Description

The routine *balances* a matrix A by performing either or both of the following two similarity transformations:

(1) The routine first attempts to permute A to block upper triangular form:

$$\dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} \dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} \dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array}$$

where P is a permutation matrix, and A'_{11} and A'_{33} are upper triangular. The diagonal elements of A'_{11} and A'_{33} are eigenvalues of A . The rest of the eigenvalues of A are the eigenvalues of the central diagonal block A'_{22} , in rows and columns ilo to ihi . Subsequent operations to compute the eigenvalues of A (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $ilo > 1$ and $ihi < n$.

If no suitable permutation exists (as is often the case), the routine sets $ilo = 1$ and $ihi = n$, and A'_{22} is the whole of A .

(2) The routine applies a diagonal similarity transformation to A' , to make the rows and columns of A'_{22} as close in norm as possible:

$$\dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} \dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} \dots \begin{array}{|c|c|} \hline 1 & * \\ \hline \end{array} \dots$$

This scaling can reduce the norm of the matrix (that is, $\|A'_{22}\| < \|A\|\$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'.
------------	--

If $job = 'N'$, then A is neither permuted nor scaled (but ilo , ih_i , and $scale$ get their values).

If $job = 'P'$, then A is permuted but not scaled.

If $job = 'S'$, then A is scaled but not permuted.

If $job = 'B'$, then A is both scaled and permuted.

n INTEGER. The order of the matrix A ($n \geq 0$).

a REAL for sgebal
 DOUBLE PRECISION for dgebal
 COMPLEX for cgebal
 DOUBLE COMPLEX for zgebal.

Arrays:

a ($lda,*$) contains the matrix A .

The second dimension of *a* must be at least $\max(1, n)$. *a* is not referenced if $job = 'N'$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

a Overwritten by the balanced matrix (*a* is not referenced if $job = 'N'$).

ilo, *ih_i* INTEGER. The values *ilo* and *ih_i* such that on exit $a(i,j)$ is zero if $i > j$ and $1 \leq j < ilo$ or $ih_i < i \leq n$.
 If $job = 'N'$ or $'S'$, then $ilo = 1$ and $ih_i = n$.

scale REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors
 Array, DIMENSION at least $\max(1, n)$.

Contains details of the permutations and scaling factors.

More precisely, if p_j is the index of the row and column interchanged with row and column j , and d_j is the scaling factor used to balance row and column j , then

$scale(j) = p_j$ for $j = 1, 2, \dots, ilo-1, ih_i+1, \dots, n$;
 $scale(j) = d_j$ for $j = ilo, ilo + 1, \dots, ih_i$.

The order in which the interchanges are made is n to ih_i+1 , then 1 to $ilo-1$.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebal` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>scale</code>	Holds the vector of length n .
<code>ilo</code>	Default value for this argument is <code>ilo = 1</code> .
<code>ihi</code>	Default value for this argument is <code>ihi = n</code> .
<code>job</code>	Must be ' <code>B</code> ', ' <code>S</code> ', ' <code>P</code> ', or ' <code>N</code> '. The default value is ' <code>B</code> '.

Application Notes

The errors are negligible, compared with those in subsequent computations.

If the matrix A is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix A'' and hence you must call `gebak` to transform them back to eigenvectors of A .

If the Schur vectors of A are required, do not call this routine with `job = 'S'` or '`B`', because then the balancing transformation is not orthogonal (not unitary for complex flavors).

If you call this routine with `job = 'P'`, then any Schur vectors computed subsequently are Schur vectors of the matrix A'' , and you need to call `gebak` (with `side = 'R'`) to transform them back to Schur vectors of A .

The total number of floating-point operations is proportional to n^2 .

?gebak

Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.

Syntax

FORTRAN 77:

```
call sgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call dgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call cgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call zgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
```

Fortran 95:

```
call gebak(v, scale [,ilo] [,ihi] [,job] [,side] [,info])
```

C:

```
lapack_int LAPACKE_sgebak( int matrix_layout, char job, char side, lapack_int n,
                           lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, float* v, lapack_int ldv );
lapack_int LAPACKE_dgebak( int matrix_layout, char job, char side, lapack_int n,
                           lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m, double* v,
                           lapack_int ldv );
lapack_int LAPACKE_cgebak( int matrix_layout, char job, char side, lapack_int n,
                           lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, lapack_complex_float* v,
                           lapack_int ldv );
lapack_int LAPACKE_zgebak( int matrix_layout, char job, char side, lapack_int n,
                           lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m,
                           lapack_complex_double* v, lapack_int ldv );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine is intended to be used after a matrix A has been balanced by a call to ?gebal, and eigenvectors of the balanced matrix A''_{22} have subsequently been computed. For a description of balancing, see [gebal](#). The balanced matrix A'' is obtained as $A'' = D^T P^* A * P^T \text{inv}(D)$, where P is a permutation matrix and D is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

If x is a right eigenvector of A'' , then $P^T \text{inv}(D) * x$ is a right eigenvector of A ; if x is a left eigenvector of A'' , then $P^T * D^* y$ is a left eigenvector of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'. The same parameter <i>job</i> as supplied to ?gebal.
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then left eigenvectors are transformed. If <i>side</i> = 'R', then right eigenvectors are transformed.
<i>n</i>	INTEGER. The number of rows of the matrix of eigenvectors ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. The values <i>ilo</i> and <i>ihi</i> , as returned by ?gebal. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then <i>ilo</i> = 1 and <i>ihi</i> = 0.)
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors Array, DIMENSION at least max(1, <i>n</i>). Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by ?gebal.
<i>m</i>	INTEGER. The number of columns of the matrix of eigenvectors ($m \geq 0$).
<i>v</i>	REAL for sgebak DOUBLE PRECISION for dgebak COMPLEX for cgebak DOUBLE COMPLEX for zgebak. Arrays: <i>v</i> (<i>ldv, *</i>) contains the matrix of left or right eigenvectors to be transformed. The second dimension of <i>v</i> must be at least max(1, <i>m</i>).

ldv INTEGER. The leading dimension of *v*; at least $\max(1, n)$.

Output Parameters

v Overwritten by the transformed eigenvectors.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebak` interface are the following:

v Holds the matrix *V* of size (*n,m*).

scale Holds the vector of length *n*.

ilo Default value for this argument is *ilo* = 1.

ih Default value for this argument is *ih* = *n*.

job Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

side Must be 'L' or 'R'. The default value is 'L'.

Application Notes

The errors in this routine are negligible.

The approximate number of floating-point operations is approximately proportional to m^2n .

?hseqr

Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

FORTRAN 77:

```
call shseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork, info)
call dhseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork, info)
call chseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
call zhseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
```

Fortran 95:

```
call hseqr(h, wr, wi [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
call hseqr(h, w [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
```

C:

```

lapack_int LAPACKE_shseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, float* h, lapack_int ldh, float* wr, float* wi, float*
z, lapack_int ldz );

lapack_int LAPACKE_dhseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, double* h, lapack_int ldh, double* wr, double* wi,
double* z, lapack_int ldz );

lapack_int LAPACKE_chseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_float* h, lapack_int ldh,
lapack_complex_float* w, lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_double* h, lapack_int ldh,
lapack_complex_double* w, lapack_complex_double* z, lapack_int ldz );

```

Include Files

Description

The routine computes all the eigenvalues, and optionally the Schur factorization, of an upper Hessenberg matrix H : $H = Z^* T^* Z^H$, where T is an upper triangular (or, for real flavors, quasi-triangular) matrix (the Schur form of H), and Z is the unitary or orthogonal matrix whose columns are the Schur vectors z_i .

You can also use this routine to compute the Schur factorization of a general matrix A which has been reduced to upper Hessenberg form H :

$$A = Q^* H^* Q^H, \text{ where } Q \text{ is unitary (orthogonal for real flavors);}$$

$$A = (QZ)^* T^* (QZ)^H.$$

In this case, after reducing A to Hessenberg form by [gehrd](#), call [orghr](#) to form Q explicitly and then pass Q to [?hseqr](#) with $compz = 'V'$.

You can also call [gebal](#) to balance the original matrix before reducing it to Hessenberg form by [?hseqr](#), so that the Hessenberg matrix H will have the structure:

$$\begin{bmatrix} H_{11} & H_{12} & H_{13} \\ 0 & H_{22} & H_{23} \\ 0 & 0 & H_{33} \end{bmatrix}$$

where H_{11} and H_{33} are upper triangular.

If so, only the central diagonal block H_{22} (in rows and columns ilo to ihi) needs to be further reduced to Schur form (the blocks H_{12} and H_{23} are also affected). Therefore the values of ilo and ihi can be supplied to [?hseqr](#) directly. Also, after calling this routine you must call [gebak](#) to permute the Schur vectors of the balanced matrix to those of the original matrix.

If [?gebal](#) has not been called, however, then ilo must be set to 1 and ihi to n . Note that if the Schur factorization of A is required, [?gebal](#) must not be called with $job = 'S'$ or $'B'$, because the balancing transformation is not unitary (for real flavors, it is not orthogonal).

?hseqr uses a multishift form of the upper Hessenberg QR algorithm. The Schur vectors are normalized so that $\|z_i\|_2 = 1$, but are determined only to within a complex factor of absolute value 1 (for the real flavors, to within a factor ± 1).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Must be 'E' or 'S'. If <i>job</i> = 'E', then eigenvalues only are required. If <i>job</i> = 'S', then the Schur form <i>T</i> is required.
<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', then no Schur vectors are computed (and the array <i>z</i> is not referenced). If <i>compz</i> = 'I', then the Schur vectors of <i>H</i> are computed (and the array <i>z</i> is initialized by the routine). If <i>compz</i> = 'V', then the Schur vectors of <i>A</i> are computed (and the array <i>z</i> must contain the matrix <i>Q</i> on entry).
<i>n</i>	INTEGER. The order of the matrix <i>H</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. If <i>A</i> has been balanced by ?gebal, then <i>ilo</i> and <i>ihi</i> must contain the values returned by ?gebal. Otherwise, <i>ilo</i> must be set to 1 and <i>ihi</i> to <i>n</i> .
<i>h, z, work</i>	REAL for shseqr DOUBLE PRECISION for dhseqr COMPLEX for chseqr DOUBLE COMPLEX for zhseqr. Arrays: <i>h</i> (<i>ldh,*</i>) The <i>n</i> -by- <i>n</i> upper Hessenberg matrix <i>H</i> . The second dimension of <i>h</i> must be at least max(1, <i>n</i>). <i>z</i> (<i>ldz,*</i>) If <i>compz</i> = 'V', then <i>z</i> must contain the matrix <i>Q</i> from the reduction to Hessenberg form. If <i>compz</i> = 'I', then <i>z</i> need not be set. If <i>compz</i> = 'N', then <i>z</i> is not referenced. The second dimension of <i>z</i> must be at least max(1, <i>n</i>) if <i>compz</i> = 'V' or 'I'; at least 1 if <i>compz</i> = 'N'. <i>work</i> (<i>lwork</i>) is a workspace array. The dimension of <i>work</i> must be at least max (1, <i>n</i>). <i>ldh</i> INTEGER. The leading dimension of <i>h</i> ; at least max(1, <i>n</i>).

<i>ldz</i>	INTEGER. The leading dimension of <i>z</i> ; If <i>compz</i> = 'N', then <i>ldz</i> ≥ 1 . If <i>compz</i> = 'V' or 'I', then <i>ldz</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> $\geq \max(1, n)$ is sufficient and delivers very good and sometimes optimal performance. However, <i>lwork</i> as large as $11*n$ may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only estimates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for details.

Output Parameters

<i>w</i>	COMPLEX for <i>chseqr</i> DOUBLE COMPLEX for <i>zhseqr</i> . Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues, unless <i>info</i> >0. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed).
<i>wr, wi</i>	REAL for <i>shseqr</i> DOUBLE PRECISION for <i>dhseqr</i> Arrays, DIMENSION at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless <i>info</i> > 0. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed).
<i>h</i>	If <i>info</i> = 0 and <i>job</i> = 'S', <i>h</i> contains the upper triangular matrix <i>T</i> from the Schur decomposition (the Schur form). If <i>info</i> = 0 and <i>job</i> = 'E', the contents of <i>h</i> are unspecified on exit. (The output value of <i>h</i> when <i>info</i> > 0 is given under the description of <i>info</i> below.)
<i>z</i>	If <i>compz</i> = 'V' and <i>info</i> = 0, then <i>z</i> contains <i>Q</i> * <i>Z</i> . If <i>compz</i> = 'I' and <i>info</i> = 0, then <i>z</i> contains the unitary or orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i> . If <i>compz</i> = 'N', then <i>z</i> is not referenced.
<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the optimal <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

If $info = i$, elements $1, 2, \dots, ilo-1$ and $i+1, i+2, \dots, n$ of wr and wi contain the real and imaginary parts of those eigenvalues that have been successively found.

If $info > 0$, and $job = 'E'$, then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through $info$ of the final output value of H .

If $info > 0$, and $job = 'S'$, then on exit $(initial\ value\ of\ H)*U = U*(final\ value\ of\ H)$, where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns $info+1$ through ih .

If $info > 0$, and $compz = 'V'$, then on exit $(final\ value\ of\ Z) = (initial\ value\ of\ Z)*U$, where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'I'$, then on exit $(final\ value\ of\ Z) = U$, where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'N'$, then Z is not accessed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hseqr` interface are the following:

h	Holds the matrix H of size (n,n) .
wr	Holds the vector of length n . Used in real flavors only.
wi	Holds the vector of length n . Used in real flavors only.
w	Holds the vector of length n . Used in complex flavors only.
z	Holds the matrix Z of size (n,n) .
job	Must be ' E ' or ' S '. The default value is ' E '.
$compz$	If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to ' I ' or ' V ' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted.

Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix $H + E$, where $\|E\|_2 < O(\varepsilon) \|H\|_2 / s_i$, and ε is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then $|\lambda_i - \mu_i| \leq c(n) * \varepsilon * \|H\|_2 / s_i$, where $c(n)$ is a modestly increasing function of n , and s_i is the reciprocal condition number of λ_i . The condition numbers s_i may be computed by calling `trsna`.

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

If only eigenvalues are computed: $7n^3$ for real flavors

$25n^3$ for complex flavors.

If the Schur form is computed: $10n^3$ for real flavors
 $35n^3$ for complex flavors.

If the full Schur factorization is computed: $20n^3$ for real flavors
 $70n^3$ for complex flavors.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hsein

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

Syntax

FORTRAN 77:

```
call shsein(side, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr, mm,
m, work, ifaill, ifailr, info)

call dhsein(side, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr, mm,

Description

The routine computes left and/or right eigenvectors of an upper Hessenberg matrix H , corresponding to selected eigenvalues.

