration that was done to A before calling this routine.

If $equed = 'N'$, no equilibration was done.

If $equed = 'Y'$, both row and column equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$. The right-hand side B has been changed accordingly.

n

INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

$nrhs$

INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

$a, af, b, work$

REAL for `sporfsx`

DOUBLE PRECISION for `dporfsx`

COMPLEX for `cporfsx`

DOUBLE COMPLEX for `zporfsx`.

Arrays: $a(1da, *), af(1daf, *), b(1db, *), work(*)$.

The array a contains the symmetric/Hermitian matrix A as specified by $uplo$. If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A and the strictly upper triangular part of a is not referenced. The second dimension of a must be at least $\max(1, n)$.

The array af contains the triangular factor L or U from the Cholesky factorization $A = U^{**}T^{*}U$ or $A = L^{*}L^{**}T$ as computed by `spotrf` for real flavors or `dpotrf` for complex flavors.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

$1da$

INTEGER. The leading dimension of a ; $1da \geq \max(1, n)$.

$1daf$

INTEGER. The leading dimension of af ; $1daf \geq \max(1, n)$.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A .

If $equed = 'N'$, s is not accessed.

If $equed = 'Y'$, each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

`ldb` INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

`x` REAL for `sporfsx`

DOUBLE PRECISION for `dporfsx`

COMPLEX for `cporfsx`

DOUBLE COMPLEX for `zporfsx`.

Array, DIMENSION ($lidx, *$).

The solution matrix X as computed by `?potrs`

`lidx` INTEGER. The leading dimension of the output array x ; $lidx \geq \max(1, n)$.

`n_err_bnds` INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See `err_bnds_norm` and `err_bnds_comp` descriptions in *Output Arguments* section below.

`nparams` INTEGER. Specifies the number of parameters set in `params`. If ≤ 0 , the `params` array is never referenced and default values are used.

`params` REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the `params` argument.

`params(la_linx_itref_i = 1)` : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

<code>=0.0</code>	No refinement is performed and no error bounds are computed.
-------------------	--

<code>=1.0</code>	Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.
-------------------	--

(Other values are reserved for future use.)

`params(la_linx_ithresh_i = 2)` : Maximum number of residual computations allowed for refinement.

Default	10
---------	----

	Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.
		<i>params(la_linrx_cwise_i = 3)</i> : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).
<i>iwork</i>		INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>		REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for <i>sporfsx</i> DOUBLE PRECISION for <i>dporfsx</i> COMPLEX for <i>cporfsx</i> DOUBLE COMPLEX for <i>zporfsx</i> . The improved solution matrix <i>X</i> .
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector <i>x(j)</i> , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x(j)</i> an exact solution.
<i>err_bnds_norm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>nrhs, n_err_bnds</i>). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: Normwise relative error in the <i>i</i> -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z.

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (`nrhs, n_err_bnds`). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then err_bnds_comp is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in $\text{err_bnds_comp}(i, :)$ corresponds to the i -th right-hand side.

The second index in $\text{err_bnds_comp}(:, \text{err})$ contains the following three fields:

$\text{err}=1$	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
$\text{err}=2$	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
$\text{err}=3$	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Output parameter only if the input contains erroneous values, namely, in $\text{params}(1)$, $\text{params}(2)$, $\text{params}(3)$. In such a case, the corresponding elements of params are filled with default values on output.

info

INTEGER. If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$). See the definition of $\text{err_bnds_norm}(:, 1)$ and $\text{err_bnds_comp}(:, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?pprfs

Refines the solution of a system of linear equations with a packed symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call spprfs( uplo, n, nrhs, ap, afp, b, ldb, x, idx, ferr, berr, work, iwork, info )
call dpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, idx, ferr, berr, work, iwork, info )

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed symmetric (Hermitian)positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution

$$\|x - x_e\|_\infty / \|x\|_\infty$$

where x_e is the exact solution.

Before calling this routine:

- call the factorization routine [?pptrf](#)
- call the solver routine [?ptrfs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, afp, b, x, work</i>	REAL for spprfs DOUBLE PRECISION for dpprfs COMPLEX for cprfs DOUBLE COMPLEX for zpprfs. Arrays: <i>ap</i> (*) contains the original packed matrix A , as supplied to ?pptrf . <i>afp</i> (*) contains the factored packed matrix A , as returned by ?pptrf . <i>b</i> (<i>ldb</i> , *) contains the right-hand side matrix B . <i>x</i> (<i>ldx</i> , *) contains the solution matrix X . <i>work</i> (*) is a workspace array. The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cpprfs</i> DOUBLE PRECISION for <i>zpprfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.
	Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pprfs* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?pbrfs

Refines the solution of a system of linear equations with a band symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pbtrf](#)
- call the solver routine [?pbtrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for spbrfs DOUBLE PRECISION for dpbrfs COMPLEX for cpbrfs DOUBLE COMPLEX for zpbrfs. Arrays: <i>ab</i> (<i>ldab</i> ,*) contains the original band matrix A , as supplied to ?pbtrf . <i>afb</i> (<i>ldafb</i> ,*) contains the factored band matrix A , as returned by ?pbtrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix B . <i>x</i> (<i>ldx</i> ,*) contains the solution matrix X . <i>work</i> (*) is a workspace array. The second dimension of <i>ab</i> and <i>afb</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; <i>ldab</i> $\geq kd + 1$.

<i>ldafb</i>	INTEGER. The leading dimension of <i>afb</i> ; $ldafb \geq kd + 1$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cpbrfs DOUBLE PRECISION for zpbrfs. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.
	Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbrfs` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>afb</i>	Holds the array <i>AF</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $8n*kd$ floating-point operations (for real flavors) or $32n*kd$ operations (for complex flavors). In addition, each step of iterative refinement involves $12n*kd$ operations (for real flavors) or $48n*kd$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4n*kd$ floating-point operations for real flavors or $16n*kd$ for complex flavors.

?ptrfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sptrfs( n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work, info )

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive definite tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$|\delta a_{ij}| \leq \beta |a_{ij}|$, $|\delta b_i| \leq \beta |b_i|$ such that $(A + \delta A)x = (b + \delta b)$.

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pttrf](#)
 - call the solver routine [?pttrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Used for complex flavors only. Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored:

If $uplo = 'U'$, the array e stores the superdiagonal of A , and A is factored as $U^H * D * U$.

If $\text{uplo} = \text{'L'}$, the array e stores the subdiagonal of A , and A is factored as $L \cdot D \cdot L^H$.

n

INTEGER. The order of the matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides; $nrhs \geq 0$.

d, df, rwork

REAL for single precision flavors **DOUBLE PRECISION** for double precision flavors

Arrays: $d(n)$, $df(n)$, $rwork(n)$.

The array d contains the n diagonal elements of the tridiagonal matrix A .

The array df contains the n diagonal elements of the diagonal matrix D from the factorization of A as computed by [?pttrf](#).

The array *rwork* is a workspace array used for complex flavors only.

e,ef,b,x,work

REAL for sptrfs

DOUBLE PRECISION for dptrfs

COMPLEX for cptrf*s*

DOUBLE COMPLEX for zptrfs.

Arrays: $e(n-1)$, $ef(n-1)$, $b(ldb, nrhs)$, $x(lidx, nrhs)$, $work(*)$.

The array e contains the $(n - 1)$ off-diagonal elements of the tridiagonal matrix A (see *uplo*).

The array *ef* contains the $(n - 1)$ off-diagonal elements of the unit bidiagonal factor *U* or *L* from the factorization computed by [?pttrf](#) (see *uplo*).

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

The array *x* contains the solution matrix *X* as computed by [?pttrs](#).

The array *work* is a workspace array. The dimension of *work* must be at least $2 * n$ for real flavors, and at least *n* for complex flavors.

ldb INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The leading dimension of *x*; $ldx \geq \max(1, n)$.

Output Parameters

x The refined solution matrix *X*.

ferr, *berr* REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptrfs` interface are as follows:

d Holds the vector of length *n*.

df Holds the vector of length *n*.

e Holds the vector of length $(n-1)$.

ef Holds the vector of length $(n-1)$.

b Holds the matrix *B* of size $(n, nrhs)$.

x Holds the matrix *X* of size $(n, nrhs)$.

ferr Holds the vector of length $(nrhs)$.

berr Holds the vector of length $(nrhs)$.

uplo Used in complex flavors only. Must be '`U`' or '`L`'. The default value is '`U`'.

?syrfs

Refines the solution of a system of linear equations with a symmetric matrix and estimates its error.

Syntax**FORTRAN 77:**

```
call ssyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, iwork, info )
call dsyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, iwork, info )
call csyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork, info )
call zsyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call syrfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

C:

```
lapack_int LAPACKE_ssyrfs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sytrf](#)
- call the solver routine [?sytrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; <i>n</i> ≥ 0.
<i>nrhs</i>	INTEGER. The number of right-hand sides; <i>nrhs</i> ≥ 0.
<i>a,af,b,x,work</i>	REAL for ssyrf DOUBLE PRECISION for dsyrf COMPLEX for csyrf DOUBLE COMPLEX for zsyrf. Arrays: <i>a</i> (<i>lda</i> ,*) contains the original matrix <i>A</i> , as supplied to ?sytrf . <i>af</i> (<i>ldaf</i> ,*) contains the factored matrix <i>A</i> , as returned by ?sytrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>idx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> ≥ $\max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> ; <i>ldaf</i> ≥ $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; <i>ldb</i> ≥ $\max(1, n)$.
<i>idx</i>	INTEGER. The leading dimension of <i>x</i> ; <i>idx</i> ≥ $\max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for csyrf DOUBLE PRECISION for zsyrf.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix X .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.
	Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syrfs` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?syrfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric indefinite matrix A and provides error bounds and backward error estimates.

Syntax**FORTRAN 77:**

```

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed` and `s` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = ' <code>U</code> ', the upper triangle of A is stored. If <code>uplo</code> = ' <code>L</code> ', the lower triangle of A is stored.
<code>equed</code>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>Y</code> '.
	Specifies the form of equilibration that was done to A before calling this routine. If <code>equed</code> = ' <code>N</code> ', no equilibration was done. If <code>equed</code> = ' <code>Y</code> ', both row and column equilibration was done, that is, A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$. The right-hand side B has been changed accordingly.
<code>n</code>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<code>a, af, b, work</code>	REAL for <code>ssyrfxsx</code> DOUBLE PRECISION for <code>dsyrfxsx</code> COMPLEX for <code>csyrfxsx</code> DOUBLE COMPLEX for <code>zsyrfxsx</code> . Arrays: <code>a(lda,*)</code> , <code>af(ldaf,*)</code> , <code>b(ldb,*)</code> , <code>work(*)</code> . The array <code>a</code> contains the symmetric/Hermitian matrix A as specified by <code>uplo</code> . If <code>uplo</code> = ' <code>U</code> ', the leading n -by- n upper triangular part of <code>a</code> contains the upper triangular part of the matrix A and the strictly lower triangular part of <code>a</code> is not referenced. If <code>uplo</code> = ' <code>L</code> ', the leading n -by- n lower triangular part of <code>a</code> contains the lower triangular part of the matrix A and the strictly upper triangular part of <code>a</code> is not referenced. The second dimension of <code>a</code> must be at least $\max(1, n)$. The array <code>af</code> contains the triangular factor L or U from the Cholesky factorization $A = U^* T^* U$ or $A = L^* L^* T$ as computed by <code>ssytrf</code> for real flavors or <code>dsytrf</code> for complex flavors.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

work()* is a workspace array. The dimension of *work* must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of af ; $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D as determined by [ssytrf](#) for real flavors or [dsytrf](#) for complex flavors.

s REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A .

If *equed* = 'N', s is not accessed.

If *equed* = 'Y', each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

x REAL for [ssyrfxsx](#)

DOUBLE PRECISION for [dsyrfxsx](#)

COMPLEX for [csyrfxsx](#)

DOUBLE COMPLEX for [zsyrfxsx](#).

Array, DIMENSION ($l dx, *$).

The solution matrix X as computed by [?sytrs](#)

l dx INTEGER. The leading dimension of the output array x ; $l dx \geq \max(1, n)$.

n_err_bnds INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

nparams INTEGER. Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

`Array, DIMENSION nparams.` Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

`params(la_linrx_itref_i = 1)` : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.
------	--

(Other values are reserved for future use.)

`params(la_linrx_ithresh_i = 2)` : Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <code>err_bnds_norm</code> and <code>err_bnds_comp</code> may no longer be trustworthy.
------------	---

`params(la_linrx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

`iwork` INTEGER. Workspace array, DIMENSION at least `max(1, n)`; used in real flavors only.

`rwork` REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least `max(1, 3*n)`; used in complex flavors only.

Output Parameters

`x` REAL for `ssyrfxsx`

DOUBLE PRECISION for `dsyrfxsx`

COMPLEX for `csyrfxsx`

DOUBLE COMPLEX for `zsyrfxsx`.

The improved solution matrix X .

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.						
	Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.						
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.						
<i>err_bnds_norm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION $(nrhs, n_{err_bnds})$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: Normwise relative error in the i -th solution vector $\frac{\max_j X_{true_{ji}} - X_{ji} }{\max_j X_{ji} }$ The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned. The first index in $err_bnds_norm(i, :)$ corresponds to the i -th right-hand side. The second index in $err_bnds_norm(:, err)$ contains the following three fields: <table border="0"><tr><td style="vertical-align: top;"><i>err=1</i></td><td>"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors.</td></tr><tr><td style="vertical-align: top;"><i>err=2</i></td><td>"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.</td></tr><tr><td style="vertical-align: top;"><i>err=3</i></td><td>Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold</td></tr></table>	<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors.	<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.	<i>err=3</i>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold
<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors.						
<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.						
<i>err=3</i>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold						

$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (`nrhs, n_err_bnds`). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If $n_err_bnds < 3$, then at most the first $(:, n_err_bnds)$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s^* (a^* \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^* \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

`params`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Output parameter only if the input contains erroneous values, namely, in `params(1)`, `params(2)`, `params(3)`. In such a case, the corresponding elements of `params` are filled with default values on output.

`info`

INTEGER. If `info` = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If `info` = $-i$, the i -th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; `rcond` = 0 is returned.

If `info` = $n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params(3)` = 0.0, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that `err_bnds_norm(j, 1)` = 0.0 or `err_bnds_comp(j, 1)` = 0.0). See the definition of `err_bnds_norm(:, 1)` and `err_bnds_comp(:, 1)`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

?herfs

Refines the solution of a system of linear equations with a complex Hermitian matrix and estimates its error.

Syntax

FORTRAN 77:

```
call cherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork, info )
call zherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a complex Hermitian full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hetrf](#)
- call the solver routine [?hetrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	COMPLEX for cherfs DOUBLE COMPLEX for zherfs. Arrays: <i>a</i> (<i>lda</i> ,*) contains the original matrix A , as supplied to ?hetrf .

af(*ldaf*, *) contains the factored matrix *A*, as returned by [?hetrf](#).

b(*ldb*, *) contains the right-hand side matrix *B*.

x(*ldx*, *) contains the solution matrix *X*.

work(*) is a workspace array.

The second dimension of *a* and *af* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 2*n)$.

lda

INTEGER. The leading dimension of *a*; *lda* $\geq \max(1, n)$.

ldaf

INTEGER. The leading dimension of *af*; *ldaf* $\geq \max(1, n)$.

ldb

INTEGER. The leading dimension of *b*; *ldb* $\geq \max(1, n)$.

ldx

INTEGER. The leading dimension of *x*; *ldx* $\geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?hetrf](#).

rwork

REAL for *cherfs*

DOUBLE PRECISION for *zherfs*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x

The refined solution matrix *X*.

ferr, *berr*

REAL for *cherfs*

DOUBLE PRECISION for *zherfs*.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *herfs* interface are as follows:

a

Holds the matrix *A* of size (*n*, *n*).

af

Holds the matrix *AF* of size (*n*, *n*).

ipiv

Holds the vector of length *n*.

<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is [?ssyrf](#)/[?dsyrf](#)

?herfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric indefinite matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call cherfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, rwork, info )
call zherfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, rwork, info )
```

C:

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed` and `s` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = ' <code>U</code> ', the upper triangle of A is stored. If <code>uplo</code> = ' <code>L</code> ', the lower triangle of A is stored.
<code>equed</code>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>Y</code> '. Specifies the form of equilibration that was done to A before calling this routine. If <code>equed</code> = ' <code>N</code> ', no equilibration was done. If <code>equed</code> = ' <code>Y</code> ', both row and column equilibration was done, that is, A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$. The right-hand side B has been changed accordingly.
<code>n</code>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<code>a, af, b, work</code>	COMPLEX for <code>cherfsx</code> DOUBLE COMPLEX for <code>zherfsx</code> . Arrays: <code>a(1da,*)</code> , <code>af(1daf,*)</code> , <code>b(1db,*)</code> , <code>work(*)</code> . The array <code>a</code> contains the Hermitian matrix A as specified by <code>uplo</code> . If <code>uplo</code> = ' <code>U</code> ', the leading n -by- n upper triangular part of <code>a</code> contains the upper triangular part of the matrix A and the strictly lower triangular part of <code>a</code> is not referenced. If <code>uplo</code> = ' <code>L</code> ', the leading n -by- n lower triangular part of <code>a</code> contains the lower triangular part of the matrix A and the strictly upper triangular part of <code>a</code> is not referenced. The second dimension of <code>a</code> must be at least $\max(1, n)$. The factored form of the matrix A . The array <code>af</code> contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ as computed by <code>ssytrf</code> for <code>cherfsx</code> or <code>dsytrf</code> for <code>zherfsx</code> .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 2*n)$.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of af ; $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D as determined by [ssytrf](#) for real flavors or [dsytrf](#) for complex flavors.

s REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A .

If $equed = 'N'$, s is not accessed.

If $equed = 'Y'$, each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

x COMPLEX for [cherfsx](#)

DOUBLE COMPLEX for [zherfsx](#).

Array, DIMENSION ($lidx, *$).

The solution matrix X as computed by [?hetrs](#)

lidx INTEGER. The leading dimension of the output array x ; $lidx \geq \max(1, n)$.

n_err_bnds INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

nparams INTEGER. Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used

for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the *params* argument.

params(la_linx_itref_i = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for *cherfsx*), 1.0D+0 (for *zherfsx*).

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.
------	--

(Other values are reserved for future use.)

params(la_linx_ithresh_i = 2) : Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.
------------	---

params(la_linx_cwise_i = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

rwork

REAL for *cherfsx*

DOUBLE PRECISION for *zherfsx*.

Workspace array, DIMENSION at least $\max(1, 3*n)$.

Output Parameters

x

COMPLEX for *cherfsx*

DOUBLE COMPLEX for *zherfsx*.

The improved solution matrix *X*.

rcond

REAL for *cherfsx*

DOUBLE PRECISION for *zherfsx*.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr

REAL for *cherfsx*

DOUBLE PRECISION for zherfsx.

Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for cherfsx

DOUBLE PRECISION for zherfsx.

Array, DIMENSION $(\text{nrhs}, n_{\text{err_bnds}})$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*($i, :$) corresponds to the i -th right-hand side.

The second index in *err_bnds_norm*($:, err$) contains the following three fields:

err=1

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for cherfsx and $\sqrt{n} * \text{dlamch}(\epsilon)$ for zherfsx.

err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for cherfsx and $\sqrt{n} * \text{dlamch}(\epsilon)$ for zherfsx. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for cherfsx and $\sqrt{n} * \text{dlamch}(\epsilon)$ for zherfsx to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for cherfsx

DOUBLE PRECISION for zherfsx.

Array, **DIMENSION** (*nrhs, n_err_bnds*) . For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side *i*, on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params(3) = 0.0*), then *err_bnds_comp* is not accessed. If *n_err_bnds < 3*, then at most the first $(:, n_err_bnds)$ entries are returned.

The first index in *err_bnds_comp(i, :)* corresponds to the *i*-th right-hand side.

The second index in *err_bnds_comp(:, err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cherfsx</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zherfsx</i> .
<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cherfsx</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zherfsx</i> . This error bound should only be trusted if the previous boolean is true.
<i>err=3</i>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cherfsx</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zherfsx</i> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix <i>Z</i> . Let $z = s^*(a^* \text{diag}(x))$, where <i>x</i> is the solution for the current right-hand side and <i>s</i> scales each row of <i>a^* diag(x)</i> by a power of the radix so all absolute row sums of <i>z</i> are approximately 1.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Output parameter only if the input contains erroneous values, namely, in $\text{params}(1)$, $\text{params}(2)$, $\text{params}(3)$. In such a case, the corresponding elements of params are filled with default values on output.

info INTEGER. If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$). See the definition of $\text{err_bnds_norm}(:, 1)$ and $\text{err_bnds_comp}(:, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?sprfs

Refines the solution of a system of linear equations with a packed symmetric matrix and estimates the solution error.

Syntax

FORTRAN 77:

```
call ssprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work, iwork,
info )
call dsprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work, iwork,

- C: mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a packed symmetric matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sptrf](#)
- call the solver routine [?ptrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap,afp,b,x,work</i>	REAL for ssprfs DOUBLE PRECISION for dsprfs COMPLEX for csprfs DOUBLE COMPLEX for zsprfs. Arrays: <i>ap</i> (*) contains the original packed matrix A , as supplied to ?sptrf .

afp(*) contains the factored packed matrix *A*, as returned by [?sptrf](#).

b(*ldb*,*) contains the right-hand side matrix *B*.

x(*ldx*,*) contains the solution matrix *X*.

work(*) is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb INTEGER. The leading dimension of *b*; *ldb* $\geq \max(1, n)$.

ldx INTEGER. The leading dimension of *x*; *ldx* $\geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?sptrf](#).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for *csprfs*

DOUBLE PRECISION for *zsprfs*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x The refined solution matrix *X*.

ferr, *berr* REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sprfs* interface are as follows:

ap Holds the array *A* of size $(n*(n+1)/2)$.

afp Holds the array *AF* of size $(n*(n+1)/2)$.

ipiv Holds the vector of length *n*.

<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?hprfs

Refines the solution of a system of linear equations with a packed complex Hermitian matrix and estimates the solution error.

Syntax

FORTRAN 77:

```
call chprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork,
info )
call zhprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work, rwork,
info )
```

Fortran 95:

```
call hprfs( ap, afp, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

C:

```
lapack_int LAPACKE_chprfs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_float* ap, const lapack_complex_float* afp, const lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb, lapack_complex_float* x,
lapack_int ldx, float* ferr, float* berr );
lapack_int LAPACKE_zhprfs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_double* ap, const lapack_complex_double* afp, const lapack_int* ipiv, const lapack_complex_double* b, lapack_int ldb, lapack_complex_double* x,
lapack_int ldx, double* ferr, double* berr );
```

The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; <i>ldb</i> $\geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> ; <i>ldx</i> $\geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hptrf .

rwork REAL for chprfs
 DOUBLE PRECISION for zhprfs.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr</i> , <i>berr</i>	REAL for <i>chprfs</i> . DOUBLE PRECISION for <i>zhprfs</i> .
	Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hprfs` interface are as follows:

<i>ap</i>	Holds the array A of size $(n * (n+1) / 2)$.
<i>afp</i>	Holds the array AF of size $(n * (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is `?ssprfs`/`?dsprfs`.

?trrfs

Estimates the error in the solution of a system of linear equations with a triangular matrix.

Syntax**FORTRAN 77:**

```
call strrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr, work,
iwork, info )

Description

The routine estimates the errors in the solution to a system of linear equations $A \cdot X = B$ or $A^T \cdot X = B$ or $A^H \cdot X = B$ with a triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?trtrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A*X = B$. If <i>trans</i> = 'T', the system has the form $A^T*X = B$. If <i>trans</i> = 'C', the system has the form $A^H*X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>a</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a</i> , <i>b</i> , <i>x</i> , <i>work</i>	REAL for strrfs DOUBLE PRECISION for dtrrfs COMPLEX for ctrrfs DOUBLE COMPLEX for ztrrfs. Arrays: <i>a</i> (<i>lda</i> , *) contains the upper or lower triangular matrix A , as specified by <i>uplo</i> . <i>b</i> (<i>ldb</i> , *) contains the right-hand side matrix B . <i>x</i> (<i>ldx</i> , *) contains the solution matrix X . <i>work</i> (*) is a workspace array. The second dimension of <i>a</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$.

<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctrffs</i> DOUBLE PRECISION for <i>ztrrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr</i> , <i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trrfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tprrfs

Estimates the error in the solution of a system of linear equations with a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, idx, ferr, berr, work, iwork,
info )
call dtprefs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, idx, ferr, berr, work, iwork,

Description

The routine estimates the errors in the solution to a system of linear equations $A \cdot X = B$ or $A^T \cdot X = B$ or $A^H \cdot X = B$ with a packed triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?ptrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
	Indicates the form of the equations: If $trans = 'N'$, the system has the form $A \cdot X = B$. If $trans = 'T'$, the system has the form $A^T \cdot X = B$. If $trans = 'C'$, the system has the form $A^H \cdot X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.
	If $diag = 'N'$, A is not a unit triangular matrix. If $diag = 'U'$, A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, b, x, work</i>	REAL for <i>stprfs</i> DOUBLE PRECISION for <i>dtprrfs</i> COMPLEX for <i>ctprrf</i> DOUBLE COMPLEX for <i>ztprrf</i> . Arrays: <i>ap(*)</i> contains the upper or lower triangular matrix A , as specified by <i>uplo</i> . <i>b(ldb, *)</i> contains the right-hand side matrix B . <i>x(lidx, *)</i> contains the solution matrix X . <i>work(*)</i> is a workspace array. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>lidx</i>	INTEGER. The leading dimension of <i>x</i> ; $lidx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for ctprfs
 DOUBLE PRECISION for ztprfs.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least max(1, <i>nrhs</i>). Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tprfs` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n^* (n+1) / 2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in `ferr` are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tbrfs

Estimates the error in the solution of a system of linear equations with a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call dtbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr, berr,

Description

The routine estimates the errors in the solution to a system of linear equations $A \cdot X = B$ or $A^T \cdot X = B$ or $A^H \cdot X = B$ with a triangular band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?tbtrs](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If $trans = 'N'$, the system has the form $A \cdot X = B$. If $trans = 'T'$, the system has the form $A^T \cdot X = B$. If $trans = 'C'$, the system has the form $A^H \cdot X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If $diag = 'N'$, A is not a unit triangular matrix. If $diag = 'U'$, A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals or sub-diagonals in the matrix A ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b, x, work</i>	REAL for stbrfs DOUBLE PRECISION for dtbrfs COMPLEX for ctbrfs DOUBLE COMPLEX for ztbrfs. Arrays: <i>ab</i> (<i>ldab</i> , *) contains the upper or lower triangular matrix A , as specified by <i>uplo</i> , in band storage format. <i>b</i> (<i>ldb</i> , *) contains the right-hand side matrix B . <i>x</i> (<i>ldx</i> , *) contains the solution matrix X . <i>work</i> (*) is a workspace array. The second dimension of <i>a</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for ctbrfs
 DOUBLE PRECISION for ztbrfs.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least max(1, <i>nrhs</i>). Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbrfs` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in `ferr` are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n*kd$ floating-point operations for real flavors or $8n*kd$ operations for complex flavors.

Routines for Matrix Inversion

It is seldom necessary to compute an explicit inverse of a matrix. In particular, do not attempt to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Routines for Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

However, matrix inversion routines are provided for the rare occasions when an explicit inverse matrix is needed.

?getri

Computes the inverse of an LU-factored general matrix.

Syntax

FORTRAN 77:

```
call sgetri( n, a, lda, ipiv, work, lwork, info )
call dgetri( n, a, lda, ipiv, work, lwork, info )
call cgetri( n, a, lda, ipiv, work, lwork, info )
call zgetri( n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call getri( a, ipiv [,info] )
```

C:

```
lapack_int LAPACKE_<?>getri( int matrix_layout, lapack_int n, <datatype>* a, lapack_int
lda, const lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a general matrix A . Before calling this routine, call [?getrf](#) to factorize A .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for sgetri DOUBLE PRECISION for dgetri COMPLEX for cgetri DOUBLE COMPLEX for zgetri. Arrays: $a(\text{lda}, *)$, $work(*)$. $a(\text{lda}, *)$ contains the factorization of the matrix A , as returned by ?getrf : $A = P \cdot L \cdot U$. The second dimension of a must be at least $\max(1, n)$. $work(*)$ is a workspace array of dimension at least $\max(1, lwork)$.

<i>lda</i>	INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?getrf .
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq n$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> .

See *Application Notes* below for the suggested value of *lwork*.

Output Parameters

<i>a</i>	Overwritten by the n -by- n matrix $\text{inv}(A)$.
<i>work(1)</i>	If $info = 0$, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value. If $info = i$, the <i>i</i> -th diagonal element of the factor <i>U</i> is zero, <i>U</i> is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *getri* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .

Application Notes

For better performance, try using $lwork = n * \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed inverse X satisfies the following error bound:

$$|XA - I| \leq c(n)\varepsilon|X||P||L||U|,$$

where $c(n)$ is a modest linear function of n ; ε is the machine precision; I denotes the identity matrix; P , L , and U are the factors of the matrix factorization $A = P^*L^*U$.

The total number of floating-point operations is approximately $(4/3)n^3$ for real flavors and $(16/3)n^3$ for complex flavors.

?potri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotri( uplo, n, a, lda, info )
call dpotri( uplo, n, a, lda, info )
call cpotri( uplo, n, a, lda, info )
call zpotri( uplo, n, a, lda, info )
```

Fortran 95:

```
call potri( a [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>potri( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A . Before calling this routine, call [?potrf](#) to factorize A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether A is upper or lower triangular:
	If <i>uplo</i> = 'U', then A is upper triangular.
	If <i>uplo</i> = 'L', then A is lower triangular.

n INTEGER. The order of the matrix A ; $n \geq 0$.

a REAL for spotri
 DOUBLE PRECISION for dpotri
 COMPLEX for cpotri
 DOUBLE COMPLEX for zpotri.

Array *a*(*lda*, *). Contains the factorization of the matrix *A*, as returned by [?potrf](#).

The second dimension of *a* must be at least $\max(1, n)$.

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potri` interface are as follows:

a Holds the matrix A of size (n, n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x: x \neq 0} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3) n^3$ for real flavors and $(8/3) n^3$ for complex flavors.

?pftri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix in RFP format using the Cholesky factorization.

Syntax

FORTRAN 77:

```
call spftri( transr, uplo, n, a, info )
call dpftri( transr, uplo, n, a, info )
call cpftri( transr, uplo, n, a, info )
call zpftri( transr, uplo, n, a, info )
```

C:

```
lapack_int LAPACKE_<?>pftri( int matrix_layout, char transr, char uplo, lapack_int n,
<datatype>* a );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization:

$$\begin{aligned} A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo='U' \\ A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo='L' \end{aligned}$$

Before calling this routine, call [?pftrf](#) to factorize A .

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data).
	If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored.
	If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored.
	If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of the RFP matrix A is stored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A .
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for spftri DOUBLE PRECISION for dpftri

COMPLEX for `cpftri`

DOUBLE COMPLEX for `zpftri`.

Array, DIMENSION ($n * (n+1) / 2$). The array `a` contains the matrix A in the RFP format.

Output Parameters

`a` The symmetric/Hermitian inverse of the original matrix in the same storage format.

`info` INTEGER. If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, the (i,i) element of the factor `U` or `L` is zero, and the inverse could not be computed.

?pptri

Computes the inverse of a packed symmetric (Hermitian) positive-definite matrix

Syntax

FORTRAN 77:

```
call spptri( uplo, n, ap, info )
call dpptri( uplo, n, ap, info )
call cpptri( uplo, n, ap, info )
call zpptri( uplo, n, ap, info )
```

Fortran 95:

```
call pptri( ap [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>pptri( int matrix_layout, char uplo, lapack_int n, <datatype>* ap );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes the inverse `inv(A)` of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A in *packed* form. Before calling this routine, call `?ptrf` to factorize A .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

`uplo` CHARACTER*1. Must be '`U`' or '`L`'.

Indicates whether the upper or lower triangular factor is stored in *ap*:

If *uplo* = 'U', then the upper triangular factor is stored.

If *uplo* = 'L', then the lower triangular factor is stored.

n

INTEGER. The order of the matrix *A*; $n \geq 0$.

ap

REAL for *spptri*

DOUBLE PRECISION for *dpptri*

COMPLEX for *cpptri*

DOUBLE COMPLEX for *zpptri*.

Array, DIMENSION at least $\max(1, n(n+1)/2)$.

Contains the factorization of the packed matrix *A*, as returned by [?pptrf](#).

The dimension *ap* must be at least $\max(1, n(n+1)/2)$.

Output Parameters

ap

Overwritten by the packed *n*-by-*n* matrix *inv(A)*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the *i*-th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pptri* interface are as follows:

ap

Holds the array *A* of size $(n^*(n+1)/2)$.

uplo

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse *X* satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\varepsilon\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\varepsilon\kappa_2(A),$$

where *c(n)* is a modest linear function of *n*, and ε is the machine precision; *I* denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix *A* is defined by $\|A\|_2 = \max_{x \neq 0} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?sytri

Computes the inverse of a symmetric matrix.

Syntax**FORTRAN 77:**

```
call ssytri( uplo, n, a, lda, ipiv, work, info )
call dsytri( uplo, n, a, lda, ipiv, work, info )
call csytri( uplo, n, a, lda, ipiv, work, info )
call zsytri( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call sytri( a, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sytri( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda, const lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric matrix A . Before calling this routine, call [?sytrf](#) to factorize A .

Input Parameters

The data types are given for the Fortran interface. A $<\text{datatype}>$ placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the Bunch-Kaufman factorization $A = P \cdot U \cdot D \cdot U^T \cdot P^T$. If $uplo = 'L'$, the array a stores the Bunch-Kaufman factorization $A = P \cdot L \cdot D \cdot L^T \cdot P^T$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for ssytri DOUBLE PRECISION for dsytri COMPLEX for csytri DOUBLE COMPLEX for zsytri. Arrays: $a(1:da, :)$ contains the factorization of the matrix A , as returned by ?sytrf .

The second dimension of a must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, 2*n)$.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

$ipiv$ INTEGER.

Array, DIMENSION at least $\max(1, n)$.

The $ipiv$ array, as returned by [?sytrf](#).

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytri` interface are as follows:

a Holds the matrix A of size (n, n) .

$ipiv$ Holds the vector of length n .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|D^T P^T X P U - I| \leq c(n) \epsilon (|D| |U^T P^T X P| U + |D| |D^{-1}|)$$

for $uplo = 'U'$, and

$$|D L^T P^T X P L - I| \leq c(n) \epsilon (|D| |L^T P^T X P| L + |D| |D^{-1}|)$$

for $uplo = 'L'$. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?sytri_rook

Computes the inverse of a symmetric matrix using $U^T D U$ or $L^T D L$ bounded Bunch-Kaufman factorization.

Syntax

FORTRAN 77:

```
call ssytri_rook( uplo, n, a, lda, ipiv, work, info )
call dsytri_rook( uplo, n, a, lda, ipiv, work, info )
call csytri_rook( uplo, n, a, lda, ipiv, work, info )
call zsytri_rook( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call sytri_rook( a, ipiv [,uplo] [,info] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric matrix A . Before calling this routine, call [?sytrf_rook](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the factorization $A = U*D*U^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the factorization $A = L*D*L^T$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i> , <i>work</i>	REAL for ssytri_rook DOUBLE PRECISION for dsytri_rook COMPLEX for csytri_rook DOUBLE COMPLEX for zsytri_rook. The real counterpart of this routine is [?sytri_rook](#).

See Also

[Matrix Storage Schemes](#)

?sytri2

Computes the inverse of a symmetric indefinite matrix through setting the leading dimension of the workspace and calling ?sytri2x.

Syntax

FORTRAN 77:

```
call ssytri2( uplo, n, a, lda, ipiv, work, lwork, info )
call dsytri2( uplo, n, a, lda, ipiv, work, lwork, info )
call csytri2( uplo, n, a, lda, ipiv, work, lwork, info )
call zsytri2( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call sytri2( a, ipiv[, uplo] [, info] )
```

C:

```
lapack_int LAPACKE_<?>sytri2( int matrix_layout, char uplo, lapack_int n, <datatype>* a, lapack_int lda, const lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric indefinite matrix A using the factorization $A = U*D*U^T$ or $A = L*D*L^T$ computed by [?sytrf](#).

The [?sytri2](#) routine sets the leading dimension of the workspace before calling [?sytri2x](#) that actually computes the inverse.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the factorization $A = U*D*U^T$.

If $uplo = 'L'$, the array a stores the factorization $A = L \cdot D \cdot L^T$.

n INTEGER. The order of the matrix A ; $n \geq 0$.

$a, work$

- REAL for ssytri2
- DOUBLE PRECISION for dsytri2
- COMPLEX for csytri2
- DOUBLE COMPLEX for zsytri2

Array a (size lda by n) contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as returned by ?sytrf.

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array of $(n+nb+1) * (nb+3)$ dimension.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

$ipiv$ INTEGER.

Array, size at least $\max(1, n)$.

Details of the interchanges and the block structure of D as returned by ?sytrf.

$lwork$ INTEGER. The dimension of the $work$ array.

$lwork \geq (n+nb+1) * (nb+3)$

where

nb is the block size parameter as returned by sytrf.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

Output Parameters

a

If $info = 0$, the symmetric inverse of the original matrix.

If $uplo = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.

If $uplo = 'L'$, the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, $D(i,i) = 0$; D is singular and its inversion could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytri2` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Indicates how the matrix A has been factored. Must be ' <code>U</code> ' or ' <code>L</code> '.

[?sytrf](#)

[?sytri2x](#)

[Matrix Storage Schemes](#)

?hetri2

Computes the inverse of a Hermitian indefinite matrix through setting the leading dimension of the workspace and calling ?hetri2x.

Syntax

FORTRAN 77:

```
call chetri2( uplo, n, a, lda, ipiv, work, lwork, info )
call zhetri2( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call hetri2( a, ipiv[, uplo][, info] )
```

C:

```
lapack_int LAPACKE_<?>hetri2( int matrix_layout, char uplo, lapack_int n, <datatype>* a, lapack_int lda, const lapack_int* ipiv );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes the inverse $\text{inv}(A)$ of a Hermitian indefinite matrix A using the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ computed by [?hetrf](#).

The `?hetri2` routine sets the leading dimension of the workspace before calling `?hetri2x` that actually computes the inverse.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
-------------------	--

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array a stores the factorization $A = U^*D^*U^H$.

If $uplo = 'L'$, the array a stores the factorization $A = L^*D^*L^H$.

n

INTEGER. The order of the matrix A ; $n \geq 0$.

$a, work$

COMPLEX for chetri2

DOUBLE COMPLEX for zhetri2

Arrays:

$a(1:da, :)$ contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as returned by ?sytrf.

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array of $(n+nb+1) * (nb+3)$ dimension.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

Details of the interchanges and the block structure of D as returned by ?hetrf.

$lwork$

INTEGER. The dimension of the $work$ array.

$lwork \geq (n+nb+1) * (nb+3)$

where

nb is the block size parameter as returned by hetrf.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

Output Parameters

a

If $info = 0$, the inverse of the original matrix.

If $info = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.

If $info = 'L'$, the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, $D(i,i) = 0$; D is singular and its inversion could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetri2` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Indicates how the input matrix A has been factored. Must be ' <code>U</code> ' or ' <code>L</code> '.

?sytri2x

Computes the inverse of a symmetric indefinite matrix after ?sytri2 sets the leading dimension of the workspace.

Syntax

FORTRAN 77:

```
call ssytri2x( uplo, n, a, lda, ipiv, work, nb, info )
call dsytri2x( uplo, n, a, lda, ipiv, work, nb, info )
call csytri2x( uplo, n, a, lda, ipiv, work, nb, info )
call zsytri2x( uplo, n, a, lda, ipiv, work, nb, info )
```

Fortran 95:

```
call sytri2x( a, ipiv, nb[, uplo][, info] )
```

C:

```
lapack_int LAPACKE_<?>sytri2x( int matrix_layout, char uplo, lapack_int n, <datatype>* a, lapack_int lda, const lapack_int* ipiv, lapack_int nb );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes the inverse `inv(A)` of a symmetric indefinite matrix A using the factorization $A = U^*D^*U^T$ or $A = L^*D^*L^T$ computed by [?sytrf](#).

The `?sytri2x` actually computes the inverse after the `?sytri2` routine sets the leading dimension of the workspace before calling `?sytri2x`.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If $uplo = 'U'$, the array a stores the factorization $A = U^*D^*U^T$.
	If $uplo = 'L'$, the array a stores the factorization $A = L^*D^*L^T$.

?hetrf

?hetri2

?sptri

Computes the inverse of a symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptri( uplo, n, ap, ipiv, work, info )
call dsptri( uplo, n, ap, ipiv, work, info )
call csptri( uplo, n, ap, ipiv, work, info )
call zsptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call sptri( ap, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sptri( int matrix_layout, char uplo, lapack_int n, <datatype>* ap, const lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a packed symmetric matrix A . Before calling this routine, call [?sptrf](#) to factorize A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' U ' or ' L '.
	Indicates how the input matrix A has been factored:
	If $uplo = 'U'$, the array <i>ap</i> stores the Bunch-Kaufman factorization $A = P \cdot U \cdot D \cdot U^T \cdot P^T$.

If $uplo = 'L'$, the array ap stores the Bunch-Kaufman factorization $A = P^*L^*D^*L^T*P^T$.

n INTEGER. The order of the matrix A ; $n \geq 0$.

$ap, work$

REAL for ssptri
 DOUBLE PRECISION for dsptri
 COMPLEX for csptri
 DOUBLE COMPLEX for zsptri.

Arrays:

$ap(*)$ contains the factorization of the matrix A , as returned by [?sptrf](#).

The dimension of ap must be at least $\max(1, n(n+1)/2)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, n)$.

$ipiv$ INTEGER.

Array, DIMENSION at least $\max(1, n)$. The $ipiv$ array, as returned by [?sptrf](#).

Output Parameters

ap Overwritten by the n -by- n matrix $\text{inv}(A)$ in packed form.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptri` interface are as follows:

ap Holds the array A of size $(n*(n+1)/2)$.

$ipiv$ Holds the vector of length n .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|D^*U^T*P^T*X*P*U - I| \leq c(n)\epsilon(|D| |U^T| |P^T| |X| |P| |U| + |D| |D^{-1}|)$$

for $uplo = 'U'$, and

$$|D^*L^T*P^T*X*P*L - I| \leq c(n)\varepsilon(|D||L^T|P^T|X|P|L| + |D||D^{-1}|)$$

for $uplo = 'L'$. Here $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?hptri

Computes the inverse of a complex Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptri( uplo, n, ap, ipiv, work, info )
call zhptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call hptri( ap, ipiv [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>hptri( int matrix_layout, char uplo, lapack_int n, <datatype>* ap, const lapack_int* ipiv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a complex Hermitian matrix A using packed storage. Before calling this routine, call [?hptrf](#) to factorize A .

Input Parameters

The data types are given for the Fortran interface. A $<\text{datatype}>$ placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If $uplo = 'U'$, the array <i>ap</i> stores the packed Bunch-Kaufman factorization $A = P^*U*D^*U^H*P^T$.
	If $uplo = 'L'$, the array <i>ap</i> stores the packed Bunch-Kaufman factorization $A = P^*L*D^*L^H*P^T$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap, work</i>	COMPLEX for chptri DOUBLE COMPLEX for zhptri.

Arrays:

ap(*) contains the factorization of the matrix *A*, as returned by [?hptrf](#).

The dimension of *ap* must be at least $\max(1, n(n+1)/2)$.

work(*) is a workspace array.

The dimension of *work* must be at least $\max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

The *ipiv* array, as returned by [?hptrf](#).

Output Parameters

ap

Overwritten by the *n*-by-*n* matrix $\text{inv}(A)$.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the *i*-th diagonal element of *D* is zero, *D* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptri` interface are as follows:

ap

Holds the array *A* of size $(n^*(n+1)/2)$.

ipiv

Holds the vector of length *n*.

uplo

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse *X* satisfies the following error bounds:

$$|D^*U^H P^T X P U - I| \leq c(n) \varepsilon (|D| |U^H| P^T |X| P |U| + |D| |D^{-1}|)$$

for *uplo* = 'U', and

$$|D^*L^H P^T X P L - I| \leq c(n) \varepsilon (|D| |L^H| P^T |X| P |L| + |D| |D^{-1}|)$$

for *uplo* = 'L'. Here *c(n)* is a modest linear function of *n*, and *ε* is the machine precision; *I* denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

The real counterpart of this routine is [?sptri](#).

?trtri

Computes the inverse of a triangular matrix.

Syntax**FORTRAN 77:**

```
call strtri( uplo, diag, n, a, lda, info )
call dtrtri( uplo, diag, n, a, lda, info )
call ctrtri( uplo, diag, n, a, lda, info )
call ztrtri( uplo, diag, n, a, lda, info )
```

Fortran 95:

```
call trtri( a [,uplo] [,diag] [,info] )
```

C:

```
lapack_int LAPACKE_<?>trtri( int matrix_layout, char uplo, char diag, lapack_int n,
<datatype>* a, lapack_int lda );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a triangular matrix A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>a</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for strtri DOUBLE PRECISION for dtrtri COMPLEX for ctrtri DOUBLE COMPLEX for ztrtri. Array: DIMENSION (, *).

Contains the matrix A .

The second dimension of a must be at least $\max(1, n)$.

lda

INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

Output Parameters

a

Overwritten by the n -by- n matrix $\text{inv}(A)$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of A is zero, A is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtri` interface are as follows:

a

Holds the matrix A of size (n, n) .

$uplo$

Must be '`U`' or '`L`'. The default value is '`U`'.

$diag$

Must be '`N`' or '`U`'. The default value is '`N`'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|XA - I| \leq c(n)\varepsilon |X| |A|$$

$$|XA - I| \leq c(n)\varepsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ε is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

?tftri

Computes the inverse of a triangular matrix stored in the Rectangular Full Packed (RFP) format.

Syntax

FORTRAN 77:

```
call stftri( transr, uplo, diag, n, a, info )
call dtftri( transr, uplo, diag, n, a, info )
call ctftri( transr, uplo, diag, n, a, info )
call ztftri( transr, uplo, diag, n, a, info )
```

C:

```
lapack_int LAPACKE_<?>tftri( int matrix_layout, char transr, char uplo, char diag,
lapack_int n, <datatype>* a );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

Computes the inverse of a triangular matrix A stored in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data).
	If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored.
	If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored.
	If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of RFP A is stored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A .
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.
	If <i>diag</i> = 'N', then A is not a unit triangular matrix.
	If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>a</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for stftri DOUBLE PRECISION for dtftri COMPLEX for ctftri DOUBLE COMPLEX for ztftri. Array, DIMENSION ($n * (n+1) / 2$). The array <i>a</i> contains the matrix A in the RFP format.

Output Parameters

<i>a</i>	The (triangular) inverse of the original matrix in the same storage format.
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, $A(i,i)$ is exactly zero. The triangular matrix is singular and its inverse cannot be computed.

?tptri

Computes the inverse of a triangular matrix using packed storage.

Syntax

FORTRAN 77:

```
call stptri( uplo, diag, n, ap, info )
call dtptri( uplo, diag, n, ap, info )
call ctptri( uplo, diag, n, ap, info )
call ztptri( uplo, diag, n, ap, info )
```

Fortran 95:

```
call tptri( ap [,uplo] [,diag] [,info] )
```

C:

```
lapack_int LAPACKE_<?>tptri( int matrix_layout, char uplo, char diag, lapack_int n,
<datatype>* ap );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a packed triangular matrix A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.

If $diag = 'N'$, then A is not a unit triangular matrix.

If $diag = 'U'$, A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array ap .

n

INTEGER. The order of the matrix A ; $n \geq 0$.

ap

REAL for stptri

DOUBLE PRECISION for dtptri

COMPLEX for ctptri

DOUBLE COMPLEX for ztptri.

Array, DIMENSION at least $\max(1, n(n+1)/2)$.

Contains the packed triangular matrix A .

Output Parameters

ap

Overwritten by the packed n -by- n matrix $\text{inv}(A)$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of A is zero, A is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tptri` interface are as follows:

ap

Holds the array A of size $(n*(n+1)/2)$.

$uplo$

Must be '`U`' or '`L`'. The default value is '`U`'.

$diag$

Must be '`N`' or '`U`'. The default value is '`N`'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|XA - I| \leq c(n)\varepsilon |X| |A|$$

$$|X - A^{-1}| \leq c(n)\varepsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ε is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

Routines for Matrix Equilibration

Routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

?geequ

Computes row and column scaling factors intended to equilibrate a general matrix and reduce its condition number.

Syntax**FORTRAN 77:**

```
call sggequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call dggequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call cggequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call zggequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
```

Fortran 95:

```
call geequ( a, r, c [,rowcnd] [,colcnd] [,amax] [,info] )
```

C:

```
lapack_int LAPACKE_sggequ( int matrix_layout, lapack_int m, lapack_int n, const float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
lapack_int LAPACKE_dggequ( int matrix_layout, lapack_int m, lapack_int n, const double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );
lapack_int LAPACKE_cggequ( int matrix_layout, lapack_int m, lapack_int n,
const lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd,

- C: mkl.h

Description

The routine computes row and column scalings intended to equilibrate an m -by- n matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

See [?laqge](#) auxiliary function that uses scaling factors computed by [?geequ](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows of the matrix A ; $m \geq 0$.

n INTEGER. The number of columns of the matrix A ; $n \geq 0$.

a

REAL for sggequ
 DOUBLE PRECISION for dggequ
 COMPLEX for cggequ
 DOUBLE COMPLEX for zggequ.
Array: DIMENSION (*lda*, *).
 Contains the m -by- n matrix A whose equilibration factors are to be computed.
 The second dimension of *a* must be at least $\max(1, n)$.
lda
 INTEGER. The leading dimension of *a*; $lda \geq \max(1, m)$.

Output Parameters

r, c

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
Arrays: $r(m), c(n)$.
 If $info = 0$, or $info > m$, the array *r* contains the row scale factors of the matrix A .
 If $info = 0$, the array *c* contains the column scale factors of the matrix A .

rowcnd

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If $info = 0$ or $info > m$, *rowcnd* contains the ratio of the smallest $r(i)$ to the largest $r(i)$.

colcnd

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If $info = 0$, *colcnd* contains the ratio of the smallest $c(i)$ to the largest $c(i)$.

amax

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Absolute value of the largest element of the matrix A .

info

INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the *i*-th parameter had an illegal value.
 If $info = i$ and
 $i \leq m$, the *i*-th row of A is exactly zero;
 $i > m$, the $(i-m)$ th column of A is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geequ` interface are as follows:

- `a` Holds the matrix A of size (m, n) .
- `r` Holds the vector of length (m) .
- `c` Holds the vector of length n .

Application Notes

All the components of r and c are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

If $\text{rowcnd} \geq 0.1$ and amax is neither too large nor too small, it is not worth scaling by r .

If $\text{colcnd} \geq 0.1$, it is not worth scaling by c .

If amax is very close to overflow or very close to underflow, the matrix A should be scaled.

?geequb

Computes row and column scaling factors restricted to a power of radix to equilibrate a general matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgeequb( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call dgeequb( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call cgeequb( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call zgeequb( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
```

C:

```
lapack_int LAPACKE_sgeequb( int matrix_layout, lapack_int m, lapack_int n, const float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
lapack_int LAPACKE_dgeequb( int matrix_layout, lapack_int m, lapack_int n,
                           const double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd,
                           double* amax );
lapack_int LAPACKE_cgeequb( int matrix_layout, lapack_int m, lapack_int n,
                           const lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd,
                           float* colcnd, float* amax );
lapack_int LAPACKE_zgeequb( int matrix_layout, lapack_int m, lapack_int n,
                           const lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd,
                           double* colcnd, double* amax );

Description

The routine computes row and column scalings intended to equilibrate an m -by- n general matrix A and reduce its condition number. The output array r returns the row scale factors and the array c - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij} = r(i) * a_{ij} * c(j)$ have an absolute value of at most the radix.