The right eigenvector x and the left eigenvector y , corresponding to an eigenvalue λ , are defined by: $H^*x = \lambda*x$ and $y^H*H = \lambda*y^H$ (or $H^H*y = \lambda^*y$). Here λ^* denotes the conjugate of λ .

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector x , $\max|x_i| = 1$, and for a complex eigenvector, $\max(|\text{Re}x_i| + |\text{Im}x_i|) = 1$.

If H has been formed by reduction of a general matrix A to upper Hessenberg form, then eigenvectors of H may be transformed to eigenvectors of A by [ormhr](#) or [unmhr](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be 'R' or 'L' or 'B'. If <i>side</i> = 'R', then only right eigenvectors are computed. If <i>side</i> = 'L', then only left eigenvectors are computed. If <i>side</i> = 'B', then all eigenvectors are computed.
<i>eisrc</i>	CHARACTER*1. Must be 'Q' or 'N'. If <i>eisrc</i> = 'Q', then the eigenvalues of H were found using hseqr ; thus if H has any zero sub-diagonal elements (and so is block triangular), then the j -th eigenvalue can be assumed to be an eigenvalue of the block containing the j -th row/column. This property allows the routine to perform inverse iteration on just one diagonal block. If <i>eisrc</i> = 'N', then no such assumption is made and the routine performs inverse iteration using the whole matrix.
<i>initv</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>initv</i> = 'N', then no initial estimates for the selected eigenvectors are supplied.

If *initv* = 'U', then initial estimates for the selected eigenvectors are supplied in *vl* and/or *vr*.

select

LOGICAL.

Array, DIMENSION at least max (1, *n*). Specifies which eigenvectors are to be computed.

For real flavors:

To obtain the real eigenvector corresponding to the real eigenvalue *wr(j)*, set *select(j)* to .TRUE..

To select the complex eigenvector corresponding to the complex eigenvalue (*wr(j)*, *wi(j)*) with complex conjugate (*wr(j+1)*, *wi(j+1)*), set *select(j)* and/or *select(j+1)* to .TRUE.; the eigenvector corresponding to the first eigenvalue in the pair is computed.

For complex flavors:

To select the eigenvector corresponding to the eigenvalue *w(j)*, set *select(j)* to .TRUE..

n

INTEGER. The order of the matrix *H* (*n* \geq 0).

h, vl, vr,

REAL for shsein

DOUBLE PRECISION for dhsein

COMPLEX for chsein

DOUBLE COMPLEX for zhsein.

Arrays:

h(Idh,)* The *n*-by-*n* upper Hessenberg matrix *H*. If an *NAN* value is detected in *h*, the routine returns with *info* = -6.

The second dimension of *h* must be at least max(1, *n*).

vl(Idvl,)*

If *initv* = 'V' and *side* = 'L' or 'B', then *vl* must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.

If *initv* = 'N', then *vl* need not be set.

The second dimension of *vl* must be at least max(1, *mm*) if *side* = 'L' or 'B' and at least 1 if *side* = 'R'.

The array *vl* is not referenced if *side* = 'R'.

vr(Idvr,)*

If *initv* = 'V' and *side* = 'R' or 'B', then *vr* must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.

If *initv* = 'N', then *vr* need not be set.

The second dimension of *vr* must be at least max(1, *mm*) if *side* = 'R' or 'B' and at least 1 if *side* = 'L'.

The array *vr* is not referenced if *side* = 'L'.
work(*) is a workspace array.
 DIMENSION at least max (1, *n**(*n*+2)) for real flavors and at least max (1, *n***n*) for complex flavors.

ldh
 INTEGER. The leading dimension of *h*; at least max(1, *n*).

w
 COMPLEX for chsein
 DOUBLE COMPLEX for zhsein.
 Array, DIMENSION at least max (1, *n*).
 Contains the eigenvalues of the matrix *H*.
 If *eigsrc* = 'Q', the array must be exactly as returned by ?hseqr.

wr, wi
 REAL for shsein
 DOUBLE PRECISION for dhsein
 Arrays, DIMENSION at least max (1, *n*) each.
 Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix *H*. Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If *eigsrc* = 'Q', the arrays must be exactly as returned by ?hseqr.

ldvl
 INTEGER. The leading dimension of *vl*.
 If *side* = 'L' or 'B', *ldvl* $\geq \max(1, n)$.
 If *side* = 'R', *ldvl* ≥ 1 .

ldvr
 INTEGER. The leading dimension of *vr*.
 If *side* = 'R' or 'B', *ldvr* $\geq \max(1, n)$.
 If *side* = 'L', *ldvr* ≥ 1 .

mm
 INTEGER. The number of columns in *vl* and/or *vr*.
 Must be at least *m*, the actual number of columns required (see *Output Parameters* below).
 For real flavors, *m* is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector (see *select*).
 For complex flavors, *m* is the number of selected eigenvectors (see *select*).
 Constraint:
 $0 \leq mm \leq n$.

rwork
 REAL for chsein
 DOUBLE PRECISION for zhsein.
 Array, DIMENSION at least max (1, *n*).

Output Parameters

select Overwritten for real flavors only.

If a complex eigenvector was selected as specified above, then `select(j)` is set to .TRUE. and `select(j+1)` to .FALSE.

w

The real parts of some elements of *w* may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

wr

Some elements of *wr* may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

vl, vr

If `side = 'L'` or `'B'`, *vl* contains the computed left eigenvectors (as specified by `select`).

If `side = 'R'` or `'B'`, *vr* contains the computed right eigenvectors (as specified by `select`).

The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues.

For real flavors: a real eigenvector corresponding to a selected real eigenvalue occupies one column; a complex eigenvector corresponding to a selected complex eigenvalue occupies two columns: the first column holds the real part and the second column holds the imaginary part.

m

INTEGER. *For real flavors:* the number of columns of *vl* and/or *vr* required to store the selected eigenvectors.

For complex flavors: the number of selected eigenvectors.

ifaill, ifailr

INTEGER.

Arrays, DIMENSION at least `max(1, mm)` each.

ifaill(i) = 0 if the *i*th column of *vl* converged;

ifaill(i) = j > 0 if the eigenvector stored in the *i*-th column of *vl* (corresponding to the *j*th eigenvalue) failed to converge.

ifailr(i) = 0 if the *i*th column of *vr* converged;

ifailr(i) = j > 0 if the eigenvector stored in the *i*-th column of *vr* (corresponding to the *j*th eigenvalue) failed to converge.

For real flavors: if the *i*th and *(i+1)*th columns of *vl* contain a selected complex eigenvector, then *ifaill(i)* and *ifaill(i+1)* are set to the same value. A similar rule holds for *vr* and *ifailr*.

The array *ifaill* is not referenced if `side = 'R'`. The array *ifailr* is not referenced if `side = 'L'`.

info

INTEGER.

If *info = 0*, the execution is successful.

If *info = -i*, the *i*-th parameter had an illegal value.

If *info > 0*, then *i* eigenvectors (as indicated by the parameters *ifaill* and/or *ifailr* above) failed to converge. The corresponding columns of *vl* and/or *vr* contain no useful information.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hsein` interface are the following:

<code>h</code>	Holds the matrix H of size (n,n) .
<code>wr</code>	Holds the vector of length n . Used in real flavors only.
<code>wi</code>	Holds the vector of length n . Used in real flavors only.
<code>w</code>	Holds the vector of length n . Used in complex flavors only.
<code>select</code>	Holds the vector of length n .
<code>vl</code>	Holds the matrix VL of size (n,mm) .
<code>vr</code>	Holds the matrix VR of size (n,mm) .
<code>ifail1</code>	Holds the vector of length (mm) . Note that there will be an error condition if <code>ifail1</code> is present and <code>vl</code> is omitted.
<code>ifailr</code>	Holds the vector of length (mm) . Note that there will be an error condition if <code>ifailr</code> is present and <code>vr</code> is omitted.
<code>initv</code>	Must be ' <code>N</code> ' or ' <code>U</code> '. The default value is ' <code>N</code> '.
<code>eigsrc</code>	Must be ' <code>N</code> ' or ' <code>Q</code> '. The default value is ' <code>N</code> '.
<code>side</code>	Restored based on the presence of arguments <code>vl</code> and <code>vr</code> as follows: <code>side = 'B'</code> , if both <code>vl</code> and <code>vr</code> are present, <code>side = 'L'</code> , if <code>vl</code> is present and <code>vr</code> omitted, <code>side = 'R'</code> , if <code>vl</code> is omitted and <code>vr</code> present, Note that there will be an error condition if both <code>vl</code> and <code>vr</code> are omitted.

Application Notes

Each computed right eigenvector x_i is the exact eigenvector of a nearby matrix $A + E_i$, such that $\|E_i\| < O(\epsilon) \|A\|$. Hence the residual is small:

$$\|Ax_i - \lambda_i x_i\| = O(\epsilon) \|A\|.$$

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

?trevc

Computes selected eigenvectors of an upper (quasi-)triangular matrix computed by `?hseqr`.

Syntax

FORTRAN 77:

```
call strevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, info)
```

```
call dtrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, info)
call ctrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, rwork,
info)
call ztrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, rwork,
info)
```

Fortran 95:

Description

The routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix T (or, for real flavors, an upper quasi-triangular matrix T). Matrices of this type are produced by the Schur factorization of a general matrix: $A = Q^* T^* Q^H$, as computed by [hseqr](#).

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w , are defined by:

$T^*x = w^*x$, $y^H T = w^*y^H$, where y^H denotes the conjugate transpose of y .

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T .

This routine returns the matrices X and/or Y of right and left eigenvectors of T , or the products Q^*X and/or Q^*Y , where Q is an input matrix.

If Q is the orthogonal/unitary factor that reduces a matrix A to Schur form T , then Q^*X and Q^*Y are the matrices of right and left eigenvectors of A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

side	CHARACTER*1. Must be 'R' or 'L' or 'B'.
------	---

If *side* = 'R', then only right eigenvectors are computed.

If *side* = 'L', then only left eigenvectors are computed.

If *side* = 'B', then all eigenvectors are computed.

howmny

CHARACTER*1. Must be 'A' or 'B' or 'S'.

If *howmny* = 'A', then all eigenvectors (as specified by *side*) are computed.

If *howmny* = 'B', then all eigenvectors (as specified by *side*) are computed and backtransformed by the matrices supplied in *vl* and *vr*.

If *howmny* = 'S', then selected eigenvectors (as specified by *side* and *select*) are computed.

select

LOGICAL.

Array, DIMENSION at least max (1, *n*).

If *howmny* = 'S', *select* specifies which eigenvectors are to be computed.

If *howmny* = 'A' or 'B', *select* is not referenced.

For real flavors:

If *omega(j)* is a real eigenvalue, the corresponding real eigenvector is computed if *select(j)* is .TRUE..

If *omega(j)* and *omega(j+1)* are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either *select(j)* or *select(j+1)* is .TRUE., and on exit *select(j)* is set to .TRUE.and *select(j+1)* is set to .FALSE..

For complex flavors:

The eigenvector corresponding to the *j*-th eigenvalue is computed if *select(j)* is .TRUE..

n

INTEGER. The order of the matrix *T* (*n* \geq 0).

t, vl, vr

REAL for strevc

DOUBLE PRECISION for dtrevc

COMPLEX for ctrevc

DOUBLE COMPLEX for ztrevc.

Arrays:

*t(l, l, *)* contains the *n*-by-*n* matrix *T* in Schur canonical form. For complex flavors *ctrevc* and *ztrevc*, contains the upper triangular matrix *T*.

The second dimension of *t* must be at least max(1, *n*).

*vl(l, l, *)*

If *howmny* = 'B' and *side* = 'L' or 'B', then *vl* must contain an *n*-by-*n* matrix *Q* (usually the matrix of Schur vectors returned by ?hseqr).

If *howmny* = 'A' or 'S', then *vl* need not be set.

The second dimension of *vl* must be at least max(1, *mm*) if *side* = 'L' or 'B' and at least 1 if *side* = 'R'.

The array *vl* is not referenced if *side* = 'R'.

vr (*ldvr,**)

If *howmny* = 'B' and *side* = 'R' or 'B', then *vr* must contain an *n*-by-*n* matrix *Q* (usually the matrix of Schur vectors returned by ?hseqr). .

If *howmny* = 'A' or 'S', then *vr* need not be set.

The second dimension of *vr* must be at least $\max(1, mm)$ if *side* = 'R' or 'B' and at least 1 if *side* = 'L'.

The array *vr* is not referenced if *side* = 'L'.

work()* is a workspace array.

DIMENSION at least $\max(1, 3*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

ldt

INTEGER. The leading dimension of *t*; at least $\max(1, n)$.

ldvl

INTEGER. The leading dimension of *vl*.

If *side* = 'L' or 'B', *ldvl* $\geq n$.

If *side* = 'R', *ldvl* ≥ 1 .

ldvr

INTEGER. The leading dimension of *vr*.

If *side* = 'R' or 'B', *ldvr* $\geq n$.

If *side* = 'L', *ldvr* ≥ 1 .

mm

INTEGER. The number of columns in the arrays *vl* and/or *vr*. Must be at least *m* (the precise number of columns required).

If *howmny* = 'A' or 'B', *m* = *n*.

If *howmny* = 'S': for real flavors, *m* is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector; for complex flavors, *m* is the number of selected eigenvectors (see *select*).

Constraint: $0 \leq m \leq n$.

rwork

REAL for *ctrevc*

DOUBLE PRECISION for *ztrrevc*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

select

If a complex eigenvector of a real matrix was selected as specified above, then *select(j)* is set to .TRUE. and *select(j+1)* to .FALSE..

t

COMPLEX for *ctrevc*

DOUBLE COMPLEX for *ztrrevc*.

ctrevc/ztrrevc modify the *t*(*ldt,**) array, which is restored on exit.

vl, vr

If *side* = 'L' or 'B', *vl* contains the computed left eigenvectors (as specified by *howmny* and *select*).

If $\text{side} = \text{'R'}$ or 'B' , vr contains the computed right eigenvectors (as specified by howmny and select).

The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues.

For real flavors: corresponding to each real eigenvalue is a real eigenvector, occupying one column; corresponding to each complex conjugate pair of eigenvalues is a complex eigenvector, occupying two columns; the first column holds the real part and the second column holds the imaginary part.

m

INTEGER.

For complex flavors: the number of selected eigenvectors.

If $\text{howmny} = \text{'A'}$ or 'B' , m is set to n .

For real flavors: the number of columns of vl and/or vr actually used to store the selected eigenvectors.

If $\text{howmny} = \text{'A'}$ or 'B' , m is set to n .

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trevc` interface are the following:

t Holds the matrix T of size (n,n) .

$select$ Holds the vector of length n .

vl Holds the matrix VL of size (n,mm) .

vr Holds the matrix VR of size (n,mm) .

$side$ If omitted, this argument is restored based on the presence of arguments vl and vr as follows:

$side = \text{'B'}$, if both vl and vr are present,

$side = \text{'L'}$, if vr is omitted,

$side = \text{'R'}$, if vl is omitted.

Note that there will be an error condition if both vl and vr are omitted.

$howmny$ If omitted, this argument is restored based on the presence of argument $select$ as follows:

$howmny = \text{'V'}$, if q is present,

$howmny = \text{'N'}$, if q is omitted.

If present, $\text{vect} = \text{'V'}$ or 'U' and the argument q must also be present.

Note that there will be an error condition if both $select$ and $howmny$ are present.

Application Notes

If x_i is an exact right eigenvector and y_i is the corresponding computed eigenvector, then the angle $\theta(y_i, x_i)$ between them is bounded as follows: $\theta(y_i, x_i) \leq (c(n)\epsilon \|T\|_2)/\text{sep}_i$ where sep_i is the reciprocal condition number of x_i . The condition number sep_i may be computed by calling ?trsna.

?trsna

Estimates condition numbers for specified eigenvalues and right eigenvectors of an upper (quasi-) triangular matrix.

Syntax

FORTRAN 77:

```
call strsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm, m, work,
ldwork, iwork, info)

call dtrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm, m, work,
ldwork, iwork, info)

call ctrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm, m, work,
ldwork, rwork, info)

call ztrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm, m, work,
ldwork, rwork, info)
```

Fortran 95:

```
call trsna(t [, s] [,sep] [,vl] [,vr] [,select] [,m] [,info])
```

C:

```
lapack_int LAPACKE_strsna( int matrix_layout, char job, char howmny,
const lapack_logical* select, lapack_int n, const float* t, lapack_int ldt,

Description

The routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix T (or, for real flavors, upper quasi-triangular matrix T in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix $A = Z^*T^*Z^H$ (with unitary or, for real flavors, orthogonal Z), from which T may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue $\lambda(i)$ as $s_i = \|v^T u\| / (\|u\|_E \|v\|_E)$ for real flavors and $s_i = \|v^H u\| / (\|u\|_E \|v\|_E)$ for complex flavors,

where:

- u and v are the right and left eigenvectors of T , respectively, corresponding to `lambda(i)`.
 - v^T/v^H denote transpose/conjugate transpose of v , respectively.

This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue λ_i is then given by $\varepsilon^* \|T\| / s_i$, where ε is the *machine precision*.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to `lambda(i)`, the routine first calls `trexc` to reorder the eigenvalues so that `lambda(i)` is in the leading position:

10.000-10.000

The reciprocal condition number of the eigenvector is then estimated as sep_i , the smallest singular value of the matrix $T_{22} - \lambda(i) * I$. This number ranges from zero (ill-conditioned) to very large (well-conditioned).

An approximate error estimate for a computed right eigenvector u corresponding to $\lambda(i)$ is then given by $\varepsilon^* \|T\| / \text{sep}_i$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

job CHARACTER*1. Must be 'E' or 'V' or 'B'.
 If *job* = 'E', then condition numbers for eigenvalues only are computed.
 If *job* = 'V', then condition numbers for eigenvectors only are computed.
 If *job* = 'B', then condition numbers for both eigenvalues and eigenvectors are computed.

howmny CHARACTER*1. Must be 'A' or 'S'.
 If *howmny* = 'A', then the condition numbers for all eigenpairs are computed.
 If *howmny* = 'S', then condition numbers for selected eigenpairs (as specified by *select*) are computed.

select LOGICAL.

Array, DIMENSION at least $\max(1, n)$ if $howmany = 'S'$ and at least 1 otherwise.

Specifies the eigenpairs for which condition numbers are to be computed if *howmny* = 'S'.

For real flavors:

To select condition numbers for the eigenpair corresponding to the real eigenvalue *lambda(j)*, *select(j)* must be set .TRUE.;

to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues *lambda(j)* and *lambda(j+1)*, *select(j)* and/or *select(j+1)* must be set .TRUE. .

For complex flavors

To select condition numbers for the eigenpair corresponding to the eigenvalue *lambda(j)*, *select(j)* must be set .TRUE. *select* is not referenced if *howmny* = 'A'.

n INTEGER. The order of the matrix *T* (*n* \geq 0).

t, vl, vr, work REAL for strsna

DOUBLE PRECISION for dtrsna

COMPLEX for ctrsna

DOUBLE COMPLEX for ztrsna.

Arrays:

t(ldt,)* contains the *n*-by-*n* matrix *T*.

The second dimension of *t* must be at least max(1, *n*).

vl(ldvl,)*

If *job* = 'E' or 'B', then *vl* must contain the left eigenvectors of *T* (or of any matrix *Q***T***Q*^H with *Q* unitary or orthogonal) corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vl*, as returned by *trevc* or *hsein*.

The second dimension of *vl* must be at least max(1, *mm*) if *job* = 'E' or 'B' and at least 1 if *job* = 'V'.

The array *vl* is not referenced if *job* = 'V'.

vr(ldvr,)*

If *job* = 'E' or 'B', then *vr* must contain the right eigenvectors of *T* (or of any matrix *Q***T***Q*^H with *Q* unitary or orthogonal) corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vr*, as returned by *trevc* or *hsein*.

The second dimension of *vr* must be at least max(1, *mm*) if *job* = 'E' or 'B' and at least 1 if *job* = 'V'.

The array *vr* is not referenced if *job* = 'V'.

work is a workspace array, its dimension (*ldwork*, *n*+6).

The array *work* is not referenced if *job* = 'E'.

ldt INTEGER. The leading dimension of *t*; at least max(1, *n*).

ldvl INTEGER. The leading dimension of *vl*.

If $job = 'E'$ or $'B'$, $ldvl \geq \max(1, n)$.
If $job = 'V'$, $ldvl \geq 1$.

$ldvr$ INTEGER. The leading dimension of vr .
If $job = 'E'$ or $'B'$, $ldvr \geq \max(1, n)$.
If $job = 'R'$, $ldvr \geq 1$.

mm INTEGER. The number of elements in the arrays s and sep , and the number of columns in vl and vr (if used). Must be at least m (the precise number required).
If $howmny = 'A'$, $m = n$;
if $howmny = 'S'$, for real flavors m is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues.
for complex flavors m is the number of selected eigenpairs (see *select*).
Constraint:
 $0 \leq m \leq n$.

$ldwork$ INTEGER. The leading dimension of $work$.
If $job = 'V'$ or $'B'$, $ldwork \geq \max(1, n)$.
If $job = 'E'$, $ldwork \geq 1$.

$rwork$ REAL for ctrnsna , ztrnsna .
Array, DIMENSION at least $\max(1, n)$. The array is not referenced if $job = 'E'$.

$iwork$ INTEGER for strnsna , dtrnsna .
Array, DIMENSION at least $\max(1, 2*(n - 1))$. The array is not referenced if $job = 'E'$.

Output Parameters

s REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.
Array, DIMENSION at least $\max(1, mm)$ if $job = 'E'$ or $'B'$ and at least 1 if $job = 'V'$.
Contains the reciprocal condition numbers of the selected eigenvalues if $job = 'E'$ or $'B'$, stored in consecutive elements of the array. Thus $s(j)$, $sep(j)$ and the j -th columns of vl and vr all correspond to the same eigenpair (but not in general the j th eigenpair unless all eigenpairs have been selected).
For real flavors: for a complex conjugate pair of eigenvalues, two consecutive elements of S are set to the same value. The array s is not referenced if $job = 'V'$.

sep REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, mm)$ if $job = 'V'$ or ' B ' and at least 1 if $job = 'E'$. Contains the estimated reciprocal condition numbers of the selected right eigenvectors if $job = 'V'$ or ' B ', stored in consecutive elements of the array.

For real flavors: for a complex eigenvector, two consecutive elements of sep are set to the same value; if the eigenvalues cannot be reordered to compute $sep(j)$, then $sep(j)$ is set to zero; this can only occur when the true value would be very small anyway. The array sep is not referenced if $job = 'E'$.

m

INTEGER.

For complex flavors: the number of selected eigenpairs.If $howmny = 'A'$, m is set to n .*For real flavors:* the number of elements of s and/or sep actually used to store the estimated condition numbers.If $howmny = 'A'$, m is set to n .*info*

INTEGER.

If $info = 0$, the execution is successful.If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsna` interface are the following:

<i>t</i>	Holds the matrix T of size (n,n) .
<i>s</i>	Holds the vector of length (mm) .
<i>sep</i>	Holds the vector of length (mm) .
<i>vl</i>	Holds the matrix VL of size (n,mm) .
<i>vr</i>	Holds the matrix VR of size (n,mm) .
<i>select</i>	Holds the vector of length n .
<i>job</i>	Restored based on the presence of arguments <i>s</i> and <i>sep</i> as follows: $job = 'B'$, if both <i>s</i> and <i>sep</i> are present, $job = 'E'$, if <i>s</i> is present and <i>sep</i> omitted, $job = 'V'$, if <i>s</i> is omitted and <i>sep</i> present. Note an error condition if both <i>s</i> and <i>sep</i> are omitted.
<i>howmny</i>	Restored based on the presence of the argument <i>select</i> as follows: $howmny = 'S'$, if <i>select</i> is present, $howmny = 'A'$, if <i>select</i> is omitted.

Note that the arguments s , vl , and vr must either be all present or all omitted.

Otherwise, an error condition is observed.

Application Notes

The computed values sep_i may overestimate the true value, but seldom by a factor of more than 3.

?trexc

Reorders the Schur factorization of a general matrix.

Syntax

FORTRAN 77:

```
call strexc(compq, n, t, ldt, q, ldq, ifst, ilst, work, info)

- C: mkl.h

Description

The routine reorders the Schur factorization of a general matrix $A = Q^H T Q^H$, so that the diagonal element or block of T with row index $ifst$ is moved to row $ilst$.

The reordered Schur form S is computed by an unitary (or, for real flavors, orthogonal) similarity transformation: $S = Z^H T Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q Z$, giving $A = P S P^H$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>compq</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>compq</i> = 'V', then the Schur vectors (<i>Q</i>) are updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> (<i>n</i> ≥ 0).
<i>t, q</i>	REAL for <i>strexc</i> DOUBLE PRECISION for <i>dtrexc</i> COMPLEX for <i>ctrexc</i> DOUBLE COMPLEX for <i>ztrexc</i> . Arrays: <i>t</i> (<i>ldt</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix <i>T</i> . The second dimension of <i>t</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> ,*) If <i>compq</i> = 'V', then <i>q</i> must contain <i>Q</i> (Schur vectors). If <i>compq</i> = 'N', then <i>q</i> is not referenced. The second dimension of <i>q</i> must be at least $\max(1, n)$ if <i>compq</i> = 'V' and at least 1 if <i>compq</i> = 'N'.
<i>ldt</i>	INTEGER. The leading dimension of <i>t</i> ; at least $\max(1, n)$.
<i>ldq</i>	INTEGER. The leading dimension of <i>q</i> ; If <i>compq</i> = 'N', then <i>ldq</i> ≥ 1. If <i>compq</i> = 'V', then <i>ldq</i> ≥ $\max(1, n)$.
<i>ifst, ilst</i>	INTEGER. $1 \leq \text{ifst} \leq n$; $1 \leq \text{ilst} \leq n$. Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix <i>T</i> . The element (or block) with row index <i>ifst</i> is moved to row <i>ilst</i> by a sequence of exchanges between adjacent elements (or blocks).
<i>work</i>	REAL for <i>strexc</i> DOUBLE PRECISION for <i>dtrexc</i> . Array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>t</i>	Overwritten by the updated matrix <i>S</i> .
<i>q</i>	If <i>compq</i> = 'V', <i>q</i> contains the updated matrix of Schur vectors.
<i>ifst, ilst</i>	Overwritten for real flavors only. If <i>ifst</i> pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; <i>ilst</i> always points to the first row of the block in its final position (which may differ from its input value by ±1).

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.
-------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trexc` interface are the following:

<i>t</i>	Holds the matrix T of size (n,n).
<i>q</i>	Holds the matrix Q of size (n,n).
<i>compq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>compq</i> = 'V', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted.