$r(i)$ and $c(j)$ are restricted to be a power of the radix between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of a but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the [?lamch](#) routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

This routine differs from [?geequ](#) by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between $\sqrt{\text{radix}}$ and $1/\sqrt{\text{radix}}$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
n	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
a	REAL for sgeequb DOUBLE PRECISION for dgeequb COMPLEX for cgeequb DOUBLE COMPLEX for zgeequb. Array: DIMENSION ($lda, *$). Contains the m -by- n matrix A whose equilibration factors are to be computed. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The leading dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

r, c	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: $r(m), c(n)$.
--------	---

If $info = 0$, or $info > m$, the array r contains the row scale factors for the matrix A .

If $info = 0$, the array c contains the column scale factors for the matrix A .

rowcnd

REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

If $info = 0$ or $info > m$, $rowcnd$ contains the ratio of the smallest $r(i)$ to the largest $r(i)$. If $rowcnd \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by r .

colcnd

REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

If $info = 0$, $colcnd$ contains the ratio of the smallest $c(i)$ to the largest $c(i)$. If $colcnd \geq 0.1$, it is not worth scaling by c .

amax

REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or very close to underflow, the matrix should be scaled.

info

INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$ and
 $i \leq m$, the i -th row of A is exactly zero;
 $i > m$, the $(i-m)$ -th column of A is exactly zero.

?gbequ

Computes row and column scaling factors intended to equilibrate a banded matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call dgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call cgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )

Description

The routine computes row and column scalings intended to equilibrate an m -by- n band matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij} = r(i) * a_{ij} * c(j)$ have absolute value 1.

See [?laqgb](#) auxiliary function that uses scaling factors computed by [?gbequ](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>ab</i>	REAL for sgbequ DOUBLE PRECISION for dgbequ COMPLEX for cgbequ DOUBLE COMPLEX for zgbequ. Array, DIMENSION (<i>ldab</i> , *). Contains the original band matrix A stored in rows from 1 to $kl + ku + 1$. The second dimension of <i>ab</i> must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of *ab*; $ldab \geq kl+ku+1$.

Output Parameters

<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: $r(m), c(n)$. If $info = 0$, or $info > m$, the array <i>r</i> contains the row scale factors of the matrix <i>A</i> . If $info = 0$, the array <i>c</i> contains the column scale factors of the matrix <i>A</i> .
<i>rowcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$ or $info > m$, <i>rowcnd</i> contains the ratio of the smallest $r(i)$ to the largest $r(i)$.
<i>colcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$, <i>colcnd</i> contains the ratio of the smallest $c(i)$ to the largest $c(i)$.
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value. If $info = i$ and $i \leq m$, the <i>i</i> -th row of <i>A</i> is exactly zero; $i > m$, the $(i-m)$ th column of <i>A</i> is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbequ` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kl+ku+1, n)$.
<i>r</i>	Holds the vector of length (m) .
<i>c</i>	Holds the vector of length n .
<i>kl</i>	If omitted, assumed $kl = ku$.

*ku*Restored as $ku = lda - kl - 1$.

Application Notes

All the components of r and c are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the [?lamch](#) routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

If $rowcnd \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by r .

If $colcnd \geq 0.1$, it is not worth scaling by c .

If $amax$ is very close to overflow or very close to underflow, the matrix A should be scaled.

?gbequb

Computes row and column scaling factors restricted to a power of radix to equilibrate a banded matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call dgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call cgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call zgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
```

C:

```
lapack_int LAPACKE_sgbequb( int matrix_layout, lapack_int m, lapack_int n, lapack_int
kl, lapack_int ku, const float* ab, lapack_int ldab, float* r, float* c, float*
rowcnd, float* colcnd, float* amax );

lapack_int LAPACKE_dgbequb( int matrix_layout, lapack_int m, lapack_int n, lapack_int
kl, lapack_int ku, const double* ab, lapack_int ldab, double* r, double* c, double*
rowcnd, double* colcnd, double* amax );

lapack_int LAPACKE_cgbequb( int matrix_layout, lapack_int m, lapack_int n, lapack_int
kl, lapack_int ku, const lapack_complex_float* ab, lapack_int ldab, float* r, float*
c, float* rowcnd, float* colcnd, float* amax );

lapack_int LAPACKE_zgbequb( int matrix_layout, lapack_int m, lapack_int n, lapack_int

Description

The routine computes row and column scalings intended to equilibrate an m -by- n banded matrix A and reduce its condition number. The output array r returns the row scale factors and the array c - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij} = r(i) * a_{ij} * c(j)$ have an absolute value of at most the radix.

$r(i)$ and $c(j)$ are restricted to be a power of the radix between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of a but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the [?lamch](#) routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

This routine differs from [?gbequ](#) by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between $\sqrt{\text{radix}}$ and $1/\sqrt{\text{radix}}$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
n	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
k_1	INTEGER. The number of subdiagonals within the band of A ; $k_1 \geq 0$.
k_u	INTEGER. The number of superdiagonals within the band of A ; $k_u \geq 0$.
ab	REAL for sgbequb DOUBLE PRECISION for dgbequb COMPLEX for cgbequb DOUBLE COMPLEX for zgbequb. Array: DIMENSION ($ldab, *$). Contains the original banded matrix A stored in rows from 1 to $k_1 + k_u + 1$. The j -th column of A is stored in the j -th column of the array ab as follows: $ab(k_u+1+i-j, j) = a(i, j)$ for $\max(1, j-k_u) \leq i \leq \min(n, j+k_1)$. The second dimension of ab must be at least $\max(1, n)$.
$ldab$	INTEGER. The leading dimension of a ; $ldab \geq \max(1, m)$.

Output Parameters

r, c	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: $r(m), c(n)$.
--------	---

If $info = 0$, or $info > m$, the array r contains the row scale factors for the matrix A .

If $info = 0$, the array c contains the column scale factors for the matrix A .

rowcnd

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

If $info = 0$ or $info > m$, *rowcnd* contains the ratio of the smallest $r(i)$ to the largest $r(i)$. If $rowcnd \geq 0.1$, and *amax* is neither too large nor too small, it is not worth scaling by r .

colcnd

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

If $info = 0$, *colcnd* contains the ratio of the smallest $c(i)$ to the largest $c(i)$. If $colcnd \geq 0.1$, it is not worth scaling by c .

amax

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest element of the matrix A . If *amax* is very close to overflow or underflow, the matrix should be scaled.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of A is nonpositive.

$i \leq m$, the i -th row of A is exactly zero;

$i > m$, the $(i-m)$ -th column of A is exactly zero.

?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spoequ( n, a, lda, s, scond, amax, info )
call dpoequ( n, a, lda, s, scond, amax, info )
call cpoequ( n, a, lda, s, scond, amax, info )

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s_i = \frac{1}{\sqrt{A_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij} = s(i) * a_{ij} * s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsy](#) auxiliary function that uses scaling factors computed by [?poequ](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for spoequ DOUBLE PRECISION for dpoequ COMPLEX for cpoequ DOUBLE COMPLEX for zpoequ . Array: DIMENSION (<i>lda</i> , *).
	Contains the n -by- n symmetric or Hermitian positive definite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced.
	The second dimension of <i>a</i> must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; $lda \geq \max(1, n)$.

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>A</i> is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `poequ` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>s</i>	Holds the vector of length <i>n</i> .

Application Notes

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?poequb

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spoequb( n, a, lda, s, scond, amax, info )
call dpoequb( n, a, lda, s, scond, amax, info )

- C: mkl.h

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm).

These factors are chosen so that the scaled matrix B with elements $b(i,j)=s(i)*a(i,j)*s(j)$ has diagonal elements equal to 1. $s(i)$ is a power of two nearest to, but not exceeding $1/\sqrt{A(i,i)}$.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for spoequb DOUBLE PRECISION for dpoequb COMPLEX for cpoequb DOUBLE COMPLEX for zpoequb. Array: DIMENSION (<i>lda</i> , *). Contains the n -by- n symmetric or Hermitian positive definite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>). If <i>scond</i> ≥ 0.1 , and <i>amax</i> is neither too large nor too small, it is not worth scaling by <i>s</i> .
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> . If <i>amax</i> is very close to overflow or underflow, the matrix should be scaled.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>A</i> is nonpositive.

?ppequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix in packed storage and reduce its condition number.

Syntax

FORTRAN 77:

```
call sppequ( uplo, n, ap, s, scond, amax, info )
call dppequ( uplo, n, ap, s, scond, amax, info )
call cppequ( uplo, n, ap, s, scond, amax, info )
call zppequ( uplo, n, ap, s, scond, amax, info )
```

Fortran 95:

```
call ppequ( ap, s [, scond] [, amax] [, uplo] [, info] )
```

C:

```
lapack_int LAPACKE_sppequ( int matrix_layout, char uplo, lapack_int n, const float* ap,
float* s, float* scond, float* amax);
lapack_int LAPACKE_dppequ( int matrix_layout, char uplo, lapack_int n, const double* ap,
double* s, double* scond, double* amax);
lapack_int LAPACKE_cppequ( int matrix_layout, char uplo, lapack_int n,
const lapack_complex_float* ap, float* s, float* scond, float* amax);
```

```
lapack_int LAPACKE_zppequ( int matrix_layout, char uplo, lapack_int n,
                           const lapack_complex_double* ap, double* s, double* scond, double* amax );
```

Include Files

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

```
, ! : : : : :
```

These factors are chosen so that the scaled matrix B with elements $b_{ij} = s(i) * a_{ij} * s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsp](#) auxiliary function that uses scaling factors computed by [?ppequ](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is packed in the array <i>ap</i> :
	If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the matrix A .
	If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>ap</i>	REAL for sppequ DOUBLE PRECISION for dppequ COMPLEX for cppequ DOUBLE COMPLEX for zppequ. Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in packed storage (see Matrix Storage Schemes).

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>A</i> is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppequ` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>s</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?pbequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive-definite band matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
call dpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
call cpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
```

```
call zpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
```

Fortran 95:

```
call pbequ( ab, s [,scond] [,amax] [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_spbequ( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
const float* ab, lapack_int ldab, float* s, float* scond, float* amax );
lapack_int LAPACKE_dpbequ( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
const double* ab, lapack_int ldab, double* s, double* scond, double* amax );
lapack_int LAPACKE_cpbequ( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
const lapack_complex_float* ab, lapack_int ldab, float* s, float* scond, float* amax );
lapack_int LAPACKE_zpbequ( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
const lapack_complex_double* ab, lapack_int ldab, double* s, double* scond, double* amax );
```

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1. This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsb](#) auxiliary function that uses scaling factors computed by [?pbequ](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is packed in the array *ab*:

If *uplo* = 'U', the array *ab* stores the upper triangular part of the matrix A .

If *uplo* = 'L', the array *ab* stores the lower triangular part of the matrix *A*.

n INTEGER. The order of matrix *A*; $n \geq 0$.

kd INTEGER. The number of superdiagonals or subdiagonals in the matrix *A*; $kd \geq 0$.

ab REAL for *spbequ*

DOUBLE PRECISION for *dpbequ*

COMPLEX for *cpbequ*

DOUBLE COMPLEX for *zpbequ*.

Array, DIMENSION (*ldab*, *).

The array *ap* contains either the upper or the lower triangular part of the matrix *A* (as specified by *uplo*) in *band storage* (see [Matrix Storage Schemes](#)).

The second dimension of *ab* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*; $ldab \geq kd + 1$.

Output Parameters

s REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*n*).

If *info* = 0, the array *s* contains the scale factors for *A*.

scond REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

If *info* = 0, *scond* contains the ratio of the smallest *s*(*i*) to the largest *s*(*i*).

amax REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest element of the matrix *A*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the *i*-th diagonal element of *A* is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pbequ* interface are as follows:

<i>ab</i>	Holds the array A of size $(kd+1, n)$.
<i>s</i>	Holds the vector of length n .
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by s .

If $amax$ is very close to overflow or very close to underflow, the matrix A should be scaled.

?syequb

Computes row and column scaling factors intended to equilibrate a symmetric indefinite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call ssyequb( uplo, n, a, lda, s, scond, amax, work, info )
call dsyequb( uplo, n, a, lda, s, scond, amax, work, info )
call csyequb( uplo, n, a, lda, s, scond, amax, work, info )
call zsyequb( uplo, n, a, lda, s, scond, amax, work, info )
```

C:

```
lapack_int LAPACKE_ssyequb( int matrix_layout, char uplo, lapack_int n, const float* a,
                             lapack_int lda, float* s, float* scond, float* amax );
lapack_int LAPACKE_dsyequb( int matrix_layout, char uplo, lapack_int n, const double* a,
                            lapack_int lda, double* s, double* scond, double* amax );
lapack_int LAPACKE_csyequb( int matrix_layout, char uplo, lapack_int n,

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:

If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A .

If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A .

n

INTEGER. The order of the matrix A ; $n \geq 0$.

a, work

REAL for ssyequb

DOUBLE PRECISION for dsyequb

COMPLEX for csyequb

DOUBLE COMPLEX for zsyequb.

Array a : DIMENSION ($lda, *$).

Contains the n -by- n symmetric indefinite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

The second dimension of a must be at least $\max(1, n)$.

$work(*)$ is a workspace array. The dimension of $work$ is at least $\max(1, 3*n)$.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n).

If $info = 0$, the array s contains the scale factors for A .

scond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

If $info = 0$, $scond$ contains the ratio of the smallest $s(i)$ to the largest $s(i)$. If $scond \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by s .

amax

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Description

The routine solves for X the system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = P \cdot L \cdot U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A \cdot X = B$.

The dsgesv and zcgesv are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (dsgesv) or single complex precision (zcgesv) and use this factorization within an iterative refinement procedure to produce a solution with double precision (dsgesv) / double complex precision (zcgesv) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision performance over double precision performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ilaenv in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

```
iter > itermax
```

or for all the right-hand sides:

```
rnmr < sqrt(n)*xnrm*anrm*eps*bwdmax
```

where

- `iter` is the number of the current iteration in the iterative refinement process
- `rnmr` is the infinity-norm of the residual
- `xnrm` is the infinity-norm of the solution
- `anrm` is the infinity-operator-norm of the matrix A
- `eps` is the machine epsilon returned by `dlamch ('Epsilon')`.

The values `itermax` and `bwdmax` are fixed to 30 and 1.0d+00 respectively.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix <i>B</i> ; $nrhs \geq 0$.
<i>a, b</i>	REAL for <code>s gesv</code> DOUBLE PRECISION for <code>d gesv</code> and <code>d s gesv</code> COMPLEX for <code>c gesv</code> DOUBLE COMPLEX for <code>z gesv</code> and <code>z c gesv</code> . Arrays: <i>a</i> (<i>lda</i> ,*) , <i>b</i> (<i>ldb</i> ,*). The array <i>a</i> contains the <i>n</i> -by- <i>n</i> coefficient matrix <i>A</i> . The array <i>b</i> contains the <i>n</i> -by- <i>nrhs</i> matrix of right hand side matrix <i>B</i> . The second dimension of <i>a</i> must be at least <code>max(1, n)</code> , the second dimension of <i>b</i> at least <code>max(1, nrhs)</code> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of the array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>work</i>	DOUBLE PRECISION for <code>d s gesv</code> DOUBLE COMPLEX for <code>z c gesv</code> . Workspace array, DIMENSION at least <code>max(1, n*nrhs)</code> . This array is used to hold the residual vectors.
<i>swork</i>	REAL for <code>d gesv</code> COMPLEX for <code>z gesv</code> . Workspace array, DIMENSION at least <code>max(1, n*(n+nrhs))</code> . This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.
<i>rwork</i>	DOUBLE PRECISION. Workspace array, DIMENSION at least <code>max(1, n)</code> .

Output Parameters

<i>a</i>	Overwritten by the factors <i>L</i> and <i>U</i> from the factorization of $A = P^* L^* U$; the unit diagonal elements of <i>L</i> are not stored. If iterative refinement has been successfully used (<i>info</i> = 0 and <i>iter</i> ≥ 0), then <i>A</i> is unchanged.
----------	---

If double precision factorization has been used (*info*= 0 and *iter* < 0), then the array *A* contains the factors *L* and *U* from the factorization $A = P \cdot L \cdot U$; the unit diagonal elements of *L* are not stored.

b Overwritten by the solution matrix *X* for `dgesv`, `sgesv`, `zgesv`, `zgesv`. Unchanged for `dgesv` and `zgesv`.

ipiv INTEGER.

Array, DIMENSION at least `max(1, n)`. The pivot indices that define the permutation matrix *P*; row *i* of the matrix was interchanged with row *ipiv(i)*. Corresponds to the single precision factorization (if *info*= 0 and *iter* ≥ 0) or the double precision factorization (if *info*= 0 and *iter* < 0).

x DOUBLE PRECISION for `dgesv`
DOUBLE COMPLEX for `zgesv`.

Array, DIMENSION (*lidx*, *nrhs*). If *info* = 0, contains the *n*-by-*nrhs* solution matrix *X*.

iter INTEGER.

If *iter* < 0: iterative refinement has failed, double precision factorization has been performed

- If *iter* = -1: the routine fell back to full precision for implementation- or machine-specific reason
- If *iter* = -2: narrowing the precision induced an overflow, the routine fell back to full precision
- If *iter* = -3: failure of `sgetrf` for `dgesv`, or `cgetrf` for `zgesv`
- If *iter* = -31: stop the iterative refinement after the 30th iteration.

If *iter* > 0: iterative refinement has been successfully used. Returns the number of iterations.

info INTEGER. If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, *U*(*i*, *i*) (computed in double precision for mixed precision subroutines) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesv` interface are as follows:

a Holds the matrix *A* of size (*n*, *n*).

b Holds the matrix *B* of size (*n*, *nrhs*).

*ipiv*Holds the vector of length n .**NOTE**Fortran 95 Interface is so far not available for the mixed precision subroutines `dgesv/zgesv`.**See Also**[ilaenv](#)[?lamch](#)[?getrf](#)**?gesvx**

Computes the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gesvx performs the following steps:

1. If $fact = 'E'$, real scaling factors r and c are computed to equilibrate the system:

```
trans = 'N': diag(r)*A*diag(c)*inv(diag(c))*X = diag(r)*B
trans = 'T': (diag(r)*A*diag(c))T*inv(diag(r))*X = diag(c)*B
trans = 'C': (diag(r)*A*diag(c))H*inv(diag(r))*X = diag(c)*B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(r)*A*diag(c)$ and B by $diag(r)*B$ (if $trans='N'$) or $diag(c)*B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the *LU* decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = P \cdot L \cdot U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{j,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(c)$ (if $trans = 'N'$) or $diag(r)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface, except for $rpivot$. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $\text{fact} = \text{'F'}$: on entry, af and ipiv contain the factored form of A . If equed is not ' N ', the matrix A has been equilibrated with scaling factors given by r and c .

a , af , and ipiv are not modified.

If $\text{fact} = \text{'N'}$, the matrix A will be copied to af and factored.

If $\text{fact} = \text{'E'}$, the matrix A will be equilibrated if necessary, then copied to af and factored.

trans

CHARACTER*1. Must be ' N ', ' T ', or ' C '.

Specifies the form of the system of equations:

If $\text{trans} = \text{'N'}$, the system has the form $A*X = B$ (No transpose).

If $\text{trans} = \text{'T'}$, the system has the form $A^T*X = B$ (Transpose).

If $\text{trans} = \text{'C'}$, the system has the form $A^H*X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

n

INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right hand sides; the number of columns of the matrices B and X ; $\text{nrhs} \geq 0$.

a , af , b , work

REAL for sgetrf

DOUBLE PRECISION for dgetrf

COMPLEX for cgetrf

DOUBLE COMPLEX for zgetrf .

Arrays: $a(\text{lda},*)$, $\text{af}(\text{ldaf},*)$, $b(\text{ldb},*)$, $\text{work}(*)$.

The array a contains the matrix A . If $\text{fact} = \text{'F'}$ and equed is not ' N ', then A must have been equilibrated by the scaling factors in r and/or c . The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $\text{fact} = \text{'F'}$. It contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = P*L*U$ as computed by ?getrf . If equed is not ' N ', then af is the factored form of the equilibrated matrix A . The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, \text{nrhs})$.

$\text{work}(*)$ is a workspace array. The dimension of work must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda

INTEGER. The leading dimension of a ; $\text{lda} \geq \max(1, n)$.

ldaf

INTEGER. The leading dimension of af ; $\text{ldaf} \geq \max(1, n)$.

ldb

INTEGER. The leading dimension of b ; $\text{ldb} \geq \max(1, n)$.

ipiv

INTEGER.

`Array, DIMENSION at least $\max(1, n)$.` The array `ipiv` is an input argument if `fact = 'F'`. It contains the pivot indices from the factorization $A = P \cdot L \cdot U$ as computed by `?getrf`; row i of the matrix was interchanged with row `ipiv(i)`.

`equed`

CHARACTER*1. Must be '`N`', '`R`', '`C`', or '`B`'.

`equed` is an input argument if `fact = 'F'`. It specifies the form of equilibration that was done:

If `equed = 'N'`, no equilibration was done (always true if `fact = 'N'`).

If `equed = 'R'`, row equilibration was done, that is, A has been premultiplied by `diag(r)`.

If `equed = 'C'`, column equilibration was done, that is, A has been postmultiplied by `diag(c)`.

If `equed = 'B'`, both row and column equilibration was done, that is, A has been replaced by `diag(r) * A * diag(c)`.

`r, c`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: `r(n)`, `c(n)`. The array `r` contains the row scale factors for A , and the array `c` contains the column scale factors for A . These arrays are input arguments if `fact = 'F'` only; otherwise they are output arguments.

If `equed = 'R'` or '`B`', A is multiplied on the left by `diag(r)`; if `equed = 'N'` or '`C`', r is not accessed.

If `fact = 'F'` and `equed = 'R'` or '`B`', each element of `r` must be positive.

If `equed = 'C'` or '`B`', A is multiplied on the right by `diag(c)`; if `equed = 'N'` or '`R`', `c` is not accessed.

If `fact = 'F'` and `equed = 'C'` or '`B`', each element of `c` must be positive.

`lidx`

INTEGER. The leading dimension of the output array `x`; `lidx $\geq \max(1, n)$` .

`iwork`

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

`rwork`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, 2*n)$; used in complex flavors only.

Output Parameters

`x`

REAL for `sgetsvx`

DOUBLE PRECISION for `dgesvx`

COMPLEX for cgesvx

DOUBLE COMPLEX for zgesvx.

Array, DIMENSION ($l_{\text{dx}}, *$).

If $\text{info} = 0$ or $\text{info} = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that A and B are modified on exit if $\text{equed} \neq 'N'$, and the solution to the *equilibrated* system is:

$\text{diag}(C)^{-1}X$, if $\text{trans} = 'N'$ and $\text{equed} = 'C'$ or $'B'$; $\text{diag}(R)^{-1}X$, if $\text{trans} = 'T'$ or $'C'$ and $\text{equed} = 'R'$ or $'B'$. The second dimension of x must be at least $\max(1, nrhs)$.

a

Array a is not modified on exit if $\text{fact} = 'F'$ or $'N'$, or if $\text{fact} = 'E'$ and $\text{equed} = 'N'$. If $\text{equed} \neq 'N'$, A is scaled on exit as follows:
 $\text{equed} = 'R'$: $A = \text{diag}(R) * A$
 $\text{equed} = 'C'$: $A = A * \text{diag}(c)$
 $\text{equed} = 'B'$: $A = \text{diag}(R) * A * \text{diag}(c)$.

af

If $\text{fact} = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = PLU$ of the original matrix A (if $\text{fact} = 'N'$) or of the equilibrated matrix A (if $\text{fact} = 'E'$). See the description of a for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(r)^{*}B$ if $\text{trans} = 'N'$ and $\text{equed} = 'R'$ or $'B'$;
overwritten by $\text{diag}(c)^{*}B$ if $\text{trans} = 'T'$ or $'C'$ and $\text{equed} = 'C'$ or $'B'$;
not changed if $\text{equed} = 'N'$.

r, c

These arrays are output arguments if $\text{fact} \neq 'F'$. See the description of r, c in *Input Arguments* section.

$rcond$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. This condition is indicated by a return code of $\text{info} > 0$.

$ferr$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x^{(j)}$ (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to $x^{(j)}$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x^{(j)} - x_{\text{true}})$ divided by the magnitude of the

largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

ipiv

If $fact = 'N'$ or $'E'$, then *ipiv* is an output argument and on exit contains the pivot indices from the factorization $A = P \cdot L \cdot U$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$).

equed

If $fact \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

work, rwork, rpivot

On exit, *work(1)* for real flavors, or *rwork(1)* for complex flavors (the Fortran interface) and *rpivot* (the C interface), contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If *work(1)* for real flavors, or *rwork(1)* for complex flavors is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution x , condition estimator $rcond$, and forward error bound *ferr* could be unreliable. If factorization fails with $0 < info \leq n$, then *work(1)* for real flavors, or *rwork(1)* for complex flavors contains the reciprocal pivot growth factor for the leading *info* columns of A .

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info = i$, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n+1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine gesvx interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .
<i>r</i>	Holds the vector of length n . Default value for each element is $r(i) = 1.0_{\text{WP}}$.
<i>c</i>	Holds the vector of length n . Default value for each element is $c(i) = 1.0_{\text{WP}}$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>equed</i>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<i>rpvgrw</i>	Real value that contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$.

?gesvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides

Syntax

FORTRAN 77:

```
call sgesvxx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b, ldb, x,

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?gesvxx performs the following steps:

1. If *fact* = 'E', scaling factors *r* and *c* are computed to equilibrate the system:

```

trans = 'N': diag(r)*A*diag(c)*inv(diag(c))*X = diag(r)*B
trans = 'T': (diag(r)*A*diag(c))T*inv(diag(r))*X = diag(c)*B
trans = 'C': (diag(r)*A*diag(c))H*inv(diag(r))*X = diag(c)*B

```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if $\text{trans} = 'N'$) or $\text{diag}(c) * B$ (if $\text{trans} = 'T'$ or $'C'$).

2. If $\text{fact} = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $\text{fact} = 'E'$) as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the rcond parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless $\text{params}(\text{la_linrx_itref_i})$ is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if $\text{trans} = 'N'$) or $\text{diag}(r)$ (if $\text{trans} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be ' <i>F</i> ', ' <i>N</i> ', or ' <i>E</i> '.
	Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
	If $\text{fact} = 'F'$, on entry, af and ipiv contain the factored form of A . If equed is not ' <i>N</i> ', the matrix A has been equilibrated with scaling factors given by r and c . Parameters a , af , and ipiv are not modified.
	If $\text{fact} = 'N'$, the matrix A will be copied to af and factored.
	If $\text{fact} = 'E'$, the matrix A will be equilibrated, if necessary, copied to af and factored.
<i>trans</i>	CHARACTER*1. Must be ' <i>N</i> ', ' <i>T</i> ', or ' <i>C</i> '.
	Specifies the form of the system of equations:
	If $\text{trans} = 'N'$, the system has the form $A * X = B$ (No transpose).
	If $\text{trans} = 'T'$, the system has the form $A^{**T} * X = B$ (Transpose).
	If $\text{trans} = 'C'$, the system has the form $A^{**H} * X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>a</i> , <i>af</i> , <i>b</i> , <i>work</i>	REAL for sgesvxx DOUBLE PRECISION for dgesvxx COMPLEX for cgesvxx

DOUBLE COMPLEX for zgesvxx.

Arrays: $a(1da, *)$, $af(1daf, *)$, $b(1db, *)$, $work(*)$.

The array a contains the matrix A . If $fact = 'F'$ and $equed$ is not ' N ', then A must have been equilibrated by the scaling factors in r and/or c . The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = P \cdot L \cdot U$ as computed by [?getrf](#). If $equed$ is not ' N ', then af is the factored form of the equilibrated matrix A . The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4 * n)$ for real flavors, and at least $\max(1, 2 * n)$ for complex flavors.

$1da$

INTEGER. The leading dimension of a ; $1da \geq \max(1, n)$.

$1daf$

INTEGER. The leading dimension of af ; $1daf \geq \max(1, n)$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P \cdot L \cdot U$ as computed by [?getrf](#); row i of the matrix was interchanged with row $ipiv(i)$.

$equed$

CHARACTER*1. Must be ' N ', ' R ', ' C ', or ' B '.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).

If $equed = 'R'$, row equilibration was done, that is, A has been premultiplied by $diag(r)$.

If $equed = 'C'$, column equilibration was done, that is, A has been postmultiplied by $diag(c)$.

If $equed = 'B'$, both row and column equilibration was done, that is, A has been replaced by $diag(r) \cdot A \cdot diag(c)$.

r, c

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: $r(n)$, $c(n)$. The array r contains the row scale factors for A , and the array c contains the column scale factors for A . These arrays are input arguments if $fact = 'F'$ only; otherwise they are output arguments.

If $equed = 'R'$ or ' B ', A is multiplied on the left by $diag(r)$; if $equed = 'N'$ or ' C ', r is not accessed.

If $fact = 'F'$ and $equed = 'R'$ or ' B ', each element of r must be positive.

If $\text{equed} = \text{'C'}$ or 'B' , A is multiplied on the right by $\text{diag}(c)$; if $\text{equed} = \text{'N'}$ or 'R' , c is not accessed.

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'C'}$ or 'B' , each element of c must be positive.

Each element of r or c should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

ldx

INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.

n_err_bnds

INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in *Output Arguments* section below.

$nparams$

INTEGER. Specifies the number of parameters set in params . If ≤ 0 , the params array is never referenced and default values are used.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the params argument.

$\text{params}(\text{la_linrx_itref_i} = 1)$: Whether to perform iterative refinement or not. Default: 1.0

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.
------	--

(Other values are reserved for future use.)

$\text{params}(\text{la_linrx_ithresh_i} = 2)$: Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.
------------	---

`params(la_linx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x

REAL for `sgevxx`

DOUBLE PRECISION for `dgevxx`

COMPLEX for `cgevxx`

DOUBLE COMPLEX for `zgevxx`.

Array, DIMENSION (*lidx*, *).

If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *X* to the original system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the equilibrated system is:

`inv(diag(c))*X`, if *trans* = 'N' and *equed* = 'C' or 'B'; or
`inv(diag(r))*X`, if *trans* = 'T' or 'C' and *equed* = 'R' or 'B'. The second dimension of *x* must be at least $\max(1, nrhs)$.

a

Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.

If *equed* ≠ 'N', *A* is scaled on exit as follows:

equed = 'R': *A* = `diag(r)*A`

equed = 'C': *A* = *A**`diag(c)`

equed = 'B': *A* = `diag(r)*A*diag(c)`.

af

If *fact* = 'N' or 'E', then *af* is an output argument and on exit returns the factors *L* and *U* from the factorization *A* = *PLU* of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E'). See the description of *a* for the form of the equilibrated matrix.

b

Overwritten by `diag(r)*B` if *trans* = 'N' and *equed* = 'R' or 'B';
overwritten by *trans* = 'T' or 'C' and *equed* = 'C' or 'B';
not changed if *equed* = 'N'.

r, c

These arrays are output arguments if *fact* ≠ 'F'. Each element of these arrays is a power of the radix. See the description of *r, c* in *Input Arguments* section.

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

rpvgrw

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading info columns of A . In *?gesvx*, this quantity is returned in *work(1)*.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $(nrhs, n_{\text{err_bnds}})$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm(i, :)* corresponds to the i -th right-hand side.

The second index in *err_bnds_norm(:, err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt(n) * \text{dlamch}(\epsilon)$ for double precision flavors.
--------------	--

<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is
--------------	--

greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z.

Let $z = s^*a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION ($\text{nrhs}, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s^* (a^* \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^* \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.
<code>ipiv</code>	If $\text{fact} = 'N'$ or $'E'$, then <code>ipiv</code> is an output argument and on exit contains the pivot indices from the factorization $A = P^* L^* U$ of the original matrix A (if $\text{fact} = 'N'$) or of the equilibrated matrix A (if $\text{fact} = 'E'$).
<code>equed</code>	If $\text{fact} \neq 'F'$, then <code>equed</code> is an output argument. It specifies the form of equilibration that was done (see the description of <code>equed</code> in <i>Input Arguments</i> section).
<code>params</code>	If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified
<code>info</code>	INTEGER. If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed. If $\text{info} = -i$, the i -th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned. If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$). See the definition of $\text{err_bnds_norm}(:, 1)$ and $\text{err_bnds_comp}(:, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?gbsv

Computes the solution to the system of linear equations with a band matrix A and multiple right-hand sides.

Syntax**FORTRAN 77:**

```
call sgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbsv( ab, b [,kl] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>gbsv( int matrix_layout, lapack_int n, lapack_int kl, lapack_int ku, lapack_int nrhs, <datatype>* ab, lapack_int ldab, lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the real or complex system of linear equations $A*X = B$, where A is an n -by- n band matrix with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals. The factored form of A is then used to solve the system of equations $A*X = B$.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of A . The number of rows in B ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides. The number of columns in B ; $nrhs \geq 0$.
<i>ab, b</i>	REAL for sgbsv DOUBLE PRECISION for dgbsv

COMPLEX for `cgbsv`

DOUBLE COMPLEX for `zgbsv`.

Arrays: $ab(1:ldab, :)$, $b(1:ldb, :)$.

The array ab contains the matrix A in band storage (see [Matrix Storage Schemes](#)). The second dimension of ab must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$ldab$ INTEGER. The leading dimension of the array ab . ($ldab \geq 2k_1 + k_u + 1$)

ldb INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ab Overwritten by L and U . The diagonal and $k_1 + k_u$ superdiagonals of U are stored in the first $1 + k_1 + k_u$ rows of ab . The multipliers used to form L are stored in the next k_1 rows.

b Overwritten by the solution matrix X .

$ipiv$ INTEGER.

Array, DIMENSION at least $\max(1, n)$. The pivot indices: row i was interchanged with row $ipiv(i)$.

$info$ INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbsv` interface are as follows:

ab Holds the array A of size $(2*k_1+k_u+1, n)$.

b Holds the matrix B of size $(n, nrhs)$.

$ipiv$ Holds the vector of length n .

k_1 If omitted, assumed $k_1 = k_u$.

ku Restored as $ku = lda - 2*k_1 - 1$.

?gbsvx

Computes the solution to the real or complex system of linear equations with a band matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax**FORTRAN 77:**

```
call sgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed, r, c, b,
ldb, x, ldx, rcond, ferr, berr, work, iwork, info )
call dgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed, r, c, b,

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, $A^T*X = B$, or $A^H*X = B$, where A is a band matrix of order n with k_l subdiagonals and k_u superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gbsvx performs the following steps:

1. If $\text{fact} = \text{'E'}$, real scaling factors r and c are computed to equilibrate the system:

```
trans = 'N': diag(r)*A*diag(c) *inv(diag(c))*X = diag(r)*B
trans = 'T': (diag(r)*A*diag(c))^T *inv(diag(r))*X = diag(c)*B
trans = 'C': (diag(r)*A*diag(c))^H *inv(diag(r))*X = diag(c)*B
```

Whether the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r)*A*\text{diag}(c)$ and B by $\text{diag}(r)*B$ (if $\text{trans} = \text{'N'}$) or $\text{diag}(c)*B$ (if $\text{trans} = \text{'T'}$ or 'C').

2. If $\text{fact} = \text{'N'}$ or 'E' , the *LU* decomposition is used to factor the matrix A (after equilibration if $\text{fact} = \text{'E'}$) as $A = L*U$, where L is a product of permutation and unit lower triangular matrices with k_l subdiagonals, and U is upper triangular with k_l+k_u superdiagonals.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $\text{info} = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if $\text{trans} = \text{'N'}$) or $\text{diag}(r)$ (if $\text{trans} = \text{'T'}$ or 'C') so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface, except for rpivot . A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F' , 'N' , or 'E' .

Specifies whether the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $\text{fact} = \text{'F'}$: on entry, afb and ipiv contain the factored form of A . If equed is not 'N' , the matrix A is equilibrated with scaling factors given by r and c .

ab , afb , and ipiv are not modified.

If $\text{fact} = \text{'N'}$, the matrix A will be copied to afb and factored.

If $\text{fact} = \text{'E'}$, the matrix A will be equilibrated if necessary, then copied to afb and factored.

trans

CHARACTER*1. Must be 'N' , 'T' , or 'C' .

Specifies the form of the system of equations:

If $\text{trans} = \text{'N'}$, the system has the form $A^*X = B$ (No transpose).

If $\text{trans} = \text{'T'}$, the system has the form $A^T * X = B$ (Transpose).

If $\text{trans} = \text{'C'}$, the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

n

INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.

kl

INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.

ku

INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.

$nrhs$

INTEGER. The number of right hand sides, the number of columns of the matrices B and X ; $nrhs \geq 0$.

$ab, afb, b, work$

REAL for sgbsvx

DOUBLE PRECISION for dgbsvx

COMPLEX for cgbsvx

DOUBLE COMPLEX for zgbsvx.

Arrays: $ab(1:dab, *)$, $afb(1:dafb, *)$, $b(1:db, *)$, $work(*)$.

The array ab contains the matrix A in band storage (see [Matrix Storage Schemes](#)). The second dimension of ab must be at least $\max(1, n)$. If $\text{fact} = \text{'F'}$ and equed is not ' N ', then A must have been equilibrated by the scaling factors in r and/or c .

The array afb is an input argument if $\text{fact} = \text{'F'}$. The second dimension of afb must be at least $\max(1, n)$. It contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = L * U$ as computed by [?gbtrf](#). U is stored as an upper triangular band matrix with $kl + ku$ superdiagonals in the first $1 + kl + ku$ rows of afb . The multipliers used during the factorization are stored in the next kl rows. If equed is not ' N ', then afb is the factored form of the equilibrated matrix A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

$ldab$

INTEGER. The leading dimension of ab ; $ldab \geq kl+ku+1$.

$ldafb$

INTEGER. The leading dimension of afb ; $ldafb \geq 2*kl+ku+1$.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $\text{fact} = \text{'F'}$. It contains the pivot indices from the factorization $A = L * U$ as computed by [?gbtrf](#); row i of the matrix was interchanged with row $ipiv(i)$.

equed

CHARACTER*1. Must be 'N', 'R', 'C', or 'B'.

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:If *equed* = 'N', no equilibration was done (always true if *fact* = 'N').If *equed* = 'R', row equilibration was done, that is, *A* has been premultiplied by *diag(r)*.If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by *diag(c)*.If *equed* = 'B', both row and column equilibration was done, that is, *A* has been replaced by *diag(r)*A*diag(c)*.*r, c*

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: *r(n), c(n)*.The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if *fact* = 'F' only; otherwise they are output arguments.If *equed* = 'R' or 'B', *A* is multiplied on the left by *diag(r)*; if *equed* = 'N' or 'C', *r* is not accessed.If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive.*ldx*INTEGER. The leading dimension of the output array *x*; *ldx* $\geq \max(1, n)$.*iwork*INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.*rwork*

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for sgbsvx

DOUBLE PRECISION for dgbsvx

COMPLEX for cgbsvx

DOUBLE COMPLEX for zgbsvx.

Array, DIMENSION (*ldx, **).

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the *equilibrated* system is: $\text{inv}(\text{diag}(c)) * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; $\text{inv}(\text{diag}(r)) * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.

The second dimension of x must be at least $\max(1, nrhs)$.

ab

Array *ab* is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.

If $equed \neq 'N'$, A is scaled on exit as follows:

$equed = 'R'$: $A = \text{diag}(r) * A$
 $equed = 'C'$: $A = A * \text{diag}(c)$
 $equed = 'B'$: $A = \text{diag}(r) * A * \text{diag}(c)$.

afb

If $fact = 'N'$ or $'E'$, then *afb* is an output argument and on exit returns details of the *LU* factorization of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of *ab* for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(r) * b$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$;
overwritten by $\text{diag}(c) * b$ if $trans = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$;
not changed if $equed = 'N'$.

r, c

These arrays are output arguments if $fact \neq 'F'$. See the description of *r, c* in *Input Arguments* section.

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done).

If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If *xtrue* is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

ipiv

If $\text{fact} = \text{'N'}$ or 'E' , then *ipiv* is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A (if $\text{fact} = \text{'N'}$) or of the equilibrated matrix A (if $\text{fact} = \text{'E'}$).

equed

If $\text{fact} \neq \text{'F'}$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

work, rwork, rpivot

On exit, *work(1)* for real flavors, or *rwork(1)* for complex flavors (the Fortran interface) and *rpivot* (the C interface), contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If *work(1)* for real flavors, or *rwork(1)* for complex flavors is much less than 1, then the stability of the *LU* factorization of the (equilibrated) matrix A could be poor. This also means that the solution x , condition estimator *rcond*, and forward error bound *ferr* could be unreliable. If factorization fails with $0 < \text{info} \leq n$, then *work(1)* for real flavors, or *rwork(1)* for complex flavors contains the reciprocal pivot growth factor for the leading *info* columns of A .

info

INTEGER. If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $\text{info} = i$, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If $\text{info} = i$, and $i = n+1$, then U is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbsvx* interface are as follows:

ab

Holds the array A of size (k_1+k_u+1, n) .

b

Holds the matrix B of size (n, nrhs) .

x

Holds the matrix X of size (n, nrhs) .

afb

Holds the array AF of size $(2*k_1+k_u+1, n)$.

ipiv

Holds the vector of length n .

<i>r</i>	Holds the vector of length <i>n</i> . Default value for each element is <i>r</i> (<i>i</i>) = 1.0_WP.
<i>c</i>	Holds the vector of length <i>n</i> . Default value for each element is <i>c</i> (<i>i</i>) = 1.0_WP.
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>equed</i>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>rpvgrw</i>	Real value that contains the reciprocal pivot growth factor norm(<i>A</i>)/norm(<i>U</i>).
<i>kl</i>	If omitted, assumed <i>kl</i> = <i>ku</i> .
<i>ku</i>	Restored as <i>ku</i> = <i>lda</i> - <i>kl</i> -1.

?gbsvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a banded matrix *A* and multiple right-hand sides

Syntax

FORTRAN 77:

```
call sgbsvxx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed, r, c,

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n banded matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($\mathcal{O}(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $\mathcal{O}(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?gbsvxx performs the following steps:

1. If *fact* = 'E', scaling factors *r* and *c* are computed to equilibrate the system:

```

trans = 'N': diag(r)*A*diag(c)*inv(diag(c))*X = diag(r)*B
trans = 'T': (diag(r)*A*diag(c))^T*inv(diag(r))*X = diag(c)*B
trans = 'C': (diag(r)*A*diag(c))^H*inv(diag(r))*X = diag(c)*B

```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) \cdot A \cdot \text{diag}(c)$ and B by $\text{diag}(r) \cdot B$ (if *trans*='N') or $\text{diag}(c) \cdot B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as $A = P \cdot L \cdot U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless $\text{params}(\text{la_linrx_itref_i})$ is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if $\text{trans} = \text{'N'}$) or $\text{diag}(r)$ (if $\text{trans} = \text{'T'}$ or 'C') so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be ' <i>F</i> ', ' <i>N</i> ', or ' <i>E</i> '.
	Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
	If <i>fact</i> = ' <i>F</i> ', on entry, <i>afb</i> and <i>ipiv</i> contain the factored form of A . If <i>equed</i> is not ' <i>N</i> ', the matrix A has been equilibrated with scaling factors given by <i>r</i> and <i>c</i> . Parameters <i>ab</i> , <i>afb</i> , and <i>ipiv</i> are not modified.
	If <i>fact</i> = ' <i>N</i> ', the matrix A will be copied to <i>afb</i> and factored.
	If <i>fact</i> = ' <i>E</i> ', the matrix A will be equilibrated, if necessary, copied to <i>afb</i> and factored.
<i>trans</i>	CHARACTER*1. Must be ' <i>N</i> ', ' <i>T</i> ', or ' <i>C</i> '.
	Specifies the form of the system of equations:
	If <i>trans</i> = ' <i>N</i> ', the system has the form $A*X = B$ (No transpose).
	If <i>trans</i> = ' <i>T</i> ', the system has the form $A**T*X = B$ (Transpose).
	If <i>trans</i> = ' <i>C</i> ', the system has the form $A**H*X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>ab</i> , <i>afb</i> , <i>b</i> , <i>work</i>	REAL for sgbsvxx DOUBLE PRECISION for dgbsvxx COMPLEX for cgbsvxx DOUBLE COMPLEX for zgbsvxx. Arrays: <i>ab</i> (<i>ldab</i> , *), <i>afb</i> (<i>ldafb</i> , *), <i>b</i> (<i>ldb</i> , *), <i>work</i> (*).

The array ab contains the matrix A in band storage, in rows 1 to $k_l + k_u + 1$. The j -th column of A is stored in the j -th column of the array ab as follows:

$$ab(k_u + 1 + i - j, j) = A(i, j) \text{ for } \max(1, j - k_u) \leq i \leq \min(n, j + k_l).$$

If $fact = 'F'$ and $equed$ is not ' N ', then AB must have been equilibrated by the scaling factors in r and/or c . The second dimension of a must be at least $\max(1, n)$.

The array afb is an input argument if $fact = 'F'$. It contains the factored form of the banded matrix A , that is, the factors L and U from the factorization $A = P^*L^*U$ as computed by [?gbtrf](#). U is stored as an upper triangular banded matrix with $k_l + k_u$ superdiagonals in rows 1 to $k_l + k_u + 1$. The multipliers used during the factorization are stored in rows $k_l + k_u + 2$ to $2*k_l + k_u + 1$. If $equed$ is not ' N ', then afb is the factored form of the equilibrated matrix A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

$ldab$

INTEGER. The leading dimension of the array ab ; $ldab \geq k_l + k_u + 1$.

$ldafb$

INTEGER. The leading dimension of the array afb ; $ldafb \geq 2*k_l + k_u + 1$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P^*L^*U$ as computed by [?gbtrf](#); row i of the matrix was interchanged with row $ipiv(i)$.

$equed$

CHARACTER*1. Must be ' N ', ' R ', ' C ', or ' B '.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).

If $equed = 'R'$, row equilibration was done, that is, A has been premultiplied by $diag(r)$.

If $equed = 'C'$, column equilibration was done, that is, A has been postmultiplied by $diag(c)$.

If $equed = 'B'$, both row and column equilibration was done, that is, A has been replaced by $diag(r)^*A^*diag(c)$.

r, c

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: $r(n)$, $c(n)$. The array r contains the row scale factors for A , and the array c contains the column scale factors for A . These arrays are input arguments if $fact = 'F'$ only; otherwise they are output arguments.

If $equed = 'R'$ or ' B ', A is multiplied on the left by $diag(r)$; if $equed = 'N'$ or ' C ', r is not accessed.

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'R'}$ or 'B' , each element of r must be positive.

If $\text{equed} = \text{'C'}$ or 'B' , A is multiplied on the right by $\text{diag}(c)$; if $\text{equed} = \text{'N'}$ or 'R' , c is not accessed.

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'C'}$ or 'B' , each element of c must be positive.

Each element of r or c should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

ldx

INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.

n_err_bnds

INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in *Output Arguments* section below.

$nparams$

INTEGER. Specifies the number of parameters set in params . If ≤ 0 , the params array is never referenced and default values are used.

$params$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the params argument.

$\text{params}(\text{la_linrx_itref_i} = 1)$: Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

$\text{params}(\text{la_linrx_ithresh_i} = 2)$: Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a
------------	--

technique other than Gaussian elimination, the `quarantees` in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params(la_linrx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

`iwork` INTEGER. Workspace array, DIMENSION at least `max(1, n)`; used in real flavors only.

`rwork` REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, size at least `max(1, 2*n)`; used in complex flavors only.

Output Parameters

`x` REAL for `sgbsvxx`
DOUBLE PRECISION for `dgbsvxx`
COMPLEX for `cgbsvxx`
DOUBLE COMPLEX for `zgbsvxx`.
Array, DIMENSION (`ldx, *`).
If `info = 0`, the array `x` contains the solution n -by- $nrhs$ matrix X to the original system of equations. Note that A and B are modified on exit if `equed ≠ 'N'`, and the solution to the equilibrated system is:

`inv(diag(c))*X`, if `trans = 'N'` and `equed = 'C'` or `'B'`; or
`inv(diag(r))*X`, if `trans = 'T'` or `'C'` and `equed = 'R'` or `'B'`. The second dimension of `x` must be at least `max(1, nrhs)`.

`ab` Array `ab` is not modified on exit if `fact = 'F'` or `'N'`, or if `fact = 'E'` and `equed = 'N'`.

If `equed ≠ 'N'`, A is scaled on exit as follows:

`equed = 'R'`: $A = diag(r)*A$
`equed = 'C'`: $A = A*diag(c)$
`equed = 'B'`: $A = diag(r)*A*diag(c)$.

`afb` If `fact = 'N'` or `'E'`, then `afb` is an output argument and on exit returns the factors L and U from the factorization $A = PLU$ of the original matrix A (if `fact = 'N'`) or of the equilibrated matrix A (if `fact = 'E'`).

`b` Overwritten by `diag(r)*B` if `trans = 'N'` and `equed = 'R'` or `'B'`;
overwritten by `trans = 'T'` or `'C'` and `equed = 'C'` or `'B'`;
not changed if `equed = 'N'`.

<i>r, c</i>	These arrays are output arguments if <i>fact</i> ≠ 'F'. Each element of these arrays is a power of the radix. See the description of <i>r, c</i> in <i>Input Arguments</i> section.
<i>rcond</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.</p>
<i>rpvgrw</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>X</i>, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i>. In ?gbsvx, this quantity is returned in <i>work</i>(1).</p>
<i>berr</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.</p>
<i>err_bnds_norm</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION $(nrhs, n_{\text{err_bnds}})$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:</p> <p>Normwise relative error in the <i>i</i>-th solution vector</p> $\frac{\max_j X_{\text{true}_{ji}} - X_{ji} }{\max_j X_{ji} }$ <p>The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.</p> <p>The first index in <i>err_bnds_norm(i, :)</i> corresponds to the <i>i</i>-th right-hand side.</p> <p>The second index in <i>err_bnds_norm(:, err)</i> contains the following three fields:</p>

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.
<code>err_bnds_comp</code>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION ($nrhs, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:</p> <p>Componentwise relative error in the i-th solution vector:</p> $\max_j \frac{ X_{true_{ji}} - X_{ji} }{ X_{ji} }$ <p>The array is indexed by the right-hand side i, on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then <code>err_bnds_comp</code> is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.</p> <p>The first index in <code>err_bnds_comp(i, :)</code> corresponds to the i-th right-hand side.</p> <p>The second index in <code>err_bnds_comp(:, err)</code> contains the following three fields:</p>

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.
<code>ipiv</code>	If <code>fact = 'N'</code> or <code>'E'</code> , then <code>ipiv</code> is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if <code>fact = 'N'</code>) or of the equilibrated matrix A (if <code>fact = 'E'</code>).
<code>equed</code>	If <code>fact ≠ 'F'</code> , then <code>equed</code> is an output argument. It specifies the form of equilibration that was done (see the description of <code>equed</code> in <i>Input Arguments</i> section).
<code>params</code>	If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. The solution to every right-hand side is guaranteed. If <code>info = -i</code> , the i -th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <code>rcond = 0</code> is returned. If <code>info = n+j</code> : The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested <code>params(3) = 0.0</code> , then the j -th right-hand side is the first with a normwise error bound

that is not guaranteed (the smallest j such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$). See the definition of $\text{err_bnds_norm}(:, 1)$ and $\text{err_bnds_comp}(:, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?gtsv

Computes the solution to the system of linear equations with a tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgtsv( n, nrhs, dl, d, du, b, ldb, info )
call dgtsv( n, nrhs, dl, d, du, b, ldb, info )
call cgtsv( n, nrhs, dl, d, du, b, ldb, info )
call zgtsv( n, nrhs, dl, d, du, b, ldb, info )
```

Fortran 95:

```
call gtsv( dl, d, du, b [,info] )
```

C:

```
lapack_int LAPACKE_<?>gtsv( int matrix_layout, lapack_int n, lapack_int nrhs,
<datatype>* dl, <datatype>* d, <datatype>* du, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the system of linear equations $A^T X = B$, where A is an n -by- n tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses Gaussian elimination with partial pivoting.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments du and dl .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

n INTEGER. The order of A , the number of rows in B ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

dl, d, du, b REAL for sgtsv

DOUBLE PRECISION for dgtsv

COMPLEX for cgtsv

DOUBLE COMPLEX for zgtsv.

Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, *)$.

The array dl contains the $(n - 1)$ subdiagonal elements of A .

The array d contains the diagonal elements of A .

The array du contains the $(n - 1)$ superdiagonal elements of A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

dl

Overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A . These elements are stored in $dl(1), \dots, dl(n-2)$.

d

Overwritten by the n diagonal elements of U .

du

Overwritten by the $(n-1)$ elements of the first superdiagonal of U .

b

Overwritten by the solution matrix X .