Application Notes

The computed matrix S is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision.

Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The values of eigenvalues however are never changed by the re-ordering.

The approximate number of floating-point operations is

for real flavors:	$6n(ifst-ilst)$ if <i>compq</i> = 'N'; $12n(ifst-ilst)$ if <i>compq</i> = 'V';
for complex flavors:	$20n(ifst-ilst)$ if <i>compq</i> = 'N'; $40n(ifst-ilst)$ if <i>compq</i> = 'V'.

?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

FORTRAN 77:

```
call strsen(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work, lwork,
iwork, liwork, info)

call dtrsen(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work, lwork,
iwork, liwork, info)

call ctrsen(job, compq, select, n, t, ldt, q, ldq, w, m, s, sep, work, lwork, info)
```

```

Description

The routine reorders the Schur factorization of a general matrix $A = Q*T*Q^T$ (for real flavors) or $A = Q*T*Q^H$ (for complex flavors) so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form R is computed by a unitary (orthogonal) similarity transformation: $R = Z^H*T*Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q*Z$, giving $A = P*R*P^H$.

Let

... :::::::

where the selected eigenvalues are precisely the eigenvalues of the leading m -by- m submatrix T_{11} . Let P be correspondingly partitioned as $(Q_1 \ Q_2)$ where Q_1 consists of the first m columns of Q . Then $A*Q_1 = Q_1*T_{11}$, and so the m columns of Q_1 form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Must be 'N' or 'E' or 'V' or 'B'. If <i>job</i> = 'N', then no condition numbers are required. If <i>job</i> = 'E', then only the condition number for the cluster of eigenvalues is computed. If <i>job</i> = 'V', then only the condition number for the invariant subspace is computed. If <i>job</i> = 'B', then condition numbers for both the cluster and the invariant subspace are computed.
<i>compq</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>compq</i> = 'V', then <i>Q</i> of the Schur vectors is updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). Specifies the eigenvalues in the selected cluster. To select an eigenvalue <i>lambda(j)</i> , <i>select(j)</i> must be .TRUE.. <i>For real flavors:</i> to select a complex conjugate pair of eigenvalues <i>lambda(j)</i> and <i>lambda(j+1)</i> (corresponding 2 by 2 diagonal block), <i>select(j)</i> and/or <i>select(j+1)</i> must be .TRUE.; the complex conjugate <i>lambda(j)</i> and <i>lambda(j+1)</i> must be either both included in the cluster or both excluded.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> (<i>n</i> \geq 0).
<i>t, q, work</i>	REAL for strsen DOUBLE PRECISION for dtrsen COMPLEX for ctrsen DOUBLE COMPLEX for ztrsen. Arrays: <i>t (ldt,*)</i> The <i>n</i> -by- <i>n</i> <i>T</i> . The second dimension of <i>t</i> must be at least max(1, <i>n</i>). <i>q (ldq,*)</i> If <i>compq</i> = 'V', then <i>q</i> must contain <i>Q</i> of Schur vectors. If <i>compq</i> = 'N', then <i>q</i> is not referenced. The second dimension of <i>q</i> must be at least max(1, <i>n</i>) if <i>compq</i> = 'V' and at least 1 if <i>compq</i> = 'N'. <i>work</i> is a workspace array, its dimension max(1, <i>lwork</i>). <i>ldt</i> INTEGER. The leading dimension of <i>t</i> ; at least max(1, <i>n</i>).

<i>ldq</i>	INTEGER. The leading dimension of <i>q</i> ; If <i>compq</i> = 'N', then <i>ldq</i> ≥ 1 . If <i>compq</i> = 'V', then <i>ldq</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . If <i>job</i> = 'V' or 'B', <i>lwork</i> $\geq \max(1, 2*m*(n-m))$. If <i>job</i> = 'E', then <i>lwork</i> $\geq \max(1, m*(n-m))$ If <i>job</i> = 'N', then <i>lwork</i> ≥ 1 for complex flavors and <i>lwork</i> $\geq \max(1, n)$ for real flavors. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. <i>iwork</i> (<i>liwork</i>) is a workspace array. The array <i>iwork</i> is not referenced if <i>job</i> = 'N' or 'E'. The actual amount of workspace required cannot exceed $n^2/2$ if <i>job</i> = 'V' or 'B'.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i> . If <i>job</i> = 'V' or 'B', <i>liwork</i> $\geq \max(1, 2m(n-m))$. If <i>job</i> = 'E' or 'E', <i>liwork</i> ≥ 1 . If <i>liwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for details.

Output Parameters

<i>t</i>	Overwritten by the updated matrix <i>R</i> .
<i>q</i>	If <i>compq</i> = 'V', <i>q</i> contains the updated matrix of Schur vectors; the first <i>m</i> columns of the <i>Q</i> form an orthogonal basis for the specified invariant subspace.
<i>w</i>	COMPLEX for <i>ctrsen</i> DOUBLE COMPLEX for <i>ztrsen</i> . Array, DIMENSION at least $\max(1, n)$. The recorded eigenvalues of <i>R</i> . The eigenvalues are stored in the same order as on the diagonal of <i>R</i> .
<i>wr, wi</i>	REAL for <i>strsen</i> DOUBLE PRECISION for <i>dtrsen</i>

Arrays, DIMENSION at least $\max(1, n)$. Contain the real and imaginary parts, respectively, of the reordered eigenvalues of R . The eigenvalues are stored in the same order as on the diagonal of R . Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m

INTEGER.

For complex flavors: the number of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see *select*).

For real flavors: the dimension of the specified invariant subspace. The value of *m* is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see *select*).

Constraint: $0 \leq m \leq n$.

s

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

If *job* = 'E' or 'B', *s* is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues.

If *m* = 0 or *n*, then *s* = 1.

For real flavors: if *info* = 1, then *s* is set to zero. *s* is not referenced if *job* = 'N' or 'V'.

sep

REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

If *job* = 'V' or 'B', *sep* is the estimated reciprocal condition number of the specified invariant subspace.

If *m* = 0 or *n*, then *sep* = $|T|$.

For real flavors: if *info* = 1, then *sep* is set to zero.

sep is not referenced if *job* = 'N' or 'E'.

work(1)

On exit, if *info* = 0, then *work(1)* returns the optimal size of *lwork*.

iwork(1)

On exit, if *info* = 0, then *iwork(1)* returns the optimal size of *liwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trsen* interface are the following:

t

Holds the matrix T of size (n,n) .

select

Holds the vector of length *n*.

<i>wr</i>	Holds the vector of length n . Used in real flavors only.
<i>wi</i>	Holds the vector of length n . Used in real flavors only.
<i>w</i>	Holds the vector of length n . Used in complex flavors only.
<i>q</i>	Holds the matrix Q of size (n,n) .
<i>compq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>compq</i> = 'V', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted.
<i>job</i>	Restored based on the presence of arguments <i>s</i> and <i>sep</i> as follows: <i>job</i> = 'B', if both <i>s</i> and <i>sep</i> are present, <i>job</i> = 'E', if <i>s</i> is present and <i>sep</i> omitted, <i>job</i> = 'V', if <i>s</i> is omitted and <i>sep</i> present, <i>job</i> = 'N', if both <i>s</i> and <i>sep</i> are omitted.

Application Notes

The computed matrix R is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\varepsilon) * \|T\|_2$, and ε is the machine precision. The computed s cannot underestimate the true reciprocal condition number by more than a factor of $(\min(m, n-m))^{1/2}$; *sep* may differ from the true value by $(m^2 * n - m^2)^{1/2}$. The angle between the computed invariant subspace and the true subspace is $O(\varepsilon) * \|A\|_2 / \text{sep}$. Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real. The values of eigenvalues however are never changed by the re-ordering.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?trsyl

Solves Sylvester equation for real quasi-triangular or complex triangular matrices.

Syntax

FORTRAN 77:

```
call strsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call dtrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ctrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ztrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
```

Fortran 95:

```
call trsyl(a, b, c, scale [, transa] [, transb] [, isgn] [, info])
```

C:

```
lapack_int LAPACKE_strsyl( int matrix_layout, char transa, char transb, lapack_int isgn,
                           lapack_int m, lapack_int n, const float* a, lapack_int lda, const float* b, lapack_int ldb,
                           float* c, lapack_int ldc, float* scale );

 - Fortran 95: lapack.f90
 - C: mkl.h

Description

The routine solves the Sylvester matrix equation $\text{op}(A) * X \pm X * \text{op}(B) = \alpha * C$, where $\text{op}(A) = A$ or A^H , and the matrices A and B are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form); $\alpha \leq 1$ is a scale factor determined by the routine to avoid overflow in X ; A is m -by- m , B is n -by- n , and C and X are both m -by- n . The matrix X is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if $\alpha_i \pm \beta_i \neq 0$, where $\{\alpha_i\}$ and $\{\beta_i\}$ are the eigenvalues of A and B , respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

If $trans = 'N'$, then $op(A) = A$.

If $trans = 'T'$, then $\text{op}(A) = A^T$

If $\text{trans} = 'C'$ then $\text{op}(A) = A^H$.

CHARACTER^AT. Must Be N^A OR T^A OR C^A.

If $\text{trans} = \cdot N \cdot$, then $\text{op}(B) = B$.

If $transb = 'T'$, then $\text{op}(B) = B^\top$ (real flavors only).

If $trans = 'C'$, then $op(B) = B^H$.

<i>isgn</i>	INTEGER. Indicates the form of the Sylvester equation. If <i>isgn</i> = +1, $\text{op}(A) * X + X * \text{op}(B) = \text{alpha} * C$. If <i>isgn</i> = -1, $\text{op}(A) * X - X * \text{op}(B) = \text{alpha} * C$.
<i>m</i>	INTEGER. The order of <i>A</i> , and the number of rows in <i>X</i> and <i>C</i> (<i>m</i> ≥ 0).
<i>n</i>	INTEGER. The order of <i>B</i> , and the number of columns in <i>X</i> and <i>C</i> (<i>n</i> ≥ 0).
<i>a, b, c</i>	REAL for <i>strsyl</i> DOUBLE PRECISION for <i>dtrsyl</i> COMPLEX for <i>ctrsyl</i> DOUBLE COMPLEX for <i>ztrsyl</i> .
	Arrays: <i>a</i> (<i>lda</i> ,*) contains the matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, m)$. <i>b</i> (<i>ldb</i> ,*) contains the matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix <i>C</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> ; at least $\max(1, n)$.

Output Parameters

<i>c</i>	Overwritten by the solution matrix <i>X</i> .
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. The value of the scale factor <i>α</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, <i>A</i> and <i>B</i> have common or close eigenvalues perturbed values were used to solve the equation.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trsyl* interface are the following:

<i>a</i>	Holds the matrix A of size (m,m) .
<i>b</i>	Holds the matrix B of size (n,n) .
<i>c</i>	Holds the matrix C of size (m,n) .
<i>trana</i>	Must be ' <i>N</i> ', ' <i>C</i> ', or ' <i>T</i> '. The default value is ' <i>N</i> '.
<i>tranb</i>	Must be ' <i>N</i> ', ' <i>C</i> ', or ' <i>T</i> '. The default value is ' <i>N</i> '.
<i>isgn</i>	Must be +1 or -1. The default value is +1.

Application Notes

Let X be the exact, Y the corresponding computed solution, and R the residual matrix: $R = C - (AY \pm YB)$. Then the residual is always small:

$$\|R\|_F = O(\varepsilon) * (\|A\|_F + \|B\|_F) * \|Y\|_F.$$

However, Y is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.

For the forward error, the following bound holds:

$$\|Y - X\|_F \leq \|R\|_F / \text{sep}(A, B)$$

but this may be a considerable overestimate. See [Golub96] for a definition of $\text{sep}(A, B)$.

The approximate number of floating-point operations for real flavors is $m^* n^* (m + n)$. For complex flavors it is 4 times greater.

Generalized Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A *generalized nonsymmetric eigenvalue problem* is as follows: given a pair of nonsymmetric (or non-Hermitian) n -by- n matrices A and B , find the *generalized eigenvalues* λ and the corresponding *generalized eigenvectors* x and y that satisfy the equations

$$Ax = \lambda Bx \quad (\text{right generalized eigenvectors } x)$$

and

$$y^H A = \lambda y^H B \quad (\text{left generalized eigenvectors } y).$$

Table "Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems" lists LAPACK routines (FORTRAN 77 interface) used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems

Routine name	Operation performed
gghrd	Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.
ggbal	Balances a pair of general real or complex matrices.
ggbak	Forms the right or left eigenvectors of a generalized eigenvalue problem.
hgeqz	Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H, T) .

Routine name	Operation performed
tgevc	Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices
tgexc	Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.
tgsen	Reorders the <i>generalized</i> Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B).
tgsyl	Solves the generalized Sylvester equation.
tgsyl	Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

?gghrd

Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.