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, $U(i, i)$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsv` interface are as follows:

dl Holds the vector of length $(n-1)$.

d Holds the vector of length n .

du Holds the vector of length $(n-1)$.

b Holds the matrix B of size $(n, nrhs)$.

?gtsvx

Computes the solution to the real or complex system of linear equations with a tridiagonal matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
             ldx, rcond, ferr, berr, work, iwork, info )

call dgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
             ldx, rcond, ferr, berr, work, iwork, info )

call cgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
             ldx, rcond, ferr, berr, work, rwork, info )

call zgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
             ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gtsvx( dl, d, du, b, x [,dlf] [,df] [,duf] [,du2] [,ipiv] [,fact] [,trans] [,ferr]
            [,berr] [,rcond] [,info] )
```

C:

- C: mkl.h

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, $A^T*X = B$, or $A^H*X = B$, where A is a tridiagonal matrix of order n , the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gtsvx performs the following steps:

1. If $\text{fact} = \text{'N'}$, the LU decomposition is used to factor the matrix A as $A = L \cdot U$, where L is a product of permutation and unit lower bidiagonal matrices and U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.
2. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $\text{info} = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'.
	Specifies whether or not the factored form of the matrix A has been supplied on entry.
	If $\text{fact} = \text{'F'}$: on entry, $d1f, df, duf, du2$, and $ipiv$ contain the factored form of A ; arrays $dl, d, du, d1f, df, duf, du2$, and $ipiv$ will not be modified.
	If $\text{fact} = \text{'N'}$, the matrix A will be copied to $d1f, df$, and duf and factored.
<i>trans</i>	CHARACTER*1. Must be 'N', 'T', or 'C'.
	Specifies the form of the system of equations:
	If $\text{trans} = \text{'N'}$, the system has the form $A \cdot X = B$ (No transpose).
	If $\text{trans} = \text{'T'}$, the system has the form $A^T \cdot X = B$ (Transpose).
	If $\text{trans} = \text{'C'}$, the system has the form $A^H \cdot X = B$ (Conjugate transpose).
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>d1, d, du, d1f, df, duf, du2, b, x, work</i>	REAL for sgtsvx DOUBLE PRECISION for dgtsvx COMPLEX for cgtsvx DOUBLE COMPLEX for zgtsvx. Arrays: $d1$, DIMENSION ($n - 1$), contains the subdiagonal elements of A . d , DIMENSION (n), contains the diagonal elements of A . du , DIMENSION ($n - 1$), contains the superdiagonal elements of A .

dif, DIMENSION (*n* - 1). If *fact* = 'F', then *dif* is an input argument and on entry contains the (*n* - 1) multipliers that define the matrix *L* from the *LU* factorization of *A* as computed by [?gttrf](#).

df, DIMENSION (*n*). If *fact* = 'F', then *df* is an input argument and on entry contains the *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.

duf, DIMENSION (*n* - 1). If *fact* = 'F', then *duf* is an input argument and on entry contains the (*n* - 1) elements of the first superdiagonal of *U*.

du2, DIMENSION (*n* - 2). If *fact* = 'F', then *du2* is an input argument and on entry contains the (*n* - 2) elements of the second superdiagonal of *U*.

b(*ldb**) contains the right-hand side matrix *B*. The second dimension of *b* must be at least $\max(1, \ nrhs)$.

x(*idx**) contains the solution matrix *X*. The second dimension of *x* must be at least $\max(1, \ nrhs)$.

work(*) is a workspace array.

DIMENSION of *work* must be at least $\max(1, \ 3*n)$ for real flavors and $\max(1, \ 2*n)$ for complex flavors.

ldb

INTEGER. The leading dimension of *b*; *ldb* $\geq \max(1, \ n)$.

idx

INTEGER. The leading dimension of *x*; *idx* $\geq \max(1, \ n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, \ n)$. If *fact* = 'F', then *ipiv* is an input argument and on entry contains the pivot indices, as returned by [?gttrf](#).

iwork

INTEGER. Workspace array, DIMENSION (*n*). Used for real flavors only.

rwork

REAL for *cgtsvx*

DOUBLE PRECISION for *zgtsvx*.

Workspace array, DIMENSION (*n*). Used for complex flavors only.

Output Parameters

x

REAL for *sgtsvx*

DOUBLE PRECISION for *dgtsvx*

COMPLEX for *cgtsvx*

DOUBLE COMPLEX for *zgtsvx*.

Array, DIMENSION (*idx*, *).

If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *X*. The second dimension of *x* must be at least $\max(1, \ nrhs)$.

d1f

If *fact* = 'N', then *d1f* is an output argument and on exit contains the $(n-1)$ multipliers that define the matrix *L* from the *LU* factorization of *A*.

df

If *fact* = 'N', then *df* is an output argument and on exit contains the n diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.

duf

If *fact* = 'N', then *duf* is an output argument and on exit contains the $(n-1)$ elements of the first superdiagonal of *U*.

du2

If *fact* = 'N', then *du2* is an output argument and on exit contains the $(n-2)$ elements of the second superdiagonal of *U*.

ipiv

The array *ipiv* is an output argument if *fact* = 'N' and, on exit, contains the pivot indices from the factorization $A = L \cdot U$; row *i* of the matrix was interchanged with row *ipiv(i)*. The value of *ipiv(i)* will always be *i* or *i+1*; *ipiv(i)=i* indicates a row interchange was not required.

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix *A*. If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info*>0.

ferr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the *j*-th column of the solution matrix *X*). If *xtrue* is the true solution corresponding to $x(j)$, *ferr(j)* is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has not been completed unless $i = n$, but the factor *U* is exactly singular, so the solution and error bounds could not be computed;

$rcond = 0$ is returned. If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsvx` interface are as follows:

dl	Holds the vector of length $(n-1)$.
d	Holds the vector of length n .
du	Holds the vector of length $(n-1)$.
b	Holds the matrix B of size $(n, nrhs)$.
x	Holds the matrix X of size $(n, nrhs)$.
$d1f$	Holds the vector of length $(n-1)$.
df	Holds the vector of length n .
duf	Holds the vector of length $(n-1)$.
$du2$	Holds the vector of length $(n-2)$.
$ipiv$	Holds the vector of length n .
$ferr$	Holds the vector of length $(nrhs)$.
$berr$	Holds the vector of length $(nrhs)$.
$fact$	Must be ' N ' or ' F '. The default value is ' N '. If $fact = 'F'$, then the arguments $d1f$, df , duf , $du2$, and $ipiv$ must be present; otherwise, an error is returned.
$trans$	Must be ' N ', ' C ', or ' T '. The default value is ' N '.

?dtsvb

Computes the solution to the system of linear equations with a diagonally dominant tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sdtsvb( n, nrhs, dl, d, du, b, ldb, info )
call ddtsvb( n, nrhs, dl, d, du, b, ldb, info )
call cdtsvb( n, nrhs, dl, d, du, b, ldb, info )
```

```
call zdtsvb( n, nrhs, dl, d, du, b, ldb, info )
```

Fortran 95:

```
call dtsvb( dl, d, du, b [, info])
```

C:

```
void sdtsvb (const MKL_INT * n, const MKL_INT * nrhs, float * dl, float * d, const
float * du, float * b, const MKL_INT * ldb, MKL_INT * info );

Description

The ?dtsvb routine solves a system of linear equations $A^*X = B$ for X , where A is an n -by- n diagonally dominant tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses the BABE (Burning At Both Ends) algorithm.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments du and dl .

Input Parameters

<i>n</i>	INTEGER. The order of A , the number of rows in B ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>dl, d, du, b</i>	REAL for sdtsvb DOUBLE PRECISION for ddtsvb COMPLEX for cdtsvb DOUBLE COMPLEX for zdtsvb. Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, *)$. The array dl contains the $(n - 1)$ subdiagonal elements of A . The array d contains the diagonal elements of A . The array du contains the $(n - 1)$ superdiagonal elements of A . The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>dl</i>	Overwritten by the $(n-1)$ elements of the subdiagonal of the lower triangular matrices L_1, L_2 from the factorization of A .
<i>d</i>	Overwritten by the n diagonal element reciprocals of U .
<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	<p>INTEGER. If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = i$, u_{ii} is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.</p>

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any i :

$1 < i < n$, and $|d_1| > |du_1|$, $|d_n| > |dl_{n-1}|$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems have no numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see [?gtsv](#)). The diagonally dominant systems are much faster than the canonical systems.

NOTE

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
 - Applying the [?dtsvb](#) factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.
-

?posv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sposv( uplo, n, nrhs, a, lda, b, ldb, info )
call dposv( uplo, n, nrhs, a, lda, b, ldb, info )

Description

The routine solves for X the real or complex system of linear equations $A*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A*X = B$.

The `dposv` and `zcposv` are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (`dposv`) or single complex precision (`zcposv`) and use this factorization within an iterative refinement procedure to produce a solution with double precision (`dposv`) / double complex precision (`zcposv`) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision/COMPLEX performance over double precision/DOUBLE COMPLEX performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to `ilaenv` in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

`iter > itermax`

or for all the right-hand sides:

`rnrmr < sqrt(n) * xnrm * anrm * eps * bwdmax,`

where

- `iter` is the number of the current iteration in the iterative refinement process
- `rnrmr` is the infinity-norm of the residual
- `xnrm` is the infinity-norm of the solution
- `anrm` is the infinity-operator-norm of the matrix A
- `eps` is the machine epsilon returned by `dlamch ('Epsilon')`.

The values `itermax` and `bwdmax` are fixed to 30 and 1.0d+00 respectively.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:If $uplo = 'U'$, the upper triangle of A is stored.If $uplo = 'L'$, the lower triangle of A is stored.*n*INTEGER. The order of matrix A ; $n \geq 0$.*nrhs*INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.*a, b*

REAL for sposv

DOUBLE PRECISION for dposv and dsposv.

COMPLEX for cposv

DOUBLE COMPLEX for zposv and zcposv.

Arrays: $a(1da, *)$, $b(1db, *)$. The array a contains the upper or the lower triangular part of the matrix A (see *uplo*). The second dimension of a must be at least $\max(1, n)$.

Note that in the case of zcposv the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.*lda*INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.*ldb*INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.*ldx*INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.*work*

DOUBLE PRECISION for dsposv

DOUBLE COMPLEX for zcposv.

Workspace array, DIMENSION ($n * nrhs$). This array is used to hold the residual vectors.*swork*

REAL for ds gesv

COMPLEX for zc gesv.

Workspace array, DIMENSION ($n * (n + nrhs)$). This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.*rwork*DOUBLE PRECISION. Workspace array, DIMENSION (n).

Output Parameters

<i>a</i>	If <i>info</i> = 0, the upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> . If iterative refinement has been successfully used (<i>info</i> = 0 and <i>iter</i> ≥ 0), then <i>A</i> is unchanged. If double precision factorization has been used (<i>info</i> = 0 and <i>iter</i> < 0), then the array <i>A</i> contains the factors <i>L</i> and <i>U</i> from the Cholesky factorization; the unit diagonal elements of <i>L</i> are not stored.
<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least <code>max(1, n)</code> . The pivot indices that define the permutation matrix <i>P</i> ; row <i>i</i> of the matrix was interchanged with row <i>ipiv(i)</i> . Corresponds to the single precision factorization (if <i>info</i> = 0 and <i>iter</i> ≥ 0) or the double precision factorization (if <i>info</i> = 0 and <i>iter</i> < 0).
<i>x</i>	DOUBLE PRECISION for <code>dsposv</code> DOUBLE COMPLEX for <code>zcpovs</code> . Array, DIMENSION (<i>Idx</i> , <i>nrhs</i>). If <i>info</i> = 0, contains the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>iter</i>	INTEGER. If <i>iter</i> < 0: iterative refinement has failed, double precision factorization has been performed <ul style="list-style-type: none"> • If <i>iter</i> = -1: the routine fell back to full precision for implementation- or machine-specific reason • If <i>iter</i> = -2: narrowing the precision induced an overflow, the routine fell back to full precision • If <i>iter</i> = -3: failure of <code>spotrf</code> for <code>dsposv</code>, or <code>cpotrf</code> for <code>zcpovs</code> • If <i>iter</i> = -31: stop the iterative refinement after the 30th iteration. If <i>iter</i> > 0: iterative refinement has been successfully used. Returns the number of iterations.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posv` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?posvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix *A*, and provides error bounds on the solution.

Syntax**FORTRAN 77:**

```
call sposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx, rcond,

Description

The routine uses the *Cholesky* factorization $A = U^T * U$ (real flavors) / $A = U^H * U$ (complex flavors) or $A = L * L^T$ (real flavors) / $A = L * L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A * X = B$, where A is a n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?posvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$A = U^T * U$ (real), $A = U^H * U$ (complex), if $uplo = 'U'$,

or $A = L * L^T$ (real), $A = L * L^H$ (complex), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be '*F*', '*N*', or '*E*'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, af contains the factored form of A . If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s .

a and af will not be modified.

If $fact = 'N'$, the matrix A will be copied to af and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.

uplo

CHARACTER*1. Must be '*U*' or '*L*'.

Indicates whether the upper or lower triangular part of A is stored:

If $uplo = 'U'$, the upper triangle of A is stored.

If $uplo = 'L'$, the lower triangle of A is stored.

n

INTEGER. The order of matrix A ; $n \geq 0$.

$nrhs$

INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

$a, af, b, work$

REAL for sposvx

DOUBLE PRECISION for dposvx

COMPLEX for cposvx

DOUBLE COMPLEX for zposvx.

Arrays: $a(1da, *), af(1daf, *), b(1db, *), work(*)$.

The array a contains the matrix A as specified by $uplo$. If $fact = 'F'$ and $equed = 'Y'$, then A must have been equilibrated by the scaling factors in s , and a must contain the equilibrated matrix $diag(s)^*A^*diag(s)$. The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the triangular factor U or L from the Cholesky factorization of A in the same storage format as A . If $equed$ is not ' N ', then af is the factored form of the equilibrated matrix $diag(s)^*A^*diag(s)$. The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

$1da$

INTEGER. The leading dimension of a ; $1da \geq \max(1, n)$.

$1daf$

INTEGER. The leading dimension of af ; $1daf \geq \max(1, n)$.

$1db$

INTEGER. The leading dimension of b ; $1db \geq \max(1, n)$.

$equed$

CHARACTER*1. Must be ' N ' or ' Y '.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

if $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);

if $equed = 'Y'$, equilibration was done, that is, A has been replaced by $diag(s)^*A^*diag(s)$.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A . This array is an input argument if $\text{fact} = \text{'F'}$ only; otherwise it is an output argument.

If $\text{equed} = \text{'N'}$, s is not accessed.

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'Y'}$, each element of s must be positive.

l_{dx}

INTEGER. The leading dimension of the output array x ; $l_{\text{dx}} \geq \max(1, n)$.

i_{work}

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

r_{work}

REAL for cposvx

DOUBLE PRECISION for zposvx .

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for sposvx

DOUBLE PRECISION for dposvx

COMPLEX for cposvx

DOUBLE COMPLEX for zposvx .

Array, DIMENSION ($l_{\text{dx}}, *$).

If $\text{info} = 0$ or $\text{info} = n+1$, the array x contains the solution matrix X to the original system of equations. Note that if $\text{equed} = \text{'Y'}$, A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) * X$. The second dimension of x must be at least $\max(1, nrhs)$.

a

Array a is not modified on exit if $\text{fact} = \text{'F'}$ or 'N' , or if $\text{fact} = \text{'E'}$ and $\text{equed} = \text{'N'}$.

If $\text{fact} = \text{'E'}$ and $\text{equed} = \text{'Y'}$, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

a_{f}

If $\text{fact} = \text{'N'}$ or 'E' , then a_{f} is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^* * T * U$ or $A = L^* * L^{\prime *} * T$ (real routines), $A = U^* * H^* * U$ or $A = L^* * L^{\prime *} * H$ (complex routines) of the original matrix A (if $\text{fact} = \text{'N'}$), or of the equilibrated matrix A (if $\text{fact} = \text{'E'}$). See the description of a for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(s) * B$, if $\text{equed} = \text{'Y'}$; not changed if $\text{equed} = \text{'N'}$.

s

This array is an output argument if $\text{fact} \neq \text{'F'}$. See the description of s in Input Arguments section.

r_{cond}

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

equed

If $fact \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posvx` interface are as follows:

a

Holds the matrix A of size (n, n) .

<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>s</i>	Holds the vector of length n . Default value for each element is $s(i) = 1.0_{\text{WP}}$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.
<i>fact</i>	Must be ' N ', ' E ', or ' F '. The default value is ' N '. If <i>fact</i> = ' F ', then <i>af</i> must be present; otherwise, an error is returned.
<i>equed</i>	Must be ' N ' or ' Y '. The default value is ' N '.

?posvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A applying the Cholesky factorization.

Syntax

FORTRAN 77:

```
call sposvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx, rcond,
rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork,
info )

Description

The routine uses the *Cholesky* factorization $A = U^T * U$ (real flavors) / $A = U^H * U$ (complex flavors) or $A = L * L^T$ (real flavors) / $A = L * L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A * X = B$, where A is an n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($\mathcal{O}(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $\mathcal{O}(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?posvxx performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If *fact* = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as

$$A = U^T * U \text{ (real)}, A = U^H * U \text{ (complex)}, \text{if } \text{uplo} = 'U',$$

$$\text{or } A = L * L^T \text{ (real)}, A = L * L^H \text{ (complex)}, \text{if } \text{uplo} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless $\text{params}(\text{la_linrx_itref_i})$ is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be 'F', 'N', or 'E'.
	Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
	If <i>fact</i> = 'F', on entry, <i>af</i> contains the factored form of A . If <i>equed</i> is not 'N', the matrix A has been equilibrated with scaling factors given by <i>s</i> . Parameters <i>a</i> and <i>af</i> are not modified.
	If <i>fact</i> = 'N', the matrix A will be copied to <i>af</i> and factored.
	If <i>fact</i> = 'E', the matrix A will be equilibrated, if necessary, copied to <i>af</i> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>a</i> , <i>af</i> , <i>b</i> , <i>work</i>	REAL for sposvxx DOUBLE PRECISION for dposvxx COMPLEX for cposvxx DOUBLE COMPLEX for zposvxx. Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *), <i>b</i> (<i>ldb</i> , *), <i>work</i> (*).
	The array <i>a</i> contains the matrix A as specified by <i>uplo</i> . If <i>fact</i> = 'F' and <i>equed</i> = 'Y', then A must have been equilibrated by the scaling factors in <i>s</i> , and <i>a</i> must contain the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$. The second dimension of <i>a</i> must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the triangular factor U or L from the Cholesky factorization of A in the same storage format as A . If $equed$ is not ' N ', then af is the factored form of the equilibrated matrix $diag(s)^*A^*diag(s)$. The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

If $equed = 'N'$, s is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda

INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.

$ldaf$

INTEGER. The leading dimension of the array af ; $ldaf \geq \max(1, n)$.

$equed$

CHARACTER*1. Must be ' N ' or ' Y '.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).

If $equed = 'Y'$, both row and column equilibration was done, that is, A has been replaced by $diag(s)^*A^*diag(s)$.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $equed = 'N'$, s is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

idx

INTEGER. The leading dimension of the output array x ; $idx \geq \max(1, n)$.

n_err_bnds

INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in the *Output Arguments* section below.

$nparams$

INTEGER. Specifies the number of parameters set in $params$. If ≤ 0 , the $params$ array is never referenced and default values are used.

$params$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION *nparams*. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params(la_linx_itref_i = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the extra-precise refinement algorithm.
------	---

(Other values are reserved for future use.)

params(la_linx_ithresh_i = 2) : Maximum number of residual computations allowed for refinement.

Default	10
---------	----

Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.
------------	---

params(la_linx_cwise_i = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least max(1, n); used in real flavors only.

rwork REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least max(1, 3*n); used in complex flavors only.

Output Parameters

x REAL for sposvxx

DOUBLE PRECISION for dposvxx

COMPLEX for cposvxx

DOUBLE COMPLEX for zposvxx.

Array, DIMENSION (lidx,*).

If $info = 0$, the array x contains the solution n -by- $nrhs$ matrix X to the original system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the equilibrated system is:

$\text{inv}(\text{diag}(s)) * X.$

a Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.

If $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

af If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^{**} T^* U$ or $A = L^* L^{**} T$ (real routines), $A = U^{**} H^* U$ or $A = L^* L^{**} H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.

b If $equed = 'N'$, B is not modified.

If $equed = 'Y'$, B is overwritten by $\text{diag}(s) * B$.

s This array is an output argument if $fact \neq 'F'$. Each element of this array is a power of the radix. See the description of s in *Input Arguments* section.

$rcond$ REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

$rpvgrw$ REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the *LU* factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading $info$ columns of A .

$berr$ REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs,n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm(i,:)* corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm(:,err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold <i>sqrt(n)*slamch(ε)</i> for single precision flavors and <i>sqrt(n)*dlamch(ε)</i> for double precision flavors.
<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold <i>sqrt(n)*slamch(ε)</i> for single precision flavors and <i>sqrt(n)*dlamch(ε)</i> for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<i>err=3</i>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold <i>sqrt(n)*slamch(ε)</i> for single precision flavors and <i>sqrt(n)*dlamch(ε)</i> for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are <i>1/(norm(1/z,inf)*norm(z,inf))</i> for some appropriately scaled matrix <i>Z</i> . Let <i>z=s*a</i> , where <i>s</i> scales each row by a power of the radix so all absolute row sums of <i>z</i> are approximately 1.
<i>err_bnds_comp</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs,n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params(3) = 0.0$), then err_bnds_comp is not accessed. If $n_err_bnds < 3$, then at most the first $(:, n_err_bnds)$ entries are returned.

The first index in $err_bnds_comp(i, :)$ corresponds to the i -th right-hand side.

The second index in $err_bnds_comp(:, err)$ contains the following three fields:

$err=1$ "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors.

$err=2$ "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

$err=3$ Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt(n) * slamch(\epsilon)$ for single precision flavors and $\sqrt(n) * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

$equed$

If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in *Input Arguments* section).

$params$

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

info INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *n+j*: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with *k* > *j* may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params(3)* = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that *err_bnds_norm(j,1)* = 0.0 or *err_bnds_comp(j,1)* = 0.0). See the definition of *err_bnds_norm(:,1)* and *err_bnds_comp(:,1)*. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

?ppsv

Computes the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix *A* and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sppsv( uplo, n, nrhs, ap, b, ldb, info )
call dppsv( uplo, n, nrhs, ap, b, ldb, info )
call cppsv( uplo, n, nrhs, ap, b, ldb, info )
call zppsv( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call ppsv( ap, b [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>ppsv( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, <datatype>* ap, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for *X* the real or complex system of linear equations $A*X = B$, where *A* is an *n*-by-*n* real symmetric/Hermitian positive-definite matrix stored in packed format, the columns of matrix *B* are individual right-hand sides, and the columns of *X* are the corresponding solutions.

The Cholesky decomposition is used to factor *A* as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if *uplo* = 'U'

or $A = L^*L^T$ (real flavors) and $A = L^*L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

$uplo$	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
ap, b	REAL for sppsv DOUBLE PRECISION for dppsv COMPLEX for cppsv DOUBLE COMPLEX for zppsv. Arrays: $ap(*)$, $b(1:db, *)$. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>packed storage</i> (see Matrix Storage Schemes). The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
ldb	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ap	If $info = 0$, the upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by $uplo$.
b	Overwritten by the solution matrix X .
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppsv` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

?ppsvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, idx, rcond, ferr,
berr, work, iwork, info )

Description

The routine uses the Cholesky factorization $A=U^T \cdot U$ (real flavors) / $A=U^H \cdot U$ (complex flavors) or $A=L \cdot L^T$ (real flavors) / $A=L \cdot L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric or Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ppsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

```
diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$A = U^T \cdot U$ (real), $A = U^H \cdot U$ (complex), if $uplo = 'U'$,

or $A = L \cdot L^T$ (real), $A = L \cdot L^H$ (complex), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be ' F ', ' N ', or ' E '.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, afp contains the factored form of A . If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s .
 ap and afp will not be modified.

If $fact = 'N'$, the matrix A will be copied to afp and factored.

If *fact* = 'E', the matrix *A* will be equilibrated if necessary, then copied to *afp* and factored.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of *A* is stored:

If *uplo* = 'U', the upper triangle of *A* is stored.

If *uplo* = 'L', the lower triangle of *A* is stored.

n

INTEGER. The order of matrix *A*; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides; the number of columns in *B*; $nrhs \geq 0$.

ap, afp, b, work

REAL for *sppsvx*

DOUBLE PRECISION for *dppsvx*

COMPLEX for *cppsvx*

DOUBLE COMPLEX for *zppsvx*.

Arrays: *ap*(*), *afp*(*), *b*(*ldb*, *), *work*(*).

The array *ap* contains the upper or lower triangle of the original symmetric/Hermitian matrix *A* in *packed storage* (see [Matrix Storage Schemes](#)). In case when *fact* = 'F' and *equed* = 'Y', *ap* must contain the equilibrated matrix *diag(s)*A*diag(s)*.

The array *afp* is an input argument if *fact* = 'F' and contains the triangular factor *U* or *L* from the Cholesky factorization of *A* in the same storage format as *A*. If *equed* is not 'N', then *afp* is the factored form of the equilibrated matrix *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

work(*) is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n + 1)/2)$; the second dimension of *b* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb

INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

equed

CHARACTER*1. Must be 'N' or 'Y'.

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:

if *equed* = 'N', no equilibration was done (always true if *fact* = 'N');

if *equed* = 'Y', equilibration was done, that is, *A* has been replaced by *diag(s)*A*diag(s)*.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A . This array is an input argument if $\text{fact} = \text{'F'}$ only; otherwise it is an output argument.

If $\text{equed} = \text{'N'}$, s is not accessed.

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'Y'}$, each element of s must be positive.

ldx

INTEGER. The leading dimension of the output array x ; $\text{ldx} \geq \max(1, n)$.

$iwork$

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

$rwork$

REAL for cppsvx ;

DOUBLE PRECISION for zppsvx .

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for sppsvx

DOUBLE PRECISION for dppsvx

COMPLEX for cppsvx

DOUBLE COMPLEX for zppsvx .

Array, DIMENSION ($\text{ldx}, *$).

If $\text{info} = 0$ or $\text{info} = n+1$, the array x contains the solution matrix X to the original system of equations. Note that if $\text{equed} = \text{'Y'}$, A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) * X$. The second dimension of x must be at least $\max(1, \text{nrhs})$.

ap

Array ap is not modified on exit if $\text{fact} = \text{'F'}$ or 'N' , or if $\text{fact} = \text{'E'}$ and $\text{equed} = \text{'N'}$.

If $\text{fact} = \text{'E'}$ and $\text{equed} = \text{'Y'}$, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

afp

If $\text{fact} = \text{'N'}$ or 'E' , then afp is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix A (if $\text{fact} = \text{'N'}$), or of the equilibrated matrix A (if $\text{fact} = \text{'E'}$). See the description of ap for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(s) * B$, if $\text{equed} = \text{'Y'}$; not changed if $\text{equed} = \text{'N'}$.

s

This array is an output argument if $\text{fact} \neq \text{'F'}$. See the description of s in Input Arguments section.

$rcond$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

equed

If $fact \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

info

INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppsvx` interface are as follows:

ap

Holds the array A of size $(n^*(n+1)/2)$.

<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>afp</i>	Holds the matrix AF of size $(n^*(n+1)/2)$.
<i>s</i>	Holds the vector of length n . Default value for each element is $s(i) = 1.0_{\text{WP}}$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.
<i>fact</i>	Must be ' N ', ' E ', or ' F '. The default value is ' N '. If <i>fact</i> = ' F ', then <i>af</i> must be present; otherwise, an error is returned.
<i>equed</i>	Must be ' N ' or ' Y '. The default value is ' N '.

?pbsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite band matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call spbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbsv( ab, b [,uplo] [,info] )
```

C:

```
lapack_int LAPACKE_<?>pbsv( int matrix_layout, char uplo, lapack_int n, lapack_int kd,
lapack_int nrhs, <datatype>* ab, lapack_int ldab, <datatype>* b, lapack_int ldb );
```

Include Files

- C: mkl.h

Description

The routine solves for X the real or complex system of linear equations $A*X = B$, where A is an n -by- n symmetric/Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if *uplo* = ' U '

or $A = L^*L^T$ (real flavors) and $A = L^*L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular band matrix and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If $uplo = 'U'$, the upper triangle of A is stored.
	If $uplo = 'L'$, the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals of the matrix A if $uplo = 'U'$, or the number of subdiagonals if $uplo = 'L'$; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ab, b</i>	REAL for spbsv DOUBLE PRECISION for dpbsv COMPLEX for cpbsv DOUBLE COMPLEX for zpbsv. Arrays: $ab(1dab, *)$, $b(1db, *)$. The array ab contains the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in <i>band storage</i> (see Matrix Storage Schemes). The second dimension of ab must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>1dab</i>	INTEGER. The leading dimension of the array ab ; $1dab \geq kd + 1$.
<i>1db</i>	INTEGER. The leading dimension of b ; $1db \geq \max(1, n)$.

Output Parameters

<i>ab</i>	The upper or lower triangular part of A (in band storage) is overwritten by the Cholesky factor U or L , as specified by <i>uplo</i> , in the same storage format as A .
<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Description

The routine uses the Cholesky factorization $A=U^T \cdot U$ (real flavors) / $A=U^H \cdot U$ (complex flavors) or $A=L \cdot L^T$ (real flavors) / $A=L \cdot L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric or Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?pbsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$diag(s) \cdot A \cdot diag(s) \cdot \text{inv}(diag(s)) \cdot X = diag(s) \cdot B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s) \cdot A \cdot diag(s)$ and B by $diag(s) \cdot B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as
$$A = U^T \cdot U \text{ (real)}, A = U^H \cdot U \text{ (complex), if } uplo = 'U',$$

$$\text{or } A = L \cdot L^T \text{ (real)}, A = L \cdot L^H \text{ (complex), if } uplo = 'L',$$

where U is an upper triangular band matrix and L is a lower triangular band matrix.
3. If the leading i -by- i principal minor is not positive definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $\text{fact} = \text{'F'}$: on entry, afb contains the factored form of A . If $\text{equed} = \text{'Y'}$, the matrix A has been equilibrated with scaling factors given by s .

ab and afb will not be modified.

If $\text{fact} = \text{'N'}$, the matrix A will be copied to afb and factored.

If $\text{fact} = \text{'E'}$, the matrix A will be equilibrated if necessary, then copied to afb and factored.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:

If $\text{uplo} = \text{'U'}$, the upper triangle of A is stored.

If $\text{uplo} = \text{'L'}$, the lower triangle of A is stored.

*n*INTEGER. The order of matrix A ; $n \geq 0$.*kd*INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.*nrhs*INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.*ab, afb, b, work*

REAL for spbsvx

DOUBLE PRECISION for dpbsvx

COMPLEX for cpbsvx

DOUBLE COMPLEX for zpbsvx.

Arrays: $\text{ab}(ldab, *)$, $\text{afb}(ldab, *)$, $\text{b}(ldb, *)$, $\text{work}(*)$.

The array ab contains the upper or lower triangle of the matrix A in *band storage* (see [Matrix Storage Schemes](#)).

If $\text{fact} = \text{'F'}$ and $\text{equed} = \text{'Y'}$, then ab must contain the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$. The second dimension of ab must be at least $\max(1, n)$.

The array afb is an input argument if $\text{fact} = \text{'F'}$. It contains the triangular factor U or L from the Cholesky factorization of the band matrix A in the same storage format as A . If $\text{equed} = \text{'Y'}$, then afb is the factored form of the equilibrated matrix A . The second dimension of afb must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$\text{work}(*)$ is a workspace array.

The dimension of work must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; $ldab \geq kd+1$.
<i>ldafb</i>	INTEGER. The leading dimension of <i>afb</i> ; $ldafb \geq kd+1$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N') if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by <i>diag(s)*A*diag(s)</i> .
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>ldx</i>	INTEGER. The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for <i>cpbsvx</i> DOUBLE PRECISION for <i>zpbsvx</i> . Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for <i>spbsvx</i> DOUBLE PRECISION for <i>dpbsvx</i> COMPLEX for <i>cpbsvx</i> DOUBLE COMPLEX for <i>zpbsvx</i> . Array, DIMENSION (<i>lidx, *</i>). If <i>info</i> = 0 or <i>info</i> = <i>n</i> +1, the array <i>x</i> contains the solution matrix <i>X</i> to the original system of equations. Note that if <i>equed</i> = 'Y', <i>A</i> and <i>B</i> are modified on exit, and the solution to the equilibrated system is <i>inv(diag(s))*X</i> . The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.
----------	---

<i>ab</i>	On exit, if <i>fact</i> = 'E' and <i>equed</i> = 'Y', <i>A</i> is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.
<i>afb</i>	If <i>fact</i> = 'N' or 'E', then <i>afb</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix <i>A</i> (if <i>fact</i> = 'N'), or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>ab</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $\text{diag}(s) * B$, if <i>equed</i> = 'Y'; not changed if <i>equed</i> = 'N'.
<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the estimated forward error bound for each solution vector $x(j)$ (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be

computed; $rcond = 0$ is returned. If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbsvx` interface are as follows:

<code>ab</code>	Holds the array A of size $(kd+1, n)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>x</code>	Holds the matrix X of size $(n, nrhs)$.
<code>afb</code>	Holds the array AF of size $(kd+1, n)$.
<code>s</code>	Holds the vector with the number of elements n . Default value for each element is $s(i) = 1.0_{WP}$.
<code>ferr</code>	Holds the vector with the number of elements $nrhs$.
<code>berr</code>	Holds the vector with the number of elements $nrhs$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>fact</code>	Must be ' <code>N</code> ', ' <code>E</code> ', or ' <code>F</code> '. The default value is ' <code>N</code> '. If <code>fact = 'F'</code> , then <code>af</code> must be present; otherwise, an error is returned.
<code>equed</code>	Must be ' <code>N</code> ' or ' <code>Y</code> '. The default value is ' <code>N</code> '.

?ptsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive definite tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sptsv( n, nrhs, d, e, b, ldb, info )
call dptsv( n, nrhs, d, e, b, ldb, info )
call cptsv( n, nrhs, d, e, b, ldb, info )
call zptsv( n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call ptsv( d, e, b [,info] )
```

C:

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

A is factored as $A = L^*D^*L^T$ (real flavors) or $A = L^*D^*L^H$ (complex flavors), and the factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>d</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, dimension at least $\max(1, n)$. Contains the diagonal elements of the tridiagonal matrix A .
<i>e, b</i>	REAL for sptsv DOUBLE PRECISION for dptsv COMPLEX for cptsv DOUBLE COMPLEX for zptsv. Arrays: $e(n - 1)$, $b(ldb, *)$. The array e contains the $(n - 1)$ subdiagonal elements of A . The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>d</i>	Overwritten by the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A .
<i>e</i>	Overwritten by the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor L from the factorization of A .
<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsvx` interface are as follows:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.

?ptsvx

Uses factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite tridiagonal matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr, work,
             info )
call dptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr, work,
             info )
call cptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr, work,
             rwork, info )
call zptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr, work,
             rwork, info )
```

Fortran 95:

```
call ptsvx( d, e, b, x [,df] [,ef] [,fact] [,ferr] [,berr] [,rcond] [,info] )
```

C:

```

lapack_int LAPACKE_sptsvx( int matrix_layout, char fact, lapack_int n, lapack_int nrhs,
                           const float* d, const float* e, float* df, float* ef, const float* b, lapack_int ldb,
                           float* x, lapack_int ldx, float* rcond, float* ferr, float* berr );

lapack_int LAPACKE_dptsvx( int matrix_layout, char fact, lapack_int n, lapack_int nrhs,
                           const double* d, const double* e, double* df, double* ef, const double* b, lapack_int ldb,
                           double* x, lapack_int ldx, double* rcond, double* ferr, double* berr );

lapack_int LAPACKE_cptsvx( int matrix_layout, char fact, lapack_int n, lapack_int nrhs,
                           const float* d, const lapack_complex_float* e, float* df, lapack_complex_float* ef,

- C: mkl.h

Description

The routine uses the Cholesky factorization $A = L^*D^*L^T$ (real)/ $A = L^*D^*L^H$ (complex) to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is a n -by- n symmetric or Hermitian positive definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ptsvx performs the following steps:

1. If $fact = 'N'$, the matrix A is factored as $A = L^*D^*L^T$ (real flavors)/ $A = L^*D^*L^H$ (complex flavors), where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^T*D^*U$ (real flavors)/ $A = U^H*D^*U$ (complex flavors).
2. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix A is supplied on entry.

If $fact = 'F'$: on entry, df and ef contain the factored form of A . Arrays d , e , df , and ef will not be modified.

If $\text{fact} = \text{'N'}$, the matrix A will be copied to df and ef , and factored.

n

INTEGER. The order of matrix A ; $n \geq 0$.

$nrhs$

INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

$d, df, rwork$

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays: $d(n)$, $df(n)$, $rwork(n)$.

The array d contains the n diagonal elements of the tridiagonal matrix A .

The array df is an input argument if $\text{fact} = \text{'F'}$ and on entry contains the n diagonal elements of the diagonal matrix D from the L^*D*L^T (real)/ L^*D*L^H (complex) factorization of A .

The array $rwork$ is a workspace array used for complex flavors only.

$e, ef, b, work$

REAL for sptsvx

DOUBLE PRECISION for dptsvx

COMPLEX for cptsvx

DOUBLE COMPLEX for zptsvx.

Arrays: $e(n - 1)$, $ef(n - 1)$, $b(ldb*)$, $work(*)$. The array e contains the $(n - 1)$ subdiagonal elements of the tridiagonal matrix A .

The array ef is an input argument if $\text{fact} = \text{'F'}$ and on entry contains the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor L from the L^*D*L^T (real)/ L^*D*L^H (complex) factorization of A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The array $work$ is a workspace array. The dimension of $work$ must be at least $2*n$ for real flavors, and at least n for complex flavors.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

ldx

INTEGER. The leading dimension of x ; $ldx \geq \max(1, n)$.

Output Parameters

x

REAL for sptsvx

DOUBLE PRECISION for dptsvx

COMPLEX for cptsvx

DOUBLE COMPLEX for zptsvx.

Array, DIMENSION ($ldx, *$).

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the system of equations. The second dimension of x must be at least $\max(1, nrhs)$.

<i>df, ef</i>	These arrays are output arguments if <i>fact</i> = 'N'. See the description of <i>df, ef</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the estimated forward error bound for each solution vector $x(j)$ (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>info</i>	INTEGER . If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then <i>U</i> is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsvx` interface are as follows:

<i>d</i>	Holds the vector of length <i>n</i> .
----------	---------------------------------------

<i>e</i>	Holds the vector of length (<i>n</i> -1).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>nrhs</i>).
<i>df</i>	Holds the vector of length <i>n</i> .
<i>ef</i>	Holds the vector of length (<i>n</i> -1).
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

?sysv

Computes the solution to the system of linear equations with a real or complex symmetric matrix *A* and multiple right-hand sides.

Syntax**FORTRAN 77:**

```
call ssy whole( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call dsy whole( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call csy whole( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zsy whole( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call sysv( a, b [,uplo] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sysv( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, <datatype>* a, lapack_int lda, lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- C: mkl.h

Description

The routine solves for *X* the real or complex system of linear equations $A \cdot X = B$, where *A* is an *n*-by-*n* symmetric matrix, the columns of matrix *B* are individual right-hand sides, and the columns of *X* are the corresponding solutions.

The diagonal pivoting method is used to factor *A* as $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$, where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of *A* is then used to solve the system of equations $A \cdot X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$.
<i>a, b, work</i>	<p>REAL for ssyssv</p> <p>DOUBLE PRECISION for dsyssv</p> <p>COMPLEX for csyssv</p> <p>DOUBLE COMPLEX for zsyssv.</p> <p>Arrays: $a(1da, *)$, $b(1db, *)$, $work(*)$.</p> <p>The array a contains the upper or the lower triangular part of the symmetric matrix A (see <i>uplo</i>). The second dimension of a must be at least $\max(1, n)$.</p> <p>The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.</p> <p><i>work</i> is a workspace array, dimension at least $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of a ; $1da \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; $1db \geq \max(1, n)$.
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array; $lwork \geq 1$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i>. See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	If <i>info</i> = 0, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by ?sytrf .
<i>b</i>	If <i>info</i> = 0, b is overwritten by the solution matrix X .
<i>ipiv</i>	INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by [?sytrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

$work(1)$

If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sysv` interface are as follows:

a Holds the matrix A of size (n, n) .

b Holds the matrix B of size $(n, nrhs)$.

$ipiv$ Holds the vector of length n .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sysv_rook

Computes the solution to the system of linear equations with a real or complex symmetric coefficient matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call ssy whole ssy whole ssy whole ssy whole  
call dsy whole dsy whole dsy whole dsy whole  
call csy whole csy whole csy whole csy whole  
call zsy whole zsy whole zsy whole zsy whole
```

Fortran 95:

```
call sysv_rook( a, b [,uplo] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>sysv_rook( int matrix_layout, char uplo, lapack_int n, lapack_int  
nrhs, <datatype>* a, lapack_int lda, lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The ?sysv_rook routine is called to compute the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.

<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>a, b, work</i>	<p>REAL for <code>ssysv_rook</code> DOUBLE PRECISION for <code>dsssv_rook</code> COMPLEX for <code>csssv_rook</code> DOUBLE COMPLEX for <code>zsssv_rook</code>.</p> <p>Arrays: <i>a</i>(size <i>lda</i> by *), <i>b</i> (size <i>ldb</i> by *), <i>work</i>(*).</p>
	The array <i>a</i> contains the upper or the lower triangular part of the symmetric matrix <i>A</i> (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$.
	The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
	<i>work</i> is a workspace array, dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$.
	If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	If <i>info</i> = 0, <i>a</i> is overwritten by the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>) from the factorization of <i>A</i> as computed by ?sytrf_rook .
<i>b</i>	If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix <i>X</i> .
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i>, as determined by ?sytrf_rook.</p> <p>If <i>ipiv</i>(<i>k</i>) > 0, then rows and columns <i>k</i> and <i>ipiv</i>(<i>k</i>) were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.</p> <p>If <i>uplo</i> = 'U' and <i>ipiv</i>(<i>k</i>) < 0 and <i>ipiv</i>(<i>k</i> - 1) < 0, then rows and columns <i>k</i> and -<i>ipiv</i>(<i>k</i>) were interchanged, rows and columns <i>k</i> - 1 and -<i>ipiv</i>(<i>k</i> - 1) were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.</p>

If $uplo = 'L'$ and $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

<i>work(1)</i>	If $info = 0$, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	<p>INTEGER. If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sysv_rook` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Description

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?sysvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix A has been supplied on entry.

If $\text{fact} = \text{'F'}$: on entry, af and ipiv contain the factored form of A . Arrays a , af , and ipiv will not be modified.

If $\text{fact} = \text{'N'}$, the matrix A will be copied to af and factored.

uplo

CHARACTER*1. Must be ' U ' or ' L '.

Indicates whether the upper or lower triangular part of A is stored:

If $\text{uplo} = \text{'U'}$, the upper triangle of A is stored.

If $\text{uplo} = \text{'L'}$, the lower triangle of A is stored.

n

INTEGER. The order of matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides, the number of columns in B ; $\text{nrhs} \geq 0$.

$a, \text{af}, b, \text{work}$

REAL for `ssysvx`

DOUBLE PRECISION for `dsysvx`

COMPLEX for `csysvx`

DOUBLE COMPLEX for `zsysvx`.

Arrays: $a(\text{lda}, *), \text{af}(\text{ldaf}, *), b(\text{ldb}, *), \text{work}(*)$.

The array a contains the upper or the lower triangular part of the symmetric matrix A (see uplo). The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $\text{fact} = \text{'F'}$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ as computed by [?sytrf](#). The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, \text{nrhs})$.

$\text{work}(*)$ is a workspace array, dimension at least $\max(1, \text{lwork})$.

lda

INTEGER. The leading dimension of a ; $\text{lda} \geq \max(1, n)$.

ldaf

INTEGER. The leading dimension of af ; $\text{ldaf} \geq \max(1, n)$.

ldb

INTEGER. The leading dimension of b ; $\text{ldb} \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array ipiv is an input argument if $\text{fact} = \text{'F'}$. It contains details of the interchanges and the block structure of D , as determined by [?sytrf](#).

If $\text{ipiv}(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.

If $\text{uplo} = \text{'U'}$ and $\text{ipiv}(i) = \text{ipiv}(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

ldx

INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.

lwork

INTEGER. The size of the *work* array.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* below for details and for the suggested value of *lwork*.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork

REAL for *csysvx*;
DOUBLE PRECISION for *zsysvx*.
Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for *ssysvx*
DOUBLE PRECISION for *dsysvx*
COMPLEX for *csysvx*
DOUBLE COMPLEX for *zsysvx*.
Array, DIMENSION (*ldx*, *).

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the system of equations. The second dimension of x must be at least $\max(1, nrhs)$.

af, ipiv

These arrays are output arguments if $fact = 'N'$.

See the description of *af, ipiv* in *Input Arguments* section.

rcond

REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A . If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If *xtrue* is the true solution corresponding to

$x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

work(1)

If $info=0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

*info*INTEGER. If $info = 0$, the execution is successful.If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sysvx` interface are as follows:

*a*Holds the matrix A of size (n, n) .*b*Holds the matrix B of size $(n, nrhs)$.*x*Holds the matrix X of size $(n, nrhs)$.*af*Holds the matrix AF of size (n, n) .*ipiv*Holds the vector of length n .*ferr*Holds the vector of length $(nrhs)$.*berr*Holds the vector of length $(nrhs)$.*uplo*Must be '`U`' or '`L`'. The default value is '`U`'.

<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.
-------------	---

Application Notes

The value of *lwork* must be at least $\max(1, m \cdot n)$, where for real flavors $m = 3$ and for complex flavors $m = 2$. For better performance, try using $lwork = \max(1, m \cdot n, n \cdot \text{blocksize})$, where *blocksize* is the optimal block size for *?sytrf*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sysvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a symmetric indefinite matrix *A* applying the diagonal pivoting factorization.

Syntax

FORTRAN 77:

Description

The routine uses the *diagonal pivoting* factorization $A=U^T \cdot U$ (real flavors) / $A=U^H \cdot U$ (complex flavors) or $A=L \cdot L^T$ (real flavors) / $A=L \cdot L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n real symmetric/Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($\mathcal{O}(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $\mathcal{O}(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?sysvxx performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) \cdot A \cdot \text{diag}(s) \cdot \text{inv}(\text{diag}(s)) \cdot X = \text{diag}(s) \cdot B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) \cdot A \cdot \text{diag}(s)$ and B by $\text{diag}(s) \cdot B$.

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as

$$A = U \cdot D \cdot U^T, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L \cdot D \cdot L^T, \text{ if } \text{uplo} = 'L',$$

where U or L is a product of permutation and unit upper (lower) triangular matrices, and D is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i, i) = 0$, so that D is exactly singular, the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless `params(la_linx_itref_i)` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $diag(r)$ so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be 'F', 'N', or 'E'.
	Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
	If <i>fact</i> = 'F', on entry, <i>af</i> and <i>ipiv</i> contain the factored form of A . If <i>equed</i> is not 'N', the matrix A has been equilibrated with scaling factors given by <i>s</i> . Parameters <i>a</i> , <i>af</i> , and <i>ipiv</i> are not modified.
	If <i>fact</i> = 'N', the matrix A will be copied to <i>af</i> and factored.
	If <i>fact</i> = 'E', the matrix A will be equilibrated, if necessary, copied to <i>af</i> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>a, af, b, work</i>	REAL for ssyvxx DOUBLE PRECISION for dsyvxx COMPLEX for csyvxx DOUBLE COMPLEX for zsyvxx. Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *), <i>b</i> (<i>ldb</i> , *), <i>work</i> (*).
	The array <i>a</i> contains the symmetric matrix A as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A and the strictly upper triangular part of <i>a</i> is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U and L from the factorization $A = U^* D^* U^{**} T$ or $A = L^* D^* L^{**} T$ as computed by [?sytrf](#). The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda

INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.

$ldaf$

INTEGER. The leading dimension of the array af ; $ldaf \geq \max(1, n)$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains details of the interchanges and the block structure of D as determined by [?sytrf](#). If $ipiv(k) > 0$, rows and columns k and $ipiv(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block.

If $ipiv = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $ipiv = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

$equed$

CHARACTER*1. Must be ' N ' or ' Y '.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).

If $equed = 'Y'$, both row and column equilibration was done, that is, A has been replaced by $\text{diag}(s)^* A^* \text{diag}(s)$.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n). The array s contains the scale factors for A . If $equed = 'Y'$, A is multiplied on the left and right by $\text{diag}(s)$.

This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

<i>lidx</i>	INTEGER. The leading dimension of the output array <i>x</i> ; $lidx \geq \max(1, n)$.								
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in the <i>Output Arguments</i> section below.								
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.								
<i>params</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION <i>nparams</i>. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params(la_linx_itref_i = 1)</i> : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).</p> <table> <tr> <td>=0.0</td><td>No refinement is performed and no error bounds are computed.</td></tr> <tr> <td>=1.0</td><td>Use the extra-precise refinement algorithm.</td></tr> </table> <p>(Other values are reserved for future use.)</p> <p><i>params(la_linx_ithresh_i = 2)</i> : Maximum number of residual computations allowed for refinement.</p> <table> <tr> <td>Default</td><td>10</td></tr> <tr> <td>Aggressive</td><td>Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.</td></tr> </table> <p><i>params(la_linx_cwise_i = 3)</i> : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).</p>	=0.0	No refinement is performed and no error bounds are computed.	=1.0	Use the extra-precise refinement algorithm.	Default	10	Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.
=0.0	No refinement is performed and no error bounds are computed.								
=1.0	Use the extra-precise refinement algorithm.								
Default	10								
Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.								
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.								
<i>rwork</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.</p>								

Output Parameters

<i>x</i>	REAL for ssyvxx DOUBLE PRECISION for dsyvxx COMPLEX for csyvxx DOUBLE COMPLEX for zsyvxx. Array, DIMENSION (<i>ldx</i> , <i>nrhs</i>). If <i>info</i> = 0, the array <i>x</i> contains the solution <i>n</i> -by- <i>nrhs</i> matrix <i>X</i> to the original system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the equilibrated system is: <i>inv(diag(s)) * X.</i>
<i>a</i>	If <i>fact</i> = 'E' and <i>equed</i> = 'Y', overwritten by <i>diag(s) * A * diag(s)</i> .
<i>af</i>	If <i>fact</i> = 'N', <i>af</i> is an output argument and on exit returns the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization <i>A</i> = <i>U</i> * <i>D</i> * <i>U</i> ** <i>T</i> or <i>A</i> = <i>L</i> * <i>D</i> * <i>L</i> ** <i>T</i> .
<i>b</i>	If <i>equed</i> = 'N', <i>B</i> is not modified. If <i>equed</i> = 'Y', <i>B</i> is overwritten by <i>diag(s) * B</i> .
<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. Each element of this array is a power of the radix. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>rpvgrw</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Contains the reciprocal pivot growth factor <i>norm(A) / norm(U)</i> . The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>X</i> , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i> .
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <i>max(1, nrhs)</i> . Contains the componentwise relative backward error for each solution vector <i>x(j)</i> , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x(j)</i> an exact solution.

`err_bnds_norm`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z.

Let $z = s * a$, where *s* scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

`Array, DIMENSION (nrhs, n_err_bnds)`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side *i*, on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params(3) = 0.0*), then *err_bnds_comp* is not accessed. If *n_err_bnds < 3*, then at most the first $(:, n_err_bnds)$ entries are returned.

The first index in *err_bnds_comp(i, :)* corresponds to the *i*-th right-hand side.

The second index in *err_bnds_comp(:, err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.
<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<i>err=3</i>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix <i>Z</i> . Let $z = s * (a * \text{diag}(x))$, where <i>x</i> is the solution for the current right-hand side and <i>s</i> scales each row of <i>a * diag(x)</i> by a power of the radix so all absolute row sums of <i>z</i> are approximately 1.

<i>ipiv</i>	If <i>fact</i> = 'N', <i>ipiv</i> is an output argument and on exit contains details of the interchanges and the block structure <i>D</i> , as determined by ssytrf for single precision flavors and dsytrf for double precision flavors.
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>params</i>	If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If $0 < \text{info} \leq n$: <i>U</i> (<i>info</i> , <i>info</i>) is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>n+j</i> : The solution corresponding to the <i>j</i> -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides <i>k</i> with <i>k</i> > <i>j</i> may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested <i>params</i> (3) = 0.0, then the <i>j</i> -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest <i>j</i> such that <i>err_bnds_norm(j,1)</i> = 0.0 or <i>err_bnds_comp(j,1)</i> = 0.0. See the definition of <i>err_bnds_norm(;;1)</i> and <i>err_bnds_comp(;;1)</i> . To get information about all of the right-hand sides, check <i>err_bnds_norm</i> or <i>err_bnds_comp</i> .

?hesv

Computes the solution to the system of linear equations with a Hermitian matrix *A* and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zhesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call hesv( a, b [,uplo] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>hesv( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, <datatype>* a, lapack_int* lda, lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for X the complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If *uplo* = 'U', the array *a* stores the upper triangular part of the matrix A , and A is factored as $U^*D^*U^H$.

If *uplo* = 'L', the array *a* stores the lower triangular part of the matrix A , and A is factored as $L^*D^*L^H$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

a, b, work

COMPLEX for chesv

DOUBLE COMPLEX for zhesv.

Arrays: *a*(*lda*, *), *b*(*ldb*, *), *work*(*). The array *a* contains the upper or the lower triangular part of the Hermitian matrix A (see *uplo*). The second dimension of *a* must be at least $\max(1, n)$.

The array *b* contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.

work is a workspace array, dimension at least $\max(1, lwork)$.

lda

INTEGER. The leading dimension of *a*; *lda* $\geq \max(1, n)$.

ldb

INTEGER. The leading dimension of *b*; *ldb* $\geq \max(1, n)$.

lwork

INTEGER. The size of the *work* array (*lwork* ≥ 1).

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* below for details and for the suggested value of *lwork*.

Output Parameters

<i>a</i>	If <i>info</i> = 0, <i>a</i> is overwritten by the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>) from the factorization of <i>A</i> as computed by ?hetrf .
<i>b</i>	If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix <i>X</i> .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least <code>max(1, n)</code> . Contains details of the interchanges and the block structure of <i>D</i> , as determined by ?hetrf . If <i>ipiv</i> (<i>i</i>) = <i>k</i> > 0, then <i>d_{ii}</i> is a 1-by-1 diagonal block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column. If <i>uplo</i> = 'U' and <i>ipiv</i> (<i>i</i>) = <i>ipiv</i> (<i>i</i> -1) = - <i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i> -1, and (<i>i</i> -1)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column. If <i>uplo</i> = 'L' and <i>ipiv</i> (<i>i</i>) = <i>ipiv</i> (<i>i</i> +1) = - <i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i> +1, and (<i>i</i> +1)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column.
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , <i>d_{ii}</i> is 0. The factorization has been completed, but <i>D</i> is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesv` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using *lwork* = *n***blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hesv_rook

Computes the solution to the system of linear equations for Hermitian matrices using the bounded Bunch-Kaufman diagonal pivoting method.

Syntax

FORTRAN 77:

```
call chesv_rook( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zhesv_rook( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call hesv_rook( a, b [,uplo] [,ipiv] [,info] )
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves for *X* the complex system of linear equations $A^*X = B$, where *A* is an *n*-by-*n* Hermitian matrix, and *X* and *B* are *n*-by-*nrhs* matrices.

The bounded Bunch-Kaufman ("rook") diagonal pivoting method is used to factor *A* as

$A = U^*D^*U^H$ if *uplo* = 'U', or

$A = L^*D^*L^H$ if *uplo* = 'L',

where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

?hetrf_rook is called to compute the factorization of a complex Hermitian matrix *A* using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of *A* is then used to solve the system of equations $A^*X = B$ by calling ?HETRS_ROOK, which uses BLAS level 2 routines.

Input Parameters

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of *A* is stored:

If *uplo* = 'U', the array *a* stores the upper triangular part of the matrix *A*.

If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A .

n

INTEGER. The number of linear equations, which is the order of matrix A ; $n \geq 0$.

nrhs

INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

a, b, work

COMPLEX for `chesv_rook`

COMPLEX*16 for `zhesv_rook`.

Arrays: a (size lda by *), b (size ldb by *), $work(*)$.

The array a contains the Hermitian matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced. The second dimension of a must be at least $\max(1, n)$.

The array b contains the n -by- $nrhs$ right hand side matrix B . The second dimension of b must be at least $\max(1, nrhs)$.

$work$ is a workspace array, dimension at least $\max(1, lwork)$.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

lwork

INTEGER. The size of the $work$ array ($lwork \geq 1$).

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* below for details and for the suggested value of $lwork$.

Output Parameters

a

If $info = 0$, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by `?hetrf_rook`.

b

If $info = 0$, b is overwritten by the n -by- $nrhs$ solution matrix X .

ipiv

INTEGER.

Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by `?hetrf_rook`.

- If $uplo = 'U'$:

If $ipiv(k) > 0$, rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

- If $uplo = 'L'$:

If $ipiv(k) > 0$, rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

$work(1)$

If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, D_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesv_rook` interface are as follows:

a Holds the matrix A of size (n, n) .

b Holds the matrix B of size $(n, nrhs)$.

$ipiv$ Holds the vector of length n .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

Description

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hesvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix A has been supplied on entry.

If $fact = 'F'$: on entry, *af* and *ipiv* contain the factored form of A . Arrays *a*, *af*, and *ipiv* are not modified.

If $fact = 'N'$, the matrix A is copied to *af* and factored.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If $uplo = 'U'$, the array a stores the upper triangular part of the Hermitian matrix A , and A is factored as $U^*D^*U^H$.

If $uplo = 'L'$, the array a stores the lower triangular part of the Hermitian matrix A ; A is factored as $L^*D^*L^H$.

n

INTEGER. The order of matrix A ; $n \geq 0$.

$nrhs$

INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

$a, af, b, work$

COMPLEX for chesvx

DOUBLE COMPLEX for zhesvx.

Arrays: $a(1da, *), af(1daf, *), b(1db, *), work(*)$.

The array a contains the upper or the lower triangular part of the Hermitian matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ as computed by [?hetrf](#). The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array of dimension at least $\max(1, lwork)$.

$1da$

INTEGER. The leading dimension of a ; $1da \geq \max(1, n)$.

$1daf$

INTEGER. The leading dimension of af ; $1daf \geq \max(1, n)$.

$1db$

INTEGER. The leading dimension of b ; $1db \geq \max(1, n)$.

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains details of the interchanges and the block structure of D , as determined by [?hetrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

$1dx$

INTEGER. The leading dimension of the output array x ; $1dx \geq \max(1, n)$.

<i>lwork</i>	INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	COMPLEX for <i>chesvx</i> DOUBLE COMPLEX for <i>zhesvx</i> . Array, DIMENSION (<i>lidx</i> , *). If <i>info</i> = 0 or <i>info</i> = <i>n</i> +1, the array <i>x</i> contains the solution matrix <i>X</i> to the system of equations. The second dimension of <i>x</i> must be at least $\max(1, \text{nrhs})$.
<i>af</i> , <i>ipiv</i>	These arrays are output arguments if <i>fact</i> = 'N'. See the description of <i>af</i> , <i>ipiv</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . An estimate of the reciprocal condition number of the matrix <i>A</i> . If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the estimated forward error bound for each solution vector <i>x(j)</i> (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to <i>x(j)</i> , <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in <i>x(j)</i> . The estimate is as reliable as the estimate for <i>rcon</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the component-wise relative backward error for each solution vector <i>x(j)</i> , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x(j)</i> an exact solution.

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	<p>INTEGER. If <code>info = 0</code>, the execution is successful.</p> <p>If <code>info = -i</code>, the i-th parameter had an illegal value.</p> <p>If <code>info = i</code>, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; <code>rcond = 0</code> is returned.</p> <p>If <code>info = i</code>, and $i = n + 1$, then D is nonsingular, but <code>rcond</code> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <code>rcond</code> would suggest.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesvx` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>x</code>	Holds the matrix X of size $(n, nrhs)$.
<code>af</code>	Holds the matrix AF of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>ferr</code>	Holds the vector of length $(nrhs)$.
<code>berr</code>	Holds the vector of length $(nrhs)$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>fact</code>	Must be ' <code>N</code> ' or ' <code>F</code> '. The default value is ' <code>N</code> '. If <code>fact = 'F'</code> , then both arguments <code>af</code> and <code>ipiv</code> must be present; otherwise, an error is returned.

Application Notes

The value of `lwork` must be at least $2 * n$. For better performance, try using `lwork = n * blocksize`, where `blocksize` is the optimal block size for `?hetrf`.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hesvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a Hermitian indefinite coefficient matrix A applying the diagonal pivoting factorization.

Syntax

FORTRAN 77:

Description

The routine uses the *diagonal pivoting* factorization to compute the solution to a complex/double complex system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?hesvxx performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by *diag(s)*A*diag(s)* and *B* by *diag(s)*B*.

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as

$$A = U * D * U^T, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L * D * L^T, \text{ if } \text{uplo} = 'L',$$

where *U* or *L* is a product of permutation and unit upper (lower) triangular matrices, and *D* is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i,i)=0$, so that *D* is exactly singular, the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A* (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for *X* and compute error bounds.
4. The system of equations is solved for *X* using the factored form of *A*.
5. By default, unless *params(1)* is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix *X* is premultiplied by *diag(r)* so that it solves the original system before equilibration.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>fact</i>	CHARACTER*1. Must be 'F', 'N', or 'E'.
	Specifies whether or not the factored form of the matrix <i>A</i> is supplied on entry, and if not, whether the matrix <i>A</i> should be equilibrated before it is factored.
	If <i>fact</i> = 'F', on entry, <i>af</i> and <i>ipiv</i> contain the factored form of <i>A</i> . If <i>equed</i> is not 'N', the matrix <i>A</i> has been equilibrated with scaling factors given by <i>s</i> . Parameters <i>a</i> , <i>af</i> , and <i>ipiv</i> are not modified.
	If <i>fact</i> = 'N', the matrix <i>A</i> will be copied to <i>af</i> and factored.
	If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated, if necessary, copied to <i>af</i> and factored.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<i>a, af, b, work</i>	COMPLEX for chesvxx DOUBLE COMPLEX for zhesvxx. Arrays: a (size lda by *), af (size $ldaf$ by *), b (ldb , *), $work(*)$. The array a contains the Hermitian matrix A as specified by <i>uplo</i> . If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A and the strictly upper triangular part of a is not referenced. The second dimension of a must be at least $\max(1, n)$. The array af is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix D and the multipliers used to obtain the factor U and L from the factorization $A = U^* D^* U^T$ or $A = L^* D^* L^T$ as computed by ?hetrf . The second dimension of af must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$. $work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 5*n)$. The leading dimension of the array a ; $lda \geq \max(1, n)$. The leading dimension of the array af ; $ldaf \geq \max(1, n)$. INTEGER. Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of D as determined by ?sytrf . If $ipiv(k) > 0$, rows and columns k and $ipiv(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.
<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'.

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:

If *equed* = 'N', no equilibration was done (always true if *fact* = 'N').

If *equed* = 'Y', both row and column equilibration was done, that is, *A* has been replaced by *diag(s)*A*diag(s)*.

s

REAL for chesvxx

DOUBLE PRECISION for zhesvxx.

Array, size (*n*). The array *s* contains the scale factors for *A*. If *equed* = 'Y', *A* is multiplied on the left and right by *diag(s)*.

This array is an input argument if *fact* = 'F' only; otherwise it is an output argument.

If *fact* = 'F' and *equed* = 'Y', each element of *s* must be positive.

Each element of *s* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array *b*; *ldb* $\geq \max(1, n)$.

ldx

INTEGER. The leading dimension of the output array *x*; *ldx* $\geq \max(1, n)$.

n_err_bnds

INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See *err_bnds_norm* and *err_bnds_comp* descriptions in the *Output Arguments* section below.

nparams

INTEGER. Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, size *nparams*. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params(1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0	No refinement is performed and no error bounds are computed.
------	--

=1.0	Use the extra-precise refinement algorithm.
------	---

(Other values are reserved for future use.)

params(2) : Maximum number of residual computations allowed for refinement.

Default	10
Aggressive	Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <code>err_bnds_norm</code> and <code>err_bnds_comp</code> may no longer be trustworthy.

`params(3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

`rwork`

REAL for `chesvxx`

DOUBLE PRECISION for `zhesvxx`.

Workspace array, size at least `max(1, 3*n)`; used in complex flavors only.

Output Parameters

`x`

COMPLEX for `chesvxx`

DOUBLE COMPLEX for `zhesvxx`.

Array, size `lidx` by `nrhs`.

If `info = 0`, the array `x` contains the solution n -by- $nrhs$ matrix X to the original system of equations. Note that A and B are modified on exit if `equed ≠ 'N'`, and the solution to the equilibrated system is:

`inv(diag(s)) * X.`

`a`

If `fact = 'E'` and `equed = 'Y'`, overwritten by `diag(s) * A * diag(s)`.

`af`

If `fact = 'N'`, `af` is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^T$ or $A = L * D * L^T$.

`b`

If `equed = 'N'`, B is not modified.

If `equed = 'Y'`, B is overwritten by `diag(s) * B`.

`s`

This array is an output argument if `fact ≠ 'F'`. Each element of this array is a power of the radix. See the description of `s` in *Input Arguments* section.

`rcond`

REAL for `chesvxx`

DOUBLE PRECISION for `zhesvxx`.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If `rcond` is less than the machine precision, in particular, if `rcond = 0`, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

`rpvgrw`

REAL for `chesvxx`

DOUBLE PRECISION for `zhesvxx`.

Contains the reciprocal pivot growth factor:

$$\|A\|/\|U\|$$

If this is much less than 1, the stability of the *LU* factorization of the (equilibrated) matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading *info* columns of *A*.

berr

REAL for chesvxx

DOUBLE PRECISION for zhesvxx.

Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for chesvxx

DOUBLE PRECISION for zhesvxx.

Array of size *nrhs* by *n_err_bnds*. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm(i,:)* corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm(:,err)* contains the following three fields:

err=1

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for chesvxx and $\sqrt(n) * \text{dlamch}(\epsilon)$ for zhesvxx.

err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for chesvxx and $\sqrt(n) * \text{dlamch}(\epsilon)$ for zhesvxx. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for chesvxx and

$\text{sqrt}(n) * \text{diamch}(\epsilon)$ for `zhesvxx` to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s^* a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

`err_bnds_comp`

REAL for `chesvxx`
DOUBLE PRECISION for `zhesvxx`.

Array of size $nrhs$ by n_err_bnds . For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If $n_err_bnds < 3$, then at most the first $(:, n_err_bnds)$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for <code>chesvxx</code> and $\text{sqrt}(n) * \text{diamch}(\epsilon)$ for <code>zhesvxx</code> .
<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for <code>chesvxx</code> and $\text{sqrt}(n) * \text{diamch}(\epsilon)$ for <code>zhesvxx</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for <code>chesvxx</code> and $\text{sqrt}(n) * \text{diamch}(\epsilon)$ for <code>zhesvxx</code> to determine

if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s^*(a^*\text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^*\text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

ipiv If $\text{fact} = 'N'$, *ipiv* is an output argument and on exit contains details of the interchanges and the block structure D , as determined by [ssytrf](#) for single precision flavors and [dsytrf](#) for double precision flavors.

equed If $\text{fact} \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

params If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

info INTEGER. If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params(3) = 0.0*, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that *err_bnds_norm(j, 1) = 0.0* or *err_bnds_comp(j, 1) = 0.0*). See the definition of *err_bnds_norm* and *err_bnds_comp* for *err = 1*. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

Description

The routine solves for X the real or complex system of linear equations $A*X = B$, where A is an n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U*D*U^T$ or $A = L*D*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ap, b</i>	REAL for sspsv DOUBLE PRECISION for dsspsv COMPLEX for cspsv DOUBLE COMPLEX for zspsv. Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*).
	The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor U or L , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ap

The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by [?sptrf](#), stored as a packed triangular matrix in the same storage format as A .

b

If $info = 0$, b is overwritten by the solution matrix X .

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by [?sptrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spsv` interface are as follows:

ap

Holds the array A of size $(n * (n+1) / 2)$.

b

Holds the matrix B of size $(n, nrhs)$.

ipiv

Holds the vector with the number of elements n .

uplo

Must be '`U`' or '`L`'. The default value is '`U`'.

?spsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

Description

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?spsvx performs the following steps:

1. If $\text{fact} = \text{'N'}$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'.
	Specifies whether or not the factored form of the matrix A has been supplied on entry.
	If $fact = 'F'$: on entry, afp and $ipiv$ contain the factored form of A . Arrays ap , afp , and $ipiv$ are not modified.
	If $fact = 'N'$, the matrix A is copied to afp and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored and how A is factored:
	If $uplo = 'U'$, the array ap stores the upper triangular part of the symmetric matrix A , and A is factored as $U*D*U^T$.
	If $uplo = 'L'$, the array ap stores the lower triangular part of the symmetric matrix A ; A is factored as $L*D*L^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ap, afp, b, work</i>	REAL for sspsvx DOUBLE PRECISION for dspsvx COMPLEX for cspsvx DOUBLE COMPLEX for zspsvx. Arrays: $ap(*)$, $afp(*)$, $b(ldb,*)$, $work(*)$.
	The array ap contains the upper or lower triangle of the symmetric matrix A in <i>packed storage</i> (see Matrix Storage Schemes).
	The array afp is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by ?sptrf , in the same storage format as A .
	The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.
	$work(*)$ is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb

INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains details of the interchanges and the block structure of *D*, as determined by [?sptrf](#).

If *ipiv*(*i*) = *k* > 0, then d_{ii} is a 1-by-1 diagonal block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.

If *uplo* = 'U' and *ipiv*(*i*) = *ipiv*(*i*-1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*-1, and (*i*-1)-th row and column of *A* was interchanged with the *m*-th row and column.

If *uplo* = 'L' and *ipiv*(*i*) = *ipiv*(*i*+1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*+1, and (*i*+1)-th row and column of *A* was interchanged with the *m*-th row and column.

ldx

INTEGER. The leading dimension of the output array *x*; $ldx \geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork

REAL for `cspsvx`

DOUBLE PRECISION for `zspsvx`.

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for `sspsvx`

DOUBLE PRECISION for `dspsvx`

COMPLEX for `cspsvx`

DOUBLE COMPLEX for `zspsvx`.

Array, DIMENSION (*ldx*, *).

If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *X* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

afp, *ipiv*

These arrays are output arguments if *fact* = 'N'. See the description of *afp*, *ipiv* in *Input Arguments* section.

rcond

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A . If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr, berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

*info*INTEGER. If $info = 0$, the execution is successful.If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spsvx` interface are as follows:

*ap*Holds the array A of size $(n * (n+1) / 2)$.*b*Holds the matrix B of size $(n, nrhs)$.*x*Holds the matrix X of size $(n, nrhs)$.*afp*Holds the array AF of size $(n * (n+1) / 2)$.*ipiv*Holds the vector with the number of elements n .*ferr*Holds the vector with the number of elements $nrhs$.*berr*Holds the vector with the number of elements $nrhs$.*uplo*Must be '`U`' or '`L`'. The default value is '`U`'.*fact*

Must be '`N`' or '`F`'. The default value is '`N`'. If $fact = 'F'$, then both arguments af and $ipiv$ must be present; otherwise, an error is returned.

?hpsv

Computes the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hpsv( ap, b [,uplo] [,ipiv] [,info] )
```

C:

```
lapack_int LAPACKE_<?>hpsv( int matrix_layout, char uplo, lapack_int n, lapack_int
nrhs, <datatype>* ap, lapack_int* ipiv, <datatype>* b, lapack_int ldb );
```

Description

The routine solves for X the system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U*D*U^H$ or $A = L*D*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular part of A is stored:
	If <i>uplo</i> = 'U', the upper triangle of A is stored.
	If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$.
<i>ap</i> , <i>b</i>	COMPLEX for chpsv DOUBLE COMPLEX for zhpsv.

Arrays: $ap(*)$, $b(ldb,*)$.

The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in *packed storage* (see [Matrix Storage Schemes](#)).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb

INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ap

The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by [?hptrf](#), stored as a packed triangular matrix in the same storage format as A .

b

If $info = 0$, b is overwritten by the solution matrix X .

$ipiv$

INTEGER.
Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by [?hptrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsv` interface are as follows:

ap

Holds the array A of size $(n*(n+1)/2)$.

b

Holds the matrix B of size $(n, nrhs)$.

$ipiv$

Holds the vector with the number of elements n .

$uplo$

Must be '`U`' or '`L`'. The default value is '`U`'.

?hpsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call chpsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr, berr,
work, rwork, info )
```

```

Description

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A^*X = B$, where A is a n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hpsvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

fact

CHARACTER*1. Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix A has been supplied on entry.

If $\text{fact} = \text{'F'}$: on entry, afp and ipiv contain the factored form of A . Arrays ap , afp , and ipiv are not modified.

If $\text{fact} = \text{'N'}$, the matrix A is copied to afp and factored.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If $\text{uplo} = \text{'U'}$, the array ap stores the upper triangular part of the Hermitian matrix A , and A is factored as U^*D*U^H .

If $\text{uplo} = \text{'L'}$, the array ap stores the lower triangular part of the Hermitian matrix A , and A is factored as L^*D*L^H .

*n*INTEGER. The order of matrix A ; $n \geq 0$.*nrhs*INTEGER. The number of right-hand sides, the number of columns in B ; $\text{nrhs} \geq 0$.*ap, afp, b, work*

COMPLEX for chpsvx

DOUBLE COMPLEX for zhpsvx.

Arrays: $\text{ap}(*)$, $\text{afp}(*)$, $\text{b}(1:\text{ldb}, *)$, $\text{work}(*)$.

The array ap contains the upper or lower triangle of the Hermitian matrix A in *packed storage* (see [Matrix Storage Schemes](#)).

The array afp is an input argument if $\text{fact} = \text{'F'}$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D*U^H$ or $A = L^*D*L^H$ as computed by [?hptrf](#), in the same storage format as A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

$\text{work}(*)$ is a workspace array.

The dimension of arrays ap and afp must be at least $\max(1, n(n+1)/2)$; the second dimension of b must be at least $\max(1, \text{nrhs})$; the dimension of work must be at least $\max(1, 2*n)$.

*ldb*INTEGER. The leading dimension of b ; $\text{ldb} \geq \max(1, n)$.*ipiv*

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array ipiv is an input argument if $\text{fact} = \text{'F'}$. It contains details of the interchanges and the block structure of D , as determined by [?hptrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

ldx

INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.

rwork

REAL for chpsvx

DOUBLE PRECISION for zhpsvx.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x

COMPLEX for chpsvx

DOUBLE COMPLEX for zhpsvx.

Array, DIMENSION ($ldx, *$).

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the system of equations. The second dimension of x must be at least $\max(1, nrhs)$.

afp, ipiv

These arrays are output arguments if $fact = 'N'$. See the description of *afp, ipiv* in *Input Arguments* section.

rcond

REAL for chpsvx

DOUBLE PRECISION for zhpsvx.

An estimate of the reciprocal condition number of the matrix A . If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

REAL for chpsvx

DOUBLE PRECISION for zhpsvx.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr

REAL for chpsvx

DOUBLE PRECISION for zhpsvx.

Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsvx` interface are as follows:

ap

Holds the array A of size $(n * (n+1) / 2)$.

b

Holds the matrix B of size (n, nrhs) .

x

Holds the matrix X of size (n, nrhs) .

afp

Holds the array AF of size $(n * (n+1) / 2)$.

ipiv

Holds the vector with the number of elements n .

ferr

Holds the vector with the number of elements nrhs .

berr

Holds the vector with the number of elements nrhs .

uplo

Must be '`U`' or '`L`'. The default value is '`U`'.

fact

Must be '`N`' or '`F`'. The default value is '`N`'. If $fact = 'F'$, then both arguments af and $ipiv$ must be present; otherwise, an error is returned.

Least Square and Eigenvalue Problem Routines

This section includes descriptions of LAPACK [computational routines](#) and [driver routines](#) for solving linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. For a full reference on LAPACK routines and related information see [\[LUG\]](#).

Least Squares Problems. A typical *least squares problem* is as follows: given a matrix A and a vector b , find the vector x that minimizes the sum of squares $\sum_i ((Ax)_i - b_i)^2$ or, equivalently, find the vector x that minimizes the 2-norm $\|Ax - b\|_2$.

In the most usual case, A is an m -by- n matrix with $m \geq n$ and $\text{rank}(A) = n$. This problem is also referred to as finding the *least squares solution* to an *overdetermined* system of linear equations (here we have more equations than unknowns). To solve this problem, you can use the QR factorization of the matrix A (see [QR Factorization](#)).

If $m < n$ and $\text{rank}(A) = m$, there exist an infinite number of solutions x which exactly satisfy $Ax = b$, and thus minimize the norm $\|Ax - b\|_2$. In this case it is often useful to find the unique solution that minimizes $\|x\|_2$. This problem is referred to as finding the *minimum-norm solution* to an *underdetermined* system of linear equations (here we have more unknowns than equations). To solve this problem, you can use the LQ factorization of the matrix A (see [LQ Factorization](#)).

In the general case you may have a *rank-deficient least squares problem*, with $\text{rank}(A) < \min(m, n)$: find the *minimum-norm least squares solution* that minimizes both $\|x\|_2$ and $\|Ax - b\|^2$. In this case (or when the rank of A is in doubt) you can use the QR factorization with pivoting or *singular value decomposition* (see [Singular Value Decomposition](#)).

Eigenvalue Problems. The eigenvalue problems (from German *eigen* "own") are stated as follows: given a matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z\text{)}$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z\text{).}$$

If A is a real symmetric or complex Hermitian matrix, the above two equations are equivalent, and the problem is called a *symmetric* eigenvalue problem. Routines for solving this type of problems are described in the section [Symmetric Eigenvalue Problems](#).

Routines for solving eigenvalue problems with nonsymmetric or non-Hermitian matrices are described in the section [Nonsymmetric Eigenvalue Problems](#).

The library also includes routines that handle *generalized symmetric-definite eigenvalue problems*: find the eigenvalues λ and the corresponding eigenvectors x that satisfy one of the following equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is symmetric or Hermitian, and B is symmetric positive-definite or Hermitian positive-definite. Routines for reducing these problems to standard symmetric eigenvalue problems are described in the section [Generalized Symmetric-Definite Eigenvalue Problems](#).

To solve a particular problem, you usually call several computational routines. Sometimes you need to combine the routines of this chapter with other LAPACK routines described in "LAPACK Routines: Linear Equations" as well as with BLAS routines described in "BLAS and Sparse BLAS Routines".

For example, to solve a set of least squares problems minimizing $\|Ax - b\|^2$ for all columns b of a given matrix B (where A and B are real matrices), you can call [?geqr](#) to form the factorization $A = QR$, then call [?ormqr](#) to compute $C = Q^H B$ and finally call the BLAS routine [?trsm](#) to solve for X the system of equations $RX = C$.

Another way is to call an appropriate driver routine that performs several tasks in one call. For example, to solve the least squares problem the driver routine [?gels](#) can be used.

Computational Routines

In the sections that follow, the descriptions of LAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

[Orthogonal Factorizations](#)

[Singular Value Decomposition](#)

[Symmetric Eigenvalue Problems](#)

[Generalized Symmetric-Definite Eigenvalue Problems](#)

[Nonsymmetric Eigenvalue Problems](#)

[Generalized Nonsymmetric Eigenvalue Problems](#)

[Generalized Singular Value Decomposition](#)

See also the respective [driver routines](#).

Orthogonal Factorizations

This section describes the LAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included.

QR Factorization. Assume that A is an m -by- n matrix to be factored.

If $m \geq n$, the QR factorization is given by

where R is an n -by- n upper triangular matrix with real diagonal elements, and Q is an m -by- m orthogonal (or unitary) matrix.

You can use the QR factorization for solving the following least squares problem: minimize $\|Ax - b\|^2$ where A is a full-rank m -by- n matrix ($m \geq n$). After factoring the matrix, compute the solution x by solving $Rx = (Q_1)^T b$.

If $m < n$, the QR factorization is given by

$$A = QR = Q(R_1 R_2)$$

where R is trapezoidal, R_1 is upper triangular and R_2 is rectangular.

The LAPACK routines do not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

LQ Factorization LQ factorization of an m -by- n matrix A is as follows. If $m \leq n$,

$$A = (L, 0) \mathcal{Q} = (L, 0) \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = (LQ_1)$$

where L is an m -by- m lower triangular matrix with real diagonal elements, and Q is an n -by- n orthogonal (or unitary) matrix.

If $m > n$, the LQ factorization is

11111

where L_1 is an n -by- n lower triangular matrix, L_2 is rectangular, and Q is an n -by- n orthogonal (or unitary) matrix.

You can use the LQ factorization to find the minimum-norm solution of an underdetermined system of linear equations $Ax = b$ where A is an m -by- n matrix of rank m ($m < n$). After factoring the matrix, compute the solution vector x as follows: solve $Ly = b$ for y , and then compute $x = (Q_1)^H y$.

[Table "Computational Routines for Orthogonal Factorization"](#) lists LAPACK routines (FORTRAN 77 interface) that perform orthogonal factorization of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Orthogonal Factorization

Matrix type, factorization	Factorize without pivoting	Factorize with pivoting	Generate matrix Q	Apply matrix Q

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the QR factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a</i> , <i>work</i>	REAL for sgeqr DOUBLE PRECISION for dgeqr COMPLEX for cgeqr DOUBLE COMPLEX for zgeqr. Arrays: <i>a</i> (<i>lda</i> ,*) contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> $\geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R . If $m < n$, the strictly lower triangular part is overwritten by the details of the unitary matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R .
<i>tau</i>	REAL for sgeqr DOUBLE PRECISION for dgeqr

COMPLEX for `cgeqrf`

DOUBLE COMPLEX for `zgeqrf`.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q .

`work(1)` If $info = 0$, on exit `work(1)` contains the minimum value of `lwork` required for optimum performance. Use this `lwork` for subsequent runs.

`info` INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqrf` interface are the following:

`a` Holds the matrix A of size (m, n) .

`tau` Holds the vector of length $\min(m, n)$

Application Notes

For better performance, try using $lwork = n * blocksize$, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

?geqrf (this routine)	to factorize $A = QR$;
ormqr	to compute $C = Q^T B$ (for real matrices);
unmqr	to compute $C = Q^H B$ (for complex matrices);
trsm (a BLAS routine)	to solve $R^T X = C$.

(The columns of the computed X are the least squares solution vectors x .)

To compute the elements of Q explicitly, call

orgqr	(for real matrices)
ungqr	(for complex matrices).

See Also

[mkl_progress](#)

?geqrfp

Computes the QR factorization of a general m -by- n matrix with non-negative diagonal elements.

Syntax

FORTRAN 77:

```
call sgeqrfp(m, n, a, lda, tau, work, lwork, info)
call dgeqrfp(m, n, a, lda, tau, work, lwork, info)
call cgeqrfp(m, n, a, lda, tau, work, lwork, info)
call zgeqrfp(m, n, a, lda, tau, work, lwork, info)
```

C:

```
lapack_int LAPACKE_<?>geqrfp( int matrix_layout, lapack_int m, lapack_int n,
<datatype>* a, lapack_int lda, <datatype>* tau );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine forms the QR factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	REAL for sgeqrfp DOUBLE PRECISION for dgeqrfp COMPLEX for cgeqrfp DOUBLE COMPLEX for zgeqrfp. Arrays: <i>a</i> (<i>lda</i> ,*) contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> $\geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R . If $m < n$, the strictly lower triangular part is overwritten by the details of the unitary matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R . The diagonal elements of the matrix R are non-negative.
<i>tau</i>	REAL for sgeqrfp DOUBLE PRECISION for dgeqrfp COMPLEX for cgeqrfp DOUBLE COMPLEX for zgeqrfp. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqrfp` interface are the following:

`a` Holds the matrix A of size (m,n) .

`tau` Holds the vector of length $\min(m,n)$

Application Notes

For better performance, try using $\text{lwork} = n * \text{blocksize}$, where blocksize is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of lwork for the first run or set $\text{lwork} = -1$.

If you choose the first option and set any of admissible lwork sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $\text{lwork} = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set lwork to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?geqrfp` (this routine) to factorize $A = QR$;

`ormqr` to compute $C = Q^T B$ (for real matrices);

`unmqr` to compute $C = Q^H B$ (for complex matrices);

`trsm` (a BLAS routine) to solve $R^*X = C$.

(The columns of the computed X are the least squares solution vectors x .)

To compute the elements of Q explicitly, call

[orgqr](#) (for real matrices)
[ungqr](#) (for complex matrices).

[mkl_progress](#)

?geqrt

Computes a blocked QR factorization of a general real or complex matrix using the compact WY representation of Q.

Syntax

FORTRAN 77:

```
call sgeqrt(m, n, nb, a, lda, t, ldt, work, info)
call dgeqrt(m, n, nb, a, lda, t, ldt, work, info)
call cgeqrt(m, n, nb, a, lda, t, ldt, work, info)
call zgeqrt(m, n, nb, a, lda, t, ldt, work, info)
```

Fortran 95:

```
call geqrt(a, t, nb [, info])
```

C:

```
lapack_int LAPACKE_<?>geqrt( int matrix_layout, lapack_int m, lapack_int n, lapack_int nb, <datatype>* a, lapack_int lda, <datatype>* t, lapack_int ldt );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & \\ v_1 & 1 & \\ v_1 & v_2 & 1 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

where v_i represents one of the vectors that define $H(i)$. The vectors are returned in the lower triangular part of array `a`.

NOTE

The 1s along the diagonal of V are not stored in a .

Let $k = \min(m, n)$. The number of blocks is $b = \text{ceiling}(k/nb)$, where each block is of order nb except for the last block, which is of order $ib = k - (b-1)*nb$. For each of the b blocks, a upper triangular block reflector factor is computed: t_1, t_2, \dots, t_b . The nb -by- nb (and ib -by- ib for the last block) ts are stored in the nb -by- n array t as

$$t = (t_1 \ t_2 \ \dots \ t_b).$$

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
nb	INTEGER. The block size to be used in the blocked QR ($\min(m, n) \geq nb \geq 1$).
$a, work$	REAL for sgeqrt DOUBLE PRECISION for dgeqrt COMPLEX for cgeqrt COMPLEX*16 for zgeqrt. Arrays: a DIMENSION (lda, n) contains the m -by- n matrix A . $work$ DIMENSION (nb, n) is a workspace array.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
ldt	INTEGER. The leading dimension of t ; at least nb .

Output Parameters

a	Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the $\min(m, n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$). The elements below the diagonal are the columns of V .
t	REAL for sgeqrt DOUBLE PRECISION for dgeqrt COMPLEX for cgeqrt COMPLEX*16 for zgeqrt. Array, DIMENSION ($ldt, \min(m, n)$). The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info < 0$ and $info = -i$, the i th argument had an illegal value.

?gemqrt

Multiples a general matrix by the orthogonal/unitary matrix Q of the QR factorization formed by ?geqrt.

Syntax**FORTRAN 77:**

```
call sgemqrt(side, trans, m, n, k, nb, v, ldv, t, ldt, c, ldc, work, info)
call dgemqrt(side, trans, m, n, k, nb, v, ldv, t, ldt, c, ldc, work, info)
call cgemqrt(side, trans, m, n, k, nb, v, ldv, t, ldt, c, ldc, work, info)
call zgemqrt(side, trans, m, n, k, nb, v, ldv, t, ldt, c, ldc, work, info)
```

Fortran 95:

```
call gemqrt( v, t, c, k, nb [, trans] [, side] [, info])
```

C:

```
lapack_int LAPACKE_<?>gemqrt(int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int nb, const <datatype>* v, lapack_int ldv,
const <datatype>* t, lapack_int ldt, <datatype>* c, lapack_int ldc)
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The ?gemqrt routine overwrites the general real or complex m -by- n matrix C with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	Q^*C	C^*Q
<i>trans</i> = 'T':	Q^T*C	C^*Q^T
<i>trans</i> = 'C':	Q^H*C	C^*Q^H

where Q is a complex orthogonal distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k) = I - V^* T^* V^T$ for real flavors, and

$Q = H(1) H(2) \dots H(k) = I - V^* T^* V^H$ for complex flavors,

generated using the compact WY representation as returned by [geqrt](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	apply Q , Q^T , or Q^H from the left.
= 'R':	apply Q , Q^T , or Q^H from the right.

<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, apply Q .
= 'T',	transpose, apply Q^T .
= 'C',	transpose, apply Q^H .

m (global) INTEGER. The number of rows in the matrix C , ($m \geq 0$).

n (global) INTEGER. The number of columns in the matrix C , ($n \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
 If $side = 'L'$, $m \geq k \geq 0$
 If $side = 'R'$, $n \geq k \geq 0$.

nb INTEGER.
 The block size used for the storage of t , $k \geq nb \geq 1$. This must be the same value of *nb* used to generate t in [geqrt](#).

v REAL for sgemqrt
 DOUBLE PRECISION for dgemqrt
 COMPLEX for cgemqrt
 COMPLEX*16 for zgemqrt.
 Array, DIMENSION (ldv, k).
 The i th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by [geqrt](#) in the first k columns of its array argument *a*.

ldv INTEGER. The leading dimension of the array *v*.
 if $side = 'L'$, *ldv* must be at least $\max(1, m)$;
 if $side = 'R'$, *ldv* must be at least $\max(1, n)$.

t REAL for sgemqrt
 DOUBLE PRECISION for dgemqrt
 COMPLEX for cgemqrt
 COMPLEX*16 for zgemqrt.
 Array, DIMENSION (ldt, k).
 The upper triangular factors of the block reflectors as returned by [geqrt](#), stored as an nb -by- n matrix.

ldt INTEGER. The leading dimension of the array *t*. *ldt* must be at least *nb*.

c REAL for sgemqrt
 DOUBLE PRECISION for dgemqrt
 COMPLEX for cgemqrt
 COMPLEX*16 for zgemqrt.
 The m -by- matrix C .

ldc INTEGER. The leading dimension of the array *c*. *ldc* must be at least $\max(1, m)$.

work REAL for sgemqrt

DOUBLE PRECISION **for** dgemqrt
 COMPLEX **for** cgemqrt
 COMPLEX*16 **for** zgemqrt.
Workspace array.
If *side* = 'L' DIMENSION *n*nb*.
If *side* = 'R' DIMENSION *m*nb*.

Output Parameters

c Overwritten by the product Q^*C , C^*Q , Q^T*C , C^*Q^T , Q^H*C , or C^*Q^H .
info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if *info* = -*i*, the *i*th argument had an illegal value.

?geqpf

Computes the QR factorization of a general *m*-by-*n* matrix with pivoting.

Syntax

FORTRAN 77:

```
call sgeqpf(m, n, a, lda, jpvt, tau, work, info)
call dgeqpf(m, n, a, lda, jpvt, tau, work, info)
call cgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
call zgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
```

Fortran 95:

```
call geqpf(a, jpvt [, tau] [, info])
```

C:

```
lapack_int LAPACKE_<?>geqpf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, lapack_int* jpvt, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine is deprecated and has been replaced by routine [geqp3](#).

The routine ?geqpf forms the QR factorization of a general *m*-by-*n* matrix *A* with column pivoting: $A^*P = Q^*R$ (see [Orthogonal Factorizations](#)). Here *P* denotes an *n*-by-*n* permutation matrix.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with *Q* in this representation.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	REAL for sgeqpf DOUBLE PRECISION for dgeqpf COMPLEX for cgeqpf DOUBLE COMPLEX for zgeqpf. Arrays: <i>a</i> (<i>lda,*</i>) contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (<i>lwork</i>) is a workspace array. The size of the <i>work</i> array must be at least $\max(1, 3*n)$ for real flavors and at least $\max(1, n)$ for complex flavors.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if $jpvt(i) > 0$, the <i>i</i> -th column of A is moved to the beginning of $A*P$ before the computation, and fixed in place during the computation. If $jpvt(i) = 0$, the <i>i</i> th column of A is a free column (that is, it may be interchanged during the computation with any other free column).
<i>rwork</i>	REAL for cgeqpf DOUBLE PRECISION for zgeqpf. A workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary (orthogonal) matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R . If $m < n$, the strictly lower triangular part is overwritten by the details of the matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R .
<i>tau</i>	REAL for sgeqpf DOUBLE PRECISION for dgeqpf COMPLEX for cgeqpf DOUBLE COMPLEX for zgeqpf. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q .

<i>jpvt</i>	Overwritten by details of the permutation matrix P in the factorization $A^*P = Q^*R$. More precisely, the columns of A^*P are the columns of A in the following order: $jpvt(1), jpvt(2), \dots, jpvt(n)$.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqpf` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>jpvt</i>	Holds the vector of length n .
<i>tau</i>	Holds the vector of length $\min(m,n)$

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

<code>?geqpf</code> (this routine)	to factorize $A^*P = Q^*R$;
<code>ormqr</code>	to compute $C = Q^T * B$ (for real matrices);
<code>unmqr</code>	to compute $C = Q^H * B$ (for complex matrices);
<code>trsm</code> (a BLAS routine)	to solve $R^*X = C$.

(The columns of the computed X are the permuted least squares solution vectors x ; the output array *jpvt* specifies the permutation order.)

To compute the elements of Q explicitly, call

<code>orgqr</code>	(for real matrices)
<code>ungqr</code>	(for complex matrices).

?geqp3

Computes the QR factorization of a general m -by- n matrix with column pivoting using level 3 BLAS.

Syntax**FORTRAN 77:**

```
call sgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call dgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call cgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
call zgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
```

Fortran 95:

```
call geqp3(a, jpvt [,tau] [,info])
```

C:

```
lapack_int LAPACKE_sgeqp3 (int matrix_layout, lapack_int m, lapack_int n, float * a,
lapack_int lda, lapack_int * jpvt, float * tau);

lapack_int LAPACKE_dgeqp3 (int matrix_layout, lapack_int m, lapack_int n, double * a,
lapack_int lda, lapack_int * jpvt, double * tau);

lapack_int LAPACKE_cgeqp3 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float * a, lapack_int lda, lapack_int * jpvt, lapack_complex_float * tau);

lapack_int LAPACKE_zgeqp3 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double * a, lapack_int lda, lapack_int * jpvt, lapack_complex_double * tau);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the QR factorization of a general m -by- n matrix A with column pivoting: $A \cdot P = Q \cdot R$ (see [Orthogonal Factorizations](#)) using Level 3 BLAS. Here P denotes an n -by- n permutation matrix. Use this routine instead of [geqpf](#) for better performance.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).

<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a, work</i>	<p>REAL for sgeqp3</p> <p>DOUBLE PRECISION for dgeqp3</p> <p>COMPLEX for cgeqp3</p> <p>DOUBLE COMPLEX for zgeqp3.</p>
	Arrays:
	<i>a</i> (<i>lda,*</i>) contains the matrix <i>A</i> .
	The second dimension of <i>a</i> must be at least $\max(1, n)$.
	<i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array; must be at least $\max(1, 3*n+1)$ for real flavors, and at least $\max(1, n+1)$ for complex flavors.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> below for details.</p>
<i>jpvt</i>	<p>INTEGER.</p> <p>Array, size at least $\max(1, n)$.</p> <p>On entry, if $jpvt(i) \neq 0$, the <i>i</i>-th column of <i>A</i> is moved to the beginning of <i>AP</i> before the computation, and fixed in place during the computation.</p> <p>If $jpvt(i) = 0$, the <i>i</i>-th column of <i>A</i> is a free column (that is, it may be interchanged during the computation with any other free column).</p>
<i>rwork</i>	<p>REAL for cgeqp3</p> <p>DOUBLE PRECISION for zgeqp3.</p> <p>A workspace array, size at least $\max(1, 2*n)$. Used in complex flavors only.</p>

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the $\min(m, n)$ -by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , present the orthogonal matrix <i>Q</i> as a product of $\min(m, n)$ elementary reflectors (see Orthogonal Factorizations).
<i>tau</i>	<p>REAL for sgeqp3</p> <p>DOUBLE PRECISION for dgeqp3</p> <p>COMPLEX for cgeqp3</p> <p>DOUBLE COMPLEX for zgeqp3.</p> <p>Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix <i>Q</i>.</p>

<i>jpvt</i>	Overwritten by details of the permutation matrix P in the factorization $A^*P = Q^*R$. More precisely, the columns of AP are the columns of A in the following order: $jpvt(1), jpvt(2), \dots, jpvt(n)$.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqp3` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>jpvt</i>	Holds the vector of length n .
<i>tau</i>	Holds the vector of length $\min(m,n)$

Application Notes

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

?geqp3 (this routine)	to factorize $A^*P = Q^*R$;
<code>ormqr</code>	to compute $C = Q^T B$ (for real matrices);
<code>unmqr</code>	to compute $C = Q^H B$ (for complex matrices);
<code>trsm</code> (a BLAS routine)	to solve $R^*X = C$.

(The columns of the computed X are the permuted least squares solution vectors x ; the output array *jpvt* specifies the permutation order.)

To compute the elements of Q explicitly, call

<code>orgqr</code>	(for real matrices)
<code>ungqr</code>	(for complex matrices).

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?orgqr

Generates the real orthogonal matrix Q of the QR factorization formed by ?geqrf.

Syntax**FORTRAN 77:**

```
call sorgqr(m, n, k, a, lda, tau, work, lwork, info)
call dorgqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgqr(a, tau [,info])
```

C:

```
lapack_int LAPACKE_<?>orgqr( int matrix_layout, lapack_int m, lapack_int n, lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates the whole or part of m -by- m orthogonal matrix Q of the QR factorization formed by the routines **geqrf/geqrf** or **geqpf/geqpf**. Use this routine after a call to **sgeqrf/dgeqrf** or **sgeqpf/dgeqpf**.

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?orgqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?orgqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of leading k columns of the matrix A :

```
call ?orgqr(m, m, k, a, lda, tau, work, lwork, info)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by leading k columns of the matrix A):

```
call ?orgqr(m, k, k, a, lda, tau, work, lwork, info)
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the **C Interface Conventions** section for the C interface principal conventions and type definitions.

m INTEGER. The order of the orthogonal matrix Q ($m \geq 0$).

n INTEGER. The number of columns of Q to be computed
($0 \leq n \leq m$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a, tau, work REAL for sorgqr

DOUBLE PRECISION for dorgqr

Arrays:

a(*lda,**) and *tau*(*) are the arrays returned by sgqr / dgqr or sgqpf / dgqpf.

The second dimension of *a* must be at least $\max(1, n)$.

The dimension of *tau* must be at least $\max(1, k)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by *n* leading columns of the m -by- m orthogonal matrix Q .

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *orgqr* interface are the following:

a Holds the matrix *A* of size (*m,n*).

tau Holds the vector of length (*k*)

Application Notes

For better performance, try using *lwork* = *n***blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly orthogonal matrix by a matrix *E* such that

$$\|E\|_2 = O(\epsilon) * \|A\|_2 \text{ where } \epsilon \text{ is the machine precision.}$$

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $n = k$, the number is approximately $(2/3)*n^2*(3m - n)$.

The complex counterpart of this routine is [ungqr](#).

?ormqr

Multiples a real matrix by the orthogonal matrix Q of the QR factorization formed by ?geqrf or ?geqpf.

Syntax

FORTRAN 77:

```
call sormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormqr(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormqr( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a real matrix *C* by *Q* or *Q*^T, where *Q* is the orthogonal matrix *Q* of the *QR* factorization formed by the routines [geqrf/geqrf](#) or [geqpf/geqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products *Q***C*, *Q*^T**C*, *C***Q*, or *C***Q*^T (overwriting the result on *C*).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

side	CHARACTER*1. Must be either 'L' or 'R'.
------	---

If $\text{side} = \text{'L'}$, Q or Q^T is applied to C from the left.

If $\text{side} = \text{'R'}$, Q or Q^T is applied to C from the right.

trans CHARACTER*1. Must be either 'N' or 'T'.

If $\text{trans} = \text{'N'}$, the routine multiplies C by Q .

If $\text{trans} = \text{'T'}$, the routine multiplies C by Q^T .

m INTEGER. The number of rows in the matrix C ($m \geq 0$).

n INTEGER. The number of columns in C ($n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

$0 \leq k \leq m$ if $\text{side} = \text{'L'}$;

$0 \leq k \leq n$ if $\text{side} = \text{'R'}$.

a, τ, c, work

REAL for sgeqr

DOUBLE PRECISION for dgeqr.

Arrays:

$a(\text{lda},*)$ and $\tau(*)$ are the arrays returned by sgeqr / dgeqr or sgeqpf / dgeqpf. The second dimension of a must be at least $\max(1, k)$. The dimension of τ must be at least $\max(1, k)$.

$c(\text{ldc},*)$ contains the matrix C .

The second dimension of c must be at least $\max(1, n)$

work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda INTEGER. The leading dimension of a . Constraints:

$\text{lda} \geq \max(1, m)$ if $\text{side} = \text{'L'}$;

$\text{lda} \geq \max(1, n)$ if $\text{side} = \text{'R'}$.

ldc INTEGER. The leading dimension of c . Constraint:

$\text{ldc} \geq \max(1, m)$.

lwork INTEGER. The size of the work array. Constraints:

$\text{lwork} \geq \max(1, n)$ if $\text{side} = \text{'L'}$;

$\text{lwork} \geq \max(1, m)$ if $\text{side} = \text{'R'}$.

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by `xerbla`.

See *Application Notes* for the suggested value of lwork .

Output Parameters

c Overwritten by the product Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (as specified by side and trans).

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormqr` interface are the following:

<code>a</code>	Holds the matrix A of size (r,k) . <code>r = m</code> if <code>side = 'L'</code> . <code>r = n</code> if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m,n) .
<code>side</code>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<code>trans</code>	Must be ' <code>N</code> ' or ' <code>T</code> '. The default value is ' <code>N</code> '.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [unmqr](#).

?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by [?geqrf](#).