Syntax**FORTRAN 77:**

```
call sgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call dgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call cgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call zgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
```

Fortran 95:

```
call gghrd(a, b [,ilo] [,ihi] [,q] [,z] [,compq] [,compz] [,info])
```

C:

```
lapack_int LAPACKE_<?>gghrd( int matrix_layout, char compq, char compz, lapack_int n,

Description

The routine reduces a pair of real/complex matrices (A, B) to generalized upper Hessenberg form using orthogonal/unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is $A^*x = \lambda^*B^*x$, and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This routine simultaneously reduces A to a Hessenberg matrix H :

$$Q^H A^* Z = H$$

and transforms B to another upper triangular matrix T :

$$Q^H B^* Z = T$$

in order to reduce the problem to its standard form $H^*y = \lambda^*T^*y$, where $y = Z^H x$.

The orthogonal/unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

$$Q_1^* A^* Z_1^H = (Q_1^* Q)^* H^* (Z_1^* Z)^H$$

$$Q_1^* B^* Z_1^H = (Q_1^* Q)^* T^* (Z_1^* Z)^H$$

If Q_1 is the orthogonal/unitary matrix from the QR factorization of B in the original equation $A^* x = \lambda^* B^* x$, then the routine ?gghrd reduces the original problem to generalized Hessenberg form.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>compq</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', matrix Q is not computed. If <i>compq</i> = 'I', Q is initialized to the unit matrix, and the orthogonal/unitary matrix Q is returned; If <i>compq</i> = 'V', Q must contain an orthogonal/unitary matrix Q_1 on entry, and the product $Q_1^* Q$ is returned.
<i>compz</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', matrix Z is not computed. If <i>compz</i> = 'I', Z is initialized to the unit matrix, and the orthogonal/unitary matrix Z is returned; If <i>compz</i> = 'V', Z must contain an orthogonal/unitary matrix Z_1 on entry, and the product $Z_1^* Z$ is returned.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. <i>ilo</i> and <i>ihi</i> mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. Values of <i>ilo</i> and <i>ihi</i> are normally set by a previous call to ggbal ; otherwise they should be set to 1 and n respectively. Constraint: If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>a, b, q, z</i>	REAL for sgghrd DOUBLE PRECISION for dgghrd COMPLEX for cgghrd DOUBLE COMPLEX for zgghrd. Arrays: <i>a</i> (<i>lda,*</i>) contains the n -by- n general matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb,*</i>) contains the n -by- n upper triangular matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq,*</i>)

If $\text{compq} = \text{'N'}$, then q is not referenced.

If $\text{compq} = \text{'V'}$, then q must contain the orthogonal/unitary matrix Q_1 , typically from the QR factorization of B .

The second dimension of q must be at least $\max(1, n)$.

z ($ldz, *$)

If $\text{compz} = \text{'N'}$, then z is not referenced.

If $\text{compz} = \text{'V'}$, then z must contain the orthogonal/unitary matrix Z_1 .

The second dimension of z must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, n)$.

ldq INTEGER. The leading dimension of q ;

If $\text{compq} = \text{'N'}$, then $ldq \geq 1$.

If $\text{compq} = \text{'I'}$ or 'V' , then $ldq \geq \max(1, n)$.

ldz INTEGER. The leading dimension of z ;

If $\text{compz} = \text{'N'}$, then $ldz \geq 1$.

If $\text{compz} = \text{'I'}$ or 'V' , then $ldz \geq \max(1, n)$.

Output Parameters

a On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H , and the rest is set to zero.

b On exit, overwritten by the upper triangular matrix $T = Q^H * B * Z$. The elements below the diagonal are set to zero.

q If $\text{compq} = \text{'I'}$, then q contains the orthogonal/unitary matrix Q ;
If $\text{compq} = \text{'V'}$, then q is overwritten by the product $Q_1 * Q$.

z If $\text{compz} = \text{'I'}$, then z contains the orthogonal/unitary matrix Z ;
If $\text{compz} = \text{'V'}$, then z is overwritten by the product $Z_1 * Z$.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gghrd` interface are the following:

a Holds the matrix A of size (n,n) .

<i>b</i>	Holds the matrix <i>B</i> of size (<i>n,n</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n,n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n,n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>compq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>compq</i> = 'I', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>compq</i> is present and <i>q</i> omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note that there will be an error condition if <i>compz</i> is present and <i>z</i> omitted.

?ggbal*Balances a pair of general real or complex matrices.***Syntax****FORTRAN 77:**

```

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine balances a pair of general real/complex matrices (A, B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to $ilo-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A^*x = \lambda * B^*x$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Specifies the operations to be performed on A and B . Must be 'N' or 'P' or 'S' or 'B'. If <i>job</i> = 'N', then no operations are done; simply set <i>ilo</i> =1, <i>ihi</i> = <i>n</i> , <i>lscale(i)</i> =1.0 and <i>rscale(i)</i> =1.0 for <i>i</i> = 1, ..., <i>n</i> . If <i>job</i> = 'P', then permute only. If <i>job</i> = 'S', then scale only. If <i>job</i> = 'B', then both permute and scale.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b</i>	REAL for sggbal DOUBLE PRECISION for dggbal COMPLEX for cggbal DOUBLE COMPLEX for zggbal. Arrays: <i>a(lda, *)</i> contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b(ldb, *)</i> contains the matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. If <i>job</i> = 'N', <i>a</i> and <i>b</i> are not referenced.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$.
<i>work</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, 6n)$ when $\text{job} = \text{'S'}$ or 'B' , or at least 1 when $\text{job} = \text{'N'}$ or 'P' .

Output Parameters

a, b	Overwritten by the balanced matrices A and B , respectively.
ilo, ihi	INTEGER. ilo and ihi are set to integers such that on exit $a(i,j)=0$ and $b(i,j)=0$ if $i > j$ and $j=1, \dots, ilo-1$ or $i=ihi+1, \dots, n$. If $\text{job} = \text{'N'}$ or 'S' , then $ilo = 1$ and $ihi = n$.
$lscale, rscale$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, n)$. $lscale$ contains details of the permutations and scaling factors applied to the left side of A and B . If P_j is the index of the row interchanged with row j , and D_j is the scaling factor applied to row j , then $\begin{aligned} lscale(j) &= P_j, \text{ for } j = 1, \dots, ilo-1 \\ &= D_j, \text{ for } j = ilo, \dots, ihi \\ &= P_j, \text{ for } j = ihi+1, \dots, n. \end{aligned}$ $rscale$ contains details of the permutations and scaling factors applied to the right side of A and B . If P_j is the index of the column interchanged with column j , and D_j is the scaling factor applied to column j , then $\begin{aligned} rscale(j) &= P_j, \text{ for } j = 1, \dots, ilo-1 \\ &= D_j, \text{ for } j = ilo, \dots, ihi \\ &= P_j, \text{ for } j = ihi+1, \dots, n \end{aligned}$ The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggbal` interface are the following:

a	Holds the matrix A of size (n,n) .
b	Holds the matrix B of size (n,n) .
$lscale$	Holds the vector of length (n) .

<i>rscale</i>	Holds the vector of length (<i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

?ggbak

Forms the right or left eigenvectors of a generalized eigenvalue problem.

Syntax**FORTRAN 77:**

```
call sggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call dggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call cggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call zggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
```

Fortran 95:

```
call ggbak(v [, ilo] [, ihi] [, lscale] [, rscale] [, job] [, info])
```

C:

```
lapack_int LAPACKE_sggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int
m, float* v, lapack_int ldv );

lapack_int LAPACKE_dggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int
m, double* v, lapack_int ldv );

lapack_int LAPACKE_cggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int
m, lapack_complex_float* v, lapack_int ldv );

lapack_int LAPACKE_zggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

$$A^*x = \lambda B^*x$$

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by [ggbal](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'. If <i>job</i> = 'N', then no operations are done; return. If <i>job</i> = 'P', then do backward transformation for permutation only. If <i>job</i> = 'S', then do backward transformation for scaling only. If <i>job</i> = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument <i>job</i> supplied to ?ggbal.
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then <i>v</i> contains left eigenvectors. If <i>side</i> = 'R', then <i>v</i> contains right eigenvectors.
<i>n</i>	INTEGER. The number of rows of the matrix <i>V</i> (<i>n</i> \geq 0).
<i>ilo, ihi</i>	INTEGER. The integers <i>ilo</i> and <i>ihi</i> determined by ?gbal. Constraint: If <i>n</i> > 0, then $1 \leq ilo \leq ihi \leq n$; if <i>n</i> = 0, then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>lscale, rscale</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least max(1, <i>n</i>). The array <i>lscale</i> contains details of the permutations and/or scaling factors applied to the left side of <i>A</i> and <i>B</i> , as returned by ?ggbal. The array <i>rscale</i> contains details of the permutations and/or scaling factors applied to the right side of <i>A</i> and <i>B</i> , as returned by ?ggbal.
<i>m</i>	INTEGER. The number of columns of the matrix <i>V</i> (<i>m</i> \geq 0).
<i>v</i>	REAL for sggbak DOUBLE PRECISION for dggbak COMPLEX for cggbak DOUBLE COMPLEX for zggbak. Array <i>v</i> (<i>ldv</i> ,*). Contains the matrix of right or left eigenvectors to be transformed, as returned by tgevc. The second dimension of <i>v</i> must be at least max(1, <i>m</i>).
<i>ldv</i>	INTEGER. The leading dimension of <i>v</i> ; at least max(1, <i>n</i>).

Output Parameters

<i>v</i>	Overwritten by the transformed eigenvectors
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggbak` interface are the following:

<i>v</i>	Holds the matrix <i>V</i> of size (<i>n,m</i>).
<i>lscale</i>	Holds the vector of length <i>n</i> .
<i>rscale</i>	Holds the vector of length <i>n</i> .
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.
<i>side</i>	If omitted, this argument is restored based on the presence of arguments <i>lscale</i> and <i>rscale</i> as follows: <i>side</i> = 'L', if <i>lscale</i> is present and <i>rscale</i> omitted, <i>side</i> = 'R', if <i>lscale</i> is omitted and <i>rscale</i> present. Note that there will be an error condition if both <i>lscale</i> and <i>rscale</i> are present or if they both are omitted.

?hgeqz

Implements the QZ method for finding the generalized eigenvalues of the matrix pair (*H,T*).

Syntax

FORTRAN 77:

```
call shgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphar, alphai, beta, q,
ldq, z, ldz, work, lwork, info)

call dhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphar, alphai, beta, q,
ldq, z, ldz, work, lwork, info)

call chgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q, ldq, z,
ldz, work, lwork, rwork, info)

call zhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q, ldq, z,
ldz, work, lwork, rwork, info)
```

Fortran 95:

```
call hgeqz(h, t [,ilo] [,ihi] [,alphar] [,alphai] [,beta] [,q] [,z] [,job] [,compq]
[,compz] [,info])
```

```
call hgeqz(h, t [,ilo] [,ihi] [,alpha] [,beta] [,q] [,z] [,job] [,compq] [, compz]
[,info])

Description

The routine computes the eigenvalues of a real/complex matrix pair (H, T) , where H is an upper Hessenberg matrix and T is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair (A, B) :

$$A = Q_1^* H^* Z_1^H, \quad B = Q_1^* T^* Z_1^H,$$

as computed by ?gghrd.

For real flavors:

If $job = 'S'$, then the Hessenberg-triangular pair (H, T) is also reduced to generalized Schur form,

$$H = Q^* S^* Z^T, \quad T = Q^* P^* Z^T,$$

where Q and Z are orthogonal matrices, P is an upper triangular matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (H, T) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, that is, if $S(j+1, j)$ is non-zero, then $P(j+1, j) = P(j, j+1) = 0$, $P(j, j) > 0$, and $P(j+1, j+1) > 0$.

For complex flavors:

If $job = 'S'$, then the Hessenberg-triangular pair (H, T) is also reduced to generalized Schur form,

$$H = Q^* S^* Z^H, T = Q^* P^* Z^H,$$

where Q and Z are unitary matrices, and S and P are upper triangular.

For all function flavors:

Optionally, the orthogonal/unitary matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q_1 , and the orthogonal/unitary matrix Z may be postmultiplied into an input matrix Z_1 .

If Q_1 and Z_1 are the orthogonal/unitary matrices from ?gghrd that reduced the matrix pair (A,B) to generalized upper Hessenberg form, then the output matrices $Q_1 Q$ and $Z_1 Z$ are the orthogonal/unitary factors from the generalized Schur factorization of (A,B) :

$$A = (Q_1 Q)^* S^* (Z_1 Z)^H, B = (Q_1 Q)^* P^* (Z_1 Z)^H.$$

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of values (α,β) . For chgeqz/zhgeqz, α and β are complex, and for shgeqz/dhgeqz, α is complex and β real. If β is nonzero, $\lambda = \alpha/\beta$ is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

$$A^* x = \lambda B^* x$$

and if α is nonzero, $\mu = \beta/\alpha$ is an eigenvalue of the alternate form of the GNEP

$$\mu^* A^* y = B^* y.$$

Real eigenvalues (for real flavors) or the values of α and β for the i -th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

$$\alpha = S(i,i), \beta = P(i,i).$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Specifies the operations to be performed. Must be 'E' or 'S'. If <i>job</i> = 'E', then compute eigenvalues only; If <i>job</i> = 'S', then compute eigenvalues and the Schur form.
<i>compq</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', left Schur vectors (<i>q</i>) are not computed; If <i>compq</i> = 'I', <i>q</i> is initialized to the unit matrix and the matrix of left Schur vectors of (H,T) is returned; If <i>compq</i> = 'V', <i>q</i> must contain an orthogonal/unitary matrix Q_1 on entry and the product $Q_1^* Q$ is returned.
<i>compz</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', right Schur vectors (<i>z</i>) are not computed; If <i>compz</i> = 'I', <i>z</i> is initialized to the unit matrix and the matrix of right Schur vectors of (H,T) is returned; If <i>compz</i> = 'V', <i>z</i> must contain an orthogonal/unitary matrix Z_1 on entry and the product $Z_1^* Z$ is returned.

n INTEGER. The order of the matrices H , T , Q , and Z

$(n \geq 0)$.

ilo, ihi

INTEGER. *ilo* and *ihi* mark the rows and columns of *H* which are in Hessenberg form. It is assumed that *H* is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$.

Constraint:

If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
if $n = 0$, then $ilo = 1$ and $ihi = 0$.

h, t, q, z, work

REAL for shgeqz
DOUBLE PRECISION for dhgeqz
COMPLEX for chgeqz
DOUBLE COMPLEX for zhgeqz.

Arrays:

On entry, *h*(*ldh,**) contains the n -by- n upper Hessenberg matrix *H*.

The second dimension of *h* must be at least $\max(1, n)$.

On entry, *t*(*ldt,**) contains the n -by- n upper triangular matrix *T*.