Syntax

FORTRAN 77:

```
call cungqr(m, n, k, a, lda, tau, work, lwork, info)
```

```
call zungqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungqr(a, tau [,info])
```

C:

```
lapack_int LAPACKE_<?>ungqr( int matrix_layout, lapack_int m, lapack_int n, lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates the whole or part of m -by- m unitary matrix Q of the QR factorization formed by the routines [geqrf/geqrf](#) or [geqpf/geqpf](#). Use this routine after a call to [cgeqrf/zgeqrf](#) or [cgeqpf/zgeqpf](#).

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?ungqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?ungqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of the leading k columns of the matrix A :

```
call ?ungqr(m, m, k, a, lda, tau, work, lwork, info)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by the leading k columns of the matrix A):

```
call ?ungqr(m, k, k, a, lda, tau, work, lwork, info)
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The order of the unitary matrix Q ($m \geq 0$).

n INTEGER. The number of columns of Q to be computed ($0 \leq n \leq m$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a, tau, work COMPLEX for cungqr
DOUBLE COMPLEX for zungqr
Arrays: *a*(*lda,**) and *tau*(*) are the arrays returned by [cgeqrf/zgeqrf](#) or [cgeqpf/zgeqpf](#).
The second dimension of *a* must be at least $\max(1, n)$.

The dimension of *tau* must be at least $\max(1, k)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by *n* leading columns of the *m*-by-*m* unitary matrix *Q*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungqr` interface are the following:

a Holds the matrix *A* of size (*m,n*).

tau Holds the vector of length (*k*).

Application Notes

For better performance, try using *lwork* = *n*blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $16*m*n*k - 8*(m + n)*k^2 + (16/3)*k^3$.

If $n = k$, the number is approximately $(8/3) * n^2 * (3m - n)$.

The real counterpart of this routine is [orgqr](#).

?unmqr

Multiples a complex matrix by the unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call cunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmqr(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmqr( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a rectangular complex matrix C by Q or Q^H , where Q is the unitary matrix Q of the QR factorization formed by the routines [geqrf/geqrf](#) or [geqpf/geqpf](#).

Depending on the parameters $side$ and $trans$, the routine can form one of the matrix products Q^*C , $Q^{H*}C$, C^*Q , or C^*Q^H (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).

<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	COMPLEX for <i>cgeqrf</i> DOUBLE COMPLEX for <i>zgeqrf</i> . Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are the arrays returned by <i>cgeqrf</i> / <i>zgeqrf</i> or <i>cgeqpf</i> / <i>zgeqpf</i> . The second dimension of <i>a</i> must be at least $\max(1, k)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix <i>C</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> . Constraints: <i>lda</i> $\geq \max(1, m)$ if <i>side</i> = 'L'; <i>lda</i> $\geq \max(1, n)$ if <i>side</i> = 'R'.
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> . Constraint: <i>ldc</i> $\geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: <i>lwork</i> $\geq \max(1, n)$ if <i>side</i> = 'L'; <i>lwork</i> $\geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^H*C , C^*Q , or C^*Q^H (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmqr` interface are the following:

<code>a</code>	Holds the matrix A of size (r,k) . $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m,n) .
<code>side</code>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<code>trans</code>	Must be ' <code>N</code> ' or ' <code>C</code> '. The default value is ' <code>N</code> '.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [ormqr](#).

?gelqf

Computes the LQ factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgelqf(m, n, a, lda, tau, work, lwork, info)
call dgelqf(m, n, a, lda, tau, work, lwork, info)
call cgelqf(m, n, a, lda, tau, work, lwork, info)
call zgelqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gelqf(a [, tau] [,info])
```

C:

```
lapack_int LAPACKE_<?>gelqf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the LQ factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>m</code>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in A ($n \geq 0$).
<code>a, work</code>	REAL for sgelqf DOUBLE PRECISION for dgelqf COMPLEX for cgelqf DOUBLE COMPLEX for zgelqf. Arrays: <code>a(lda,*)</code> contains the matrix A . The second dimension of <code>a</code> must be at least $\max(1, n)$. <code>work</code> is a workspace array, its dimension $\max(1, lwork)$.
<code>lda</code>	INTEGER. The leading dimension of <code>a</code> ; at least $\max(1, m)$.
<code>lwork</code>	INTEGER. The size of the <code>work</code> array; at least $\max(1, m)$. If <code>lwork = -1</code> , then a workspace query is assumed; the routine only calculates the optimal size of the <code>work</code> array, returns this value as the first entry of the <code>work</code> array, and no error message related to <code>lwork</code> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <code>lwork</code> .

Output Parameters

<code>a</code>	Overwritten by the factorization data as follows:
----------------	---

If $m \leq n$, the elements above the diagonal are overwritten by the details of the unitary (orthogonal) matrix Q , and the lower triangle is overwritten by the corresponding elements of the lower triangular matrix L .

If $m > n$, the strictly upper triangular part is overwritten by the details of the matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n lower trapezoidal matrix L .

tau

REAL for sgelqf

DOUBLE PRECISION for dgelqf

COMPLEX for cgelqf

DOUBLE COMPLEX for zgelqf.

Array, DIMENSION at least $\max(1, \min(m, n))$.Contains additional information on the matrix Q .*work(1)*If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.*info*

INTEGER.

If $info = 0$, the execution is successful.If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gelqf* interface are the following:

a Holds the matrix A of size (m,n) .

tau Holds the vector of length $\min(m,n)$.

Application Notes

For better performance, try using *lwork* = $m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\varepsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To find the minimum-norm solution of an underdetermined least squares problem minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

?gelqf (this routine)	to factorize $A = L^*Q$;
trsm (a BLAS routine)	to solve $L^*Y = B$ for Y ;
ormlq	to compute $X = (Q_1)^T Y$ (for real matrices);
unmlq	to compute $X = (Q_1)^H Y$ (for complex matrices).

(The columns of the computed X are the minimum-norm solution vectors x . Here A is an m -by- n matrix with $m < n$; Q_1 denotes the first m columns of Q).

To compute the elements of Q explicitly, call

orglq	(for real matrices)
unglq	(for complex matrices).

[mkl_progress](#)

?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call sorglq(m, n, k, a, lda, tau, work, lwork, info)
call dorglq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orglq(a, tau [,info])
```

C:

```
lapack_int LAPACKE_<?>orglq( int matrix_layout, lapack_int m, lapack_int n, lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates the whole or part of n -by- n orthogonal matrix Q of the LQ factorization formed by the routines [gelqf/gelqf](#). Use this routine after a call to [sgelqf/dgelqf](#).

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n \geq p$. To compute the whole matrix Q , use:

```
call ?orglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?orglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the LQ factorization of the leading k rows of A , use:

```
call ?orglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of A , use:

```
call ?orgqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows of Q to be computed
 $(0 \leq m \leq n)$.

n INTEGER. The order of the orthogonal matrix Q ($n \geq m$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).

a, tau, work REAL for `sorglq`
 DOUBLE PRECISION for `dorglq`
 Arrays: *a*(*lda*,*) and *tau*(*) are the arrays returned by [sgelqf/dgelqf](#).

The second dimension of *a* must be at least $\max(1, n)$.

The dimension of *tau* must be at least $\max(1, k)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array; at least $\max(1, m)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by *m* leading rows of the n -by- n orthogonal matrix Q .

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orglq` interface are the following:

<code>a</code>	Holds the matrix A of size (m,n) .
<code>tau</code>	Holds the vector of length (k) .

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $m = k$, the number is approximately $(2/3)*m^2*(3n - m)$.

The complex counterpart of this routine is [unglq](#).

?ormlq

Multiples a real matrix by the orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call sormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormlq(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_sormlq( int matrix_layout, char side, char trans, lapack_int m,
                           lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the LQ factorization formed by the routine [gelqf/gelqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^T*C , C^*Q , or C^*Q^T (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	REAL for sormlq DOUBLE PRECISION for dormlq. Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are arrays returned by ?gelqf. The second dimension of <i>a</i> must be: at least $\max(1, m)$ if <i>side</i> = 'L'; at least $\max(1, n)$ if <i>side</i> = 'R'. The dimension of <i>tau</i> must be at least $\max(1, k)$.

c(*ldc*,*) contains the matrix *C*.

The second dimension of *c* must be at least $\max(1, n)$

work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda

INTEGER. The leading dimension of *a*; *lda* $\geq \max(1, k)$.

ldc

INTEGER. The leading dimension of *c*; *ldc* $\geq \max(1, m)$.

lwork

INTEGER. The size of the *work* array. Constraints:

lwork $\geq \max(1, n)$ if *side* = 'L';

lwork $\geq \max(1, m)$ if *side* = 'R'.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c

Overwritten by the product Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (as specified by *side* and *trans*).

work(1)

If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ormlq* interface are the following:

a Holds the matrix *A* of size (*k,m*).

tau Holds the vector of length (*k*).

c Holds the matrix *C* of size (*m,n*).

side Must be 'L' or 'R'. The default value is 'L'.

trans Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using *lwork* = *n***blocksize* (if *side* = 'L') or *lwork* = *m***blocksize* (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork= -1*.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork= -1*, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [unmlq](#).

?unglq

Generates the complex unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call cunglq(m, n, k, a, lda, tau, work, lwork, info)
call zunglq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unglq(a, tau [,info])
```

C:

```
lapack_int LAPACKE_<?>unglq( int matrix_layout, lapack_int m, lapack_int n, lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates the whole or part of n -by- n unitary matrix Q of the *LQ* factorization formed by the routines [gelqf/gelqf](#). Use this routine after a call to [cgelqf/zgelqf](#).

Usually Q is determined from the *LQ* factorization of an p -by- n matrix A with $n < p$. To compute the whole matrix Q , use:

```
call ?unglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?unglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the *LQ* factorization of the leading k rows of the matrix A , use:

```
call ?unglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of the matrix A , use:

```
call ?ungqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows of Q to be computed ($0 \leq m \leq n$).
<i>n</i>	INTEGER. The order of the unitary matrix Q ($n \geq m$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).
<i>a, tau, work</i>	<p>COMPLEX for <code>cunglq</code> DOUBLE COMPLEX for <code>zunglq</code></p> <p>Arrays: <i>a</i>(<i>lda</i>,*) and <i>tau</i>(*) are the arrays returned by <code>sgelqf/dgelqf</code>.</p> <p>The second dimension of <i>a</i> must be at least <code>max(1, n)</code>.</p> <p>The dimension of <i>tau</i> must be at least <code>max(1, k)</code>.</p> <p><i>work</i> is a workspace array, its dimension <code>max(1, lwork)</code>.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least <code>max(1, m)</code> .
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array; at least <code>max(1, m)</code>.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code>.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	Overwritten by <i>m</i> leading rows of the n -by- n unitary matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unglq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to `-1`, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly unitary matrix by a matrix E such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

The total number of floating-point operations is approximately $16*m*n*k - 8*(m + n)*k^2 + (16/3)*k^3$.

If $m = k$, the number is approximately $(8/3)*m^2*(3n - m)$.

The real counterpart of this routine is [orglq](#).

?unmlq

Multiplies a complex matrix by the unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call cunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmlq(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmlq( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a real m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the LQ factorization formed by the routine [gelqf/gelqf](#).

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q_H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	COMPLEX for <code>cunmlq</code> DOUBLE COMPLEX for <code>zunmlq</code> . Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are arrays returned by <code>?gelqf</code> . The second dimension of <i>a</i> must be: at least $\max(1, m)$ if <i>side</i> = 'L'; at least $\max(1, n)$ if <i>side</i> = 'R'. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> $\geq \max(1, k)$. <i>ldc</i> INTEGER. The leading dimension of <i>c</i> ; <i>ldc</i> $\geq \max(1, m)$. <i>lwork</i> INTEGER. The size of the <i>work</i> array. Constraints: <i>lwork</i> $\geq \max(1, n)$ if <i>side</i> = 'L'; <i>lwork</i> $\geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> .

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (as specified by <i>side</i> and <i>trans</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmqlq` interface are the following:

<i>a</i>	Holds the matrix A of size (k,m).
<i>tau</i>	Holds the vector of length (k).
<i>c</i>	Holds the matrix C of size (m,n).
<i>side</i>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<i>trans</i>	Must be ' <code>N</code> ' or ' <code>C</code> '. The default value is ' <code>N</code> '.

Application Notes

For better performance, try using *lwork* = $n*blocksize$ (if *side* = '`L`') or *lwork* = $m*blocksize$ (if *side* = '`R`') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [ormlq](#).

?geqlf

Computes the *QL factorization* of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgeqlf(m, n, a, lda, tau, work, lwork, info)
call dgeqlf(m, n, a, lda, tau, work, lwork, info)
call cgeqlf(m, n, a, lda, tau, work, lwork, info)
call zgeqlf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call geqlf(a [, tau] [,info])
```

C:

```
lapack_int LAPACKE_<?>geqlf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the QL factorization of a general m -by- n matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgeqlf

DOUBLE PRECISION for dgeqlf

COMPLEX for cgeqlf

DOUBLE COMPLEX for zgeqlf.

Arrays: *a*(*lda,**) contains the matrix A .

The second dimension of *a* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

*lwork*INTEGER. The size of the *work* array; at least $\max(1, n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a

Overwritten on exit by the factorization data as follows:

If $m \geq n$, the lower triangle of the subarray $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; in both cases, the remaining elements, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

tau

REAL for sgeqlf

DOUBLE PRECISION for dgeqlf

COMPLEX for cgeqlf

DOUBLE COMPLEX for zgeqlf.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .

work(1)

If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *geqlf* interface are the following:

*a*Holds the matrix A of size (m,n) .*tau*Holds the vector of length $\min(m,n)$.

Application Notes

For better performance, try using $lwork = n * \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1 .

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using `lwork =n*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to `-1`, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `orgql`.

?ormql

Multiples a real matrix by the orthogonal matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call sormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormql(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormql( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the *QL* factorization formed by the routine `geqlf/geqlf`.

Depending on the parameters `side` and `trans`, the routine `ormql` can form one of the matrix products Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (overwriting the result over C).

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'.
-------------------	---

If $\text{side} = \text{'L'}$, Q or Q^T is applied to C from the left.

If $\text{side} = \text{'R'}$, Q or Q^T is applied to C from the right.

trans

CHARACTER*1. Must be either 'N' or 'T'.

If $\text{trans} = \text{'N'}$, the routine multiplies C by Q .

If $\text{trans} = \text{'T'}$, the routine multiplies C by Q^T .

m

INTEGER. The number of rows in the matrix C ($m \geq 0$).

n

INTEGER. The number of columns in C ($n \geq 0$).

k

INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

$0 \leq k \leq m$ if $\text{side} = \text{'L'}$;

$0 \leq k \leq n$ if $\text{side} = \text{'R'}$.

a, τ, c, work

REAL for `sormql`

DOUBLE PRECISION for `dormql`.

Arrays: $a(\text{lda},*)$, $\tau(*)$, $c(\text{ldc},*)$.

On entry, the i th column of a must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by `sgeqlf/dgeqlf` in the last k columns of its array argument a .

The second dimension of a must be at least $\max(1, k)$.

$\tau(i)$ must contain the scalar factor of the elementary reflector H_i , as returned by `sgeqlf/dgeqlf`.

The dimension of τ must be at least $\max(1, k)$.

$c(\text{ldc},*)$ contains the m -by- n matrix C .

The second dimension of c must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda

INTEGER. The leading dimension of a ;

if $\text{side} = \text{'L'}$, $\text{lda} \geq \max(1, m)$;

if $\text{side} = \text{'R'}$, $\text{lda} \geq \max(1, n)$.

ldc

INTEGER. The leading dimension of c ; $\text{ldc} \geq \max(1, m)$.

lwork

INTEGER. The size of the work array. Constraints:

$\text{lwork} \geq \max(1, n)$ if $\text{side} = \text{'L'}$;

$\text{lwork} \geq \max(1, m)$ if $\text{side} = \text{'R'}$.

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by `xerbla`.

See *Application Notes* for the suggested value of lwork .

Output Parameters

<i>c</i>	Overwritten by the product $Q^* C$, $Q^T * C$, $C^* Q$, or $C^* Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormql` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r,k</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using *lwork* = *n*blocksize* (if *side* = 'L') or *lwork* = *m*blocksize* (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is `unmql`.

?unmql

Multiplies a complex matrix by the unitary matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call cunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmql(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmql( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the QL factorization formed by the routine [geqlf/geqlf](#).

Depending on the parameters *side* and *trans*, the routine [unmql](#) can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result over C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>tau</i> , <i>c</i> , <i>work</i>	COMPLEX for cunmql DOUBLE COMPLEX for zunmql .

Arrays: $a(lda, *)$, $\tau(*)$, $c(ldc, *)$, $work(lwork)$.

On entry, the i -th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by `cgeqlf/zgeqlf` in the last k columns of its array argument a .

The second dimension of a must be at least $\max(1, k)$.

$\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `cgeqlf/zgeqlf`.

The dimension of τ must be at least $\max(1, k)$.

$c(ldc, *)$ contains the m -by- n matrix C .

The second dimension of c must be at least $\max(1, n)$

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

ldc INTEGER. The leading dimension of c ; $ldc \geq \max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array. Constraints:

$lwork \geq \max(1, n)$ if $side = 'L'$;

$lwork \geq \max(1, m)$ if $side = 'R'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c Overwritten by the product Q^*C , Q^H*C , C^*Q , or C^*Q^H (as specified by $side$ and $trans$).

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmql` interface are the following:

a Holds the matrix A of size (r, k) .

$r = m$ if $side = 'L'$.

$r = n$ if $side = 'R'$.

<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>side</i>	Must be ' <i>L</i> ' or ' <i>R</i> '. The default value is ' <i>L</i> '.
<i>trans</i>	Must be ' <i>N</i> ' or ' <i>C</i> '. The default value is ' <i>N</i> '.

Application Notes

For better performance, try using *lwork* = *n*blocksize* (if *side* = '*L*') or *lwork* = *m*blocksize* (if *side* = '*R*') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [ormql](#).

?gerqf

Computes the *RQ* factorization of a general *m*-by-*n* matrix.

Syntax

FORTRAN 77:

```
call sgerqf(m, n, a, lda, tau, work, lwork, info)
call dgerqf(m, n, a, lda, tau, work, lwork, info)
call cgerqf(m, n, a, lda, tau, work, lwork, info)
call zgerqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gerqf(a [, tau] [, info])
```

C:

```
lapack_int LAPACKE_<?>gerqf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the *RQ* factorization of a general *m*-by-*n* matrix *A*. No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	REAL for sgerqf DOUBLE PRECISION for dgerqf COMPLEX for cgerqf DOUBLE COMPLEX for zgerqf. Arrays: <i>a</i> (<i>lda,*</i>) contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$. <i>lwork</i> INTEGER. The size of the <i>work</i> array; $lwork \geq \max(1, m)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten on exit by the factorization data as follows: if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ th subdiagonal contain the m -by- n upper trapezoidal matrix R ; in both cases, the remaining elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of $\min(m,n)$ elementary reflectors.
<i>tau</i>	REAL for sgerqf

DOUBLE PRECISION for dgerqf
COMPLEX for cgerqf
DOUBLE COMPLEX for zgerqf.
Array, DIMENSION at least max (1, min(m, n)).
Contains scalar factors of the elementary reflectors for the matrix Q .

work(1)
If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info
INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gerqf` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n).
<i>tau</i>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork = -1*.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork = -1*, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

orgrq	to generate matrix Q (for real matrices);
ungrq	to generate matrix Q (for complex matrices);
ormrq	to apply matrix Q (for real matrices);
unmrq	to apply matrix Q (for complex matrices).

[mkl_progress](#)

?orgqr

Generates the real matrix Q of the RQ factorization formed by ?gerqf.

Syntax**FORTRAN 77:**

```
call sorgrq(m, n, k, a, lda, tau, work, lwork, info)
call dorgqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgrq(a, tau [,info])
```

C:

```
lapack_int LAPACKE_<?>orgrq( int matrix_layout, lapack_int m, lapack_int n, lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the routines gerqf/gerqf. Use this routine after a call to sgerqf/dgerqf.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix Q ($n \geq m$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i> , <i>tau</i> , <i>work</i>	REAL for sorgrq DOUBLE PRECISION for dorgqr Arrays: <i>a</i> (<i>lda</i> ,*), <i>tau</i> (*). On entry, the $(m - k + i)$ -th row of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by sgerqf/dgerqf in the last k rows of its array argument <i>a</i> ; <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by sgerqf/dgerqf; The second dimension of <i>a</i> must be at least $\max(1, n)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.

<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; at least $\max(1, m)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> .
	See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the m -by- n matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgqr` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n).
<i>tau</i>	Holds the vector of length (k).

Application Notes

For better performance, try using *lwork* = $m * \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is `ungrq`.

?ungqr

Generates the complex matrix Q of the RQ factorization formed by `?gerqf`.

Syntax

FORTRAN 77:

```
call cungrq(m, n, k, a, lda, tau, work, lwork, info)
call zungrq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

Specific details for the routine `ungrq` interface are the following:

a	Holds the matrix A of size (m,n) .
tau	Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = m * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `orgrq`.

?ormrq

Multiples a real matrix by the orthogonal matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call sormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormrq(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormrq( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors $H_i : Q = H_1 H_2 \dots H_k$ as returned by the RQ factorization routine [gerqf/gerqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (overwriting the result over C).

Input Parameters

The data types are given for the Fortran interface. A *<datatype>* placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.
<i>a</i> , <i>tau</i> , <i>c</i> , <i>work</i>	REAL for sormrq DOUBLE PRECISION for dormrq. Arrays: <i>a</i> (<i>lda</i> ,*), <i>tau</i> (*), <i>c</i> (<i>ldc</i> ,*). On entry, the <i>i</i> th row of <i>a</i> must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by <i>sgerqf/dgerqf</i> in the last k rows of its array argument <i>a</i> .

The second dimension of a must be at least $\max(1, m)$ if $\text{side} = \text{'L'}$, and at least $\max(1, n)$ if $\text{side} = \text{'R'}$.

$\tau_{\text{au}}(i)$ must contain the scalar factor of the elementary reflector H_i , as returned by `sgerqf/dgerqf`.

The dimension of τ_{au} must be at least $\max(1, k)$.

$c(ldc,*)$ contains the m -by- n matrix C .

The second dimension of c must be at least $\max(1, n)$

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, k)$.

ldc INTEGER. The leading dimension of c ; $ldc \geq \max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array. Constraints:

$lwork \geq \max(1, n)$ if $\text{side} = \text{'L'}$;

$lwork \geq \max(1, m)$ if $\text{side} = \text{'R'}$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c Overwritten by the product Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (as specified by side and trans).

$work(1)$ If $\text{info} = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrq` interface are the following:

a Holds the matrix A of size (k,m) .

τ_{au} Holds the vector of length (k) .

c Holds the matrix C of size (m,n) .

$side$ Must be 'L' or 'R' . The default value is 'L' .

$trans$ Must be 'N' or 'T' . The default value is 'N' .

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [unmrq](#).

?unmrq

Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call cunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrq(a, tau, c [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmrq( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)H^* H(2)H^* \dots H(k)H$ has returned by the RQ factorization routine [gerqf/gerqf](#).

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products Q^*C , $Q^{H*}C$, C^*Q , or C^*Q^H (overwriting the result over C).

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.
<i>a</i> , <i>tau</i> , <i>c</i> , <i>work</i>	COMPLEX for cunmqr DOUBLE COMPLEX for zunmqr. Arrays: $a(lda,*), tau(*), c ldc,*), work(lwork)$. On entry, the <i>i</i> th row of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by cgerqf/zgerqf in the last <i>k</i> rows of its array argument <i>a</i> . The second dimension of <i>a</i> must be at least $\max(1, m)$ if <i>side</i> = 'L', and at least $\max(1, n)$ if <i>side</i> = 'R'. <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by cgerqf/zgerqf. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (<i>ldc</i> ,*) contains the <i>m</i> -by- <i>n</i> matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> $\geq \max(1, k)$. <i>ldc</i> INTEGER. The leading dimension of <i>c</i> ; <i>ldc</i> $\geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (as specified by <i>side</i> and <i>trans</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmraq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k,m</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>side</i>	Must be ' <i>L</i> ' or ' <i>R</i> '. The default value is ' <i>L</i> '.
<i>trans</i>	Must be ' <i>N</i> ' or ' <i>C</i> '. The default value is ' <i>N</i> '.

Application Notes

For better performance, try using *lwork* = *n*blocksize* (if *side* = '*L*') or *lwork* = *m*blocksize* (if *side* = '*R*') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `ormrq`.

?tzrzf

Reduces the upper trapezoidal matrix *A* to upper triangular form.

Syntax

FORTRAN 77:

```
call stzrzf(m, n, a, lda, tau, work, lwork, info)
```

```
call dtzrzf(m, n, a, lda, tau, work, lwork, info)
call ctzrzf(m, n, a, lda, tau, work, lwork, info)
call ztzrzf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call tzrzf(a [, tau] [,info])
```

C:

```
lapack_int LAPACKE_<?>tzrzf( int matrix_layout, lapack_int m, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix A to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix $A = [A1 A2] = [A(1:m, 1:m), A(1:m, m+1:n)]$ is factored as

$$A = [R \ O] * Z,$$

where Z is an n -by- n orthogonal/unitary matrix, R is an m -by- m upper triangular matrix, and O is the m -by-($n-m$) zero matrix.

See [larz](#) that applies an elementary reflector returned by `?tzrzf` to a general matrix.

The `?tzrzf` routine replaces the deprecated `?tzrqf` routine.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq m$).

a, work REAL for stzrzf

DOUBLE PRECISION for dtzrzf

COMPLEX for ctzrzf

DOUBLE COMPLEX for ztzrzf.

Arrays: $a(lda,*)$, $work(lwork)$. The leading m -by- n upper trapezoidal part of the array a contains the matrix A to be factorized.

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

lwork INTEGER. The size of the $work$ array;

lwork $\geq \max(1, m)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a</i>	Overwritten on exit by the factorization data as follows: the leading <i>m</i> -by- <i>m</i> upper triangular part of <i>a</i> contains the upper triangular matrix <i>R</i> , and elements <i>m</i> + 1 to <i>n</i> of the first <i>m</i> rows of <i>a</i> , with the array <i>tau</i> , represent the orthogonal matrix <i>Z</i> as a product of <i>m</i> elementary reflectors.
<i>tau</i>	REAL for <i>stzrzf</i> DOUBLE PRECISION for <i>dtzrzf</i> COMPLEX for <i>ctzrzf</i> DOUBLE COMPLEX for <i>ztzrzf</i> . Array, DIMENSION at least $\max(1, m)$. Contains scalar factors of the elementary reflectors for the matrix <i>Z</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tzrzf* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>tau</i>	Holds the vector of length (<i>m</i>).

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, *Z*(*k*), which is used to introduce zeros into the (*m* - *k* + 1)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where for real flavors

$$T(k) = I - tau u(k)^* u(k)^T, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

and for complex flavors

$$T(k) = I - tau u(k)^* u(k)^H, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

tau is a scalar and *z(k)* is an *l*-element vector. *tau* and *z(k)* are chosen to annihilate the elements of the *k*-th row of *A*.

The scalar *tau* is returned in the *k*-th element of *tau* and the vector *u(k)* in the *k*-th row of *A*, such that the elements of *z(k)* are in *a(k, m+1), ..., a(k, n)*.

The elements of *R* are returned in the upper triangular part of *A*.

The matrix *Z* is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

For better performance, try using *lwork = m*blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the blocked algorithm.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork = -1*.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork = -1*, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

[ormrz](#) to apply matrix Q (for real matrices)

[unmrz](#) to apply matrix Q (for complex matrices).

?ormrz

Multiples a real matrix by the orthogonal matrix defined from the factorization formed by ?tzrzf.

Syntax

FORTRAN 77:

```
call sormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call dormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

- C: mkl.h

Description

The ?ormrz routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the factorization routine **tzrzf/tzrf**.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^T*C , C^*Q , or C^*Q^T (overwriting the result over C).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

The ?ormrz routine replaces the deprecated ?latzm routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.
<i>l</i>	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors. Constraints: $0 \leq l \leq m$, if <i>side</i> = 'L';

$0 \leq l \leq n$, if $\text{side} = 'R'$.

$a, tau, c, work$

REAL for sormrz

DOUBLE PRECISION for dormrz.

Arrays: $a(lda,*), tau(*), c(ldc,*)$.

On entry, the i th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by stzrzf/dtzrzf in the last k rows of its array argument a .

The second dimension of a must be at least $\max(1, m)$ if $\text{side} = 'L'$, and at least $\max(1, n)$ if $\text{side} = 'R'$.

$tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by stzrzf/dtzrzf.

The dimension of tau must be at least $\max(1, k)$.

$c(ldc,*)$ contains the m -by- n matrix C .

The second dimension of c must be at least $\max(1, n)$

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of a ; $lda \geq \max(1, k)$.

ldc

INTEGER. The leading dimension of c ; $ldc \geq \max(1, m)$.

$lwork$

INTEGER. The size of the $work$ array. Constraints:

$lwork \geq \max(1, n)$ if $\text{side} = 'L'$;

$lwork \geq \max(1, m)$ if $\text{side} = 'R'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See [Application Notes](#) for the suggested value of $lwork$.

Output Parameters

c

Overwritten by the product Q^*C , Q^T*C , C^*Q , or C^*Q^T (as specified by side and trans).

$work(1)$

If $\text{info} = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrz` interface are the following:

<code>a</code>	Holds the matrix A of size (k,m) .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m,n) .
<code>side</code>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<code>trans</code>	Must be ' <code>N</code> ' or ' <code>T</code> '. The default value is ' <code>N</code> '.

Application Notes

For better performance, try using $lwork = n * \text{blocksize}$ (if `side = 'L'`) or $lwork = m * \text{blocksize}$ (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [unmrz](#).

?unmrz

Multiplies a complex matrix by the unitary matrix defined from the factorization formed by ?tzrzf.

Syntax

FORTRAN 77:

```
call cunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call zunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrz(a, tau, c, l [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmrz( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, const <datatype>* a, lapack_int lda,
const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix defined as a product of k elementary reflectors $H(i)$:

$Q = H(1)^H * H(2)^H * \dots * H(k)^H$ as returned by the factorization routine [tzrzf/tzrzf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^{H*}C$, C^*Q , or C^*Q^H (overwriting the result over C).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
 $info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmrz` interface are the following:

a	Holds the matrix A of size (k,m) .
τ	Holds the vector of length (k) .
c	Holds the matrix C of size (m,n) .
$side$	Must be ' L ' or ' R '. The default value is ' L '.
$trans$	Must be ' N ' or ' C '. The default value is ' N '.

Application Notes

For better performance, try using $lwork = n*blocksize$ (if $side = 'L'$) or $lwork = m*blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [ormrz](#).

?ggqrft

Computes the generalized QR factorization of two matrices.

Syntax

FORTRAN 77:

```
call sggqrft(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggqrft(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggqrft(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call zggqrft(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
```

Fortran 95:

```
call ggqrft(a, b [,taua] [,taub] [,info])
```

C:

```
lapack_int LAPACKE_<?>ggqrft( int matrix_layout, lapack_int n, lapack_int m, lapack_int p, <datatype>* a, lapack_int lda, <datatype>* taua, <datatype>* b, lapack_int ldb, <datatype>* taub );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the generalized QR factorization of an *n*-by-*m* matrix *A* and an *n*-by-*p* matrix *B* as *A* = *Q***R*, *B* = *Q***T***Z*, where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

$$R = \begin{cases} m & \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}, \quad \text{if } n \geq m \\ n - m & \end{cases}$$

or

$$R = \begin{matrix} n & m - n \\ R_{11} & R_{12} \end{matrix}, \quad \text{if } n < m$$

where R_{11} is upper triangular, and

$$T = \begin{matrix} p - n & n \\ 0 & T_{12} \end{matrix}, \quad \text{if } n \leq p,$$

$$T = \begin{matrix} p \\ n - p \\ p \end{matrix} \begin{pmatrix} T_{11} \\ T_{12} \\ T_{21} \end{pmatrix}, \quad \text{if } n > p,$$

where T_{12} or T_{21} is a p -by- p upper triangular matrix.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $B^{-1}A$ as:

$$B^{-1} * A = Z^{T*} (T^{-1} * R) \text{ (for real flavors) or } B^{-1} * A = Z^{H*} (T^{-1} * R) \text{ (for complex flavors).}$$

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The number of rows of the matrices A and B ($n \geq 0$).
<i>m</i>	INTEGER. The number of columns in A ($m \geq 0$).
<i>p</i>	INTEGER. The number of columns in B ($p \geq 0$).
<i>a, b, work</i>	REAL for <code>sggqr</code> DOUBLE PRECISION for <code>dggqr</code> COMPLEX for <code>cggqr</code> DOUBLE COMPLEX for <code>zggqr</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, m)$. $b(lsb,*)$ contains the matrix B . The second dimension of b must be at least $\max(1, p)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array; must be at least $\max(1, n, m, p)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a, b

Overwritten by the factorization data as follows:

on exit, the elements on and above the diagonal of the array *a* contain the $\min(n,m)$ -by-*m* upper trapezoidal matrix *R* (*R* is upper triangular if $n \geq m$); the elements below the diagonal, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of $\min(n,m)$ elementary reflectors;

if $n \leq p$, the upper triangle of the subarray *b*(1:*n*, *p*-*n*+1:*p*) contains the *n*-by-*n* upper triangular matrix *T*;

if $n > p$, the elements on and above the (*n*-*p*)th subdiagonal contain the *n*-by-*p* upper trapezoidal matrix *T*; the remaining elements, with the array *taub*, represent the orthogonal/unitary matrix *Z* as a product of elementary reflectors.

taua, taub

REAL for sggqr

DOUBLE PRECISION for dggqr

COMPLEX for cggqr

DOUBLE COMPLEX for zggqr.

Arrays, DIMENSION at least max (1, $\min(n, m)$) for *taua* and at least max (1, $\min(n, p)$) for *taub*. The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*.

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*.

work(1)

If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggqr* interface are the following:

a Holds the matrix *A* of size (*n,m*).

b Holds the matrix *B* of size (*n,p*).

*tau*a Holds the vector of length $\min(n,m)$.

taub Holds the vector of length $\min(n,p)$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(1)H(2)\dots H(k)$, where $k = \min(n, m)$.

Each $H(i)$ has the form

$H(i) = I - \tau_{ai} v v^T$ for real flavors, or

$H(i) = I - \tau \alpha u^* v^* v^H$ for complex flavors,

where τ_{au} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$, $v(i) = 1$.

On exit, $v(i+1:n)$ is stored in $a(i+1:n, i)$ and τ_{au} is stored in $\tau_{au}(i)$.

The matrix Z is represented as a product of elementary reflectors

$Z = H(1)H(2)\dots H(k)$, where $k = \min(n, p)$.

Each $H(i)$ has the form

$H(i) = I - taub^* v^* v^T$ for real flavors, or

$H(i) = I - taub^* v^* v^H$ for complex flavors.

where $taub$ is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$, $v(p-k+i) = 1$.

On exit, $y(1:p-k+i-1)$ is stored in $b(n-k+i, 1:p-k+i-1)$ and $taub$ is stored in $taub(i)$.

For better performance, try using `lwork = max(n, m, p) * max(nb1, nb2, nb3)`, where `nb1` is the optimal blocksize for the QR factorization of an n -by- m matrix, `nb2` is the optimal blocksize for the RQ factorization of an n -by- p matrix, and `nb3` is the optimal blocksize for a call of `ormqr/unmqr`.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggrgf

Computes the generalized RQ factorization of two matrices.

Syntax

FORTRAN 77:

```

call sggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call zgaraf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)

```

Fortran 95:

```
call ggrqf(a, b [,taua] [,taub] [,info])
```

C:

```
lapack_int LAPACKE_<?>ggrqf( int matrix_layout, lapack_int m, lapack_int p, lapack_int n,
<datatype>* a, lapack_int lda, <datatype>* taua, <datatype>* b, lapack_int ldb,
<datatype>* taub );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the generalized *RQ* factorization of an m -by- n matrix A and an p -by- n matrix B as $A = R^*Q$, $B = Z^*T^*Q$, where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{matrix} n - m & m \\ m & \begin{pmatrix} 0 & R_{12} \end{pmatrix} \end{matrix}, \quad \text{if } m \leq n,$$

or

$$R = \begin{matrix} n \\ m - n \\ n \end{matrix} \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix}, \quad \text{if } m > n,$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{matrix} n \\ p - n \end{matrix} \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}, \quad \text{if } p \geq n,$$

or

$$T = \begin{matrix} p & n - p \\ p & \begin{pmatrix} T_{11} & T_{12} \end{pmatrix} \end{matrix}, \quad \text{if } p < n,$$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the *GRQ* factorization of A and B implicitly gives the *RQ* factorization of A^*B^{-1} as:

$A^*B^{-1} = (R^*T^{-1}) * Z^T$ (for real flavors) or $A^*B^{-1} = (R^*T^{-1}) * Z^H$ (for complex flavors).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>p</i>	INTEGER. The number of rows in B ($p \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
<i>a, b, work</i>	REAL for sggqrqf DOUBLE PRECISION for dggrqf COMPLEX for cggrqf DOUBLE COMPLEX for zggrqf. Arrays: <i>a</i> (<i>lda,*</i>) contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb,*</i>) contains the p -by- n matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$. <i>ldb</i> INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, p)$. <i>lwork</i> INTEGER. The size of the <i>work</i> array; must be at least $\max(1, n, m, p)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a, b</i>	Overwritten by the factorization data as follows: on exit, if $m \leq n$, the upper triangle of the subarray <i>a</i> (1: <i>m</i> , <i>n</i> - <i>m</i> +1: <i>n</i>) contains the m -by- m upper triangular matrix R ; if $m > n$, the elements on and above the $(m-n)$ th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array <i>taua</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; the elements on and above the diagonal of the array <i>b</i> contain the $\min(p, n)$ -by- n upper trapezoidal matrix T (T is upper triangular if $p \geq n$); the elements below the diagonal, with the array <i>taub</i> , represent the orthogonal/unitary matrix Z as a product of elementary reflectors.
-------------	---

<i>taua, taub</i>	REAL for sggrqf DOUBLE PRECISION for dggrqf COMPLEX for cggrqf DOUBLE COMPLEX for zggrqf. Arrays, DIMENSION at least max (1, min(m, n)) for <i>taua</i> and at least max (1, min(p, n)) for <i>taub</i> . The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggrqf* interface are the following:

<i>a</i>	Holds the matrix A of size (m, n).
<i>b</i>	Holds the matrix A of size (p, n).
<i>taua</i>	Holds the vector of length $\min(m, n)$.
<i>taub</i>	Holds the vector of length $\min(p, n)$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)H(2)\dots H(k), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{aua} v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau_{aua} v v^H \text{ for complex flavors,}$$

where *taua* is a real/complex scalar, and *v* is a real/complex vector with $v(n-k+i+1:n) = 0$, $v(n-k+i) = 1$.

On exit, $v(1:n-k+i-1)$ is stored in $a(m-k+i, 1:n-k+i-1)$ and *taua* is stored in *taua(i)*.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1)H(2)\dots H(k), \text{ where } k = \min(p, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{aub} v v^T \text{ for real flavors, or}$$

$H(i) = I - taub * v * v^H$ for complex flavors,

where $taub$ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$, $v(i) = 1$.

On exit, $v(i+1:p)$ is stored in $b(i+1:p, i)$ and $taub$ is stored in $taub(i)$.

For better performance, try using

$lwork \geq \max(n, m, p) * \max(nb1, nb2, nb3)$,

where $nb1$ is the optimal blocksize for the RQ factorization of an m -by- n matrix, $nb2$ is the optimal blocksize for the QR factorization of an p -by- n matrix, and $nb3$ is the optimal blocksize for a call of $?ormrq/?unmrq$.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tpqrt

Computes a blocked QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q .

Syntax

FORTRAN 77:

```
call stpqrt(m, n, l, nb, a, lda, b, ldb, t, ldt, work, info)
call dtpqrt(m, n, l, nb, a, lda, b, ldb, t, ldt, work, info)
call ctpqrt(m, n, l, nb, a, lda, b, ldb, t, ldt, work, info)
call ztpqrt(m, n, l, nb, a, lda, b, ldb, t, ldt, work, info)
```

Fortran 95:

```
call tpqrt(a, b, t, nb [, info])
```

C:

```
lapack_int LAPACKE_<?>tpqrt(int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_int nb, <datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb, <datatype>* t, lapack_int ldt)
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The input matrix C is an $(n+m)$ -by- n matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \begin{array}{l} \leftarrow n \times n \text{ upper triangular} \\ \leftarrow m \times n \text{ pentagonal} \end{array}$$

where A is an n -by- n upper triangular matrix, and B is an m -by- n pentagonal matrix consisting of an $(m-l)$ -by- n rectangular matrix $B1$ on top of an l -by- n upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \begin{array}{l} \leftarrow (m-l) \times n \text{ rectangular} \\ \leftarrow l \times n \text{ upper trapezoidal} \end{array}$$

The upper trapezoidal matrix $B2$ consists of the first l rows of an n -by- n upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If $l=0$, B is an m -by- n rectangular matrix. If $m=l=n$, B is upper triangular. The matrix W contains the elementary reflectors $H(i)$ in the i th column below the diagonal (of A) in the $(n+m)$ -by- n input matrix C so that W can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \begin{array}{l} \leftarrow n \times n \text{ identity} \\ \leftarrow m \times n \text{ pentagonal} \end{array}$$

Thus, V contains all of the information needed for W , and is returned in array b .

NOTE

Note that V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \begin{array}{l} \leftarrow (m-l) \times n \text{ rectangular} \\ \leftarrow l \times n \text{ upper trapezoidal} \end{array}$$

The columns of V represent the vectors which define the $H(i)$ s. The number of blocks is $k = \text{ceiling}(n/nb)$, where each block is of order nb except for the last block, which is of order $ib = n - (k-1)*nb$. For each of the k blocks, an upper triangular block reflector factor is computed: $T1, T2, \dots, Tb$. The nb -by- nb (ib -by- ib for the last block) T is are stored in the nb -by- n array t as

$$t = [T1 \ T2 \ \dots \ TB].$$

Input Parameters

m	INTEGER. The total number of rows in the matrix B ($m \geq 0$).
n	INTEGER. The number of columns in B and the order of the triangular matrix A ($n \geq 0$).
l	INTEGER. The number of rows of the upper trapezoidal part of B ($\min(m, n) \geq l \geq 0$).

<i>nb</i>	INTEGER. The block size to use in the blocked QR factorization ($n \geq nb \geq 1$).
<i>a, b, work</i>	<p>REAL for <code>stpmqrt</code></p> <p>DOUBLE PRECISION for <code>dtpmqrt</code></p> <p>COMPLEX for <code>ctpmqrt</code></p> <p>COMPLEX*16 for <code>ztpmqrt</code>.</p> <p>Arrays: <i>a</i> DIMENSION (<i>lda, n</i>) contains the <i>n</i>-by-<i>n</i> upper triangular matrix <i>A</i>.</p> <p><i>b</i> DIMENSION (<i>ldb, n</i>), the pentagonal <i>m</i>-by-<i>n</i> matrix <i>B</i>. The first (<i>m-l</i>) rows contain the rectangular <i>B1</i> matrix, and the next <i>l</i> rows contain the upper trapezoidal <i>B2</i> matrix.</p> <p><i>work</i> DIMENSION (<i>nb, n</i>) is a workspace array.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, m)$.
<i>ldt</i>	INTEGER. The leading dimension of <i>t</i> ; at least <i>nb</i> .

Output Parameters

<i>a</i>	The elements on and above the diagonal of the array contain the upper triangular matrix <i>R</i> .
<i>b</i>	The pentagonal matrix <i>V</i> .
<i>t</i>	<p>REAL for <code>stpmqrt</code></p> <p>DOUBLE PRECISION for <code>dtpmqrt</code></p> <p>COMPLEX for <code>ctpmqrt</code></p> <p>COMPLEX*16 for <code>ztpmqrt</code>.</p> <p>Array, DIMENSION (<i>ldt, n</i>).</p> <p>The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> < 0 and <i>info</i> = -<i>i</i>, the <i>i</i>th argument had an illegal value.</p>

?tpmqrt

Applies a real or complex orthogonal matrix obtained from a "triangular-pentagonal" complex block reflector to a general real or complex matrix, which consists of two blocks.

Syntax

FORTRAN 77:

```
call stpmqrt(side, trans, m, n, k, l, nb, v, ldv, t, ldt, a, lda, b, ldb, work, info)
call dtpmqrt(side, trans, m, n, k, l, nb, v, ldv, t, ldt, a, lda, b, ldb, work, info)
```

```
call ctpmqrt(side, trans, m, n, k, l, nb, v, ldv, t, ldt, a, lda, b, ldb, work, info)
call ztpmqrt(side, trans, m, n, k, l, nb, v, ldv, t, ldt, a, lda, b, ldb, work, info)
```

Fortran 95:

```
call tpmqrt( v, t, a, b, k, nb [, trans] [, side] [, info])
```

C:

```
lapack_int LAPACKE_<?>tpmqrt(int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const <datatype>* v,
lapack_int ldv, const <datatype>* t, lapack_int ldt, <datatype>* a, lapack_int lda,
<datatype>* b, lapack_int ldb)
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The columns of the pentagonal matrix V contain the elementary reflectors $H(1), H(2), \dots, H(k)$; V is composed of a rectangular block $V1$ and a trapezoidal block $V2$:

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$$

The size of the trapezoidal block $V2$ is determined by the parameter l , where $0 \leq l \leq k$. $V2$ is upper trapezoidal, consisting of the first l rows of a k -by- k upper triangular matrix.

If $l=k$, $V2$ is upper triangular;

If $l=0$, there is no trapezoidal block, so $V = V1$ is rectangular.

If $side = 'L'$:

$$C = \begin{bmatrix} A \\ B \end{bmatrix}$$

where A is k -by- n , B is m -by- n and V is m -by- k .

If $side = 'R'$:

$$C = [A \quad B]$$

where A is m -by- k , B is m -by- n and V is n -by- k .

The real/complex orthogonal matrix Q is formed from V and T .

If $trans='N'$ and $side='L'$, c contains $Q * C$ on exit.

If $trans='T'$ and $side='L'$, c contains $Q^T * C$ on exit.

If $trans='C'$ and $side='L'$, c contains $Q^H * C$ on exit.

If $\text{trans} = \text{'N'}$ and $\text{side} = \text{'R'}$, C contains $C * Q$ on exit.

If $\text{trans} = \text{'T'}$ and $\text{side} = \text{'R'}$, C contains $C * Q^T$ on exit.

If $\text{trans} = \text{'C'}$ and $\text{side} = \text{'R'}$, C contains $C * Q^H$ on exit.

Input Parameters

<i>side</i>	CHARACTER*1
	= 'L': apply Q , Q^T , or Q^H from the left.
	= 'R': apply Q , Q^T , or Q^H from the right.
<i>trans</i>	CHARACTER*1
	= 'N', no transpose, apply Q .
	= 'T', transpose, apply Q^T .
	= 'C', transpose, apply Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix B , ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix B , ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q .
<i>l</i>	INTEGER. The order of the trapezoidal part of V ($k \geq l \geq 0$).
<i>nb</i>	INTEGER. The block size used for the storage of t , $k \geq nb \geq 1$. This must be the same value of nb used to generate t in tpqrt .
<i>v</i>	REAL for stpmqrt DOUBLE PRECISION for dtpmqrt COMPLEX for ctpmqrt COMPLEX*16 for ztpmqrt . DIMENSION (ldv, k) The i th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by tpqrt in array argument b .
<i>ldv</i>	INTEGER. The leading dimension of the array v . If $\text{side} = \text{'L'}$, ldv must be at least $\max(1, m)$; If $\text{side} = \text{'R'}$, ldv must be at least $\max(1, n)$.
<i>t</i>	REAL for stpmqrt DOUBLE PRECISION for dtpmqrt COMPLEX for ctpmqrt COMPLEX*16 for ztpmqrt . Array, DIMENSION (ldt, k).

The upper triangular factors of the block reflectors as returned by [tpqrt](#), stored as an nb -by- k matrix.

lbt INTEGER. The leading dimension of the array *t*. *lbt* must be at least *nb*.

a REAL for *stpmqrt*

DOUBLE PRECISION for *dtpmqrt*

COMPLEX for *ctpmqrt*

COMPLEX*16 for *ztpmqrt*.

If *side* = 'L', DIMENSION (*lda*, *n*).

If *side* = 'R', DIMENSION (*lda*, *k*).

The k -by- n or m -by- k matrix *A*.

lda INTEGER. The leading dimension of the array *a*.

If *side* = 'L', *lda* must be at least $\max(1, k)$.

If *side* = 'R', *lda* must be at least $\max(1, m)$.

b REAL for *stpmqrt*

DOUBLE PRECISION for *dtpmqrt*

COMPLEX for *ctpmqrt*

COMPLEX*16 for *ztpmqrt*.

DIMENSION (*ldb*, *n*).

The m -by- n matrix *B*.

ldb INTEGER. The leading dimension of the array *b*. *ldb* must be at least $\max(1, m)$.

work REAL for *stpmqrt*

DOUBLE PRECISION for *dtpmqrt*

COMPLEX for *ctpmqrt*

COMPLEX*16 for *ztpmqrt*.

Workspace array. If *side* = 'L' DIMENSION $n * nb$. If *side* = 'R' DIMENSION $m * nb$.

Output Parameters

a Overwritten by the corresponding block of the product Q^*C , C^*Q , Q^T*C , C^*Q^T , $Q^{H*}C$, or C^*Q^H .

b Overwritten by the corresponding block of the product Q^*C , C^*Q , Q^T*C , C^*Q^T , $Q^{H*}C$, or C^*Q^H .

info (global) INTEGER.

= 0: the execution is successful.

< 0: if *info* = $-i$, the *i*th argument had an illegal value.

Singular Value Decomposition - LAPACK Computational Routines

This section describes LAPACK routines for computing the *singular value decomposition* (SVD) of a general m -by- n matrix A :

$$A = U\Sigma V^H.$$

In this decomposition, U and V are unitary (for complex A) or orthogonal (for real A); Σ is an m -by- n diagonal matrix with real diagonal elements σ_i :

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_{\min(m, n)} \geq 0.$$

The diagonal elements σ_i are *singular values* of A . The first $\min(m, n)$ columns of the matrices U and V are, respectively, *left* and *right singular vectors* of A . The singular values and singular vectors satisfy

$$Av_i = \sigma_i u_i \text{ and } A^H v_i = \sigma_i v_i$$

where u_i and v_i are the i -th columns of U and V , respectively.

To find the SVD of a general matrix A , call the LAPACK routine `?gebrd` or `?gbbrd` for reducing A to a bidiagonal matrix B by a unitary (orthogonal) transformation: $A = QBP^H$. Then call `?bdsqr`, which forms the SVD of a bidiagonal matrix: $B = U_1 \Sigma V_1^H$.

Thus, the sought-for SVD of A is given by $A = U\Sigma V^H = (QU_1)\Sigma(V_1^H P^H)$.

Table "Computational Routines for Singular Value Decomposition (SVD)" lists LAPACK routines (FORTRAN 77 interface) that perform singular value decomposition of matrices. The corresponding routine names in the Fortran 95 interface are the same except that the first character is removed.

Computational Routines for Singular Value Decomposition (SVD)

Operation	Real matrices	Complex matrices
Reduce A to a bidiagonal matrix B : $A = QBP^H$ (full storage)	<code>?gebrd</code>	<code>?gebrd</code>
Reduce A to a bidiagonal matrix B : $A = QBP^H$ (band storage)	<code>?gbbrd</code>	<code>?gbbrd</code>
Generate the orthogonal (unitary) matrix Q or P	<code>?orgbr</code>	<code>?ungbr</code>
Apply the orthogonal (unitary) matrix Q or P	<code>?ormbr</code>	<code>?unmbr</code>
Form singular value decomposition of the bidiagonal matrix B : $B = U\Sigma V^H$	<code>?bdsqr</code> <code>?bdsdc</code>	<code>?bdsqr</code>

Decision Tree: Singular Value Decomposition

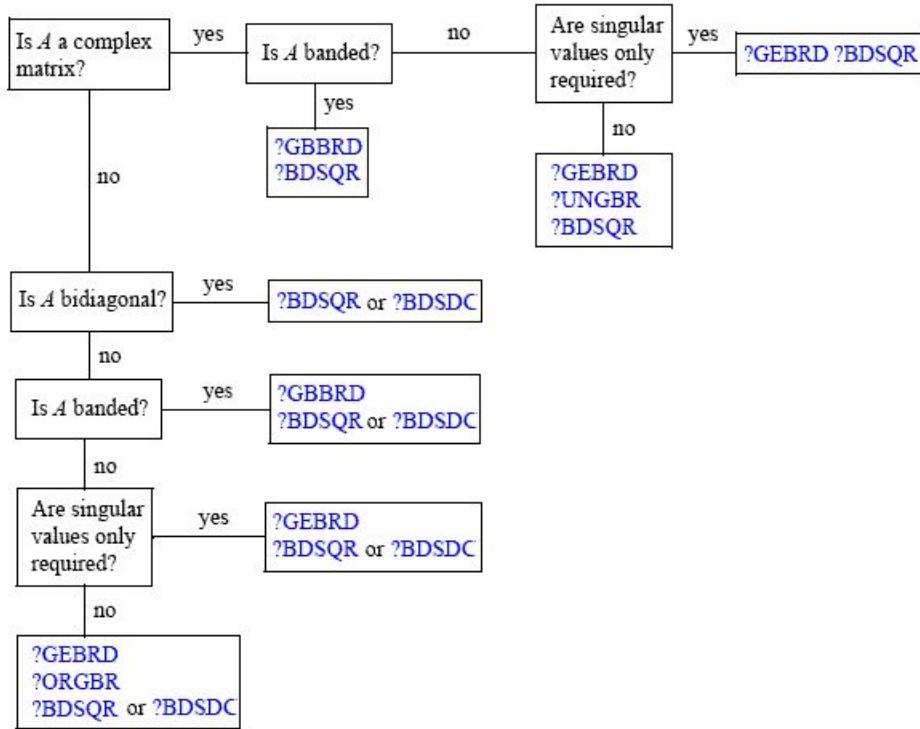

Figure "Decision Tree: Singular Value Decomposition" presents a decision tree that helps you choose the right sequence of routines for SVD, depending on whether you need singular values only or singular vectors as well, whether A is real or complex, and so on.

You can use the SVD to find a minimum-norm solution to a (possibly) rank-deficient least squares problem of minimizing $\|Ax - b\|^2$. The effective rank k of the matrix A can be determined as the number of singular values which exceed a suitable threshold. The minimum-norm solution is

$$x = V_k(\Sigma_k)^{-1}c$$

where Σ_k is the leading k -by- k submatrix of Σ , the matrix V_k consists of the first k columns of $V = PV_1$, and the vector c consists of the first k elements of $U^Hb = U_1^HQ^Hb$.

?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

FORTRAN 77:

```

call sgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call dgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call cgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call zgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
  
```

Fortran 95:

```
call gebrd(a [, d] [, e] [,tauq] [,taup] [,info])
```

C:

```
lapack_int LAPACKE_sgebrd( int matrix_layout, lapack_int m, lapack_int n, float* a,
                           lapack_int lda, float* d, float* e, float* tauq, float* taup );
```

```

lapack_int LAPACKE_dgebrd( int matrix_layout, lapack_int m, lapack_int n, double* a,
                           lapack_int lda, double* d, double* e, double* tauq, double* taup );
lapack_int LAPACKE_cgebrd( int matrix_layout, lapack_int m, lapack_int n,
                           lapack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float* tauq,
                           lapack_complex_float* taup );
lapack_int LAPACKE_zgebrd( int matrix_layout, lapack_int m, lapack_int n,
                           lapack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double* tauq,
                           lapack_complex_double* taup );

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a general m -by- n matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

$$A = QBP^H = Q \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P^H,$$

If $m \geq n$, the reduction is given by

where B_1 is an n -by- n upper diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; Q_1 consists of the first n columns of Q .

If $m < n$, the reduction is given by

$$A = Q^* B^* P^H = Q^* (B_1 0)^* P^H = Q_1^* B_1^* P_1^H,$$

where B_1 is an m -by- m lower diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; P_1 consists of the first m rows of P .

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

- to compute Q and P explicitly, call [orgbr](#).
- to multiply a general matrix by Q or P , call [ormbr](#).

If the matrix A is complex,

- to compute Q and P explicitly, call [ungbr](#).
- to multiply a general matrix by Q or P , call [unmbr](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgebrd

DOUBLE PRECISION for dgebrd

COMPLEX for cgebrd
DOUBLE COMPLEX for zgebrd.

Arrays:

a(*lda*,*) contains the matrix *A*.

The second dimension of *a* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

lwork INTEGER.

The dimension of *work*; at least $\max(1, m, n)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a If $m \geq n$, the diagonal and first super-diagonal of *a* are overwritten by the upper bidiagonal matrix *B*. Elements below the diagonal are overwritten by details of *Q*, and the remaining elements are overwritten by details of *P*.

If $m < n$, the diagonal and first sub-diagonal of *a* are overwritten by the lower bidiagonal matrix *B*. Elements above the diagonal are overwritten by details of *P*, and the remaining elements are overwritten by details of *Q*.

d REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains the diagonal elements of *B*.

e REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of *B*.

taug, *taup* REAL for sgebrd

DOUBLE PRECISION for dgebrd

COMPLEX for cgebrd

DOUBLE COMPLEX for zgebrd.

Arrays, DIMENSION at least $\max(1, \min(m, n))$. Contain further details of the matrices *Q* and *P*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.

If *info* = 0, the execution is successful.If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebrd` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>d</i>	Holds the vector of length min(<i>m,n</i>).
<i>e</i>	Holds the vector of length min(<i>m,n</i>)-1.
<i>taug</i>	Holds the vector of length min(<i>m,n</i>).
<i>taup</i>	Holds the vector of length min(<i>m,n</i>).

Application Notes

For better performance, try using *lwork* = (*m* + *n*) * *blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrices *Q*, *B*, and *P* satisfy $QBP^H = A + E$, where $\|E\|_2 = c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of *n*, and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(4/3) * n^2 * (3*m - n) \text{ for } m \geq n,$$

$$(4/3) * m^2 * (3*n - m) \text{ for } m < n.$$

The number of operations for complex flavors is four times greater.

If *n* is much less than *m*, it can be more efficient to first form the QR factorization of *A* by calling `geqr` and then reduce the factor *R* to bidiagonal form. This requires approximately $2*n^2*(m + n)$ floating-point operations.

If *m* is much less than *n*, it can be more efficient to first form the LQ factorization of *A* by calling `gelq` and then reduce the factor *L* to bidiagonal form. This requires approximately $2*m^2*(m + n)$ floating-point operations.

?gbbrd

Reduces a general band matrix to bidiagonal form.

Syntax**FORTRAN 77:**

```
call sgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc, work,

- C: mkl.h

Description

The routine reduces an m -by- n band matrix A to upper bidiagonal matrix B : $A = Q^H B P^H$. Here the matrices Q and P are orthogonal (for real A) or unitary (for complex A). They are determined as products of Givens rotation matrices, and may be formed explicitly by the routine if required. The routine can also update a matrix C as follows: $C = Q^H C$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>vect</i>	CHARACTER*1. Must be 'N' or 'Q' or 'P' or 'B'. If <i>vect</i> = 'N', neither <i>Q</i> nor P^H is generated. If <i>vect</i> = 'Q', the routine generates the matrix <i>Q</i> . If <i>vect</i> = 'P', the routine generates the matrix P^H . If <i>vect</i> = 'B', the routine generates both <i>Q</i> and P^H .
<i>m</i>	INTEGER. The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>ncc</i>	INTEGER. The number of columns in <i>C</i> ($ncc \geq 0$).
<i>k1</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($k1 \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab, c, work</i>	REAL for sgbbrd DOUBLE PRECISION for dgbbrd COMPLEX for cgbbrd DOUBLE COMPLEX for zgbbrd. Arrays: <i>ab</i> (<i>ldab</i> ,*) contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>c</i> (<i>ldc</i> ,*) contains an <i>m</i> -by- <i>ncc</i> matrix <i>C</i> . If <i>ncc</i> = 0, the array <i>c</i> is not referenced. The second dimension of <i>c</i> must be at least $\max(1, ncc)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $2 * \max(m, n)$ for real flavors, or $\max(m, n)$ for complex flavors.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ($ldab \geq k1 + ku + 1$).
<i>ldq</i>	INTEGER. The leading dimension of the output array <i>q</i> . $ldq \geq \max(1, m)$ if <i>vect</i> = 'Q' or 'B', $ldq \geq 1$ otherwise.
<i>ldpt</i>	INTEGER. The leading dimension of the output array <i>pt</i> . $ldpt \geq \max(1, n)$ if <i>vect</i> = 'P' or 'B', $ldpt \geq 1$ otherwise.
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$ if <i>ncc</i> > 0; $ldc \geq 1$ if <i>ncc</i> = 0.
<i>rwork</i>	REAL for cgbbrd DOUBLE PRECISION for zgbbrd. A workspace array, DIMENSION at least $\max(m, n)$.

Output Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>ab</i>	Overwritten by values generated during the reduction.
<i>d</i>	<code>REAL</code> for single-precision flavors <code>DOUBLE PRECISION</code> for double-precision flavors. <code>Array, DIMENSION at least max(1, min(<i>m, n</i>)).</code> Contains the diagonal elements of the matrix <i>B</i> .
<i>e</i>	<code>REAL</code> for single-precision flavors <code>DOUBLE PRECISION</code> for double-precision flavors. <code>Array, DIMENSION at least max(1, min(<i>m, n</i>) - 1).</code> Contains the off-diagonal elements of <i>B</i> .
<i>q, pt</i>	<code>REAL</code> for <code>sgebrd</code> <code>DOUBLE PRECISION</code> for <code>dgebrd</code> <code>COMPLEX</code> for <code>cgebrd</code> <code>DOUBLE COMPLEX</code> for <code>zgebrd</code> . Arrays: <i>q</i> (<i>ldq, *</i>) contains the output <i>m</i> -by- <i>m</i> matrix <i>Q</i> . The second dimension of <i>q</i> must be at least <code>max(1, m)</code> . <i>p</i> (<i>ldpt, *</i>) contains the output <i>n</i> -by- <i>n</i> matrix <i>P</i> ^T . The second dimension of <i>pt</i> must be at least <code>max(1, n)</code> .
<i>c</i>	Overwritten by the product $Q^H * C$. <i>c</i> is not referenced if <i>ncc</i> = 0.
<i>info</i>	<code>INTEGER</code> . If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbbrd` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size (<i>k</i> <i>l</i> + <i>ku</i> +1, <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m, ncc</i>).
<i>d</i>	Holds the vector with the number of elements <code>min(m,n)</code> .

<i>e</i>	Holds the vector with the number of elements $\min(m,n)-1$.
<i>q</i>	Holds the matrix Q of size (m,m) .
<i>pt</i>	Holds the matrix PT of size (n,n) .
<i>m</i>	If omitted, assumed $m = n$.
<i>k1</i>	If omitted, assumed $k1 = ku$.
<i>ku</i>	Restored as $ku = lda - k1 - 1$.
<i>vect</i>	Restored based on the presence of arguments <i>q</i> and <i>pt</i> as follows: <i>vect</i> = 'B', if both <i>q</i> and <i>pt</i> are present, <i>vect</i> = 'Q', if <i>q</i> is present and <i>pt</i> omitted, <i>vect</i> = 'P', if <i>q</i> is omitted and <i>pt</i> present, <i>vect</i> = 'N', if both <i>q</i> and <i>pt</i> are omitted.

Application Notes

The computed matrices Q , B , and P satisfy $Q^*B^*P^H = A + E$, where $\|E\|_2 = c(n)\varepsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ε is the machine precision.

If $m = n$, the total number of floating-point operations for real flavors is approximately the sum of:

$6*n^2*(k1 + ku)$ if *vect* = 'N' and *ncc* = 0,

$3*n^2*ncc*(k1 + ku - 1)/(k1 + ku)$ if *C* is updated, and

$3*n^3*(k1 + ku - 1)/(k1 + ku)$ if either *Q* or P^H is generated (double this if both).

To estimate the number of operations for complex flavors, use the same formulas with the coefficients 20 and 10 (instead of 6 and 3).

?orgbr

Generates the real orthogonal matrix Q or PT determined by ?gebrd.

Syntax

FORTRAN 77:

```
call sorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
call dorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgbr(a, tau [,vect] [,info])
```

C:

```
lapack_int LAPACKE_<?>orgbr( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine generates the whole or part of the orthogonal matrices Q and P^T formed by the routines [gebrd](#)/[gebrd](#). Use this routine after a call to [sgebrd](#)/[dgebrd](#). All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole m -by- m matrix Q :

```
call ?orgbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$:

```
call ?orgbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^T :

```
call ?orgbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P^T if $m < n$:

```
call ?orgbr('P', m, n, m, a ... )
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>vect</i>	CHARACTER*1. Must be ' <i>Q</i> ' or ' <i>P</i> '.
	If <i>vect</i> = ' <i>Q</i> ', the routine generates the matrix Q .
	If <i>vect</i> = ' <i>P</i> ', the routine generates the matrix P^T .
<i>m, n</i>	INTEGER. The number of rows (m) and columns (n) in the matrix Q or P^T to be returned ($m \geq 0, n \geq 0$).
	If <i>vect</i> = ' <i>Q</i> ', $m \geq n \geq \min(m, k)$.
	If <i>vect</i> = ' <i>P</i> ', $n \geq m \geq \min(n, k)$.
<i>k</i>	If <i>vect</i> = ' <i>Q</i> ', the number of columns in the original m -by- k matrix reduced by gebrd .
	If <i>vect</i> = ' <i>P</i> ', the number of rows in the original k -by- n matrix reduced by gebrd .
<i>a</i>	REAL for sorgbr DOUBLE PRECISION for dorgbr
	The vectors which define the elementary reflectors, as returned by gebrd .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $\text{lda} \geq \max(1, m)$.
<i>tau</i>	REAL for sorgbr DOUBLE PRECISION for dorgbr

Array, DIMENSION $\min(m, k)$ if *vect* = 'Q', $\min(n, k)$ if *vect* = 'P'. Scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q and P^T as returned by **gebrd** in the array *tauq* or *taup*.

work REAL **for** *sorgbr*

DOUBLE PRECISION **for** *dorgbr*

Workspace array, DIMENSION $\max(1, lwork)$.

lwork INTEGER. Dimension of the array *work*. See *Application Notes* for the suggested value of *lwork*.

If *lwork* = -1 then the routine performs a workspace query and calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by **xerbla**.

Output Parameters

a Overwritten by the orthogonal matrix Q or P^T (or the leading rows or columns thereof) as specified by *vect*, *m*, and *n*.

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *orgbr* interface are the following:

a Holds the matrix A of size (m,n) .

tau Holds the vector of length $\min(m,k)$ where

$k = m$, if *vect* = 'P',

$k = n$, if *vect* = 'Q'.

vect Must be 'Q' or 'P'. The default value is 'Q'.

Application Notes

For better performance, try using *lwork* = $\min(m, n) * \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the blocked algorithm.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\varepsilon)$.

The approximate numbers of floating-point operations for the cases listed in *Description* are as follows:

To form the whole of Q :

$(4/3) * n * (3m^2 - 3m*n + n^2)$ if $m > n$;

$(4/3) * m^3$ if $m \leq n$.

To form the n leading columns of Q when $m > n$:

$(2/3) * n^2 * (3m - n^2)$ if $m > n$.

To form the whole of P^T :

$(4/3) * n^3$ if $m \geq n$;

$(4/3) * m * (3n^2 - 3m*n + m^2)$ if $m < n$.

To form the m leading columns of P^T when $m < n$:

$(2/3) * n^2 * (3m - n^2)$ if $m > n$.

The complex counterpart of this routine is [ungbr](#).

?ormbr

Multiples an arbitrary real matrix by the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

FORTRAN 77:

```
call sormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormbr( int matrix_layout, char vect, char side, char trans,
lapack_int m, lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda,
const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

Given an arbitrary real matrix C , this routine forms one of the matrix products Q^*C , Q^TC , C^*Q , C^*Q^T , P^*C , P^TC , C^*P , C^*P^T , where Q and P are orthogonal matrices computed by a call to [gebrd/gebrd](#). The routine overwrites the product on C .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q or P^T :

If $\text{side} = \text{'L'}$, $r = m$; if $\text{side} = \text{'R'}$, $r = n$.

<i>vect</i>	CHARACTER*1. Must be ' Q ' or ' P '. If $\text{vect} = \text{'Q'}$, then Q or Q^T is applied to C . If $\text{vect} = \text{'P'}$, then P or P^T is applied to C .
<i>side</i>	CHARACTER*1. Must be ' L ' or ' R '. If $\text{side} = \text{'L'}$, multipliers are applied to C from the left. If $\text{side} = \text{'R'}$, they are applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be ' N ' or ' T '. If $\text{trans} = \text{'N'}$, then Q or P is applied to C . If $\text{trans} = \text{'T'}$, then Q^T or P^T is applied to C .
<i>m</i>	INTEGER. The number of rows in C .
<i>n</i>	INTEGER. The number of columns in C .
<i>k</i>	INTEGER. One of the dimensions of A in ?gebrd: If $\text{vect} = \text{'Q'}$, the number of columns in A ; If $\text{vect} = \text{'P'}$, the number of rows in A . Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$.
<i>a, c, work</i>	REAL for sormbr DOUBLE PRECISION for dormbr. Arrays: $a(\text{lda},*)$ is the array a as returned by ?gebrd. Its second dimension must be at least $\max(1, \min(r, k))$ for $\text{vect} = \text{'Q'}$, or $\max(1, r)$ for $\text{vect} = \text{'P'}$. $c(\text{ldc},*)$ holds the matrix C . Its second dimension must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of a . Constraints: $\text{lda} \geq \max(1, r)$ if $\text{vect} = \text{'Q'}$; $\text{lda} \geq \max(1, \min(r, k))$ if $\text{vect} = \text{'P'}$.
<i>ldc</i>	INTEGER. The leading dimension of c ; $\text{ldc} \geq \max(1, m)$.
<i>tau</i>	REAL for sormbr

DOUBLE PRECISION for `dormbr`.
 Array, DIMENSION at least max (1, min(r , k)).
 For `vect = 'Q'`, the array `tauq` as returned by `?gebrd`. For `vect = 'P'`, the array `taup` as returned by `?gebrd`.

`lwork` INTEGER. The size of the `work` array. Constraints:

$lwork \geq \max(1, n)$ if `side = 'L'`;
 $lwork \geq \max(1, m)$ if `side = 'R'`.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`.

See *Application Notes* for the suggested value of `lwork`.

Output Parameters

`c` Overwritten by the product Q^*C , Q^T*C , C^*Q , C^*Q^T , P^*C , P^T*C , C^*P , or C^*P^T , as specified by `vect`, `side`, and `trans`.

`work(1)` If `info = 0`, on exit `work(1)` contains the minimum value of `lwork` required for optimum performance. Use this `lwork` for subsequent runs.

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormbr` interface are the following:

`a` Holds the matrix A of size $(r, \min(nq, k))$ where
 $r = nq$, if `vect = 'Q'`,
 $r = \min(nq, k)$, if `vect = 'P'`,
 $nq = m$, if `side = 'L'`,
 $nq = n$, if `side = 'R'`,
 $k = m$, if `vect = 'P'`,
 $k = n$, if `vect = 'Q'`.

`tau` Holds the vector of length $\min(nq, k)$.

`c` Holds the matrix C of size (m, n) .

`vect` Must be '`Q`' or '`P`'. The default value is '`Q`'.

`side` Must be '`L`' or '`R`'. The default value is '`L`'.

trans Must be '`N`' or '`T`'. The default value is '`N`'.

Application Notes

For better performance, try using

```
lwork = n*blocksize for side = 'L', or
lwork = m*blocksize for side = 'R',
```

where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

```
2*n*k(2*m - k) if side = 'L' and m ≥ k;
2*m*k(2*n - k) if side = 'R' and n ≥ k;
2*m^2*n if side = 'L' and m < k;
2*n^2*m if side = 'R' and n < k.
```

The complex counterpart of this routine is [unmbr](#).

?ungbr

Generates the complex unitary matrix *Q* or *P^H* determined by ?gebrd.

Syntax

FORTRAN 77:

```
call cungbr(vect, m, n, k, a, lda, tau, work, lwork, info)
call zungbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungbr(a, tau [,vect] [,info])
```

C:

```
lapack_int LAPACKE_<?>ungbr( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`

- C: mkl.h

Description

The routine generates the whole or part of the unitary matrices Q and P^H formed by the routines [gebrd](#)/[gebrd](#). Use this routine after a call to [cgebrd](#)/[zgebrd](#). All valid combinations of arguments are described in *Input Parameters*; in most cases you need the following:

To compute the whole m -by- m matrix Q , use:

```
call ?ungbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$, use:

```
call ?ungbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^H , use:

```
call ?ungbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P^H if $m < n$, use:

```
call ?ungbr('P', m, n, m, a ... )
```

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>vect</i>	CHARACTER*1. Must be ' <i>Q</i> ' or ' <i>P</i> '.
	If <i>vect</i> = ' <i>Q</i> ', the routine generates the matrix Q .
	If <i>vect</i> = ' <i>P</i> ', the routine generates the matrix P^H .
<i>m</i>	INTEGER. The number of required rows of Q or P^H .
<i>n</i>	INTEGER. The number of required columns of Q or P^H .
<i>k</i>	INTEGER. One of the dimensions of A in ?gebrd :
	If <i>vect</i> = ' <i>Q</i> ', the number of columns in A ;
	If <i>vect</i> = ' <i>P</i> ', the number of rows in A .
	Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$.
	For <i>vect</i> = ' <i>Q</i> ': $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$.
	For <i>vect</i> = ' <i>P</i> ': $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.
<i>a, work</i>	COMPLEX for cungbr DOUBLE COMPLEX for zungbr .
	Arrays: <i>a</i> (<i>lda</i> ,*) is the array a as returned by ?gebrd . The second dimension of a must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, \text{lwork})$.

<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>tau</i>	COMPLEX for <i>cungbr</i> DOUBLE COMPLEX for <i>zungbr</i> . For <i>vect</i> = 'Q', the array <i>tauq</i> as returned by <i>?gebrd</i> . For <i>vect</i> = 'P', the array <i>taup</i> as returned by <i>?gebrd</i> . The dimension of <i>tau</i> must be at least $\max(1, \min(m, k))$ for <i>vect</i> = 'Q', or $\max(1, \min(m, k))$ for <i>vect</i> = 'P'.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraint: <i>lwork</i> < $\max(1, \min(m, n))$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the orthogonal matrix <i>Q</i> or <i>P</i> ^T (or the leading rows or columns thereof) as specified by <i>vect</i> , <i>m</i> , and <i>n</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ungbr* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>tau</i>	Holds the vector of length $\min(m, k)$ where <i>k</i> = <i>m</i> , if <i>vect</i> = 'P', <i>k</i> = <i>n</i> , if <i>vect</i> = 'Q'.
<i>vect</i>	Must be 'Q' or 'P'. The default value is 'Q'.

Application Notes

For better performance, try using *lwork* = $\min(m, n) * \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\varepsilon)$.

The approximate numbers of possible floating-point operations are listed below:

To compute the whole matrix *Q*:

$(16/3)n(3m^2 - 3m*n + n^2)$ if $m > n$;

$(16/3)m^3$ if $m \leq n$.

To form the *n* leading columns of *Q* when $m > n$:

$(8/3)n^2(3m - n^2)$.

To compute the whole matrix *P*^H:

$(16/3)n^3$ if $m \geq n$;

$(16/3)m(3n^2 - 3m*n + m^2)$ if $m < n$.

To form the *m* leading columns of *P*^H when $m < n$:

$(8/3)n^2(3m - n^2)$ if $m > n$.

The real counterpart of this routine is [orgbr](#).

?unmbr

Multiples an arbitrary complex matrix by the unitary matrix Q or P determined by ?gebrd.

Syntax

FORTRAN 77:

```
call cunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmbr( int matrix_layout, char vect, char side, char trans,
lapack_int m, lapack_int n, lapack_int k, const <datatype>* a, lapack_int lda,
const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

Given an arbitrary complex matrix C , this routine forms one of the matrix products Q^*C , Q^H*C , C^*Q , C^*Q^H , P^*C , P^H*C , C^*P , or C^*P^H , where Q and P are unitary matrices computed by a call to [gebrd/gebrd](#). The routine overwrites the product on C .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q or P^H :

If $\text{side} = \text{'L'}$, $r = m$; if $\text{side} = \text{'R'}$, $r = n$.

vect CHARACTER*1. Must be ' Q ' or ' P '.
 If $\text{vect} = \text{'Q'}$, then Q or Q^H is applied to C .
 If $\text{vect} = \text{'P'}$, then P or P^H is applied to C .

side CHARACTER*1. Must be ' L ' or ' R '.
 If $\text{side} = \text{'L'}$, multipliers are applied to C from the left.
 If $\text{side} = \text{'R'}$, they are applied to C from the right.

trans CHARACTER*1. Must be ' N ' or ' C '.
 If $\text{trans} = \text{'N'}$, then Q or P is applied to C .
 If $\text{trans} = \text{'C'}$, then Q^H or P^H is applied to C .

m INTEGER. The number of rows in C .

n INTEGER. The number of columns in C .

k INTEGER. One of the dimensions of A in ?gebrd:
 If $\text{vect} = \text{'Q'}$, the number of columns in A ;
 If $\text{vect} = \text{'P'}$, the number of rows in A .
 Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$.

a, c, work COMPLEX for cunmbr
 DOUBLE COMPLEX for zunmbr.

Arrays:

$a(lda,*)$ is the array a as returned by ?gebrd.

Its second dimension must be at least $\max(1, \min(r, k))$ for $\text{vect} = \text{'Q'}$, or $\max(1, r)$ for $\text{vect} = \text{'P'}$.

$c(ldc,*)$ holds the matrix C .

Its second dimension must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a . Constraints:
 $lda \geq \max(1, r)$ if $\text{vect} = \text{'Q'}$;
 $lda \geq \max(1, \min(r, k))$ if $\text{vect} = \text{'P'}$.

lrc INTEGER. The leading dimension of *c*; *lrc* $\geq \max(1, m)$.

tau COMPLEX for *cunmbr*
DOUBLE COMPLEX for *zunmbr*.
Array, DIMENSION at least $\max(1, \min(r, k))$.
For *vect* = 'Q', the array *tauq* as returned by ?gebrd. For *vect* = 'P', the array *taup* as returned by ?gebrd.

lwork INTEGER. The size of the *work* array.
lwork $\geq \max(1, n)$ if *side* = 'L';
lwork $\geq \max(1, m)$ if *side* = 'R'.
lwork ≥ 1 if *n*=0 or *m*=0.
For optimum performance *lwork* $\geq \max(1, n*nb)$ if *side* = 'L', and *lwork* $\geq \max(1, m*nb)$ if *side* = 'R', where *nb* is the optimal blocksize. (*nb* = 0 if *m* = 0 or *n* = 0.)
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , $Q^{H*}C$, C^*Q , C^*Q^H , P^*C , $P^{H*}C$, C^*P , or C^*P^H , as specified by *vect*, *side*, and *trans*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *unmbr* interface are the following:

a Holds the matrix *A* of size $(r, \min(nq, k))$ where
r = *nq*, if *vect* = 'Q',
r = $\min(nq, k)$, if *vect* = 'P',
nq = *m*, if *side* = 'L',
nq = *n*, if *side* = 'R',
k = *m*, if *vect* = 'P',

	$k = n$, if <code>vect = 'Q'</code> .
<code>tau</code>	Holds the vector of length $\min(nq, k)$.
<code>c</code>	Holds the matrix C of size (m, n) .
<code>vect</code>	Must be ' <code>Q</code> ' or ' <code>P</code> '. The default value is ' <code>Q</code> '.
<code>side</code>	Must be ' <code>L</code> ' or ' <code>R</code> '. The default value is ' <code>L</code> '.
<code>trans</code>	Must be ' <code>N</code> ' or ' <code>C</code> '. The default value is ' <code>N</code> '.

Application Notes

For better performance, use

`lwork = n*blocksize` for `side = 'L'`, or

`lwork = m*blocksize` for `side = 'R'`,

where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$8*n*k(2*m - k)$ if `side = 'L'` and $m \geq k$;

$8*m*k(2*n - k)$ if `side = 'R'` and $n \geq k$;

$8*m^2*n$ if `side = 'L'` and $m < k$;

$8*n^2*m$ if `side = 'R'` and $n < k$.

The real counterpart of this routine is [ormbr](#).

?bdsqr

Computes the singular value decomposition of a general matrix that has been reduced to bidiagonal form.

Syntax

FORTRAN 77:

```
call sbdsqr(uplo, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work, info)
call dbdsqr(uplo, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work, info)
call cbdsqr(uplo, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, rwork, info)

Description

The routine computes the singular values and, optionally, the right and/or left singular vectors from the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form $B = Q * S * P^H$ where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns $U * Q$ instead of Q , and, if right singular vectors are requested, this subroutine returns $P_H * VT$ instead of P_H , for given real/complex input matrices U and VT . When U and VT are the orthogonal/unitary matrices that reduce a general matrix A to bidiagonal form: $A = U * B * VT$, as computed by `?gebrd`, then

$$A = (U * Q) * S * (P^H * VT)$$

is the SVD of A . Optionally, the subroutine may also compute $Q_H * C$ for a given real/complex input matrix C .

See also [lasq1](#), [lasq2](#), [lasq3](#), [lasq4](#), [lasq5](#), [lasq6](#) used by this routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', B is an upper bidiagonal matrix.
	If <i>uplo</i> = 'L', B is a lower bidiagonal matrix.

n INTEGER. The order of the matrix B ($n \geq 0$).

<i>ncvt</i>	INTEGER. The number of columns of the matrix VT , that is, the number of right singular vectors ($ncvt \geq 0$). Set $ncvt = 0$ if no right singular vectors are required.
<i>nru</i>	INTEGER. The number of rows in U , that is, the number of left singular vectors ($nru \geq 0$). Set $nru = 0$ if no left singular vectors are required.
<i>ncc</i>	INTEGER. The number of columns in the matrix C used for computing the product $Q^H * C$ ($ncc \geq 0$). Set $ncc = 0$ if no matrix C is supplied.
<i>d, e</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of B . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the $(n-1)$ off-diagonal elements of B . The dimension of <i>e</i> must be at least $\max(1, n)$.
<i>work</i>	REAL for sbdsqr DOUBLE PRECISION for dbdsqr. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 4*n)$.
<i>rwork</i>	REAL for cbdsqr DOUBLE PRECISION for zbdsqr. <i>rwork</i> (*) is a workspace array. If $ncvt = nru = ncc = 0$, the dimension of <i>rwork</i> must be $\max(1, 2*n)$. Otherwise, the dimension of <i>rwork</i> must be $\max(1, 4*n-4)$.
<i>vt, u, c</i>	REAL for sbdsqr DOUBLE PRECISION for dbdsqr COMPLEX for cbdsqr DOUBLE COMPLEX for zbdsqr. Arrays: <i>vt</i> (<i>ldvt</i> ,*) contains an n -by- $ncvt$ matrix VT . The second dimension of <i>vt</i> must be at least $\max(1, ncvt)$. <i>vt</i> is not referenced if $ncvt = 0$. <i>u</i> (<i>ldu</i> ,*) contains an nru by n unit matrix U . The second dimension of <i>u</i> must be at least $\max(1, n)$. <i>u</i> is not referenced if $nru = 0$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C for computing the product $Q^H * C$.

The second dimension of c must be at least $\max(1, ncc)$. The array is not referenced if $ncc = 0$.

$ldvt$ INTEGER. The leading dimension of vt . Constraints:

$ldvt \geq \max(1, n)$ if $ncvt > 0$;

$ldvt \geq 1$ if $ncvt = 0$.

ldu INTEGER. The leading dimension of u . Constraint:

$ldu \geq \max(1, nru)$.

ldc INTEGER. The leading dimension of c . Constraints:

$ldc \geq \max(1, n)$ if $ncc > 0$; $ldc \geq 1$ otherwise.

Output Parameters

d	On exit, if $info = 0$, overwritten by the singular values in decreasing order (see $info$).
e	On exit, if $info = 0$, e is destroyed. See also $info$ below.
c	Overwritten by the product $Q^H * C$.
vt	On exit, this array is overwritten by $P^H * VT$.
u	On exit, this array is overwritten by $U * Q$.
$info$	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info > i$,</p> <p>If $ncvt = nru = ncc = 0$,</p> <ul style="list-style-type: none"> • $info = 1$, a split was marked by a positive value in e • $info = 2$, the current block of z not diagonalized after $30*n$ iterations (in the inner while loop) • $info = 3$, termination criterion of the outer while loop is not met (the program created more than n unreduced blocks). <p>In all other cases when $ncvt = nru = ncc = 0$, the algorithm did not converge; d and e contain the elements of a bidiagonal matrix that is orthogonally similar to the input matrix B; if $info = i$, i elements of e have not converged to zero.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsqr` interface are the following:

d Holds the vector of length (n).

<i>e</i>	Holds the vector of length (<i>n</i>).
<i>vt</i>	Holds the matrix VT of size (<i>n</i> , <i>ncvt</i>).
<i>u</i>	Holds the matrix U of size (<i>nru</i> , <i>n</i>).
<i>c</i>	Holds the matrix C of size (<i>n</i> , <i>ncc</i>).
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.
<i>ncvt</i>	If argument <i>vt</i> is present, then <i>ncvt</i> is equal to the number of columns in matrix VT ; otherwise, <i>ncvt</i> is set to zero.
<i>nru</i>	If argument <i>u</i> is present, then <i>nru</i> is equal to the number of rows in matrix U ; otherwise, <i>nru</i> is set to zero.
<i>ncc</i>	If argument <i>c</i> is present, then <i>ncc</i> is equal to the number of columns in matrix C ; otherwise, <i>ncc</i> is set to zero.

Note that two variants of Fortran 95 interface for `bdsqr` routine are needed because of an ambiguous choice between real and complex cases appear when *vt*, *u*, and *c* are omitted. Thus, the name `rbdsqr` is used in real cases (single or double precision), and the name `bdsqr` is used in complex cases (single or double precision).

Application Notes

Each singular value and singular vector is computed to high relative accuracy. However, the reduction to bidiagonal form (prior to calling the routine) may decrease the relative accuracy in the small singular values of the original matrix if its singular values vary widely in magnitude.

If s_i is an exact singular value of B , and s_i is the corresponding computed value, then

$$|s_i - \sigma_i| \leq p(m, n) * \varepsilon * \sigma_i$$

where $p(m, n)$ is a modestly increasing function of *m* and *n*, and ε is the machine precision.

If only singular values are computed, they are computed more accurately than when some singular vectors are also computed (that is, the function $p(m, n)$ is smaller).

If u_i is the corresponding exact left singular vector of B , and w_i is the corresponding computed left singular vector, then the angle $\theta(u_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq p(m, n) * \varepsilon / \min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|).$$

Here $\min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|)$ is the *relative gap* between σ_i and the other singular values. A similar error bound holds for the right singular vectors.

The total number of real floating-point operations is roughly proportional to n^2 if only the singular values are computed. About $6n^2 * nru$ additional operations ($12n^2 * nru$ for complex flavors) are required to compute the left singular vectors and about $6n^2 * ncvt$ operations ($12n^2 * ncvt$ for complex flavors) to compute the right singular vectors.

?bdsdc

Computes the singular value decomposition of a real bidiagonal matrix using a divide and conquer method.

Syntax

FORTRAN 77:

```
call sbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
call dbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
```

Fortran 95:

```
call bdsdc(d, e [,u] [,vt] [,q] [,iq] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>bdsdc( int matrix_layout, char uplo, char compq, lapack_int n,
<datatype>* d, <datatype>* e, <datatype>* u, lapack_int ldu, <datatype>* vt,
lapack_int ldvt, <datatype>* q, lapack_int* iq );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B : $B = U\Sigma V^T$, using a divide and conquer method, where Σ is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and V are orthogonal matrices of left and right singular vectors, respectively. ?bdsdc can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This routine

uses ?lasd0, ?lasd1, ?lasd2, ?lasd3, ?lasd4, ?lasd5, ?lasd6, ?lasd7, ?lasd8, ?lasd9, ?lasda, ?lasdq, ?lasdt.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', B is an upper bidiagonal matrix.
	If <i>uplo</i> = 'L', B is a lower bidiagonal matrix.
<i>compq</i>	CHARACTER*1. Must be 'N', 'P', or 'I'.
	If <i>compq</i> = 'N', compute singular values only.
	If <i>compq</i> = 'P', compute singular values and compute singular vectors in compact form.
	If <i>compq</i> = 'I', compute singular values and singular vectors.
<i>n</i>	INTEGER. The order of the matrix B ($n \geq 0$).
<i>d, e, work</i>	REAL for sbdsdc DOUBLE PRECISION for dbdsdc. Arrays: <i>d</i> (*) contains the n diagonal elements of the bidiagonal matrix B . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of the bidiagonal matrix B . The dimension of <i>e</i> must be at least $\max(1, n)$.

work(*) is a workspace array.

The dimension of *work* must be at least:

$\max(1, 4*n)$, if *compq* = 'N';

$\max(1, 6*n)$, if *compq* = 'P';

$\max(1, 3*n^2+4*n)$, if *compq* = 'I'.

ldu

INTEGER. The leading dimension of the output array *u*; *ldu* ≥ 1 .

If singular vectors are desired, then *ldu* $\geq \max(1, n)$.

ldvt

INTEGER. The leading dimension of the output array *vt*; *ldvt* ≥ 1 .

If singular vectors are desired, then *ldvt* $\geq \max(1, n)$.

iwork

INTEGER. Workspace array, dimension at least $\max(1, 8*n)$.

Output Parameters

d

If *info* = 0, overwritten by the singular values of *B*.

e

On exit, *e* is overwritten.

u, *vt*, *q*

REAL for sbdsdc

DOUBLE PRECISION for dbdsdc.

Arrays: *u*(*ldu*, *), *vt*(*ldvt*, *), *q*(*).

If *compq* = 'I', then on exit *u* contains the left singular vectors of the bidiagonal matrix *B*, unless *info* $\neq 0$ (seeinfo). For other values of *compq*, *u* is not referenced.

The second dimension of *u* must be at least $\max(1,n)$.

If *compq* = 'I', then on exit *vt*^T contains the right singular vectors of the bidiagonal matrix *B*, unless *info* $\neq 0$ (seeinfo). For other values of *compq*, *vt* is not referenced. The second dimension of *vt* must be at least $\max(1,n)$.

If *compq* = 'P', then on exit, if *info* = 0, *q* and *iq* contain the left and right singular vectors in a compact form. Specifically, *q* contains all the REAL (for sbdsdc) or DOUBLE PRECISION (for dbdsdc) data for singular vectors. For other values of *compq*, *q* is not referenced. See *Application notes* for details.

iq

INTEGER.

Array: *iq*(*).

If *compq* = 'P', then on exit, if *info* = 0, *q* and *iq* contain the left and right singular vectors in a compact form. Specifically, *iq* contains all the INTEGER data for singular vectors. For other values of *compq*, *iq* is not referenced. See *Application notes* for details.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If $\text{info} = i$, the algorithm failed to compute a singular value. The update process of divide and conquer failed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsdc` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length n .
u	Holds the matrix U of size (n,n) .
vt	Holds the matrix VT of size (n,n) .
q	Holds the vector of length (ldq) , where $ldq \geq n * (11 + 2 * smlsiz + 8 * \text{int}(\log_2(n / (smlsiz + 1))))$ and $smlsiz$ is returned by <code>ilaenv</code> and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25).
$compq$	Restored based on the presence of arguments u , vt , q , and iq as follows: $compq = 'N'$, if none of u , vt , q , and iq are present, $compq = 'I'$, if both u and vt are present. Arguments u and vt must either be both present or both omitted, $compq = 'P'$, if both q and iq are present. Arguments q and iq must either be both present or both omitted. Note that there will be an error condition if all of u , vt , q , and iq arguments are present simultaneously.

Symmetric Eigenvalue Problems

Symmetric eigenvalue problems are posed as follows: given an n -by- n real symmetric or complex Hermitian matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation $Az = \lambda z$ (or, equivalently, $z^H A = \lambda z^H$).

In such eigenvalue problems, all n eigenvalues are real not only for real symmetric but also for complex Hermitian matrices A , and there exists an orthonormal system of n eigenvectors. If A is a symmetric or Hermitian positive-definite matrix, all eigenvalues are positive.

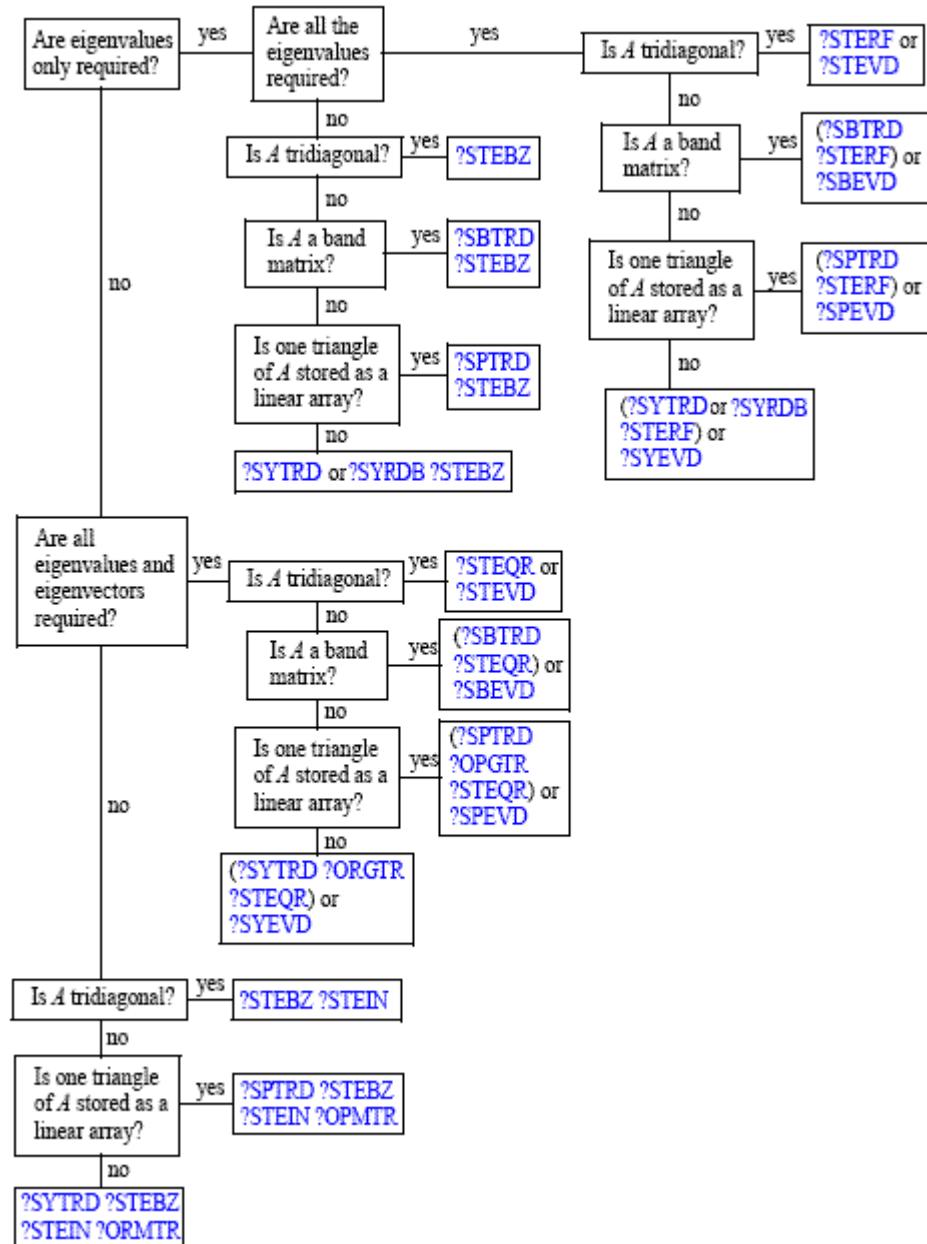

To solve a symmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to tridiagonal form and then solve the eigenvalue problem with the tridiagonal matrix obtained. LAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines (for FORTRAN 77 interface) are listed in [Table "Computational Routines for Solving Symmetric Eigenvalue Problems"](#). The corresponding routine names in the Fortran 95 interface are without the first symbol.

There are different routines for symmetric eigenvalue problems, depending on whether you need all eigenvectors or only some of them or eigenvalues only, whether the matrix A is positive-definite or not, and so on.

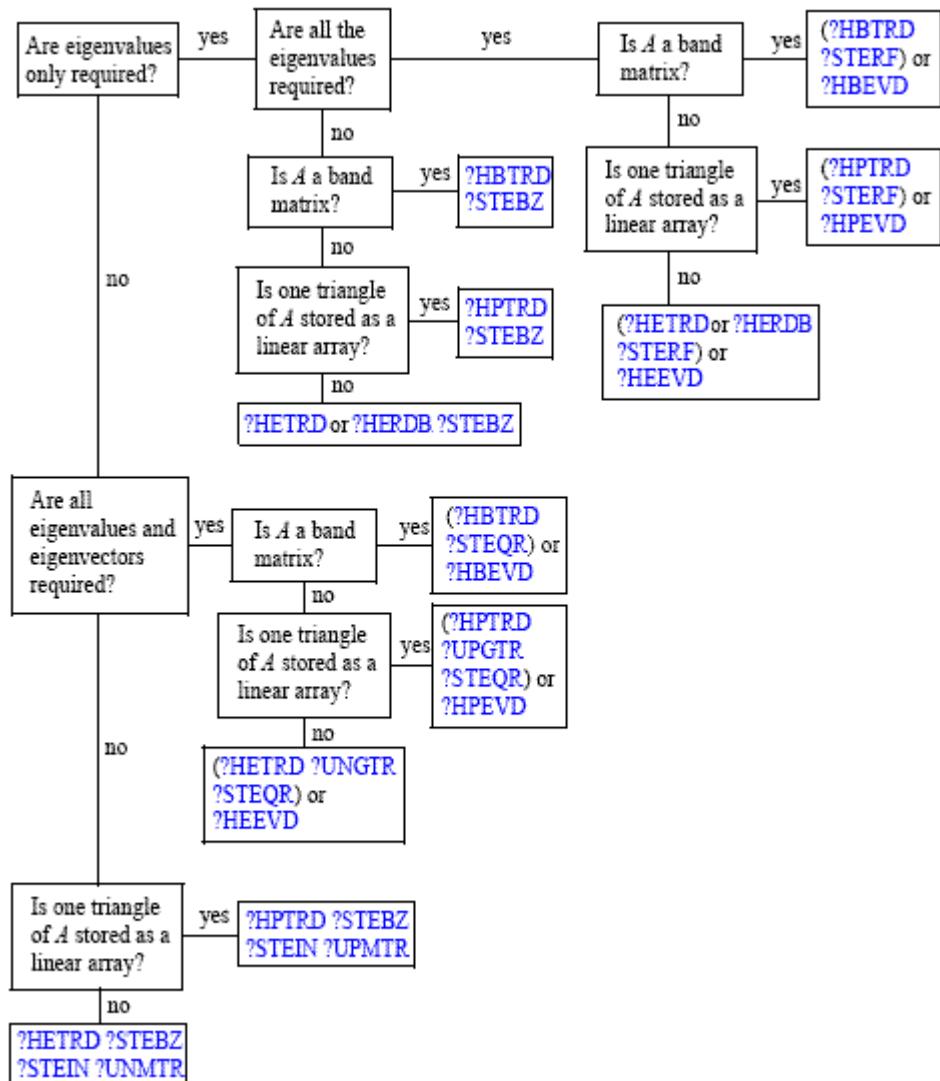

These routines are based on three primary algorithms for computing eigenvalues and eigenvectors of symmetric problems: the divide and conquer algorithm, the QR algorithm, and bisection followed by inverse iteration. The divide and conquer algorithm is generally more efficient and is recommended for computing all eigenvalues and eigenvectors. Furthermore, to solve an eigenvalue problem using the divide and conquer algorithm, you need to call only one routine. In general, more than one routine has to be called if the QR algorithm or bisection followed by inverse iteration is used.

The decision tree in [Figure "Decision Tree: Real Symmetric Eigenvalue Problems"](#) will help you choose the right routine or sequence of routines for eigenvalue problems with real symmetric matrices. [Figure "Decision Tree: Complex Hermitian Eigenvalue Problems"](#) presents a similar decision tree for complex Hermitian matrices.

Decision Tree: Real Symmetric Eigenvalue Problems

Decision Tree: Complex Hermitian Eigenvalue Problems

Computational Routines for Solving Symmetric Eigenvalue Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to tridiagonal form $A = QTQ^H$ (full storage)	sytrd syrdb	hetrd herdb
Reduce to tridiagonal form $A = QTQ^H$ (packed storage)	sptrd	hptrd
Reduce to tridiagonal form $A = QTQ^H$ (band storage).	sbtrd	hbtrd
Generate matrix Q (full storage)	orgtr	ungtr
Generate matrix Q (packed storage)	opgtr	upgtr
Apply matrix Q (full storage)	ormtr	unmtr
Apply matrix Q (packed storage)	opmtr	upmtr

Operation	Real symmetric matrices	Complex Hermitian matrices
Find all eigenvalues of a tridiagonal matrix T	<code>sterf</code>	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T	<code>steqr stedc</code>	<code>steqr stedc</code>
Find all eigenvalues and eigenvectors of a tridiagonal positive-definite matrix T .	<code>pteqr</code>	<code>pteqr</code>
Find selected eigenvalues of a tridiagonal matrix T	<code>stebz steqr</code>	<code>stegr</code>
Find selected eigenvectors of a tridiagonal matrix T	<code>stein stegr</code>	<code>stein stegr</code>
Find selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix T	<code>stemr</code>	<code>stemr</code>
Compute the reciprocal condition numbers for the eigenvectors	<code>disna</code>	<code>disna</code>

?sytrd*Reduces a real symmetric matrix to tridiagonal form.***Syntax****FORTRAN 77:**

```
call ssytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call dsytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call sytrd(a, tau [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sytrd( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda, <datatype>* d, <datatype>* e, <datatype>* tau );
```

Description

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^T Q^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

This routine calls `latrd` to reduce a real symmetric matrix to tridiagonal form by an orthogonal similarity transformation.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> .
	If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> ≥ 0).
<i>a, work</i>	REAL for ssytrd DOUBLE PRECISION for dsytrd. <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>A</i> is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> ≥ <i>n</i>). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors.
<i>d, e, tau</i>	REAL for ssytrd DOUBLE PRECISION for dsytrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$\tau_{\text{au}}(*)$ stores further details of the orthogonal matrix Q in the first $n-1$ elements. $\tau_{\text{au}}(n)$ is used as workspace.

The dimension of τ_{au} must be at least $\max(1, n)$.

$\text{work}(1)$
If $\text{info}=0$, on exit $\text{work}(1)$ contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.

info INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrd` interface are the following:

a Holds the matrix A of size (n,n) .

τ_{au} Holds the vector of length $(n-1)$.

uplo Must be ' U ' or ' L '. The default value is ' U '.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

For better performance, try using $\text{lwork} = n * \text{blocksize}$, where blocksize is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of lwork for the first run, or set $\text{lwork} = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array work on exit. Use this value ($\text{work}(1)$) for subsequent runs.

If $\text{lwork} = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (work). This operation is called a workspace query.

Note that if lwork is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \varepsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ε is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`orgtr` to form the computed matrix Q explicitly

`ormtr` to multiply a real matrix by Q .

The complex counterpart of this routine is [hetrd](#).

?syrdb

Reduces a real symmetric matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call ssyrd(b, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call dsyrd(b, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^*T^*Q$ and optionally multiplies matrix Z by Q , or simply forms Q .

This routine reduces a full symmetric matrix A to the banded symmetric matrix B , and then to the tridiagonal symmetric matrix T with a Successive Bandwidth Reduction approach after C. Bischof's works (see for instance, [[Bischof00](#)]). ?syrd is functionally close to ?sytrd routine but the tridiagonal form may differ from those obtained by ?sytrd. Unlike ?sytrd, the orthogonal matrix Q cannot be restored from the details of matrix A on exit.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only A is reduced to T . If <i>jobz</i> = 'V', then A is reduced to T and A contains Q on exit. If <i>jobz</i> = 'U', then A is reduced to T and Z contains Z^*Q on exit.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The bandwidth of the banded matrix B ($kd \geq 1$, $kd \leq n-1$).
<i>a, z, work</i>	REAL for ssyrd. DOUBLE PRECISION for dsyrd. $a(1:da, :)$ is an array containing either upper or lower triangular part of the matrix A , as specified by <i>uplo</i> . The second dimension of a must be at least $\max(1, n)$. $z(1:dz, :)$, the second dimension of z must be at least $\max(1, n)$. If <i>jobz</i> = 'U', then the matrix z is multiplied by Q .

If $\text{jobz} = \text{'N'}$ or 'V' , then z is not referenced.

$\text{work}(lwork)$ is a workspace array.

lda

INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldz

INTEGER. The leading dimension of z ; at least $\max(1, n)$. Not referenced if $\text{jobz} = \text{'N'}$

lwork

INTEGER. The size of the work array ($\text{lwork} \geq (2kd+1)n+kd$).

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by xerbla .

See *Application Notes* for the suggested value of lwork .

Output Parameters

a

If $\text{jobz} = \text{'V'}$, then overwritten by Q matrix.

If $\text{jobz} = \text{'N'}$ or 'U' , then overwritten by the banded matrix B and details of the orthogonal matrix Q_B to reduce A to B as specified by uplo .

z

On exit,

if $\text{jobz} = \text{'U'}$, then the matrix z is overwritten by Z^*Q .

If $\text{jobz} = \text{'N'}$ or 'V' , then z is not referenced.

d, e, tau

DOUBLE PRECISION.

Arrays:

$d(*)$ contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$tau(*)$ stores further details of the orthogonal matrix Q .

The dimension of tau must be at least $\max(1, n-kd-1)$.

$\text{work}(1)$

If $\text{info}=0$, on exit $\text{work}(1)$ contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Application Notes

For better performance, try using $\text{lwork} = n * (3 * kd + 3)$.

If it is not clear how much workspace to supply, use a generous value of lwork for the first run, or set $\text{lwork} = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using *kd* equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using ?syrd instead of ?sytrd on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. ?syrd becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than ?sytrd.

Avoid applying ?syrd for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to *Z* is doubled compared to the traditional one-step reduction. In that case it is better to apply ?sytrd and ?ormtr/?orgtr to obtain tridiagonal form along with the orthogonal transformation matrix *Q*.