The second dimension of *t* must be at least $\max(1, n)$.

q (*ldq,**):

On entry, if *compq* = 'V', this array contains the orthogonal/unitary matrix Q_1 used in the reduction of (A,B) to generalized Hessenberg form.

If *compq* = 'N', then *q* is not referenced.

The second dimension of *q* must be at least $\max(1, n)$.

z (*ldz,**):

On entry, if *compz* = 'V', this array contains the orthogonal/unitary matrix Z_1 used in the reduction of (A,B) to generalized Hessenberg form.

If *compz* = 'N', then *z* is not referenced.

The second dimension of *z* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

ldh

INTEGER. The leading dimension of *h*; at least $\max(1, n)$.

ldt

INTEGER. The leading dimension of *t*; at least $\max(1, n)$.

ldq

INTEGER. The leading dimension of *q*;

If *compq* = 'N', then *ldq* ≥ 1 .

If *compq* = 'I' or 'V', then *ldq* $\geq \max(1, n)$.

ldz

INTEGER. The leading dimension of *z*;

If *compz* = 'N', then *ldz* ≥ 1 .

If *compz* = 'I' or 'V', then *ldz* $\geq \max(1, n)$.

lwork

INTEGER. The dimension of the array *work*.

lwork $\geq \max(1, n)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by **xerbla**. See *Application Notes* for details.

rwork

REAL for chgeqz

DOUBLE PRECISION for zhgeqz.

Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.

Output Parameters

h

For real flavors:

If *job* = 'S', then on exit *h* contains the upper quasi-triangular matrix *S* from the generalized Schur factorization.

If *job* = 'E', then on exit the diagonal blocks of *h* match those of *S*, but the rest of *h* is unspecified.

For complex flavors:

If *job* = 'S', then, on exit, *h* contains the upper triangular matrix *S* from the generalized Schur factorization.

If *job* = 'E', then on exit the diagonal of *h* matches that of *S*, but the rest of *h* is unspecified.

t

If *job* = 'S', then, on exit, *t* contains the upper triangular matrix *P* from the generalized Schur factorization.

For real flavors:

2-by-2 diagonal blocks of *P* corresponding to 2-by-2 blocks of *S* are reduced to positive diagonal form, that is, if *h*(*j*+1,*j*) is non-zero, then *t*(*j*+1, *j*)=*t*(*j*, *j*+1)=0 and *t*(*j*, *j*) and *t*(*j*+1, *j*+1) will be positive.

If *job* = 'E', then on exit the diagonal blocks of *t* match those of *P*, but the rest of *t* is unspecified.

For complex flavors:

if *job* = 'E', then on exit the diagonal of *t* matches that of *P*, but the rest of *t* is unspecified.

alphar, alphai

REAL for shgeqz;

DOUBLE PRECISION for dhgeqz.

Arrays, DIMENSION at least $\max(1, n)$. The real and imaginary parts, respectively, of each scalar *alpha* defining an eigenvalue of GNEP.

If *alphai*(*j*) is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-th eigenvalues are a complex conjugate pair, with

alphai(*j*+1) = -*alphai*(*j*).

alpha

COMPLEX for chgeqz;

DOUBLE COMPLEX for zhgeqz.

Array, DIMENSION at least max(1, n).

The complex scalars *alpha* that define the eigenvalues of GNEP. *alphai(i) = S(i,i)* in the generalized Schur factorization.

beta

REAL for shgeqz
DOUBLE PRECISION for dhgeqz
COMPLEX for chgeqz
DOUBLE COMPLEX for zhgeqz.

Array, DIMENSION at least max(1, n).

For real flavors:

The scalars *beta* that define the eigenvalues of GNEP.

Together, the quantities *alpha = (alphar(j), alphai(j))* and *beta = beta(j)* represent the j-th eigenvalue of the matrix pair (A, B) , in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.

For complex flavors:

The real non-negative scalars *beta* that define the eigenvalues of GNEP.

beta(i) = P(i,i) in the generalized Schur factorization. Together, the quantities *alpha = alpha(j)* and *beta = beta(j)* represent the j-th eigenvalue of the matrix pair (A, B) , in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.

q

On exit, if *compq = 'I'*, *q* is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair (H, T) , and if *compq = 'V'*, *q* is overwritten by the orthogonal/unitary matrix of left Schur vectors of (A, B) .

z

On exit, if *compz = 'I'*, *z* is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair (H, T) , and if *compz = 'V'*, *z* is overwritten by the orthogonal/unitary matrix of right Schur vectors of (A, B) .

work(1)

If *info ≥ 0*, on exit, *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.

If *info = 0*, the execution is successful.

If *info = -i*, the *i*-th parameter had an illegal value.

If *info = 1, ..., n*, the QZ iteration did not converge.

(H, T) is not in Schur form, but *alphar(i)*, *alphai(i)* (for real flavors), *alpha(i)* (for complex flavors), and *beta(i)*, $i=info+1, \dots, n$ should be correct.

If *info = n+1, ..., 2n*, the shift calculation failed.

(H, T) is not in Schur form, but *alphar(i)*, *alphai(i)* (for real flavors), *alpha(i)* (for complex flavors), and *beta(i)*, $i = info-n+1, \dots, n$ should be correct.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hgeqz` interface are the following:

<i>h</i>	Holds the matrix H of size (n,n) .
<i>t</i>	Holds the matrix T of size (n,n) .
<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alphai</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>q</i>	Holds the matrix Q of size (n,n) .
<i>z</i>	Holds the matrix Z of size (n,n) .
<i>ilo</i>	Default value for this argument is $ilo = 1$.
<i>ihi</i>	Default value for this argument is $ihi = n$.
<i>job</i>	Must be 'E' or 'S'. The default value is 'E'.
<i>compq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>compq</i> = 'I', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>compq</i> is present and <i>q</i> omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note an error condition if <i>compz</i> is present and <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgevc

Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.

Syntax

FORTRAN 77:

```
call stgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm, m, work, info)
call dtgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm, m, work, info)
call ctgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm, m, work, rwork, info)
call ztgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm, m, work, rwork, info)
```

Fortran 95:

```
call tgevc(s, p [,howmny] [,select] [,vl] [,vr] [,m] [,info])
```

C:

```
lapack_int LAPACKE_<?>tgevc( int matrix_layout, char side, char howmny,
const lapack_logical* select, lapack_int n, const <datatype>* s, lapack_int lds,
const <datatype>* p, lapack_int ldp, <datatype>* vl, lapack_int ldvl, <datatype>* vr,
lapack_int ldvr, lapack_int mm, lapack_int* m );
```

Description

The routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices (S, P), where S is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and P is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair (A, B):

$$A = Q^* S^* Z^H, B = Q^* P^* Z^H$$

as computed by ?gghrd plus ?hgeqz.

The right eigenvector x and the left eigenvector y of (S, P) corresponding to an eigenvalue w are defined by:

$$S^* x = w^* P^* x, Y^H S = w^* Y^H P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal elements of S and P .

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P) , or the products Z^*X and/or Q^*Y , where Z and Q are input matrices.

If Q and Z are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair (A,B) , then Z^*X and Q^*Y are the matrices of right and left eigenvectors of (A,B) .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>side</i>	CHARACTER*1. Must be 'R', 'L', or 'B'. If <i>side</i> = 'R', compute right eigenvectors only. If <i>side</i> = 'L', compute left eigenvectors only. If <i>side</i> = 'B', compute both right and left eigenvectors.
<i>howmny</i>	CHARACTER*1. Must be 'A', 'B', or 'S'. If <i>howmny</i> = 'A', compute all right and/or left eigenvectors. If <i>howmny</i> = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in <i>vr</i> and/or <i>vl</i> . If <i>howmny</i> = 'S', compute selected right and/or left eigenvectors, specified by the logical array <i>select</i> .
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). If <i>howmny</i> = 'S', <i>select</i> specifies the eigenvectors to be computed. If <i>howmny</i> = 'A' or 'B', <i>select</i> is not referenced. <i>For real flavors:</i> If <i>omega(j)</i> is a real eigenvalue, the corresponding real eigenvector is computed if <i>select(j)</i> is .TRUE.. If <i>omega(j)</i> and <i>omega(j+1)</i> are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either <i>select(j)</i> or <i>select(j+1)</i> is .TRUE., and on exit <i>select(j)</i> is set to .TRUE. and <i>select(j+1)</i> is set to .FALSE.. <i>For complex flavors:</i> The eigenvector corresponding to the <i>j</i> -th eigenvalue is computed if <i>select(j)</i> is .TRUE.. <i>n</i>
<i>s, p, vl, vr, work</i>	REAL for stgevc DOUBLE PRECISION for dtgevc COMPLEX for ctgevc DOUBLE COMPLEX for ztgevc. Arrays:

$s(lsd,*)$ contains the matrix S from a generalized Schur factorization as computed by `?hgeqz`. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.

The second dimension of s must be at least $\max(1, n)$.

$p(lap,*)$ contains the upper triangular matrix P from a generalized Schur factorization as computed by `?hgeqz`.

For real flavors, 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

For complex flavors, P must have real diagonal elements. The second dimension of p must be at least $\max(1, n)$.

If $side = 'L'$ or $'B'$ and $howmny = 'B'$, $vl(ldvl,*)$ must contain an n -by- n matrix Q (usually the orthogonal/unitary matrix Q of left Schur vectors returned by `?hgeqz`). The second dimension of vl must be at least $\max(1, mm)$.

If $side = 'R'$, vl is not referenced.

If $side = 'R'$ or $'B'$ and $howmny = 'B'$, $vr(ldrv,*)$ must contain an n -by- n matrix Z (usually the orthogonal/unitary matrix Z of right Schur vectors returned by `?hgeqz`). The second dimension of vr must be at least $\max(1, mm)$.

If $side = 'L'$, vr is not referenced.

$work(*)$ is a workspace array.

DIMENSION at least $\max(1, 6*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

lds

INTEGER. The leading dimension of s ; at least $\max(1, n)$.

ldp

INTEGER. The leading dimension of p ; at least $\max(1, n)$.

$ldvl$

INTEGER. The leading dimension of vl ;

If $side = 'L'$ or $'B'$, then $ldvl \geq n$.

If $side = 'R'$, then $ldvl \geq 1$.

$ldvr$

INTEGER. The leading dimension of vr ;

If $side = 'R'$ or $'B'$, then $ldvr \geq n$.

If $side = 'L'$, then $ldvr \geq 1$.

mm

INTEGER. The number of columns in the arrays vl and/or vr ($mm \geq m$).

$rwork$

REAL for `ctgevc` DOUBLE PRECISION for `ztgevc`. Workspace array, DIMENSION at least $\max(1, 2*n)$. Used in complex flavors only.

Output Parameters

vl

On exit, if $side = 'L'$ or $'B'$, vl contains:

if $howmny = 'A'$, the matrix Y of left eigenvectors of (S,P) ;

if $howmny = 'B'$, the matrix $Q*Y$;

if *howmny* = 'S', the left eigenvectors of (*S,P*) specified by *select*, stored consecutively in the columns of *vl*, in the same order as their eigenvalues.

For real flavors:

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

vr

On exit, if *side* = 'R' or 'B', *vr* contains:

if *howmny* = 'A', the matrix *X* of right eigenvectors of (*S,P*);

if *howmny* = 'B', the matrix *Z*X*;

if *howmny* = 'S', the right eigenvectors of (*S,P*) specified by *select*, stored consecutively in the columns of *vr*, in the same order as their eigenvalues.

For real flavors:

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

m

INTEGER. The number of columns in the arrays *vl* and/or *vr* actually used to store the eigenvectors.

If *howmny* = 'A' or 'B', *m* is set to *n*.

For real flavors:

Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

For complex flavors:

Each selected eigenvector occupies one column.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

For real flavors:

if *info* = *i*>0, the 2-by-2 block (*i*:*i*+1) does not have a complex eigenvalue.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgevc` interface are the following:

s Holds the matrix *S* of size (*n,n*).

p Holds the matrix *P* of size (*n,n*).

select Holds the vector of length *n*.

vl Holds the matrix *VL* of size (*n,mm*).

<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n,mm</i>).
<i>side</i>	Restored based on the presence of arguments <i>vl</i> and <i>vr</i> as follows: <i>side</i> = ' <i>B</i> ', if both <i>vl</i> and <i>vr</i> are present, <i>side</i> = ' <i>L</i> ', if <i>vl</i> is present and <i>vr</i> omitted, <i>side</i> = ' <i>R</i> ', if <i>vl</i> is omitted and <i>vr</i> present, Note that there will be an error condition if both <i>vl</i> and <i>vr</i> are omitted.
<i>howmny</i>	If omitted, this argument is restored based on the presence of argument <i>select</i> as follows: <i>howmny</i> = ' <i>S</i> ', if <i>select</i> is present, <i>howmny</i> = ' <i>A</i> ', if <i>select</i> is omitted. If present, <i>howmny</i> must be equal to ' <i>A</i> ' or ' <i>B</i> ' and the argument <i>select</i> must be omitted. Note that there will be an error condition if both <i>howmny</i> and <i>select</i> are present.

?tgexc

Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.