?herdb

Reduces a complex Hermitian matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call cherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call zherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces a complex Hermitian matrix *A* to symmetric tridiagonal form *T* by a unitary similarity transformation: $A = Q^*T^*Q$ and optionally multiplies matrix *Z* by *Q*, or simply forms *Q*.

This routine reduces a full symmetric matrix *A* to the banded symmetric matrix *B*, and then to the tridiagonal symmetric matrix *T* with a Successive Bandwidth Reduction approach after C. Bischof's works (see for instance, [Bischof00]). ?herdb is functionally close to ?hetrd routine but the tridiagonal form may differ from those obtained by ?hetrd. Unlike ?hetrd, the orthogonal matrix *Q* cannot be restored from the details of matrix *A* on exit.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only <i>A</i> is reduced to <i>T</i> . If <i>jobz</i> = 'V', then <i>A</i> is reduced to <i>T</i> and <i>A</i> contains <i>Q</i> on exit. If <i>jobz</i> = 'U', then <i>A</i> is reduced to <i>T</i> and <i>Z</i> contains <i>Z*Q</i> on exit.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> .

If $uplo = 'L'$, a stores the lower triangular part of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

kd INTEGER. The bandwidth of the banded matrix B ($kd \geq 1$, $kd \leq n-1$).

$a, z, work$ COMPLEX for cherdb.

DOUBLE COMPLEX for zherdb.

$a(Ida,*)$ is an array containing either upper or lower triangular part of the matrix A , as specified by $uplo$.

The second dimension of a must be at least $\max(1, n)$.

$z(Idz,*)$, the second dimension of z must be at least $\max(1, n)$.

If $jobz = 'U'$, then the matrix z is multiplied by Q .

If $jobz = 'N'$ or ' V ', then z is not referenced.

$work(lwork)$ is a workspace array.

lda INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldz INTEGER. The leading dimension of z ; at least $\max(1, n)$. Not referenced if $jobz = 'N'$

$lwork$ INTEGER. The size of the $work$ array ($lwork \geq (2kd+1)n+kd$).

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by **xerbla**.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a If $jobz = 'V'$, then overwritten by Q matrix.

If $jobz = 'N'$ or ' U ', then overwritten by the banded matrix B and details of the unitary matrix Q_B to reduce A to B as specified by $uplo$.

z On exit,

if $jobz = 'U'$, then the matrix z is overwritten by Z^*Q .

If $jobz = 'N'$ or ' V ', then z is not referenced.

d, e REAL for cherdb.

DOUBLE PRECISION for zherdb.

Arrays:

$d(*)$ contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$tau(*)$ stores further details of the orthogonal matrix Q .

The dimension of *tau* must be at least $\max(1, n-kd-1)$.

<i>tau</i>	COMPLEX for <i>cherdb</i> . DOUBLE COMPLEX for <i>zherdb</i> .
	Array, DIMENSION at least $\max(1, n-1)$
	Stores further details of the unitary matrix Q_B . The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>work(1)</i>	If <i>info</i> =0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Application Notes

For better performance, try using $lwork = n * (3 * kd + 3)$.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using *kd* equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using *?herdb* instead of *?hetrd* on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. *?herdb* becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than *?hetrd*.

Avoid applying *?herdb* for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to *Z* is doubled compared to the traditional one-step reduction. In that case it is better to apply *?hetrd* and *?unmtr*/*?ungtr* to obtain tridiagonal form along with the unitary transformation matrix *Q*.

?orgtr

Generates the real orthogonal matrix *Q* determined by *?sytrd*.

Syntax

FORTRAN 77:

```
call sorgtr(uplo, n, a, lda, tau, work, lwork, info)
call dorgtr(uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgtr(a, tau [,uplo] [,info])
```

C:

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine explicitly generates the n -by- n orthogonal matrix Q formed by [sytrd](#) when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T T Q$. Use this routine after a call to [?sytrd](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Use the same <i>uplo</i> as supplied to ?sytrd .
<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>a</i> , <i>tau</i> , <i>work</i>	REAL for sorgtr DOUBLE PRECISION for dorgtr. Arrays: <i>a</i> (<i>lda</i> ,*) is the array <i>a</i> as returned by ?sytrd . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>tau</i> (*) is the array <i>tau</i> as returned by ?sytrd . The dimension of <i>tau</i> must be at least $\max(1, n-1)$. <i>work</i> is a workspace array, its dimension $\max(1, \textit{lwork})$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$. <i>lwork</i> INTEGER. The size of the <i>work</i> array ($\textit{lwork} \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the orthogonal matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgtr` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For better performance, try using `lwork = (n-1)*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is [ungtr](#).

?ormtr

Multiples a real matrix by the real orthogonal matrix Q determined by ?sytrd.

Syntax

FORTRAN 77:

```
call sormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call dormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormtr( int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by [sytrd](#) when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T T Q$. Use this routine after a call to [?sytrd](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^* C$, $Q^T C$, $C Q$, or $C^* Q^T$ (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?sytrd .
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	REAL for sormtr DOUBLE PRECISION for dormtr <i>a</i> (<i>lda</i> ,*) and <i>tau</i> are the arrays returned by ?sytrd . The second dimension of <i>a</i> must be at least $\max(1, r)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, \text{ lwork})$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $\text{lda} \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> ; $\text{ldc} \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints:

```
lwork ≥ max(1, n) if side = 'L';
lwork ≥ max(1, m) if side = 'R'.
```

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , C^*Q , or C^*Q^T (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r,r</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r-1</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using *lwork* = *n***blocksize* for *side* = 'L', or *lwork* = *m***blocksize* for *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix *E* such that $\|E\|^2 = O(\epsilon) * \|C\|^2$.

The total number of floating-point operations is approximately $2*m^2*n$, if *side* = 'L', or $2*n^2*m$, if *side* = 'R'.

The complex counterpart of this routine is [unmtr](#).

?hetrd

Reduces a complex Hermitian matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call zhetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call hetrd(a, tau [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_chetrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float*
tau );
lapack_int LAPACKE_zhetrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double*
tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a complex Hermitian matrix *A* to symmetric tridiagonal form *T* by a unitary similarity transformation: $A = Q*T*Q^H$. The unitary matrix *Q* is not formed explicitly but is represented as a product of *n*-1 elementary reflectors. Routines are provided to work with *Q* in this representation. (They are described later in this section.)

This routine calls [latrd](#) to reduce a complex Hermitian matrix *A* to Hermitian tridiagonal form by a unitary similarity transformation.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a, work</i>	COMPLEX for chetrd DOUBLE COMPLEX for zhetrd. <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>A</i> is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> \geq <i>n</i>). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors.
<i>d, e</i>	REAL for chetrd DOUBLE PRECISION for zhetrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$.

	$e(*)$ contains the off-diagonal elements of T .
	The dimension of e must be at least $\max(1, n-1)$.
tau	COMPLEX for <code>chetrd</code> DOUBLE COMPLEX for <code>zhetrd</code> . Array, DIMENSION at least $\max(1, n-1)$. Stores further details of the unitary matrix Q .
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrd` interface are the following:

a	Holds the matrix A of size (n,n) .
tau	Holds the vector of length $(n-1)$.
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3) n^3$.

After calling this routine, you can call the following:

<code>ungtr</code>	to form the computed matrix Q explicitly
--------------------	--

unmtr to multiply a complex matrix by Q .

The real counterpart of this routine is [sytrd](#).

?ungtr

Generates the complex unitary matrix Q determined by [?hetrd](#).

Syntax

FORTRAN 77:

```
call cungtr(uplo, n, a, lda, tau, work, lwork, info)
call zungtr(uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungtr(a, tau [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>ungtr( int matrix_layout, char uplo, lapack_int n, <datatype>* a,
lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine explicitly generates the n -by- n unitary matrix Q formed by [hetrd](#) when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to [?hetrd](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?hetrd .
<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>a</i> , <i>tau</i> , <i>work</i>	COMPLEX for cungtr DOUBLE COMPLEX for zungtr. Arrays: <i>a</i> (<i>lda</i> ,*) is the array <i>a</i> as returned by ?hetrd . The second dimension of <i>a</i> must be at least max(1, <i>n</i>). <i>tau</i> (*) is the array <i>tau</i> as returned by ?hetrd . The dimension of <i>tau</i> must be at least max(1, <i>n</i> -1). <i>work</i> is a workspace array, its dimension max(1, <i>lwork</i>).

<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array (<i>lwork</i> $\geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the unitary matrix <i>Q</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n,n</i>).
<i>tau</i>	Holds the vector of length (<i>n-1</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using *lwork* = (*n-1*) * *blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [orgtr](#).

?unmtr

Multiples a complex matrix by the complex unitary matrix Q determined by ?hetrd.

Syntax**FORTRAN 77:**

```
call cunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call zunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmtr( int matrix_layout, char side, char trans,
lapack_int m, lapack_int n, const <datatype>* a, lapack_int lda, const <datatype>*
tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix Q formed by `hetrd` when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to `?hetrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^H*C , C^*Q , or C^*Q^H (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

side CHARACTER*1. Must be either 'L' or 'R'.

If *side* = 'L', Q or Q^H is applied to C from the left.

If *side* = 'R', Q or Q^H is applied to C from the right.

uplo CHARACTER*1. Must be 'U' or 'L'.

Use the same *uplo* as supplied to `?hetrd`.

trans CHARACTER*1. Must be either 'N' or 'T'.

If *trans* = 'N', the routine multiplies C by Q .

If *trans* = 'T', the routine multiplies C by Q^H .

m INTEGER. The number of rows in the matrix C ($m \geq 0$).

<i>n</i>	INTEGER. The number of columns in <i>C</i> ($n \geq 0$).
<i>a, c, tau, work</i>	COMPLEX for <i>cunmtr</i> DOUBLE COMPLEX for <i>zunmtr</i> . <i>a</i> (<i>lda,*</i>) and <i>tau</i> are the arrays returned by <i>?hetrd</i> . The second dimension of <i>a</i> must be at least $\max(1, r)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (<i>ldc,*</i>) contains the matrix <i>C</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, \text{lwork})$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $\text{lda} \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> ; $\text{ldc} \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $\text{lwork} \geq \max(1, n)$ if <i>side</i> = 'L'; $\text{lwork} \geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^H*C , C^*Q , or C^*Q^H (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *unmtr* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r,r</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r-1</i>).

<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>side</i>	Must be ' <i>L</i> ' or ' <i>R</i> '. The default value is ' <i>L</i> '.
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.
<i>trans</i>	Must be ' <i>N</i> ' or ' <i>C</i> '. The default value is ' <i>N</i> '.

Application Notes

For better performance, try using *lwork* = *n*blocksize* (for *side* = '*L*') or *lwork* = *m*blocksize* (for *side* = '*R*') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if *side* = '*L*' or $8*n^2*m$ if *side* = '*R*'.

The real counterpart of this routine is [ormtr](#).

?sptrd

Reduces a real symmetric matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call ssprtd(uplo, n, ap, d, e, tau, info)
call dsprtd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call sptrd(ap, tau [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sprtd( int matrix_layout, char uplo, lapack_int n, <datatype>* ap, <datatype>* d, <datatype>* e, <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a packed real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^T T Q$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation. See *Application Notes* below for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangle of A .
	If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangle of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap</i>	REAL for ssprtd DOUBLE PRECISION for dsprtd. Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by <i>uplo</i>) in the packed form described in "Matrix Arguments" in Appendix B .

Output Parameters

<i>ap</i>	Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by <i>uplo</i> .
<i>d, e, tau</i>	REAL for ssprtd DOUBLE PRECISION for dsprtd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of T . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> (*) stores further details of the matrix Q . The dimension of <i>tau</i> must be at least $\max(1, n-1)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptrd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>tau</code>	Holds the vector with the number of elements $n-1$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Note that diagonal (`d`) and off-diagonal (`e`) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The matrix Q is represented as a product of $n-1$ *elementary reflectors*, as follows :

- If `uplo = 'U'`, $Q = H(n-1) \dots H(2)H(1)$

Each $H(i)$ has the form

$H(i) = I - tau * v * v^T$ for real flavors, or

$H(i) = I - tau * v * v^H$ for complex flavors,

where tau is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$.

On exit, tau is stored in $tau(i)$, and $v(1:i-1)$ is stored in AP , overwriting $A(1:i-1, i+1)$.

- If `uplo = 'L'`, $Q = H(1)H(2) \dots H(n-1)$

Each $H(i)$ has the form

$H(i) = I - tau * v * v^T$ for real flavors, or

$H(i) = I - tau * v * v^H$ for complex flavors,

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$.

On exit, tau is stored in $tau(i)$, and $v(i+2:n)$ is stored in AP , overwriting $A(i+2:n, i)$.

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`opgtr` to form the computed matrix Q explicitly

`opmtr` to multiply a real matrix by Q .

The complex counterpart of this routine is `hptrd`.

?opgtr

Generates the real orthogonal matrix Q determined by `?sptrd`.

Syntax

FORTRAN 77:

```
call sopgtr(uplo, n, ap, tau, q, ldq, work, info)
call dopgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call opgtr(ap, tau, q [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>opgtr( int matrix_layout, char uplo, lapack_int n,
const <datatype>* ap, const <datatype>* tau, <datatype>* q, lapack_int ldq );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine explicitly generates the n -by- n orthogonal matrix Q formed by [?sptrd](#) when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T T Q$. Use this routine after a call to [?sptrd](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' U ' or ' L '. Use the same <i>uplo</i> as supplied to ?sptrd .
<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>ap</i> , <i>tau</i>	REAL for sopgtr DOUBLE PRECISION for dopgtr . Arrays <i>ap</i> and <i>tau</i> , as returned by ?sptrd . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, n-1)$.
<i>ldq</i>	INTEGER. The leading dimension of the output array <i>q</i> ; at least $\max(1, n)$.
<i>work</i>	REAL for sopgtr DOUBLE PRECISION for dopgtr . Workspace array, DIMENSION at least $\max(1, n-1)$.

Output Parameters

<i>q</i>	REAL for sopgtr DOUBLE PRECISION for dopgtr . Array, DIMENSION (<i>ldq</i> ,*). Contains the computed matrix Q . The second dimension of <i>q</i> must be at least $\max(1, n)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opgtr` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>tau</code>	Holds the vector with the number of elements $n - 1$.

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by [sptrd](#) when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T T^* Q^T$. Use this routine after a call to [sptrd](#).

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q^* C$, $Q^T C$, $C^* Q$, or $C^* Q^T$ (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q :

If $\text{side} = \text{'L'}$, $r = m$; if $\text{side} = \text{'R'}$, $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If $\text{side} = \text{'L'}$, Q or Q^T is applied to C from the left. If $\text{side} = \text{'R'}$, Q or Q^T is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?sptrd.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If $\text{trans} = \text{'N'}$, the routine multiplies C by Q . If $\text{trans} = \text{'T'}$, the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>ap</i> , <i>tau</i> , <i>c</i> , <i>work</i>	REAL for sopmtr DOUBLE PRECISION for dopmtr. <i>ap</i> and <i>tau</i> are the arrays returned by ?sptrd. The dimension of <i>ap</i> must be at least $\max(1, r(r+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$ if $\text{side} = \text{'L'}$; $\max(1, m)$ if $\text{side} = \text{'R'}$.
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> ; $\text{ldc} \geq \max(1, n)$.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , C^*Q , or C^*Q^T (as specified by <i>side</i> and <i>trans</i>).
<i>info</i>	INTEGER. If $\text{info} = 0$, the execution is successful. If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opmtr` interface are the following:

<code>ap</code>	Holds the array A of size $(r*(r+1)/2)$, where $r = m$ if <code>side</code> = 'L'. $r = n$ if <code>side</code> = 'R'.
<code>tau</code>	Holds the vector with the number of elements $r - 1$.
<code>c</code>	Holds the matrix C of size (m,n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $2*m^2*n$ if `side` = 'L', or $2*n^2*m$ if `side` = 'R'.

The complex counterpart of this routine is [upmtr](#).

?hptrd

Reduces a complex Hermitian matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call chptrd(uplo, n, ap, d, e, tau, info)
call zhptrd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call hptrd(ap, tau [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_chptrd( int matrix_layout, char uplo, lapack_int n,
                           lapack_complex_float* ap, float* d, float* e, lapack_complex_float* tau );
lapack_int LAPACKE_zhptrd( int matrix_layout, char uplo, lapack_int n,
                           lapack_complex_double* ap, double* d, double* e, lapack_complex_double* tau );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine reduces a packed complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangle of A .
	If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangle of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap</i>	COMPLEX for chptrd DOUBLE COMPLEX for zhptrd. Array, DIMENSION at least max(1, $n(n+1)/2$). Contains either upper or lower triangle of A (as specified by <i>uplo</i>) in the packed form described in "Matrix Arguments" in Appendix B .

Output Parameters

<i>ap</i>	Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by <i>uplo</i> .
<i>d, e</i>	REAL for chptrd DOUBLE PRECISION for zhptrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix T . The dimension of <i>d</i> must be at least max(1, <i>n</i>). <i>e</i> (*) contains the off-diagonal elements of T . The dimension of <i>e</i> must be at least max(1, <i>n</i> -1).
<i>tau</i>	COMPLEX for chptrd DOUBLE COMPLEX for zhptrd. Arrays, DIMENSION at least max(1, <i>n</i> -1). Contains further details of the orthogonal matrix Q .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>tau</code>	Holds the vector with the number of elements $n - 1$.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Note that diagonal (`d`) and off-diagonal (`e`) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

<code>upgtr</code>	to form the computed matrix Q explicitly
<code>upmtr</code>	to multiply a complex matrix by Q .

The real counterpart of this routine is `sprtrd`.

?upgtr

Generates the complex unitary matrix Q determined by `?hptrd`.

Syntax

FORTRAN 77:

```
call cupgtr(uplo, n, ap, tau, q, ldq, work, info)
call zupgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call upgtr(ap, tau, q [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>upgtr( int matrix_layout, char uplo, lapack_int n,
const <datatype>* ap, const <datatype>* tau, <datatype>* q, lapack_int ldq );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine explicitly generates the n -by- n unitary matrix Q formed by `hptrd` when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q*T*Q^H$. Use this routine after a call to `?hptrd`.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '. Use the same <i>uplo</i> as supplied to ?hptrd.
<i>n</i>	INTEGER. The order of the matrix <i>Q</i> (<i>n</i> \geq 0).
<i>ap</i> , <i>tau</i>	COMPLEX for cupgtr DOUBLE COMPLEX for zugptr. Arrays <i>ap</i> and <i>tau</i> , as returned by ?hptrd. The dimension of <i>ap</i> must be at least max(1, <i>n</i> (<i>n</i> +1)/2). The dimension of <i>tau</i> must be at least max(1, <i>n</i> -1).
<i>ldq</i>	INTEGER. The leading dimension of the output array <i>q</i> ; at least max(1, <i>n</i>).
<i>work</i>	COMPLEX for cupgtr DOUBLE COMPLEX for zugptr. Workspace array, DIMENSION at least max(1, <i>n</i> -1).

Output Parameters

<i>q</i>	COMPLEX for cupgtr DOUBLE COMPLEX for zugptr. Array, DIMENSION (<i>ldq</i> ,*). Contains the computed matrix <i>Q</i> . The second dimension of <i>q</i> must be at least max(1, <i>n</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *upgtr* interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size (<i>n</i> *(<i>n</i> +1)/2).
<i>tau</i>	Holds the vector with the number of elements <i>n</i> - 1.
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.

Application Notes

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [opgtr](#).

?upmtr

Multiples a complex matrix by the unitary matrix Q determined by ?hptrd.

Syntax

FORTRAN 77:

```
call cupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
call zupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
```

Fortran 95:

```
call upmtr(ap, tau, c [,side] [,uplo] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>upmtr( int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const <datatype>* ap, const <datatype>* tau, <datatype>*
c, lapack_int ldc );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix formed by [hptrd](#) when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q*T*Q^H$. Use this routine after a call to [?hptrd](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result on C).

Input Parameters

The data types are given for the Fortran interface. A *<datatype>* placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

side CHARACTER*1. Must be either 'L' or 'R'.

If *side* = 'L', Q or Q^H is applied to C from the left.

If *side* = 'R', Q or Q^H is applied to C from the right.

uplo CHARACTER*1. Must be 'U' or 'L'.

Use the same *uplo* as supplied to ?hptrd.

trans

CHARACTER*1. Must be either 'N' or 'T'.

If *trans* = 'N', the routine multiplies C by Q .

If *trans* = 'T', the routine multiplies C by Q^H .

m

INTEGER. The number of rows in the matrix C ($m \geq 0$).

n

INTEGER. The number of columns in C ($n \geq 0$).

ap, tau, c,

COMPLEX for cupmtr

DOUBLE COMPLEX for zugmtr.

ap and *tau* are the arrays returned by ?hptrd.

The dimension of *ap* must be at least $\max(1, r(r+1)/2)$.

The dimension of *tau* must be at least $\max(1, r-1)$.

c(*ldc*,*) contains the matrix C .

The second dimension of *c* must be at least $\max(1, n)$

work(*) is a workspace array.

The dimension of *work* must be at least

$\max(1, n)$ if *side* = 'L';

$\max(1, m)$ if *side* = 'R'.

ldc

INTEGER. The leading dimension of *c*; *ldc* $\geq \max(1, n)$.

Output Parameters

c

Overwritten by the product Q^*C , Q^H*C , C^*Q , or C^*Q^H (as specified by *side* and *trans*).

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `upmtr` interface are the following:

ap

Holds the array A of size $(r*(r+1)/2)$, where

$r = m$ if *side* = 'L'.

$r = n$ if *side* = 'R'.

tau

Holds the vector with the number of elements $n - 1$.

c

Holds the matrix C of size (m,n) .

<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\varepsilon) * \|C\|_2$, where ε is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if *side* = 'L' or $8*n^2*m$ if *side* = 'R'.

The real counterpart of this routine is [opmtr](#).

?sbtrd

Reduces a real symmetric band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call ssbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call dsbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call sbtrd(ab[, q] [,vect] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sbtrd( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, <datatype>* ab, lapack_int ldab, <datatype>* d, <datatype>* e,
<datatype>* q, lapack_int ldq );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q*T*Q^T$. The orthogonal matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>vect</i>	CHARACTER*1. Must be 'V' or 'N'.
	If <i>vect</i> = 'V', the routine returns the explicit matrix Q .

If $\text{vect} = \text{'N'}$, the routine does not return Q .

uplo CHARACTER*1. Must be ' U ' or ' L '.

If $\text{uplo} = \text{'U'}$, ab stores the upper triangular part of A .

If $\text{uplo} = \text{'L'}$, ab stores the lower triangular part of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

kd INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).

$ab, q, work$ REAL for ssbtrd

DOUBLE PRECISION for dsbtrd.

ab ($ldab, *$) is an array containing either upper or lower triangular part of the matrix A (as specified by uplo) in band storage format.

The second dimension of ab must be at least $\max(1, n)$.

q ($ldq, *$) is an array.

If $\text{vect} = \text{'U'}$, the q array must contain an n -by- n matrix X .

If $\text{vect} = \text{'N'}$ or ' V ', the q parameter need not be set.

The second dimension of q must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, n)$.

$ldab$ INTEGER. The leading dimension of ab ; at least $kd+1$.

ldq INTEGER. The leading dimension of q . Constraints:

$ldq \geq \max(1, n)$ if $\text{vect} = \text{'V'}$;

$ldq \geq 1$ if $\text{vect} = \text{'N'}$.

Output Parameters

ab

On exit, the diagonal elements of the array ab are overwritten by the diagonal elements of the tridiagonal matrix T . If $kd > 0$, the elements on the first superdiagonal (if $\text{uplo} = \text{'U'}$) or the first subdiagonal (if $\text{uplo} = \text{'L'}$) are overwritten by the off-diagonal elements of T . The rest of ab is overwritten by values generated during the reduction.

d, e, q

REAL for ssbtrd

DOUBLE PRECISION for dsbtrd.

Arrays:

$d(*)$ contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$q(ldq, *)$ is not referenced if $\text{vect} = \text{'N'}$.

If `vect = 'V'`, q contains the n -by- n matrix Q .

The second dimension of q must be:

at least $\max(1, n)$ if `vect = 'V'`;

at least 1 if `vect = 'N'`.

`info` INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbtrd` interface are the following:

`ab` Holds the array A of size $(kd+1, n)$.

`q` Holds the matrix Q of size (n, n) .

`uplo` Must be '`U`' or '`L`'. The default value is '`U`'.

`vect` If omitted, this argument is restored based on the presence of argument `q` as follows: `vect = 'V'`, if `q` is present, `vect = 'N'`, if `q` is omitted.

If present, `vect` must be equal to '`V`' or '`U`' and the argument `q` must also be present. Note that there will be an error condition if `vect` is present and `q` omitted.

Note that diagonal (`d`) and off-diagonal (`e`) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\varepsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ε is the machine precision. The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\varepsilon)$.

The total number of floating-point operations is approximately $6n^2*kd$ if `vect = 'N'`, with $3n^3*(kd-1)/kd$ additional operations if `vect = 'V'`.

The complex counterpart of this routine is [hbtrd](#).

?hbtrd

Reduces a complex Hermitian band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call zhbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call hbtrd(ab [, q] [, vect] [, uplo] [, info])
```

C:

```
lapack_int LAPACKE_chbtrd( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* d, float* e,
lapack_complex_float* q, lapack_int ldq );
```

```
lapack_int LAPACKE_zhbtrd( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* d, double* e,
lapack_complex_double* q, lapack_int ldq );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a complex Hermitian band matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>vect</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>vect</i> = 'V', the routine returns the explicit matrix Q . If <i>vect</i> = 'N', the routine does not return Q .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).
<i>ab</i> , <i>work</i>	COMPLEX for chbtrd DOUBLE COMPLEX for zhbtrd. <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the matrix A (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; at least $kd+1$.
<i>ldq</i>	INTEGER. The leading dimension of <i>q</i> . Constraints:

```

 $ldq \geq \max(1, n)$  if  $\text{vect} = 'V'$ ;  

 $ldq \geq 1$  if  $\text{vect} = 'N'$ .

```

Output Parameters

<i>ab</i>	On exit, the diagonal elements of the array <i>ab</i> are overwritten by the diagonal elements of the tridiagonal matrix <i>T</i> . If <i>kd</i> > 0, the elements on the first superdiagonal (if <i>uplo</i> = 'U') or the first subdiagonal (if <i>uplo</i> = 'L') are overwritten by the off-diagonal elements of <i>T</i> . The rest of <i>ab</i> is overwritten by values generated during the reduction.
<i>d, e</i>	<p>REAL for chbtrd</p> <p>DOUBLE PRECISION for zhbtrd.</p> <p>Arrays:</p> <p><i>d</i>(*) contains the diagonal elements of the matrix <i>T</i>.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i>(*) contains the off-diagonal elements of <i>T</i>.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n-1)$.</p>

<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbtrd` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size (<i>kd</i> +1, <i>n</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>vect</i> = 'V', if <i>q</i> is present, <i>vect</i> = 'N', if <i>q</i> is omitted.

If present, *vect* must be equal to 'V' or 'U' and the argument *q* must also be present. Note that there will be an error condition if *vect* is present and *q* omitted.

Note that diagonal (*d*) and off-diagonal (*e*) elements of the matrix *T* are omitted because they are kept in the matrix *A* on exit.

Application Notes

The computed matrix *T* is exactly similar to a matrix *A + E*, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $20n^2 * kd$ if *vect* = 'N', with $10n^3 * (kd-1) / kd$ additional operations if *vect* = 'V'.

The real counterpart of this routine is [sbtrd](#).

?sterf

Computes all eigenvalues of a real symmetric tridiagonal matrix using QR algorithm.

Syntax

FORTRAN 77:

```
call ssterf(n, d, e, info)
call dsterf(n, d, e, info)
```

Fortran 95:

```
call sterf(d, e [,info])
```

C:

```
lapack_int LAPACKE_<?>sterf( lapack_int n, <datatype>* d, <datatype>* e );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues of a real symmetric tridiagonal matrix *T* (which can be obtained by reducing a symmetric or Hermitian matrix to tridiagonal form). The routine uses a square-root-free variant of the QR algorithm.

If you need not only the eigenvalues but also the eigenvectors, call [steqr](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

n INTEGER. The order of the matrix *T* ($n \geq 0$).

d, e REAL for ssterf

DOUBLE PRECISION for `dsterf`.

Arrays:

`d(*)` contains the diagonal elements of T .

The dimension of `d` must be at least $\max(1, n)$.

`e(*)` contains the off-diagonal elements of T .

The dimension of `e` must be at least $\max(1, n-1)$.

Output Parameters

`d`

The n eigenvalues in ascending order, unless `info > 0`.

See also `info`.

`e`

On exit, the array is overwritten; see `info`.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = i`, the algorithm failed to find all the eigenvalues after $30n$ iterations:

i off-diagonal elements have not converged to zero. On exit, `d` and `e` contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sterf` interface are the following:

`d`

Holds the vector of length n .

`e`

Holds the vector of length $(n-1)$.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\varepsilon) * \|T\|_2$, where ε is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \varepsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about $14n^2$.

?steqr

Computes all eigenvalues and eigenvectors of a symmetric or Hermitian matrix reduced to tridiagonal form (QR algorithm).

Syntax

FORTRAN 77:

```
call ssteqr(compz, n, d, e, z, ldz, work, info)
call dsteqr(compz, n, d, e, z, ldz, work, info)
call csteqr(compz, n, d, e, z, ldz, work, info)
call zsteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rsteqr(d, e [,z] [,compz] [,info])
call steqr(d, e [,z] [,compz] [,info])
```

C:

```
lapack_int LAPACKE_ssteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, float* z, lapack_int ldz );
lapack_int LAPACKE_dsteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, double* z, lapack_int ldz );
lapack_int LAPACKE_csteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, lapack_complex_float* z, lapack_int ldz );

- C: mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z\Lambda Z^T$. Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^*z_i = \lambda_i^*z_i \text{ for } i = 1, 2, \dots, n.$$

The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.

You can also use the routine for computing the eigenvalues and eigenvectors of an arbitrary real symmetric (or complex Hermitian) matrix A reduced to tridiagonal form T : $A = Q^*T^*Q^H$. In this case, the spectral factorization is as follows: $A = Q^*T^*Q^H = (Q^*Z)^*\Lambda^*(Q^*Z)^H$. Before calling `?steqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	?sytrd, ?orgtr	?hetrd, ?ungtr
packed storage	?sptrd, ?opgtr	?hptrd, ?upgtr
band storage	?sbtrd (<i>vect='V'</i>)	?hbtrd (<i>vect='V'</i>)

If you need eigenvalues only, it's more efficient to call `sterf`. If T is positive-definite, `pteqr` can compute small eigenvalues more accurately than `?steqr`.

To solve the problem by a single call, use one of the divide and conquer routines [stevd](#), [syevd](#), [spevd](#), or [sbevd](#) for real symmetric matrices or [heevd](#), [hpevd](#), or [hbevd](#) for complex Hermitian matrices.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array <i>z</i> must contain the matrix Q on entry).
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d</i> , <i>e</i> , <i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of T . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be: at least 1 if <i>compz</i> = 'N'; at least $\max(1, 2*n-2)$ if <i>compz</i> = 'V' or 'I'.
<i>z</i>	REAL for <i>ssteqr</i> DOUBLE PRECISION for <i>dsteqr</i> COMPLEX for <i>csteqr</i> DOUBLE COMPLEX for <i>zsteqr</i> . Array, DIMENSION (<i>ldz</i> , *) If <i>compz</i> = 'N' or 'I', <i>z</i> need not be set. If <i>vect</i> = 'V', <i>z</i> must contain the n -by- n matrix Q . The second dimension of <i>z</i> must be: at least 1 if <i>compz</i> = 'N'; at least $\max(1, n)$ if <i>compz</i> = 'V' or 'I'. <i>work</i> (<i>lwork</i>) is a workspace array.
<i>ldz</i>	INTEGER. The leading dimension of <i>z</i> . Constraints: $ldz \geq 1$ if <i>compz</i> = 'N';

$ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

Output Parameters

d	The n eigenvalues in ascending order, unless $info > 0$. See also $info$.
e	On exit, the array is overwritten; see $info$.
z	If $info = 0$, contains the n orthonormal eigenvectors, stored by columns. (The i -th column corresponds to the i th eigenvalue.)
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations: i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T . If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `steqr` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length $(n-1)$.
z	Holds the matrix Z of size (n,n) .
$compz$	If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to ' I ' or ' V ' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted. Note that two variants of Fortran 95 interface for <code>steqr</code> routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name <code>rsteqr</code> is used in real cases (single or double precision), and the name <code>steqr</code> is used in complex cases (single or double precision).

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about

$24n^2$ if $compz = 'N'$;

$7n^3$ (for complex flavors, $14n^3$) if $compz = 'V'$ or $'I'$.

?stemr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz, tryrac,
work, lwork, iwork, liwork, info)

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the *dqds* algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L^*D^*LT factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T ,

- Compute $T - \sigma I = L^*D^*LT$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of L and D cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see steps c and d.
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to step c for any clusters that remain.

For more details, see: [\[Dhillon04\]](#), [\[Dhillon04-02\]](#), [\[Dhillon97\]](#)

The routine works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs (NaN stands for "not a number"). This permits the use of efficient inner loops avoiding a check for zero divisors.

LAPACK routines can be used to reduce a complex Hermitean matrix to real symmetric tridiagonal form.

(Any complex Hermitean tridiagonal matrix has real values on its diagonal and potentially complex numbers on its off-diagonals. By applying a similarity transform with an appropriate diagonal matrix $\text{diag}(1, e^{i\phi_1}, \dots, e^{i\phi_{n-1}})$, the complex Hermitean matrix can be transformed into a real symmetric matrix and complex arithmetic can be entirely avoided.) While the eigenvectors of the real symmetric tridiagonal matrix are real, the eigenvectors of original complex Hermitean matrix have complex entries in general. Since LAPACK drivers overwrite the matrix data with the eigenvectors, zstemr accepts complex workspace to facilitate interoperability with zunmtr or zugmtr.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues.

If $\text{range} = \text{'V'}$, the routine computes all eigenvalues in the half-open interval: $(\text{vl}, \text{vu}]$.

If $\text{range} = \text{'I'}$, the routine computes eigenvalues with indices il to iu .

n

INTEGER. The order of the matrix T ($n \geq 0$).

d

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (n).

Contains n diagonal elements of the tridiagonal matrix T .

e

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION ($n-1$).

Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix T in elements 1 to $n-1$ of e . $e(n)$ need not be set on input, but is used internally as workspace.

vl, vu

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

If $\text{range} = \text{'V'}$, the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $\text{vl} < \text{vu}$.

If $\text{range} = \text{'A'}$ or 'I' , vl and vu are not referenced.

il, iu

INTEGER.

If $\text{range} = \text{'I'}$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq \text{il} \leq \text{iu} \leq n$, if $n > 0$.

If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

ldz

INTEGER. The leading dimension of the output array z .

if $\text{jobz} = \text{'V'}$, then $\text{ldz} \geq \max(1, n)$;

$\text{ldz} \geq 1$ otherwise.

nzc

INTEGER. The number of eigenvectors to be held in the array z .

If $\text{range} = \text{'A'}$, then $\text{nzc} \geq \max(1, n)$;

If $\text{range} = \text{'V'}$, then nzc is greater than or equal to the number of eigenvalues in the half-open interval: $(\text{vl}, \text{vu}]$.

If $\text{range} = \text{'I'}$, then $\text{nzc} \geq \text{iu} - \text{il} + 1$.

If $\text{nzc} = -1$, then a workspace query is assumed; the routine calculates the number of columns of the array z that are needed to hold the eigenvectors.

This value is returned as the first entry of the array z , and no error message related to nzc is issued by the routine `xerbla`.

tryrac

LOGICAL.

If `tryrac = .TRUE.`, it indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can use possibly faster algorithms.

If `tryrac = .FALSE.`, the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques.

`work` `REAL` for single precision flavors

`DOUBLE PRECISION` for double precision flavors.

Workspace array, DIMENSION (`lwork`).

`lwork` `INTEGER`.

The dimension of the array `work`,

`lwork ≥ max(1, 18*n)`.

If `lwork=-1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`.

`iwork` `INTEGER`.

Workspace array, DIMENSION (`liwork`).

`liwork` `INTEGER`.

The dimension of the array `iwork`.

`lwork≥max(1, 10*n)` if the eigenvectors are desired, and `lwork≥max(1, 8*n)` if only the eigenvalues are to be computed.

If `liwork=-1`, then a workspace query is assumed; the routine only calculates the optimal size of the `iwork` array, returns this value as the first entry of the `iwork` array, and no error message related to `liwork` is issued by `xerbla`.

Output Parameters

`d` On exit, the array `d` is overwritten.

`e` On exit, the array `e` is overwritten.

`m` `INTEGER`.

The total number of eigenvalues found, $0 \leq m \leq n$.

If `range = 'A'`, then $m=n$, and if If `range = 'I'`, then $m=iu-il+1$.

`w` `REAL` for single precision flavors

`DOUBLE PRECISION` for double precision flavors.

Array, DIMENSION (n).

The first m elements contain the selected eigenvalues in ascending order.

z REAL for sstemr
 DOUBLE PRECISION for dstemr
 COMPLEX for cstemr
 DOUBLE COMPLEX for zstemr.
 Array *z*(*ldz*, *), the second dimension of *z* must be at least $\max(1, m)$.
 If *jobz* = 'V', and *info* = 0, then the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w(i)*.
 If *jobz* = 'N', then *z* is not referenced.
 Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an can be computed with a workspace query by setting *nzc*=-1, see description of the parameter *nzc*.

isuppz INTEGER.
 Array, DIMENSION ($2 \times \max(1, m)$).
 The support of the eigenvectors in *z*, that is the indices indicating the nonzero elements in *z*. The *i*-th computed eigenvector is nonzero only in elements *isuppz*($2*i-1$) through *isuppz*($2*i$). This is relevant in the case when the matrix is split. *isuppz* is only accessed when *jobz* = 'V' and *n*>0.

tryrac On exit, TRUE. *tryrac* is set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.

work(1) On exit, if *info* = 0, then *work(1)* returns the optimal (and minimal) size of *lwork*.

iwork(1) On exit, if *info* = 0, then *iwork(1)* returns the optimal size of *liwork*.

info INTEGER.
 If = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = 1, internal error in ?larre occurred,
 if *info* = 2, internal error in ?larry occurred.

?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax**FORTRAN 77:**

```

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric or complex Hermitian matrix can also be found if [sytrd/hetrd](#) or [sptrd/hptrd](#) or [sbtrd/hbtrd](#) has been used to reduce this matrix to tridiagonal form.

See also [laed0](#), [laed1](#), [laed2](#), [laed3](#), [laed4](#), [laed5](#), [laed6](#), [laed7](#), [laed8](#), [laed9](#), and [laeda](#) used by this function.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix. If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of original symmetric/Hermitian matrix. On entry, the array <i>z</i> must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The order of the symmetric tridiagonal matrix (<i>n</i> \geq 0).
<i>d</i> , <i>e</i> , <i>rwork</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of the tridiagonal matrix.

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the subdiagonal elements of the tridiagonal matrix.

The dimension of e must be at least $\max(1, n-1)$.

$rwork$ is a workspace array, its dimension $\max(1, lrwork)$.

$z, work$

REAL for sstedc

DOUBLE PRECISION for dstedc

COMPLEX for cstedc

DOUBLE COMPLEX for zstedc.

Arrays: $z(ldz, *)$, $work(*)$.

If $compz = 'V'$, then, on entry, z must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.

The second dimension of z must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldz

INTEGER. The leading dimension of z . Constraints:

$ldz \geq 1$ if $compz = 'N'$;

$ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

$lwork$

INTEGER. The dimension of the array $work$.

For real functions sstedc and dstedc:

- If $compz = 'N'$ or $n \leq 1$, $lwork$ must be at least 1.
- If $compz = 'V'$ and $n > 1$, $lwork$ must be at least $1 + 3*n + 2*n*\log_2(n) + 4*n^2$, where $\log_2(n)$ is the smallest integer k such that $2^k \geq n$.
- If $compz = 'I'$ and $n > 1$ then $lwork$ must be at least $1 + 4*n + n^2$.

Note that for $compz = 'I'$ or $'V'$ and if n is less than or equal to the minimum divide size, usually 25, then $lwork$ need only be $\max(1, 2*(n-1))$.

For complex functions cstedc and zstedc:

- If $compz = 'N'$ or $'I'$, or $n \leq 1$, $lwork$ must be at least 1.
- If $compz = 'V'$ and $n > 1$, $lwork$ must be at least n^2 .

Note that for $compz = 'V'$, and if n is less than or equal to the minimum divide size, usually 25, then $lwork$ need only be 1.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for the required value of $lwork$.

$lrwork$

INTEGER. The dimension of the array $rwork$ (used for complex flavors only).

If $compz = 'N'$, or $n \leq 1$, $lrwork$ must be at least 1.

If $\text{compz} = \text{'V'}$ and $n > 1$, lrwork must be at least $(1 + 3*n + 2*n*\log_2(n) + 4*n^2)$, where $\log_2(n)$ is the smallest integer k such that $2^k \geq n$.

If $\text{compz} = \text{'I'}$ and $n > 1$, lrwork must be at least $(1 + 4*n + 2*n^2)$.

Note that for $\text{compz} = \text{'V'}$ or 'I' , and if n is less than or equal to the minimum divide size, usually 25, then lrwork need only be $\max(1, 2*(n-1))$.

If $\text{lrwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work , rwork and iwork arrays, returns these values as the first entries of the work , rwork and iwork arrays, and no error message related to lwork or lrwork or liwork is issued by [xerbla](#). See *Application Notes* for the required value of lrwork .

iwork

INTEGER. Workspace array, its dimension $\max(1, \text{liwork})$.

liwork

INTEGER. The dimension of the array iwork .

If $\text{compz} = \text{'N'}$, or $n \leq 1$, liwork must be at least 1.

If $\text{compz} = \text{'V'}$ and $n > 1$, liwork must be at least $(6 + 6*n + 5*n*\log_2(n))$, where $\log_2(n)$ is the smallest integer k such that $2^k \geq n$.

If $\text{compz} = \text{'I'}$ and $n > 1$, liwork must be at least $(3 + 5*n)$.

Note that for $\text{compz} = \text{'V'}$ or 'I' , and if n is less than or equal to the minimum divide size, usually 25, then liwork need only be 1.

If $\text{liwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work , rwork and iwork arrays, returns these values as the first entries of the work , rwork and iwork arrays, and no error message related to lwork or lrwork or liwork is issued by [xerbla](#). See *Application Notes* for the required value of liwork .

Output Parameters

d

The n eigenvalues in ascending order, unless $\text{info} \neq 0$.

See also info .

e

On exit, the array is overwritten; see info .

z

If $\text{info} = 0$, then if $\text{compz} = \text{'V'}$, z contains the orthonormal eigenvectors of the original symmetric/Hermitian matrix, and if $\text{compz} = \text{'I'}$, z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $\text{compz} = \text{'N'}$, z is not referenced.

$\text{work}(1)$

On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the optimal lwork .

$\text{rwork}(1)$

On exit, if $\text{info} = 0$, then $\text{rwork}(1)$ returns the optimal lrwork (for complex flavors only).

$\text{iwork}(1)$

On exit, if $\text{info} = 0$, then $\text{iwork}(1)$ returns the optimal liwork .

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value. If $\text{info} = i$, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $i/(n+1)$ through $\text{mod}(i, n+1)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stedc` interface are the following:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>z</i>	Holds the matrix Z of size (n,n) .
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: $\text{compz} = 'I'$, if <i>z</i> is present, $\text{compz} = 'N'$, if <i>z</i> is omitted. If present, <i>compz</i> must be equal to ' <i>I</i> ' or ' <i>V</i> ' and the argument <i>z</i> must also be present. Note that there will be an error condition if <i>compz</i> is present and <i>z</i> omitted.

Note that two variants of Fortran 95 interface for `stedc` routine are needed because of an ambiguous choice between real and complex cases appear when *z* and *work* are omitted. Thus, the name `rstedc` is used in real cases (single or double precision), and the name `stedc` is used in complex cases (single or double precision).

Application Notes

The required size of workspace arrays must be as follows.

For `sstedc/dstedc`:

If $\text{compz} = 'N'$ or $n \leq 1$ then *lwork* must be at least 1.

If $\text{compz} = 'V'$ and $n > 1$ then *lwork* must be at least $(1 + 3n + 2n \cdot \log_2 n + 4n^2)$, where $\log_2(n) =$ smallest integer k such that $2^k \geq n$.

If $\text{compz} = 'I'$ and $n > 1$ then *lwork* must be at least $(1 + 4n + n^2)$.

If $\text{compz} = 'N'$ or $n \leq 1$ then *liwork* must be at least 1.

If $\text{compz} = 'V'$ and $n > 1$ then *liwork* must be at least $(6 + 6n + 5n \cdot \log_2 n)$.

If $\text{compz} = 'I'$ and $n > 1$ then *liwork* must be at least $(3 + 5n)$.

For `cstedc/zstedc`:

If $\text{compz} = 'N'$ or '*I*', or $n \leq 1$, *lwork* must be at least 1.

If $\text{compz} = 'V'$ and $n > 1$, *lwork* must be at least n^2 .

If $\text{compz} = 'N'$ or $n \leq 1$, *lrwork* must be at least 1.

If $\text{compz} = 'V'$ and $n > 1$, *lrwork* must be at least $(1 + 3n + 2n \cdot \log_2 n + 4n^2)$, where $\log_2(n) =$ smallest integer k such that $2^k \geq n$.

If $\text{compz} = 'I'$ and $n > 1$, *lrwork* must be at least $(1 + 4n + 2n^2)$.

The required value of *liwork* for complex flavors is the same as for real flavors.

If $lwork$ (or $liwork$ or $lrwork$, if supplied) is equal to -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$, $rwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$, $lrwork$) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stegr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call ssteqr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call dstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call cstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call zstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)
```

Fortran 95:

```
call rstegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
call stegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_ssteqr( int matrix_layout, char jobz, char range, lapack_int n,

- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

?sregr is a compatibility wrapper around the improved [stemr](#) routine. See its description for further details.

Note that the *abstol* parameter no longer provides any benefit and hence is no longer used.

See also auxiliary [lasq2](#) [lasq5](#), [lasq6](#), used by this routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>jobz</i>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. If <i>job</i> = ' <code>N</code> ', then only eigenvalues are computed. If <i>job</i> = ' <code>V</code> ', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be ' <code>A</code> ' or ' <code>V</code> ' or ' <code>I</code> '. If <i>range</i> = ' <code>A</code> ', the routine computes all eigenvalues. If <i>range</i> = ' <code>V</code> ', the routine computes eigenvalues <i>lambda(i)</i> in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = ' <code>I</code> ', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>d(*)</i> contains the diagonal elements of T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e(*)</i> contains the subdiagonal elements of T in elements 1 to $n-1$; <i>e(n)</i> need not be set on input, but it is used as a workspace. The dimension of <i>e</i> must be at least $\max(1, n)$. <i>work(lwork)</i> is a workspace array.
<i>vl, vu</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>range</i> = ' <code>V</code> ', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$.

If $\text{range} = \text{'A'}$ or 'I' , vl and vu are not referenced.

il, iu
INTEGER.
If $\text{range} = \text{'I'}$, the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$.
If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

$abstol$
REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

ldz
INTEGER. The leading dimension of the output array z . Constraints:
 $ldz < 1$ if $\text{jobz} = \text{'N'}$;
 $ldz < \max(1, n)$ $\text{jobz} = \text{'V'}$, an.

$lwork$
INTEGER.
The dimension of the array $work$,
 $lwork \geq \max(1, 18*n)$ if $\text{jobz} = \text{'V'}$, and
 $lwork \geq \max(1, 12*n)$ if $\text{jobz} = \text{'N'}$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* below for details.

$iwork$
INTEGER.
Workspace array, size ($liwork$).

$liwork$
INTEGER.
The dimension of the array $iwork$, $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed..
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [xerbla](#). See *Application Notes* below for details.

Output Parameters

d, e
On exit, d and e are overwritten.

m
INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
If $\text{range} = \text{'A'}$, $m = n$, and if $\text{range} = \text{'I'}$, $m = iu - il + 1$.

w
REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.
 Array, size at least $\max(1, n)$.
 The selected eigenvalues in ascending order, stored in $w(1)$ to $w(m)$.

z REAL for sssteqr

DOUBLE PRECISION for dstegr

COMPLEX for cstegr

DOUBLE COMPLEX for zstegr.

Array $z(Idz, *)$, the second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, and if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used. Supplying n columns is always safe.

isuppz INTEGER.

Array, size at least $(2 * \max(1, m))$.

The support of the eigenvectors in z , that is the indices indicating the nonzero elements in z . The i -th computed eigenvector is nonzero only in elements $isuppz(2*i-1)$ through $isuppz(2*i)$. This is relevant in the case when the matrix is split. *isuppz* is only accessed when $jobz = 'V'$, and $n > 0$.

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

iwork(1)

On exit, if $info = 0$, then *iwork(1)* returns the required minimal size of *liwork*.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1x$, internal error in ?larre occurred,

If $info = 2x$, internal error in ?larrv occurred. Here the digit $x = \text{abs}(iinfo) < 10$, where *iinfo* is the non-zero error code returned by ?larre or ?larrv, respectively.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *steqr* interface are the following:

<i>d</i>	Holds the vector of length <i>n</i> .
<i>e</i>	Holds the vector of length <i>n</i> .
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n,m</i>).
<i>isuppz</i>	Holds the vector of length (2*m).
<i>vl</i>	Default value for this argument is <i>vl</i> = - HUGE (<i>vl</i>) where HUGE(<i>a</i>) means the largest machine number of the same precision as argument <i>a</i> .
<i>vu</i>	Default value for this argument is <i>vu</i> = HUGE (<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this argument is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Note that two variants of Fortran 95 interface for `steqr` routine are needed because of an ambiguous choice between real and complex cases appear when *z* is omitted. Thus, the name `rstegr` is used in real cases (single or double precision), and the name `steqr` is used in complex cases (single or double precision).

Application Notes

Currently `?steqr` is only set up to find *all* the *n* eigenvalues and eigenvectors of *T* in $O(n^2)$ time, that is, only *range* = 'A' is supported.

`?steqr` works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution of `?steqr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?pteqr

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call spteqr(compz, n, d, e, z, ldz, work, info)
call dpteqr(compz, n, d, e, z, ldz, work, info)
call cpteqr(compz, n, d, e, z, ldz, work, info)
call zpteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rpteqr(d, e [,z] [,compz] [,info])
call pteqr(d, e [,z] [,compz] [,info])
```

C:

```
lapack_int LAPACKE_sppeqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, float* z, lapack_int ldz );
lapack_int LAPACKE_dpteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, double* z, lapack_int ldz );
lapack_int LAPACKE_cpteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, lapack_complex_float* z, lapack_int ldz );
lapack_int LAPACKE_zpteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric positive-definite tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z^* \Lambda^* Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

(The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.)

You can also use the routine for computing the eigenvalues and eigenvectors of real symmetric (or complex Hermitian) positive-definite matrices A reduced to tridiagonal form T : $A = Q^* T^* Q^H$. In this case, the spectral factorization is as follows: $A = Q^* T^* Q^H = (QZ)^* \Lambda^* (QZ)^H$. Before calling ?pteqr, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	?sytrd, ?orgtr	?hetrd, ?ungtr
packed storage	?sptrd, ?opgtr	?hptrd, ?upgtr
band storage	?sbtrd (<i>vect</i> ='V')	?hbtrd (<i>vect</i> ='V')

The routine first factorizes T as L^*D*L^H where L is a unit lower bidiagonal matrix, and D is a diagonal matrix. Then it forms the bidiagonal matrix $B = L^*D^{1/2}$ and calls `?bdsqr` to compute the singular values of B , which are the same as the eigenvalues of T .

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array <i>z</i> must contain the matrix Q on entry).
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of T . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be: at least 1 if <i>compz</i> = 'N'; at least $\max(1, 4*n-4)$ if <i>compz</i> = 'V' or 'I'.
<i>z</i>	REAL for <code>spteqr</code> DOUBLE PRECISION for <code>dpteqr</code> COMPLEX for <code>cpteqr</code> DOUBLE COMPLEX for <code>zpteqr</code> . Array, DIMENSION (<i>ldz</i> ,*) If <i>compz</i> = 'N' or 'I', <i>z</i> need not be set. If <i>compz</i> = 'V', <i>z</i> must contain the n -by- n matrix Q . The second dimension of <i>z</i> must be:

at least 1 if $\text{compz} = \text{'N'}$;
 at least $\max(1, n)$ if $\text{compz} = \text{'V'}$ or 'I' .

ldz INTEGER. The leading dimension of z . Constraints:
 $\text{ldz} \geq 1$ if $\text{compz} = \text{'N'}$;
 $\text{ldz} \geq \max(1, n)$ if $\text{compz} = \text{'V'}$ or 'I' .

Output Parameters

d The n eigenvalues in descending order, unless $\text{info} > 0$.
 See also info .

e On exit, the array is overwritten.

z If $\text{info} = 0$, contains the n orthonormal eigenvectors, stored by columns.
 (The i -th column corresponds to the i -th eigenvalue.)

info INTEGER.
 If $\text{info} = 0$, the execution is successful.
 If $\text{info} = i$, the leading minor of order i (and hence T itself) is not positive-definite.
 If $\text{info} = n + i$, the algorithm for computing singular values failed to converge; i off-diagonal elements have not converged to zero.
 If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pteqr` interface are the following:

d Holds the vector of length n .

e Holds the vector of length $(n-1)$.

z Holds the matrix Z of size (n,n) .

compz If omitted, this argument is restored based on the presence of argument z as follows:
 $\text{compz} = \text{'I'}$, if z is present,
 $\text{compz} = \text{'N'}$, if z is omitted.
 If present, compz must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if compz is present and z omitted.

Note that two variants of Fortran 95 interface for `pteqr` routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name `rpteqr` is used in real cases (single or double precision), and the name `pteqr` is used in complex cases (single or double precision).

Application Notes

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \varepsilon * K * \lambda_i$$

where $c(n)$ is a modestly increasing function of n , ε is the machine precision, and $K = \|DTD\|_2 * \|D(DTD)^{-1}\|_2$, D is diagonal with $d_{ii} = t_{ii}^{-1/2}$.

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq c(n)\varepsilon K / \min_{i \neq j}(|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|).$$

Here $\min_{i \neq j}(|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|)$ is the *relative gap* between λ_i and the other eigenvalues.

The total number of floating-point operations depends on how rapidly the algorithm converges.

Typically, it is about

$30n^2$ if $compz = 'N'$;

$6n^3$ (for complex flavors, $12n^3$) if $compz = 'V'$ or $'I'$.

?stebz

Computes selected eigenvalues of a real symmetric tridiagonal matrix by bisection.

Syntax

FORTRAN 77:

```
call sstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w, iblock,
isplit, work, iwork, info)

call dstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w, iblock,
isplit, work, iwork, info)
```

Fortran 95:

```
call stebz(d, e, m, nsplit, w, iblock, isplit [, order] [,vl] [,vu] [,il] [,iu]
[,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>stebz( char range, char order, lapack_int n, <datatype> vl,
<datatype> vu, lapack_int il, lapack_int iu, <datatype> abstol, const <datatype>* d,
const <datatype>* e, lapack_int* m, lapack_int* nsplit, <datatype>* w, lapack_int*
iblock, lapack_int* isplit );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes some (or all) of the eigenvalues of a real symmetric tridiagonal matrix T by bisection. The routine searches for zero or negligible off-diagonal elements to see if T splits into block-diagonal form $T = \text{diag}(T_1, T_2, \dots)$. Then it performs bisection on each of the blocks T_i and returns the block index of each computed eigenvalue, so that a subsequent call to [stein](#) can also take advantage of the block structure.