Syntax**FORTRAN 77:**

```
call stgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work, lwork,
info)

call dtgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work, lwork,
info)

call ctgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)

call ztgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)
```

Fortran 95:

```
call tgexc(a, b [,ifst] [,ilst] [,z] [,q] [,info])
```

C:

```
lapack_int LAPACKE_<?>tgexc( int matrix_layout, lapack_logical wantq, lapack_logical
wantz, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb,
<datatype>* q, lapack_int ldq, <datatype>* z, lapack_int ldz, lapack_int* ifst,
lapack_int* ilst );
```

Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (*A,B*) using an orthogonal/unitary equivalence transformation

$$(A, B) = Q^* (A, B) * Z^H,$$

so that the diagonal block of (A, B) with row index $ifst$ is moved to row $ilst$. Matrix pair (A, B) must be in a generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and B is upper triangular. Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'.$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>wantq, wantz</i>	LOGICAL. If <i>wantq</i> = .TRUE., update the left transformation matrix Q ; If <i>wantq</i> = .FALSE., do not update Q ; If <i>wantz</i> = .TRUE., update the right transformation matrix Z ; If <i>wantz</i> = .FALSE., do not update Z .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b, q, z</i>	REAL for <i>stgexc</i> DOUBLE PRECISION for <i>dtgexc</i> COMPLEX for <i>ctgexc</i> DOUBLE COMPLEX for <i>ztgexc</i> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> ,*) If <i>wantq</i> = .FALSE., then <i>q</i> is not referenced. If <i>wantq</i> = .TRUE., then <i>q</i> must contain the orthogonal/unitary matrix Q . The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>z</i> (<i>ldz</i> ,*) If <i>wantz</i> = .FALSE., then <i>z</i> is not referenced. If <i>wantz</i> = .TRUE., then <i>z</i> must contain the orthogonal/unitary matrix Z . The second dimension of <i>z</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldq</i>	INTEGER. The leading dimension of <i>q</i> ; If <i>wantq</i> = .FALSE., then <i>ldq</i> ≥ 1 .

	If <code>wantq</code> = .TRUE., then $ldq \geq \max(1, n)$.
<code>ldz</code>	INTEGER. The leading dimension of Z ; If <code>wantz</code> = .FALSE., then $ldz \geq 1$. If <code>wantz</code> = .TRUE., then $ldz \geq \max(1, n)$.
<code>ifst, ilst</code>	INTEGER. Specify the reordering of the diagonal blocks of (A, B) . The block with row index <code>ifst</code> is moved to row <code>ilst</code> , by a sequence of swapping between adjacent blocks. Constraint: $1 \leq ifst, ilst \leq n$.
<code>work</code>	REAL for <code>stgexc</code> ; DOUBLE PRECISION for <code>dtgexc</code> . Workspace array, DIMENSION ($/work$). Used in real flavors only.
<code>lwork</code>	INTEGER. The dimension of <code>work</code> ; must be at least $4n + 16$. If <code>lwork</code> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <code>work</code> array, returns this value as the first entry of the <code>work</code> array, and no error message related to <code>lwork</code> is issued by <code>xerbla</code> . See <i>Application Notes</i> for details.

Output Parameters

<code>a, b, q, z</code>	Overwritten by the updated matrices A, B, Q , and Z respectively.
<code>ifst, ilst</code>	Overwritten for real flavors only. If <code>ifst</code> pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; <code>ilst</code> always points to the first row of the block in its final position (which may differ from its input value by ± 1).
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i -th parameter had an illegal value. If <code>info</code> = 1, the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and <code>ilst</code> points to the first row of the current position of the block being moved.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgexc` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>b</code>	Holds the matrix B of size (n,n) .
<code>z</code>	Holds the matrix Z of size (n,n) .
<code>q</code>	Holds the matrix Q of size (n,n) .

<i>wantq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>wantq</i> = .TRUE., if <i>q</i> is present, <i>wantq</i> = .FALSE., if <i>q</i> is omitted.
<i>wantz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>wantz</i> = .TRUE., if <i>z</i> is present, <i>wantz</i> = .FALSE., if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgse

Reorders the generalized Schur decomposition of a pair of matrices (*A,B*) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (*A,B*).

Syntax

FORTRAN 77:

```
call stgse(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphar, alphai, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call dtgse(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphar, alphai, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call ctgse(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q, ldq, z,
ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call ztgse(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q, ldq, z,
ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call tgse(a, b, select [,alphar] [,alphai] [,beta] [,ijob] [,q] [,z] [,pl] [,pr] [,dif]
[,m] [,info])
call tgse(a, b, select [,alpha] [,beta] [,ijob] [,q] [,z] [,pl] [,pr] [,dif] [,m]
[,info])
```

C:

```

Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A, B) (in terms of an orthogonal/unitary equivalence transformation $Q^T (A, B) Z$ for real flavors or $Q^H (A, B) Z$ for complex flavors), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A, B) . The leading columns of Q and Z form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

(A, B) must be in generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is, A and B are both upper triangular.

?tgse also computes the generalized eigenvalues

$\omega_j = (\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$ (for real flavors)

$\omega_j = \text{alpha}(j)/\text{beta}(j)$ (for complex flavors)

of the reordered matrix pair (A, B) .

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, that is, the separation(s) between the matrix pairs (A_{11}, B_{11}) and (A_{22}, B_{22}) that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the (1,1)-block.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>ijob</i>	INTEGER. Specifies whether condition numbers are required for the cluster of eigenvalues (<i>pl</i> and <i>pr</i>) or the deflating subspaces <i>Difu</i> and <i>Difl</i> .
-------------	---

If $i_{job} = 0$, only reorder with respect to $select$;
 If $i_{job} = 1$, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (pl and pr);
 If $i_{job} = 2$, compute upper bounds on Dif_u and Dif_l , using F-norm-based estimate ($dif(1:2)$);
 If $i_{job} = 3$, compute estimate of Dif_u and Dif_l , sing 1-norm-based estimate ($dif(1:2)$). This option is about 5 times as expensive as $i_{job} = 2$;
 If $i_{job} = 4$, compute pl , pr and dif (i.e., options 0, 1 and 2 above). This is an economic version to get it all;
 If $i_{job} = 5$, compute pl , pr and dif (i.e., options 0, 1 and 3 above).

$wantq, wantz$

LOGICAL.

If $wantq = .TRUE.$, update the left transformation matrix Q ;
 If $wantq = .FALSE.$, do not update Q ;
 If $wantz = .TRUE.$, update the right transformation matrix Z ;
 If $wantz = .FALSE.$, do not update Z .

$select$

LOGICAL.

Array, DIMENSION at least $\max(1, n)$. Specifies the eigenvalues in the selected cluster.

To select an eigenvalue $\omega(j)$, $select(j)$ must be $.TRUE.$. For real flavors: to select a complex conjugate pair of eigenvalues $\omega(j)$ and $\omega(j+1)$ (corresponding 2 by 2 diagonal block), $select(j)$ and/or $select(j+1)$ must be set to $.TRUE.$; the complex conjugate $\omega(j)$ and $\omega(j+1)$ must be either both included in the cluster or both excluded.

n

INTEGER. The order of the matrices A and B ($n \geq 0$).

$a, b, q, z, work$

REAL for $stgse$

DOUBLE PRECISION for $dtgse$

COMPLEX for $ctgse$

DOUBLE COMPLEX for $ztgse$.

Arrays:

$a(l_{da}, *)$ contains the matrix A .

For real flavors: A is upper quasi-triangular, with (A, B) in generalized real Schur canonical form.

For complex flavors: A is upper triangular, in generalized Schur canonical form.

The second dimension of a must be at least $\max(1, n)$.

$b(l_{db}, *)$ contains the matrix B .

For real flavors: B is upper triangular, with (A, B) in generalized real Schur canonical form.

For complex flavors: B is upper triangular, in generalized Schur canonical form. The second dimension of b must be at least $\max(1, n)$.

q (ldq,)*

If *wantq* = .TRUE., then *q* is an *n*-by-*n* matrix;
 If *wantq* = .FALSE., then *q* is not referenced.
 The second dimension of *q* must be at least $\max(1, n)$.

z (ldz,)*

If *wantz* = .TRUE., then *z* is an *n*-by-*n* matrix;
 If *wantz* = .FALSE., then *z* is not referenced.
 The second dimension of *z* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda
 INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

ldb
 INTEGER. The leading dimension of *b*; at least $\max(1, n)$.

ldq
 INTEGER. The leading dimension of *q*; *ldq* ≥ 1 .
 If *wantq* = .TRUE., then *ldq* $\geq \max(1, n)$.

ldz
 INTEGER. The leading dimension of *z*; *ldz* ≥ 1 .
 If *wantz* = .TRUE., then *ldz* $\geq \max(1, n)$.

lwork
 INTEGER. The dimension of the array *work*.
For real flavors:
 If *ijob* = 1, 2, or 4, *lwork* $\geq \max(4n+16, 2m(n-m))$.
 If *ijob* = 3 or 5, *lwork* $\geq \max(4n+16, 4m(n-m))$.
For complex flavors:
 If *ijob* = 1, 2, or 4, *lwork* $\geq \max(1, 2m(n-m))$.
 If *ijob* = 3 or 5, *lwork* $\geq \max(1, 4m(n-m))$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* for details.

iwork
 INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork
 INTEGER. The dimension of the array *iwork*.
For real flavors:
 If *ijob* = 1, 2, or 4, *liwork* $\geq n+6$.
 If *ijob* = 3 or 5, *liwork* $\geq \max(n+6, 2m(n-m))$.
For complex flavors:
 If *ijob* = 1, 2, or 4, *liwork* $\geq n+2$.
 If *ijob* = 3 or 5, *liwork* $\geq \max(n+2, 2m(n-m))$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

a, b	Overwritten by the reordered matrices A and B , respectively.
$alphar, alphai$	<p>REAL for <code>stgSEN</code>;</p> <p>DOUBLE PRECISION for <code>dtgSEN</code>.</p> <p>Arrays, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in real flavors.</p> <p>See <i>beta</i>.</p>
$alpha$	<p>COMPLEX for <code>ctgSEN</code>;</p> <p>DOUBLE COMPLEX for <code>ztgSEN</code>.</p> <p>Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors.</p> <p>See <i>beta</i>.</p>
$beta$	<p>REAL for <code>stgSEN</code></p> <p>DOUBLE PRECISION for <code>dtgSEN</code></p> <p>COMPLEX for <code>ctgSEN</code></p> <p>DOUBLE COMPLEX for <code>ztgSEN</code>.</p> <p>Array, DIMENSION at least $\max(1, n)$.</p> <p><i>For real flavors:</i></p> <p>On exit, $(alphar(j) + alphai(j)*i)/beta(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.</p> <p>$alphar(j) + alphai(j)*i$ and $beta(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations.</p> <p>If $alphai(j)$ is zero, then the j-th eigenvalue is real; if positive, then the j-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $alphai(j+1)$ negative.</p> <p><i>For complex flavors:</i></p> <p>The diagonal elements of A and B, respectively, when the pair (A, B) has been reduced to generalized Schur form. $alpha(i)/beta(i)$, $i=1, \dots, n$ are the generalized eigenvalues.</p> <p>If $wantq = .TRUE.$, then, on exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B). The leading m columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).</p>

z If *wantz* = .TRUE., then, on exit, *Z* has been postmultiplied by the left orthogonal transformation matrix which reorder (*A*, *B*). The leading *m* columns of *Z* form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).

m INTEGER.
 The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); $0 \leq m \leq n$.

pl, pr REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.
 If *ijob* = 1, 4, or 5, *pl* and *pr* are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster.
 $0 < pl, pr \leq 1$. If *m* = 0 or *m* = *n*, *pl* = *pr* = 1.
 If *ijob* = 0, 2 or 3, *pl* and *pr* are not referenced

dif REAL for single precision flavors;DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (2).
 If *ijob* $\geq 2, *dif(1:2)* store the estimates of *Difu* and *Difl*.
 If *ijob* = 2 or 4, *dif(1:2)* are F-norm-based upper bounds on *Difu* and *Difl*.
 If *ijob* = 3 or 5, *dif(1:2)* are 1-norm-based estimates of *Difu* and *Difl*.
 If *m* = 0 or *n*, *dif(1:2)* = F-norm([*A*, *B*]).
 If *ijob* = 0 or 1, *dif* is not referenced.$

work(1) If *ijob* is not 0 and *info* = 0, on exit, *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

iwork(1) If *ijob* is not 0 and *info* = 0, on exit, *iwork(1)* contains the minimum value of *liwork* required for optimum performance. Use this *liwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = $-i$, the *i*-th parameter had an illegal value.
 If *info* = 1, Reordering of (*A*, *B*) failed because the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is very ill-conditioned. (*A*, *B*) may have been partially reordered.
 If requested, 0 is returned in *dif(*)*, *pl* and *pr*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsen` interface are the following:

<i>a</i>	Holds the matrix A of size (n,n) .
<i>b</i>	Holds the matrix B of size (n,n) .
<i>select</i>	Holds the vector of length n .
<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alphai</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>q</i>	Holds the matrix Q of size (n,n) .
<i>z</i>	Holds the matrix Z of size (n,n) .
<i>dif</i>	Holds the vector of length (2).
<i>ijob</i>	Must be 0, 1, 2, 3, 4, or 5. The default value is 0.
<i>wantq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>wantq</i> = .TRUE., if <i>q</i> is present, <i>wantq</i> = .FALSE., if <i>q</i> is omitted.
<i>wantz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>wantz</i> = .TRUE., if <i>z</i> is present, <i>wantz</i> = .FALSE., if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsvl

Solves the generalized Sylvester equation.

Syntax

FORTRAN 77:

```
call stgsvl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf, scale,
dif, work, lwork, iwork, info)
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves the generalized Sylvester equation:

$$A^*R - L^*B = \text{scale}^*C$$

$$D^*R - L^*E = \text{scale}^*F$$

where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively, with real/complex entries. (A, D) and (B, E) must be in generalized real-Schur/Schur canonical form, that is, A, B are upper quasi-triangular/triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F) . The factor scale , $0 \leq \text{scale} \leq 1$, is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve $Z^*x = \text{scale}^*b$, where Z is defined as

$$Z = \begin{pmatrix} \text{kron}(I_n, A) - \text{kron}(B^T, I_m) \\ \text{kron}(I_n, D) - \text{kron}(E^T, I_m) \end{pmatrix}$$

Here I_k is the identity matrix of size k and X' is the transpose/conjugate-transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

If $\text{trans} = 'T'$ (for real flavors), or $\text{trans} = 'C'$ (for complex flavors), the routine `?tgssyl` solves the transposed/conjugate-transposed system $Z' * y = \text{scale} * b$, which is equivalent to solve for R and L in

$$A'^* R + D'^* L = \text{scale} * C$$

$$R^* B^* + L^* E^* = \text{scale} * (-F)$$

This case ($\text{trans} = 'T'$ for `stgssyl/dtgssyl` or $\text{trans} = 'C'$ for `ctgssyl/ztgssyl`) is used to compute an one-norm-based estimate of $\text{Dif}[(A, D), (B, E)]$, the separation between the matrix pairs (A, D) and (B, E) , using `lacon/lacon`.