See also [laebz](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: <i>vl</i> < <i>lambda</i> (<i>i</i>) ≤ <i>vu</i> . If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>order</i>	CHARACTER*1. Must be 'B' or 'E'. If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> (<i>n</i> ≥ 0).
<i>vl</i> , <i>vu</i>	REAL for ssstebz DOUBLE PRECISION for dstebz. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: <i>vl</i> < <i>lambda</i> (<i>i</i>) ≤ <i>vu</i> . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il</i> , <i>iu</i>	INTEGER. Constraint: 1 ≤ <i>il</i> ≤ <i>iu</i> ≤ <i>n</i> . If <i>range</i> = 'I', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) such that <i>il</i> ≤ <i>i</i> ≤ <i>iu</i> (assuming that the eigenvalues <i>lambda</i> (<i>i</i>) are in ascending order). If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for ssstebz DOUBLE PRECISION for dstebz. The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width <i>abstol</i> . If <i>abstol</i> ≤ 0.0, then the tolerance is taken as <i>eps</i> * <i>T</i> , where <i>eps</i> is the machine precision, and <i>T</i> is the 1-norm of the matrix <i>T</i> .
<i>d</i> , <i>e</i> , <i>work</i>	REAL for ssstebz DOUBLE PRECISION for dstebz. Arrays: <i>d</i> (*) contains the diagonal elements of <i>T</i> . The dimension of <i>d</i> must be at least max(1, <i>n</i>). <i>e</i> (*) contains the off-diagonal elements of <i>T</i> .

The dimension of e must be at least $\max(1, n-1)$.
 $work(*)$ is a workspace array.
The dimension of $work$ must be at least $\max(1, 4n)$.

$iwork$ INTEGER. Workspace.

Array, DIMENSION at least $\max(1, 3n)$.

Output Parameters

m INTEGER. The actual number of eigenvalues found.

$nsplit$ INTEGER. The number of diagonal blocks detected in T .

w REAL for `sstebz`

DOUBLE PRECISION for `dstebz`.

Array, DIMENSION at least $\max(1, n)$. The computed eigenvalues, stored in $w(1)$ to $w(m)$.

$iblock, isplit$ INTEGER.

Arrays, DIMENSION at least $\max(1, n)$.

A positive value $iblock(i)$ is the block number of the eigenvalue stored in $w(i)$ (see also $info$).
The leading $nsplit$ elements of $isplit$ contain points at which T splits into blocks T_i as follows: the block T_1 contains rows/columns 1 to $isplit(1)$; the block T_2 contains rows/columns $isplit(1)+1$ to $isplit(2)$, and so on.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = 1$, for $range = 'A'$ or $'V'$, the algorithm failed to compute some of the required eigenvalues to the desired accuracy; $iblock(i) < 0$ indicates that the eigenvalue stored in $w(i)$ failed to converge.

If $info = 2$, for $range = 'I'$, the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with $range = 'A'$.

If $info = 3$:

for $range = 'A'$ or $'V'$, same as $info = 1$;

for $range = 'I'$, same as $info = 2$.

If $info = 4$, no eigenvalues have been computed. The floating-point arithmetic on the computer is not behaving as expected.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stebz` interface are the following:

<i>d</i>	Holds the vector of length <i>n</i> .
<i>e</i>	Holds the vector of length (<i>n</i> -1).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>iblock</i>	Holds the vector of length <i>n</i> .
<i>isplit</i>	Holds the vector of length <i>n</i> .
<i>order</i>	Must be 'B' or 'E'. The default value is 'B'.
<i>vl</i>	Default value for this argument is <i>vl</i> = - HUGE (<i>vl</i>) where HUGE(<i>a</i>) means the largest machine number of the same precision as argument <i>a</i> .
<i>vu</i>	Default value for this argument is <i>vu</i> = HUGE (<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this argument is <i>abstol</i> = 0.0_WP.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

The eigenvalues of *T* are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

?stein

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call dstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call cstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call zstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
```

Fortran 95:

```
call stein(d, e, w, iblock, isplit, z [,ifailv] [,info])
```

C:

```

lapack_int LAPACKE_sstein( int matrix_layout, lapack_int n, const float* d,
                           const float* e, lapack_int m, const float* w, const lapack_int* iblock,
                           const lapack_int* isplit, float* z, lapack_int ldz, lapack_int* ifailv );
lapack_int LAPACKE_dstein( int matrix_layout, lapack_int n, const double* d,
                           const double* e, lapack_int m, const double* w, const lapack_int* iblock,
                           const lapack_int* isplit, double* z, lapack_int ldz, lapack_int* ifailv );
lapack_int LAPACKE_cstein( int matrix_layout, lapack_int n, const float* d,
                           const float* e, lapack_int m, const float* w, const lapack_int* iblock,
                           const lapack_int* isplit, lapack_complex_float* z, lapack_int ldz, lapack_int* ifailv );
lapack_int LAPACKE_zstein( int matrix_layout, lapack_int n, const double* d,
                           const double* e, lapack_int m, const double* w, const lapack_int* iblock,
                           const lapack_int* isplit, lapack_complex_double* z, lapack_int ldz, lapack_int* ifailv );

```

Include Files

- C: mkl.h

Description

The routine computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by ?stebz with $order = 'B'$, but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after ?stebz, it can take advantage of the block structure by performing inverse iteration on each block T_i separately, which is more efficient than using the whole matrix T .

If T has been formed by reduction of a full symmetric or Hermitian matrix A to tridiagonal form, you can transform eigenvectors of T to eigenvectors of A by calling ?ormtr or ?opmtr (for real flavors) or by calling ?unmtr or ?upmtr (for complex flavors).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>m</i>	INTEGER. The number of eigenvectors to be returned.
<i>d</i> , <i>e</i> , <i>w</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the sub-diagonal elements of T stored in elements 1 to $n-1$. The dimension of <i>e</i> must be at least $\max(1, n-1)$.

$w(*)$ contains the eigenvalues of T , stored in $w(1)$ to $w(m)$ (as returned by `stebz`). Eigenvalues of T_1 must be supplied first, in non-decreasing order; then those of T_2 , again in non-decreasing order, and so on. Constraint:

`if iblock(i) = iblock(i+1), w(i) ≤ w(i+1).`

The dimension of w must be at least $\max(1, n)$.

`iblock, isplit`

INTEGER.

Arrays, DIMENSION at least $\max(1, n)$. The arrays `iblock` and `isplit`, as returned by `?stebz` with `order = 'B'`.

If you did not call `?stebz` with `order = 'B'`, set all elements of `iblock` to 1, and `isplit(1)` to n .)

`ldz`

INTEGER. The leading dimension of the output array z ; $ldz \geq \max(1, n)$.

`work`

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array, DIMENSION at least $\max(1, 5n)$.

`iwork`

INTEGER.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

`z`

REAL for `sstein`

DOUBLE PRECISION for `dstein`

COMPLEX for `cstein`

DOUBLE COMPLEX for `zstein`.

Array, DIMENSION ($ldz, *$).

If `info = 0`, z contains the m orthonormal eigenvectors, stored by columns. (The i -th column corresponds to the i -th specified eigenvalue.)

`ifailv`

INTEGER.

Array, DIMENSION at least $\max(1, m)$.

If `info = i > 0`, the first i elements of `ifailv` contain the indices of any eigenvectors that failed to converge.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = i`, then i eigenvectors (as indicated by the parameter `ifailv`) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns of the array z .

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stein` interface are the following:

<code>d</code>	Holds the vector of length n .
<code>e</code>	Holds the vector of length n .
<code>w</code>	Holds the vector of length n .
<code>iblock</code>	Holds the vector of length n .
<code>isplit</code>	Holds the vector of length n .
<code>z</code>	Holds the matrix Z of size (n,m) .
<code>ifailv</code>	Holds the vector of length (m) .

Application Notes

Each computed eigenvector z_i is an exact eigenvector of a matrix $T+E_i$, where $\|E_i\|_2 = O(\epsilon) * \|T\|_2$. However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by `?steqr`.

?disna

Computes the reciprocal condition numbers for the eigenvectors of a symmetric/ Hermitian matrix or for the left or right singular vectors of a general matrix.

Syntax

FORTRAN 77:

```
call sdisna(job, m, n, d, sep, info)
call ddisna(job, m, n, d, sep, info)
```

Fortran 95:

```
call disna(d, sep [,job] [,minmn] [,info])
```

C:

```
lapack_int LAPACKE_<?>disna( char job, lapack_int m, lapack_int n, const <datatype>* d,
<datatype>* sep );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m -by- n matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the i -th computed vector is given by

`slamch('E') * (anorm / sep(i))`

where $\text{anorm} = \|\mathbf{A}\|_2 = \max(|d(j)|)$. $\text{sep}(i)$ is not allowed to be smaller than `slamch('E') * anorm` in order to limit the size of the error bound.

?disna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

job CHARACTER*1. Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed:

job = 'E': for the eigenvectors of a symmetric/Hermitian matrix;

job = 'L': for the left singular vectors of a general matrix;

job = 'R': for the right singular vectors of a general matrix.

m INTEGER. The number of rows of the matrix ($m \geq 0$).

n INTEGER.

If *job* = 'L', or 'R', the number of columns of the matrix ($n \geq 0$).
Ignored if *job* = 'E'.

d REAL for sdisna

DOUBLE PRECISION for ddisna.

Array, dimension at least $\max(1,m)$ if *job* = 'E', and at least $\max(1, \min(m,n))$ if *job* = 'L' or 'R'.

This array must contain the eigenvalues (if *job* = 'E') or singular values (if *job* = 'L' or 'R') of the matrix, in either increasing or decreasing order.

If singular values, they must be non-negative.

Output Parameters

sep REAL for sdisna

DOUBLE PRECISION for ddisna.

Array, dimension at least $\max(1,m)$ if *job* = 'E', and at least $\max(1, \min(m,n))$ if *job* = 'L' or 'R'. The reciprocal condition numbers of the vectors.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `disna` interface are the following:

<code>d</code>	Holds the vector of length $\min(m,n)$.
<code>sep</code>	Holds the vector of length $\min(m,n)$.
<code>job</code>	Must be 'E', 'L', or 'R'. The default value is 'E'.
<code>minmn</code>	Indicates which of the values m or n is smaller. Must be either 'M' or 'N', the default is 'M'. If <code>job</code> = 'E', this argument is superfluous, If <code>job</code> = 'L' or 'R', this argument is used by the routine.

Generalized Symmetric-Definite Eigenvalue Problems

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues λ and the corresponding eigenvectors z that satisfy one of these equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is an n -by- n symmetric or Hermitian matrix, and B is an n -by- n symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist n real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices A and B).

Routines described in this section allow you to reduce the above generalized problems to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling LAPACK routines described earlier in this chapter (see [Symmetric Eigenvalue Problems](#)).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix B must first be factorized using either `potrf` or `pptrf`.

The reduction routine for the banded matrices A and B uses a split Cholesky factorization for which a specific routine `pbstf` is provided. This refinement halves the amount of work required to form matrix C .

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists LAPACK routines (FORTRAN 77 interface) that can be used to solve generalized symmetric-definite eigenvalue problems. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Matrix type	Reduce to standard problems (full storage)	Reduce to standard problems (packed storage)	Reduce to standard problems (band matrices)	Factorize band matrix
real symmetric matrices	<code>sygst</code>	<code>spgst</code>	<code>sbgst</code>	<code>pbstf</code>
complex Hermitian matrices	<code>hegst</code>	<code>hpgst</code>	<code>hbgst</code>	<code>pbstf</code>

?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call ssygst(itype, uplo, n, a, lda, b, ldb, info)
call dsygst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call sygst(a, b [,itype] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sygst( int matrix_layout, lapack_int itype, char uplo, lapack_int n, <datatype>* a, lapack_int lda, const <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*z = \lambda * B^*z, \quad A^*B^*z = \lambda * z, \quad \text{or} \quad B^*A^*z = \lambda * z$$

to the standard form $C^*y = \lambda * y$. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call ?potrf to compute the Cholesky factorization: $B = U^T * U$ or $B = L * L^T$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, the generalized eigenproblem is $A^*z = \lambda * B^*z$ for <i>uplo</i> = 'U': $C = \text{inv}(U^T) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$; for <i>uplo</i> = 'L': $C = \text{inv}(L) * A * \text{inv}(L^T)$, $z = \text{inv}(L^T) * y$. If <i>itype</i> = 2, the generalized eigenproblem is $A^*B^*z = \lambda * z$ for <i>uplo</i> = 'U': $C = U * A * U^T$, $z = \text{inv}(U) * y$; for <i>uplo</i> = 'L': $C = L^T * A * L$, $z = \text{inv}(L^T) * y$. If <i>itype</i> = 3, the generalized eigenproblem is $B^*A^*z = \lambda * z$ for <i>uplo</i> = 'U': $C = U * A * U^T$, $z = U^T * y$; for <i>uplo</i> = 'L': $C = L^T * A * L$, $z = L * y$.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangle of <i>A</i> ; you must supply <i>B</i> in the factored form $B = U^T * U$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangle of <i>A</i> ; you must supply <i>B</i> in the factored form $B = L * L^T$.

<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>a, b</i>	REAL for ssygst DOUBLE PRECISION for dsygst. Arrays: <i>a</i> (<i>lda</i> ,*) contains the upper or lower triangle of <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the Cholesky-factored matrix <i>B</i> : $B = U^T * U$ or $B = L * L^T$ (as returned by ?potrf). The second dimension of <i>b</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	The upper or lower triangle of <i>A</i> is overwritten by the upper or lower triangle of <i>C</i> , as specified by the arguments <i>itype</i> and <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygst` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n,n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n,n</i>).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

Forming the reduced matrix *C* is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if *itype* = 1) or *B* (if *itype* = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hegst

Reduces a complex Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call chegst(itype, uplo, n, a, lda, b, ldb, info)
call zhegst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call hegst(a, b [,itype] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_chegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda, const lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_zhegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda, const lapack_complex_double * b, lapack_int ldb);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a complex Hermitian positive-definite generalized eigenvalue problem to standard form.

<i>itype</i>	Problem	Result
1	$A^*x = \lambda^*B^*x$	A overwritten by $\text{inv}(U^H)^*A^*\text{inv}(U)$ or $\text{inv}(L)^*A^*\text{inv}(L^H)$
2	$A^*B^*x = \lambda^*x$	A overwritten by $U^*A^*U^H$ or $L^H^*A^*L$
3	$B^*A^*x = \lambda^*x$	

Before calling this routine, you must call ?potrf to compute the Cholesky factorization: $B = U^H * U$ or $B = L * L^H$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for <i>uplo</i> = 'U': $C = (U^H)^{-1} * A^*U^{-1}$; for <i>uplo</i> = 'L': $C = L^{-1} * A^*(L^H)^{-1}$. If <i>itype</i> = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$ for <i>uplo</i> = 'U': $C = U^*A^*U^H$; for <i>uplo</i> = 'L': $C = L^H * A^*L$. If <i>itype</i> = 3, the generalized eigenproblem is $B^*A^*z = \lambda^*z$
--------------	---

```

for uplo = 'U': C = U*A*UH;
for uplo = 'L': C = LH*A*L.

uplo
CHARACTER*1. Must be 'U' or 'L'.

If uplo = 'U', the array a stores the upper triangle of A; you must supply
B in the factored form B = UH*U.

If uplo = 'L', the array a stores the lower triangle of A; you must supply
B in the factored form B = L*LH.

n
INTEGER. The order of the matrices A and B (n ≥ 0).

a, b
COMPLEX for chegst
DOUBLE COMPLEX for zhegst.

Arrays:
a(lda,*) contains the upper or lower triangle of A.
The second dimension of a must be at least max(1, n).
b ldb,*) contains the Cholesky-factored matrix B:
B = UH*U or B = L*LH (as returned by ?potrf).
The second dimension of b must be at least max(1, n).

lda
INTEGER. The leading dimension of a; at least max(1, n).

ldb
INTEGER. The leading dimension of b; at least max(1, n).

```

Output Parameters

a The upper or lower triangle of A is overwritten by the upper or lower triangle of C, as specified by the arguments *itype* and *uplo*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegst` interface are the following:

a	Holds the matrix A of size (n,n).
b	Holds the matrix B of size (n,n).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by B^{-1} (if $itype = 1$) or B (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?spgst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

FORTRAN 77:

```
call sspgst(itype, uplo, n, ap, bp, info)
call dspgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call spgst(ap, bp [,itype] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>spgst( int matrix_layout, lapack_int itype, char uplo, lapack_int n, <datatype>* ap, const <datatype>* bp );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x$$

to the standard form $C^*y = \lambda^*y$, using packed matrix storage. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call ?pptrf to compute the Cholesky factorization: $B = U^T * U$ or $B = L * L^T$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for <i>uplo</i> = 'U': $C = \text{inv}(U^T) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$; for <i>uplo</i> = 'L': $C = \text{inv}(L) * A * \text{inv}(L^T)$, $z = \text{inv}(L^T) * y$. If <i>itype</i> = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$ for <i>uplo</i> = 'U': $C = U^T * A * U^T$, $z = \text{inv}(U) * y$;
--------------	---

```

for uplo = 'L': C = LT*A*L, z = inv(LT)*y.
If itype = 3, the generalized eigenproblem is B*A*z = lambda*z
for uplo = 'U': C = U*A*UT, z = UT*y;
for uplo = 'L': C = LT*A*L, z = L*y.

uplo
CHARACTER*1. Must be 'U' or 'L'.

If uplo = 'U', ap stores the packed upper triangle of A;
you must supply B in the factored form B = UT*U.

If uplo = 'L', ap stores the packed lower triangle of A;
you must supply B in the factored form B = L*LT.

n
INTEGER. The order of the matrices A and B (n ≥ 0).

ap, bp
REAL for sspgst
DOUBLE PRECISION for dspgst.

Arrays:
ap(*) contains the packed upper or lower triangle of A.
The dimension of ap must be at least max(1, n*(n+1)/2).
bp(*) contains the packed Cholesky factor of B (as returned by ?ptrf with
the same uplo value).
The dimension of bp must be at least max(1, n*(n+1)/2).

```

Output Parameters

ap The upper or lower triangle of A is overwritten by the upper or lower triangle of C, as specified by the arguments *itype* and *uplo*.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spgst* interface are the following:

<i>ap</i>	Holds the array A of size (n*(n+1)/2).
<i>bp</i>	Holds the array B of size (n*(n+1)/2).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $\text{itype} = 1$) or B (if $\text{itype} = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hpgst

Reduces a generalized eigenvalue problem with a Hermitian matrix to a standard eigenvalue problem using packed storage.

Syntax

FORTRAN 77:

```
call chpgst(itype, uplo, n, ap, bp, info)
call zhpgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call hpgst(ap, bp [,itype] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>hpgst( int matrix_layout, lapack_int itype, char uplo, lapack_int n, <datatype>* ap, const <datatype>* bp );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces generalized eigenproblems with Hermitian matrices

$$A^*z = \lambda^*B^*z, A^*B^*z = \lambda^*z, \text{ or } B^*A^*z = \lambda^*z.$$

to standard eigenproblems $C^*y = \lambda^*y$, using packed matrix storage. Here A is a complex Hermitian matrix, and B is a complex Hermitian positive-definite matrix. Before calling this routine, you must call ?pptrf to compute the Cholesky factorization: $B = U^H * U$ or $B = L * L^H$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for <i>uplo</i> = 'U': $C = \text{inv}(U^H) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$; for <i>uplo</i> = 'L': $C = \text{inv}(L) * A * \text{inv}(L^H)$, $z = \text{inv}(L^H) * y$. If <i>itype</i> = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$ for <i>uplo</i> = 'U': $C = U^*A^*U^H$, $z = \text{inv}(U) * y$;
--------------	---

```

for uplo = 'L': C = LH*A*L, z = inv(LH)*y.
If itype = 3, the generalized eigenproblem is B*A*z = lambda*z
for uplo = 'U': C = U*A*UH, z = UH*y;
for uplo = 'L': C = LH*A*L, z = L*y.

uplo
CHARACTER*1. Must be 'U' or 'L'.

If uplo = 'U', ap stores the packed upper triangle of A; you must supply
B in the factored form B = UH*U.

If uplo = 'L', ap stores the packed lower triangle of A; you must supply B
in the factored form B = L*LH.

n
INTEGER. The order of the matrices A and B (n ≥ 0).

ap, bp
COMPLEX for chpgstDOUBLE COMPLEX for zhpgst.

Arrays:

ap(*) contains the packed upper or lower triangle of A.
The dimension of a must be at least max(1, n*(n+1)/2).
bp(*) contains the packed Cholesky factor of B (as returned by ?pptrf with
the same uplo value).
The dimension of b must be at least max(1, n*(n+1)/2).

```

Output Parameters

ap The upper or lower triangle of A is overwritten by the upper or lower triangle of C, as specified by the arguments *itype* and *uplo*.

info INTEGER.

If info = 0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine hpgst interface are the following:

<i>ap</i>	Holds the array A of size (n*(n+1)/2).
<i>bp</i>	Holds the array B of size (n*(n+1)/2).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $\text{itype} = 1$) or B (if $\text{itype} = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?sbgst

Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

FORTRAN 77:

```
call ssbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
call dsbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
```

Fortran 95:

```
call sbgst(ab, bb [,x] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sbgst( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, <datatype>* ab, lapack_int ldab, const <datatype>* bb,
lapack_int ldbb, <datatype>* x, lapack_int ldx );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

To reduce the real symmetric-definite generalized eigenproblem $A^*z = \lambda^*B^*z$ to the standard form $C^*y = \lambda^*y$, where A , B and C are banded, this routine must be preceded by a call to **pbstf/pbstf**, which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^T * S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^T * A * X$, where $X = \text{inv}(S) * Q$ and Q is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , X^*z is an eigenvector of the original system.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

vect	CHARACTER*1. Must be 'N' or 'V'. If vect = 'N', then matrix X is not returned; If vect = 'V', then matrix X is returned.
uplo	CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, ab stores the upper triangular part of A .
If $uplo = 'L'$, ab stores the lower triangular part of A .

n INTEGER. The order of the matrices A and B ($n \geq 0$).
 ka INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
 kb INTEGER. The number of super- or sub-diagonals in B ($ka \geq kb \geq 0$).
 $ab, bb, work$ REAL for ssbgst
DOUBLE PRECISION for dsbgst
 ab ($ldab, *$) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by $uplo$) in band storage format.
The second dimension of the array ab must be at least $\max(1, n)$.
 bb ($ldb, *$) is an array containing the banded split Cholesky factor of B as specified by $uplo$, n and kb and returned by pbstf/pbstf.
The second dimension of the array bb must be at least $\max(1, n)$.
 $work(*)$ is a workspace array, dimension at least $\max(1, 2*n)$

$ldab$ INTEGER. The leading dimension of the array ab ; must be at least $ka+1$.
 ldb INTEGER. The leading dimension of the array bb ; must be at least $kb+1$.
 ldx The leading dimension of the output array x . Constraints: if $vect = 'N'$, then $ldx \geq 1$;
if $vect = 'V'$, then $ldx \geq \max(1, n)$.

Output Parameters

ab On exit, this array is overwritten by the upper or lower triangle of C as specified by $uplo$.
 x REAL for ssbgst
DOUBLE PRECISION for dsbgst
Array.
If $vect = 'V'$, then x ($ldx, *$) contains the n -by- n matrix $X = \text{inv}(S) * Q$.
If $vect = 'N'$, then x is not referenced.
The second dimension of x must be:
at least $\max(1, n)$, if $vect = 'V'$;
at least 1, if $vect = 'N'$.
 $info$ INTEGER.
If $info = 0$, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgst` interface are the following:

<code>ab</code>	Holds the array A of size $(ka+1, n)$.
<code>bb</code>	Holds the array B of size $(kb+1, n)$.
<code>x</code>	Holds the matrix X of size (n, n) .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>vect</code>	Restored based on the presence of the argument <code>x</code> as follows: <code>vect = 'V'</code> , if <code>x</code> is present, <code>vect = 'N'</code> , if <code>x</code> is omitted.

Application Notes

Forming the reduced matrix C involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

If ka and kb are much less than n then the total number of floating-point operations is approximately $6n^2 * kb$, when `vect = 'N'`. Additional $(3/2)n^3 * (kb/ka)$ operations are required when `vect = 'V'`.

?hbgst

Reduces a complex Hermitian positive-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

FORTRAN 77:

```
call chbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork, info)
call zhbgs(t vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork, info)
```

Fortran 95:

```
call hbgst(ab, bb [,x] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>hbgst( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, <datatype>* ab, lapack_int ldab, const <datatype>* bb,
lapack_int ldbb, <datatype>* x, lapack_int ldx );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

To reduce the complex Hermitian positive-definite generalized eigenproblem $A^*z = \lambda^*B^*z$ to the standard form $C^*x = \lambda^*y$, where A , B and C are banded, this routine must be preceded by a call to [pbstf/pbstf](#), which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^H S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^H A X$, where $X = \text{inv}(S) * Q$, and Q is a unitary matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , X^*z is an eigenvector of the original system.

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite band matrix B . It is to be used in conjunction with [sbgst/hbgst](#).

The factorization has the form $B = S^T * S$ (or $B = S^H * S$ for complex flavors), where S is a band matrix of the same bandwidth as B and the following structure: S is upper triangular in the first $(n+kb)/2$ rows and lower triangular in the remaining rows.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo	CHARACTER*1. Must be 'U' or 'L'.
	If $uplo = 'U'$, bb stores the upper triangular part of B .
	If $uplo = 'L'$, bb stores the lower triangular part of B .
n	INTEGER. The order of the matrix B ($n \geq 0$).
kb	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
bb	REAL for spbstf DOUBLE PRECISION for dpbstf COMPLEX for cpbstf

DOUBLE COMPLEX for zpbstf.

bb (*lddb,**) is an array containing either upper or lower triangular part of the matrix *B* (as specified by *uplo*) in band storage format.

The second dimension of the array *bb* must be at least $\max(1, n)$.

lddb

INTEGER. The leading dimension of *bb*; must be at least *kb+1*.

Output Parameters

bb

On exit, this array is overwritten by the elements of the split Cholesky factor *S*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = *i*, then the factorization could not be completed, because the updated element b_{ii} would be the square root of a negative number; hence the matrix *B* is not positive-definite.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbstf` interface are the following:

bb Holds the array *B* of size (*kb+1,n*).

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed factor *S* is the exact factor of a perturbed matrix *B* + *E*, where

$$|E| \leq c(kb + 1)\varepsilon |S^H| |S|, \quad |e_{ij}| \leq c(kb + 1)\varepsilon \sqrt{b_{ii} b_{jj}}$$

c(n) is a modest linear function of *n*, and ε is the machine precision.

The total number of floating-point operations for real flavors is approximately $n(kb+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that *kb* is much less than *n*.

After calling this routine, you can call `sbgst/hgst` to solve the generalized eigenproblem $Az = \lambda Bz$, where *A* and *B* are banded and *B* is positive-definite.

Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A *nonsymmetric eigenvalue problem* is as follows: given a nonsymmetric (or non-Hermitian) matrix *A*, find the *eigenvalues* λ and the corresponding *eigenvectors* *z* that satisfy the equation

$$Az = \lambda z \quad (\text{right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z\text{).}$$

Nonsymmetric eigenvalue problems have the following properties:

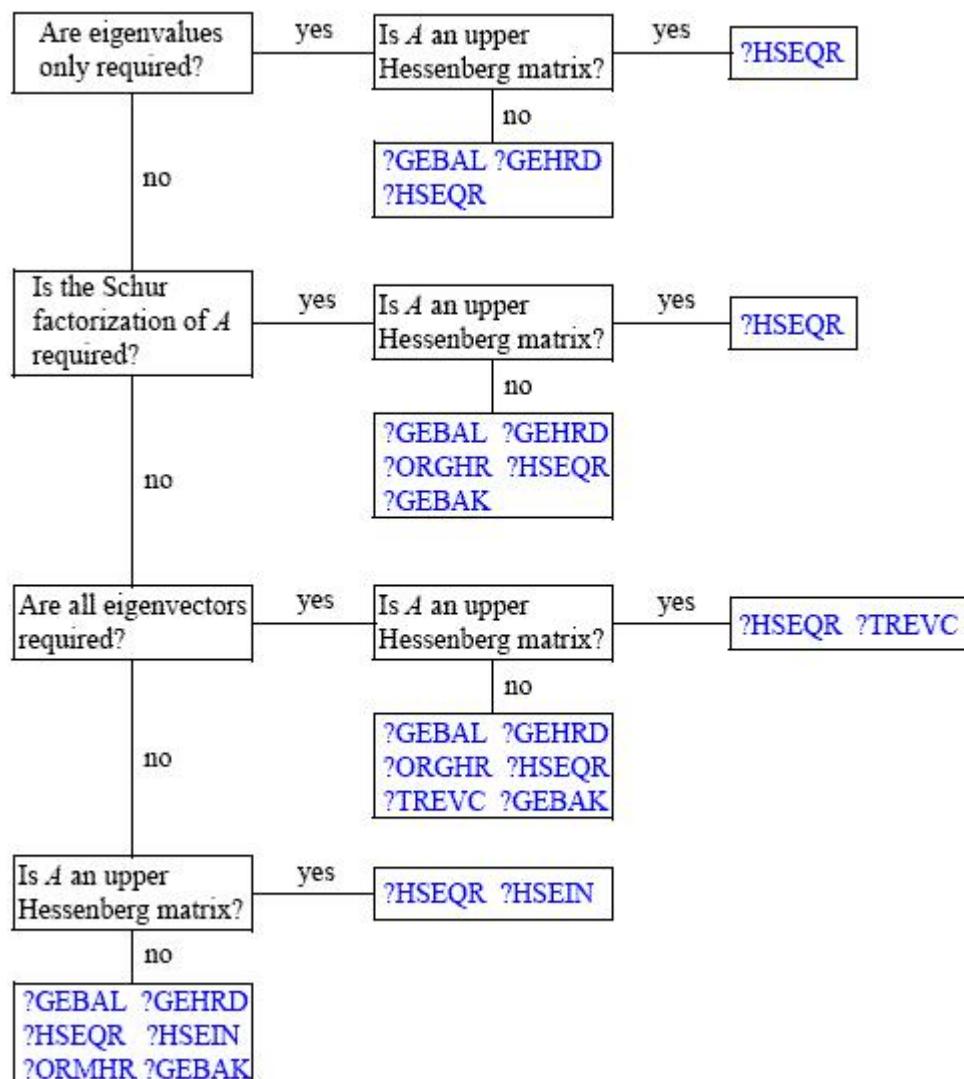

- The number of eigenvectors may be less than the matrix order (but is not less than the number of *distinct eigenvalues* of A).
- Eigenvalues may be complex even for a real matrix A .
- If a real nonsymmetric matrix has a complex eigenvalue $a+bi$ corresponding to an eigenvector z , then $a-bi$ is also an eigenvalue. The eigenvalue $a-bi$ corresponds to the eigenvector whose elements are complex conjugate to the elements of z .

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. [Table "Computational Routines for Solving Nonsymmetric Eigenvalue Problems"](#) lists LAPACK routines (FORTRAN 77 interface) to reduce the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$ as well as routines to solve eigenvalue problems with Hessenberg matrices, forming the Schur factorization of such matrices and computing the corresponding condition numbers. The corresponding routine names in the Fortran 95 interface are without the first symbol.

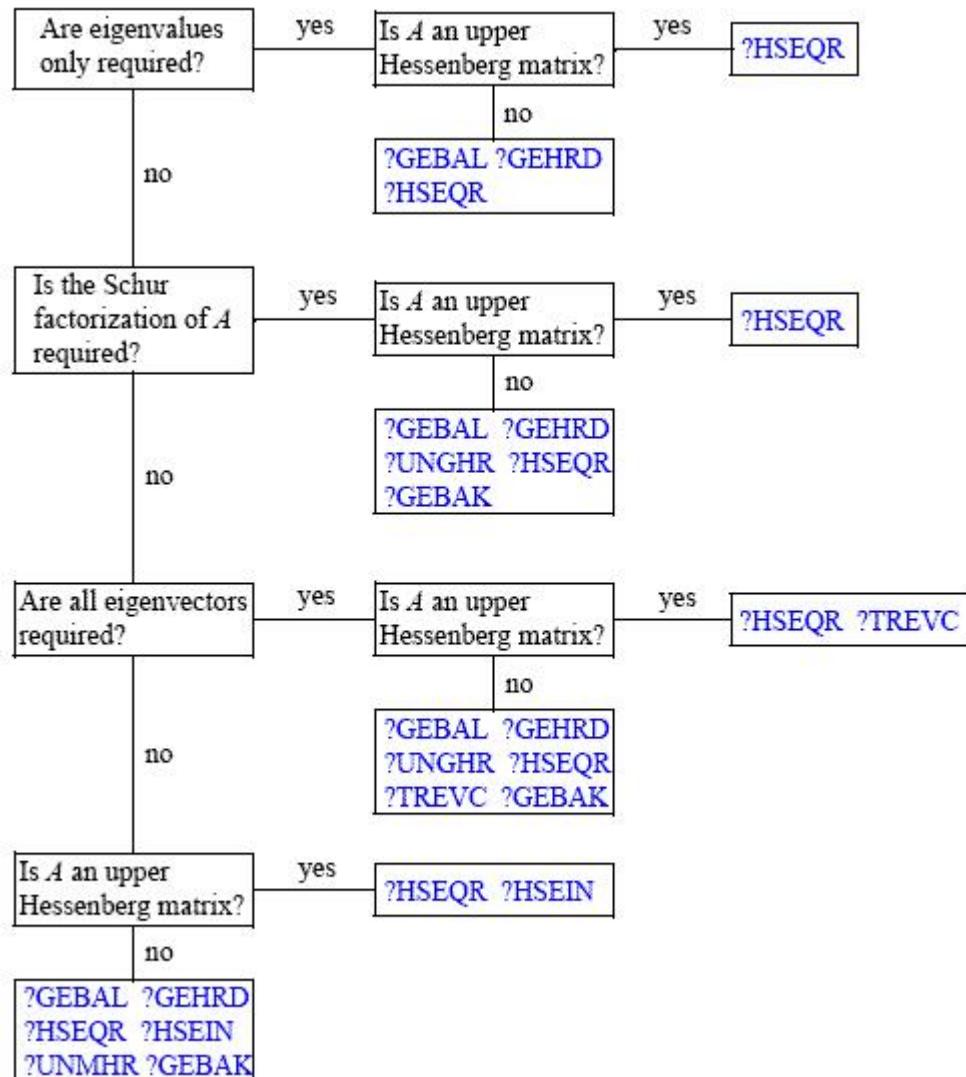

The decision tree in [Figure "Decision Tree: Real Nonsymmetric Eigenvalue Problems"](#) helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in [Figure "Decision Tree: Complex Non-Hermitian Eigenvalue Problems"](#).

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine reduces a general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $A = Q^*H^*Q^H$. Here H has real subdiagonal elements.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. If A is an output by ?gebal, then <i>ilo</i> and <i>ihi</i> must contain the values returned by that routine. Otherwise <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> . (If <i>n</i> > 0, then $1 \leq \text{ilo} \leq \text{ihi} \leq n$; if <i>n</i> = 0, <i>ilo</i> = 1 and <i>ihi</i> = 0.)
<i>a, work</i>	REAL for sgehrd DOUBLE PRECISION for dgehrd COMPLEX for cgehrd DOUBLE COMPLEX for zgehrd. Arrays: <i>a</i> (<i>lda,*</i>) contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (<i>lwork</i>) is a workspace array. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; at least $\max(1, n)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the upper Hessenberg matrix H and details of the matrix Q . The subdiagonal elements of H are real.
<i>tau</i>	REAL for sgehrd

DOUBLE PRECISION for dgehrd
 COMPLEX for cgehrd
 DOUBLE COMPLEX for zgehrd.
Array, DIMENSION at least max (1, $n-1$).
 Contains additional information on the matrix Q .

work(1)
 If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info
 INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gehrd` interface are the following:

<i>a</i>	Holds the matrix A of size (n,n) .
<i>tau</i>	Holds the vector of length $(n-1)$.
<i>ilo</i>	Default value for this argument is $ilo = 1$.
<i>ihi</i>	Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Hessenberg matrix H is exactly similar to a nearby matrix $A + E$, where $\|E\|_2 < c(n)\epsilon\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is $(2/3)*(ihi - ilo)^2(2ihi + 2ilo + 3n)$; for complex flavors it is 4 times greater.

?orghr

Generates the real orthogonal matrix Q determined by ?gehrd.

Syntax**FORTRAN 77:**

```
call sorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
call dorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orghr(a, tau [,ilo] [,ihi] [,info])
```

C:

```
lapack_int LAPACKE_<?>orghr( int matrix_layout, lapack_int n, lapack_int ilo,
lapack_int ihi, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine explicitly generates the orthogonal matrix Q that has been determined by a preceding call to sgehrd/dgehrd. (The routine ?gehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^*H^*Q^T$, and represents the matrix Q as a product of $ihi - ilo$ elementary reflectors. Here ilo and ihi are values determined by sgebal/dgebal when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

The matrix Q generated by ?orghr has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns ilo to ihi .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, <i>ilo</i> = 1 and <i>ihi</i> = 0.)
<i>a, tau, work</i>	REAL for sorghr

DOUBLE PRECISION for `dorghr`

Arrays: $a(1:\text{lda},*)$ contains details of the vectors which define the elementary reflectors, as returned by `?gehrd`.

The second dimension of a must be at least $\max(1, n)$.

$\tau(1:\text{tau})$ contains further details of the elementary reflectors, as returned by `?gehrd`.

The dimension of τ must be at least $\max(1, n-1)$.

work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda

INTEGER. The leading dimension of a ; at least $\max(1, n)$.

lwork

INTEGER. The size of the work array;

$\text{lwork} \geq \max(1, \text{ihi}-\text{ilo})$.

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by `xerbla`.

See *Application Notes* for the suggested value of lwork .

Output Parameters

a

Overwritten by the n -by- n orthogonal matrix Q .

$\text{work}(1)$

If $\text{info} = 0$, on exit $\text{work}(1)$ contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orghr` interface are the following:

a Holds the matrix A of size (n,n) .

τ Holds the vector of length $(n-1)$.

ilo Default value for this argument is $\text{ilo} = 1$.

ihi Default value for this argument is $\text{ihi} = n$.

Application Notes

For better performance, try using $\text{lwork} = (\text{ihi}-\text{ilo}) * \text{blocksize}$ where blocksize is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)(ihi-ilo)^3$.

The complex counterpart of this routine is [unghr](#).

?ormhr

Multiples an arbitrary real matrix C by the real orthogonal matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call sormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
call dormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>ormhr( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const <datatype>* a, lapack_int lda,
const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a matrix *C* by the orthogonal matrix *Q* that has been determined by a preceding call to sgehrd/dgehrd. (The routine ?gehrd reduces a real general matrix *A* to upper Hessenberg form *H* by an orthogonal similarity transformation, $A = Q^*H^*Q^T$, and represents the matrix *Q* as a product of *ihi-ilo* elementary reflectors. Here *ilo* and *ihi* are values determined by sgebal/dgebal when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.)

With ?ormhr, you can form one of the matrix products Q^*C , Q^T*C , C^*Q , or C^*Q^T , overwriting the result on *C* (which may be any real rectangular matrix).

A common application of ?ormhr is to transform a matrix *V* of eigenvectors of *H* to the matrix *QV* of eigenvectors of *A*.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms Q^*C or Q^T*C . If <i>side</i> = 'R', then the routine forms C^*Q or C^*Q^T .
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T'. If <i>trans</i> = 'N', then <i>Q</i> is applied to <i>C</i> . If <i>trans</i> = 'T', then Q^T is applied to <i>C</i> .
<i>m</i>	INTEGER. The number of rows in <i>C</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>C</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd. If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$. If $m = 0$ and <i>side</i> = 'L', then <i>ilo</i> = 1 and <i>ihi</i> = 0. If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$. If $n = 0$ and <i>side</i> = 'R', then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>a, tau, c, work</i>	REAL for sormhr DOUBLE PRECISION for dormhr Arrays: <i>a</i> (<i>lda,*</i>) contains details of the vectors which define the <i>elementary reflectors</i> , as returned by ?gehrd. The second dimension of <i>a</i> must be at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'. <i>tau</i> (*) contains further details of the <i>elementary reflectors</i> , as returned by ?gehrd . The dimension of <i>tau</i> must be at least $\max(1, m-1)$ if <i>side</i> = 'L' and at least $\max(1, n-1)$ if <i>side</i> = 'R'. <i>c</i> (<i>ldc,*</i>) contains the <i>m</i> by <i>n</i> matrix <i>C</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'. <i>ldc</i> INTEGER. The leading dimension of <i>c</i> ; at least $\max(1, m)$. <i>lwork</i> INTEGER. The size of the <i>work</i> array. If <i>side</i> = 'L', <i>lwork</i> $\geq \max(1, n)$.

If $\text{side} = \text{'R'}$, $\text{lwork} \geq \max(1, m)$.

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by [xerbla](#).

See [Application Notes](#) for the suggested value of lwork .

Output Parameters

c	C is overwritten by product $Q^* C$, $Q^T * C$, $C * Q$, or $C * Q^T$ as specified by side and trans .
$\text{work}(1)$	If $\text{info} = 0$, on exit $\text{work}(1)$ contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.
info	INTEGER. If $\text{info} = 0$, the execution is successful. If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormhr` interface are the following:

a	Holds the matrix A of size (r,r) . $r = m$ if $\text{side} = \text{'L'}$. $r = n$ if $\text{side} = \text{'R'}$.
τ	Holds the vector of length $(r-1)$.
c	Holds the matrix C of size (m,n) .
ilo	Default value for this argument is $\text{ilo} = 1$.
ihi	Default value for this argument is $\text{ihi} = n$.
side	Must be 'L' or 'R' . The default value is 'L' .
trans	Must be 'N' or 'T' . The default value is 'N' .

Application Notes

For better performance, lwork should be at least $n*\text{blocksize}$ if $\text{side} = \text{'L'}$ and at least $m*\text{blocksize}$ if $\text{side} = \text{'R'}$, where blocksize is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of lwork for the first run or set $\text{lwork} = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$2n(ihi-ilo)^2$ if *side* = 'L';

$2m(ihi-ilo)^2$ if *side* = 'R'.

The complex counterpart of this routine is [unmhr](#).

?unghr

Generates the complex unitary matrix *Q* determined by [?gehrd](#).

Syntax

FORTRAN 77:

```
call cunghr(n, ilo, ih, a, lda, tau, work, lwork, info)
call zunghr(n, ilo, ih, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unghr(a, tau [,ilo] [,ih] [,info])
```

C:

```
lapack_int LAPACKE_<?>unghr( int matrix_layout, lapack_int n, lapack_int ilo,
lapack_int ih, <datatype>* a, lapack_int lda, const <datatype>* tau );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine is intended to be used following a call to [cgehrd/zgehrd](#), which reduces a complex matrix *A* to upper Hessenberg form *H* by a unitary similarity transformation: $A = Q^*H^*Q^H$. [?gehrd](#) represents the matrix *Q* as a product of *ih*-*ilo* elementary reflectors. Here *ilo* and *ih* are values determined by [cgebal/zgebal](#) when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ih* = *n*.

Use the routine [unghr](#) to generate *Q* explicitly as a square matrix. The matrix *Q* has the structure:

where Q_{22} occupies rows and columns $i\text{lo}$ to $i\text{hi}$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>i\text{lo}, i\text{hi}</i>	INTEGER. These must be the same parameters <i>i\text{lo}</i> and <i>i\text{hi}</i> , respectively, as supplied to ?gehrd . (If $n > 0$, then $1 \leq i\text{lo} \leq i\text{hi} \leq n$. If $n = 0$, then <i>i\text{lo} = 1</i> and <i>i\text{hi} = 0</i> .)
<i>a, tau, work</i>	COMPLEX for cunghr DOUBLE COMPLEX for zunghr. Arrays: <i>a</i> (<i>l\text{da}, *</i>) contains details of the vectors which define the <i>elementary reflectors</i> , as returned by ?gehrd. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>tau</i> (*) contains further details of the <i>elementary reflectors</i> , as returned by ?gehrd . The dimension of <i>tau</i> must be at least $\max(1, n-1)$. <i>work</i> is a workspace array, its dimension $\max(1, l\text{work})$. <i>l\text{da}</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$. <i>l\text{work}</i> INTEGER. The size of the <i>work</i> array; $l\text{work} \geq \max(1, i\text{hi}-i\text{lo})$. If <i>l\text{work} = -1</i> , then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>l\text{work}</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>l\text{work}</i> .

Output Parameters

<i>a</i>	Overwritten by the n -by- n unitary matrix Q .
<i>work</i> (1)	If <i>info = 0</i> , on exit <i>work</i> (1) contains the minimum value of <i>l\text{work}</i> required for optimum performance. Use this <i>l\text{work}</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info = 0</i> , the execution is successful. If <i>info = -i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmhr` interface are the following:

- `a` Holds the matrix A of size (n,n) .
- `tau` Holds the vector of length $(n-1)$.
- `ilo` Default value for this argument is $ilo = 1$.
- `ihi` Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = (ihi-ilo)*blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of real floating-point operations is $(16/3)(ihi-ilo)^3$.

The real counterpart of this routine is `orghr`.

?unmhr

Multiplies an arbitrary complex matrix C by the complex unitary matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call cunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
call zunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>unmhr( int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const <datatype>* a, lapack_int lda,
const <datatype>* tau, <datatype>* c, lapack_int ldc );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine multiplies a matrix C by the unitary matrix Q that has been determined by a preceding call to cgehrd/zgehrd. (The routine ?gehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^H H Q^T$, and represents the matrix Q as a product of $ihi-ilo$ elementary reflectors. Here ilo and ihi are values determined by cgebal/zgebal when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

With ?unmhr, you can form one of the matrix products $Q^H C$, $Q^H C^H$, $C^H Q$, or $C^H Q^H$, overwriting the result on C (which may be any complex rectangular matrix). A common application of this routine is to transform a matrix V of eigenvectors of H to the matrix QV of eigenvectors of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^H C$ or $Q^H C^H$. If <i>side</i> = 'R', then the routine forms $C^H Q$ or $C^H Q^H$.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'C'. If <i>trans</i> = 'N', then Q is applied to C . If <i>trans</i> = 'T', then Q^H is applied to C .
<i>m</i>	INTEGER. The number of rows in C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>ilo</i> , <i>ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd . If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$. If $m = 0$ and <i>side</i> = 'L', then <i>ilo</i> = 1 and <i>ihi</i> = 0. If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$. If $n = 0$ and <i>side</i> = 'R', then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>a</i> , <i>tau</i> , <i>c</i> , <i>work</i>	COMPLEX for cunmhr DOUBLE COMPLEX for zunmhr. Arrays: <i>a</i> (<i>lda</i> ,*) contains details of the vectors which define the elementary reflectors, as returned by ?gehrd. The second dimension of <i>a</i> must be at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'.

tau(*) contains further details of the elementary reflectors, as returned by ?gehrd.

The dimension of *tau* must be at least max (1, *m*-1)

if *side* = 'L' and at least max (1, *n*-1) if *side* = 'R'.

c (*lrc*,*) contains the *m*-by-*n* matrix *C*. The second dimension of *c* must be at least max(1, *n*).

work is a workspace array, its dimension max(1, *lwork*).

lda INTEGER. The leading dimension of *a*; at least max(1, *m*) if *side* = 'L' and at least max (1, *n*) if *side* = 'R'.

ldc INTEGER. The leading dimension of *c*; at least max(1, *m*).

lwork INTEGER. The size of the *work* array.

If *side* = 'L', *lwork* $\geq \max(1, n)$.

If *side* = 'R', *lwork* $\geq \max(1, m)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c *C* is overwritten by *Q***C*, or *Q*^H**C*, or *C***Q*^H, or *C***Q* as specified by *side* and *trans*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmhr` interface are the following:

a Holds the matrix *A* of size (*r*,*r*).

r = *m* if *side* = 'L'.

r = *n* if *side* = 'R'.

tau Holds the vector of length (*r*-1).

c Holds the matrix *C* of size (*m*,*n*).

<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, *lwork* should be at least $n * \text{blocksize}$ if *side* = 'L' and at least $m * \text{blocksize}$ if *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$8n(ihi-ilo)^2$ if *side* = 'L';

$8m(ihi-ilo)^2$ if *side* = 'R'.

The real counterpart of this routine is [ormhr](#).

?gebal

Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

Syntax

FORTRAN 77:

```
call sgebal(job, n, a, lda, ilo, ihi, scale, info)
call dgebal(job, n, a, lda, ilo, ihi, scale, info)
call cgebal(job, n, a, lda, ilo, ihi, scale, info)
call zgebal(job, n, a, lda, ilo, ihi, scale, info)
```

Fortran 95:

```
call gebal(a [, scale] [,ilo] [,ihi] [,job] [,info])
```

C:

```
lapack_int LAPACKE_sgebal( int matrix_layout, char job, lapack_int n, float* a,
                           lapack_int lda, lapack_int* ilo, lapack_int* ihi, float* scale );
lapack_int LAPACKE_dgebal( int matrix_layout, char job, lapack_int n, double* a,