If $i\text{job} \geq 1$, `?tgssyl` computes a Frobenius norm-based estimate of $\text{Dif}[(A, D), (B, E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z . This is a level 3 BLAS algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>trans</code>	CHARACTER*1. Must be ' <code>N</code> ', ' <code>T</code> ', or ' <code>C</code> '.
	If <code>trans = 'N'</code> , solve the generalized Sylvester equation.
	If <code>trans = 'T'</code> , solve the 'transposed' system (for real flavors only).
	If <code>trans = 'C'</code> , solve the 'conjugate transposed' system (for complex flavors only).
<code>ijob</code>	INTEGER. Specifies what kind of functionality to be performed:
	If <code>ijob = 0</code> , solve the generalized Sylvester equation only;
	If <code>ijob = 1</code> , perform the functionality of <code>ijob = 0</code> and <code>ijob = 3</code> ;
	If <code>ijob = 2</code> , perform the functionality of <code>ijob = 0</code> and <code>ijob = 4</code> ;
	If <code>ijob = 3</code> , only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (look ahead strategy is used);
	If <code>ijob = 4</code> , only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (?gecon on sub-systems is used). If <code>trans = 'T'</code> or ' <code>C</code> ', <code>ijob</code> is not referenced.
<code>m</code>	INTEGER. The order of the matrices A and D , and the row dimension of the matrices C, F, R and L .
<code>n</code>	INTEGER. The order of the matrices B and E , and the column dimension of the matrices C, F, R and L .
<code>a, b, c, d, e, f, work</code>	REAL for <code>stgssyl</code> DOUBLE PRECISION for <code>dtgssyl</code> COMPLEX for <code>ctgssyl</code>

DOUBLE COMPLEX for `ztgsyl`.

Arrays:

`a(lda,*)` contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix A .

The second dimension of `a` must be at least $\max(1, m)$.

`b ldb,*)` contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix B . The second dimension of `b` must be at least $\max(1, n)$.

`c ldc,*)` contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by `trans`)

The second dimension of `c` must be at least $\max(1, n)$.

`d ldd,*)` contains the upper triangular matrix D .

The second dimension of `d` must be at least $\max(1, m)$.

`e lde,*)` contains the upper triangular matrix E .

The second dimension of `e` must be at least $\max(1, n)$.

`f ldf,*)` contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by `trans`)

The second dimension of `f` must be at least $\max(1, n)$.

`work` is a workspace array, its dimension $\max(1, \text{lwork})$.

`lda`

INTEGER. The leading dimension of `a`; at least $\max(1, m)$.

`ldb`

INTEGER. The leading dimension of `b`; at least $\max(1, n)$.

`ldc`

INTEGER. The leading dimension of `c`; at least $\max(1, m)$.

`lld`

INTEGER. The leading dimension of `d`; at least $\max(1, m)$.

`lde`

INTEGER. The leading dimension of `e`; at least $\max(1, n)$.

`ldf`

INTEGER. The leading dimension of `f`; at least $\max(1, m)$.

`lwork`

INTEGER.

The dimension of the array `work`. $\text{lwork} \geq 1$.

If `ijob = 1` or `2` and `trans = 'N'`, $\text{lwork} \geq \max(1, 2*m*n)$.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* for details.

`iwork`

INTEGER. Workspace array, DIMENSION at least $(m+n+6)$ for real flavors, and at least $(m+n+2)$ for complex flavors.

Output Parameters

`c`

If `ijob=0, 1, or 2`, overwritten by the solution R .

If $i_{job}=3$ or 4 and $trans = 'N'$, c holds R , the solution achieved during the computation of the Dif-estimate.

f

If $i_{job}=0$, 1 , or 2 , overwritten by the solution L .

If $i_{job}=3$ or 4 and $trans = 'N'$, f holds L , the solution achieved during the computation of the Dif-estimate.

dif

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

On exit, dif is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, dif is an upper bound of $Dif[(A, D), (B, E)] = \sigma_{\min}(Z)$, where Z as in (2).

If $i_{job} = 0$, or $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), dif is not touched.

scale

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

On exit, $scale$ is the scaling factor in the generalized Sylvester equation.

If $0 < scale < 1$, c and f hold the solutions R and L , respectively, to a slightly perturbed system but the input matrices A , B , D and E have not been changed.

If $scale = 0$, c and f hold the solutions R and L , respectively, to the homogeneous system with $C = F = 0$. Normally, $scale = 1$.

work(1)

If $info = 0$, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info > 0$, (A, D) and (B, E) have common or close eigenvalues.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsyl` interface are the following:

a Holds the matrix A of size (m,m) .

b Holds the matrix B of size (n,n) .

c Holds the matrix C of size (m,n) .

d Holds the matrix D of size (m,m) .

e Holds the matrix E of size (n,n) .

f Holds the matrix F of size (m,n) .

<i>ijob</i>	Must be 0, 1, 2, 3, or 4. The default value is 0.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsna

Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

Syntax

FORTRAN 77:

```
call stgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s, dif, mm, m, work, lwork, iwork, info)
call dtgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s, dif, mm, m, work, lwork, iwork, info)
call ctgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s, dif, mm, m, work, lwork, iwork, info)
call ztgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s, dif, mm, m, work, lwork, iwork, info)
```

Fortran 95:

```
call tgsna(a, b [,s] [,dif] [,vl] [,vr] [,select] [,m] [,info])
```

C:

Description

The real flavors stgsna/dtgsna of this routine estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair ($Q^*A^*Z^T, Q^*B^*Z^T$) with orthogonal matrices Q and Z .

(A, B) must be in generalized real Schur form (as returned by [gges/gges](#)), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex flavors ctgsna/ztgsna estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>job</i>	CHARACTER*1. Specifies whether condition numbers are required for eigenvalues or eigenvectors. Must be 'E' or 'V' or 'B'. If <i>job</i> = 'E', for eigenvalues only (compute <i>s</i>). If <i>job</i> = 'V', for eigenvectors only (compute <i>dif</i>). If <i>job</i> = 'B', for both eigenvalues and eigenvectors (compute both <i>s</i> and <i>dif</i>).
<i>howmny</i>	CHARACTER*1. Must be 'A' or 'S'. If <i>howmny</i> = 'A', compute condition numbers for all eigenpairs. If <i>howmny</i> = 'S', compute condition numbers for selected eigenpairs specified by the logical array <i>select</i> .
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). If <i>howmny</i> = 'S', <i>select</i> specifies the eigenpairs for which condition numbers are required. If <i>howmny</i> = 'A', <i>select</i> is not referenced. <i>For real flavors:</i> To select condition numbers for the eigenpair corresponding to a real eigenvalue $\omega(j)$, <i>select(j)</i> must be set to .TRUE.; to select condition numbers corresponding to a complex conjugate pair of eigenvalues $\omega(j)$ and $\omega(j+1)$, either <i>select(j)</i> or <i>select(j+1)</i> must be set to .TRUE..

For complex flavors:

To select condition numbers for the corresponding j -th eigenvalue and/or eigenvector, *select(j)* must be set to .TRUE..

n

INTEGER. The order of the square matrix pair (A, B)
($n \geq 0$).

a, b, vl, vr, work

REAL for stgsna
DOUBLE PRECISION for dtgsna
COMPLEX for ctgsna
DOUBLE COMPLEX for ztgsna.

Arrays:

a(*lda,**) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix A in the pair (A, B).

The second dimension of *a* must be at least $\max(1, n)$.

b(*ldb,**) contains the upper triangular matrix B in the pair (A, B). The second dimension of *b* must be at least $\max(1, n)$.

If *job* = 'E' or 'B', *vl*(*ldvl,**) must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vl*, as returned by ?tgevc.

If *job* = 'V', *vl* is not referenced. The second dimension of *vl* must be at least $\max(1, m)$.

If *job* = 'E' or 'B', *vr*(*ldvr,**) must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vr*, as returned by ?tgevc.

If *job* = 'V', *vr* is not referenced. The second dimension of *vr* must be at least $\max(1, m)$.

work is a workspace array, its dimension $\max(1, lwork)$.

If *job* = 'E', *work* is not referenced.

lda

INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

ldb

INTEGER. The leading dimension of *b*; at least $\max(1, n)$.

ldvl

INTEGER. The leading dimension of *vl*; *ldvl* ≥ 1 .

If *job* = 'E' or 'B', then *ldvl* $\geq \max(1, n)$.

ldvr

INTEGER. The leading dimension of *vr*; *ldvr* ≥ 1 .

If *job* = 'E' or 'B', then *ldvr* $\geq \max(1, n)$.

mm

INTEGER. The number of elements in the arrays *s* and *dif* (*mm* $\geq m$).

lwork

INTEGER. The dimension of the array *work*.

lwork $\geq \max(1, n)$.

If $\text{job} = \text{'V'}$ or 'B' , $\text{lwork} \geq 2*n*(n+2)+16$ for real flavors, and $\text{lwork} \geq \max(1, 2*n*n)$ for complex flavors.

If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER. Workspace array, DIMENSION at least $(n+6)$ for real flavors, and at least $(n+2)$ for complex flavors.

If $\text{job} = \text{'E'}$, $iwork$ is not referenced.

Output Parameters

s

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION (mm) .

If $\text{job} = \text{'E'}$ or 'B' , contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array.

If $\text{job} = \text{'V'}$, s is not referenced.

For real flavors:

For a complex conjugate pair of eigenvalues two consecutive elements of s are set to the same value. Thus, $s(j)$, $\text{dif}(j)$, and the j -th columns of v_l and v_r all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected).

dif

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION (mm) .

If $\text{job} = \text{'V'}$ or 'B' , contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.

If the eigenvalues cannot be reordered to compute $\text{dif}(j)$, $\text{dif}(j)$ is set to 0; this can only occur when the true value would be very small anyway.

If $\text{job} = \text{'E'}$, dif is not referenced.

For real flavors:

For a complex eigenvector, two consecutive elements of dif are set to the same value.

For complex flavors:

For each eigenvalue/vector specified by select , dif stores a Frobenius norm-based estimate of Difl .

m

INTEGER. The number of elements in the arrays s and dif used to store the specified condition numbers; for each selected eigenvalue one element is used.

If $\text{howmny} = \text{'A'}$, m is set to n .

$\text{work}(1)$

$\text{work}(1)$

If job is not ' E ' and $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsna` interface are the following:

a	Holds the matrix A of size (n,n) .
b	Holds the matrix B of size (n,n) .
s	Holds the vector of length (mm) .
dif	Holds the vector of length (mm) .
vl	Holds the matrix VL of size (n,mm) .
vr	Holds the matrix VR of size (n,mm) .
$select$	Holds the vector of length n .
$howmny$	Restored based on the presence of the argument $select$ as follows: $howmny = 'S'$, if $select$ is present, $howmny = 'A'$, if $select$ is omitted.
job	Restored based on the presence of arguments s and dif as follows: $job = 'B'$, if both s and dif are present, $job = 'E'$, if s is present and dif omitted, $job = 'V'$, if s is omitted and dif present. Note that there will be an error condition if both s and dif are omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Generalized Singular Value Decomposition

This section describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices A and B as

$$U^H A Q = D_1 * \begin{pmatrix} 0 & R \end{pmatrix},$$

$$V^H B Q = D_2 * (0 \quad R),$$

where U , V , and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 , D_2 are “diagonal” matrices of the structure detailed in the routines description section.

Table “Computational Routines for Generalized Singular Value Decomposition” lists LAPACK routines (FORTRAN 77 interface) that perform generalized singular value decomposition of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Generalized Singular Value Decomposition

Routine name	Operation performed
ggsvp	Computes the preprocessing decomposition for the generalized SVD
tgsja	Computes the generalized SVD of two upper triangular or trapezoidal matrices

You can use routines listed in the above table as well as the driver routine [ggsvd](#) to find the GSVD of a pair of general rectangular matrices.

?ggsvp

Computes the preprocessing decomposition for the generalized SVD.

Syntax

FORTRAN 77:

```
call sggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u, ldu, v,
ldv, q, ldq, iwork, tau, work, info)

call dggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u, ldu, v,
ldv, q, ldq, iwork, tau, work, info)

call cggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u, ldu, v,
ldv, q, ldq, iwork, rwork, tau, work, info)

call zggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u, ldu, v,
ldv, q, ldq, iwork, rwork, tau, work, info)
```

Fortran 95:

```
call ggsvp(a, b, tola, tolb [, k] [,l] [,u] [,v] [,q] [,info])
```

C:

```
lapack_int LAPACKE_sggsvp( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int p, lapack_int n, float* a, lapack_int lda, float* b,
lapack_int ldb, float tola, float tolb, lapack_int* k, lapack_int* l, float* u,
lapack_int ldu, float* v, lapack_int ldv, float* q, lapack_int ldq );

lapack_int LAPACKE_dggsvp( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int p, lapack_int n, double* a, lapack_int lda, double* b,
lapack_int ldb, double tola, double tolb, lapack_int* k, lapack_int* l, double* u,
lapack_int ldu, double* v, lapack_int ldv, double* q, lapack_int ldq );

lapack_int LAPACKE_cggsvp( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int p, lapack_int n, lapack_complex_float* a, lapack_int lda,
lapack_complex_float* b, lapack_int ldb, float tola, float tolb, lapack_int* k,
lapack_int* l, lapack_complex_float* u, lapack_int ldu, lapack_complex_float* v,
lapack_int ldv, lapack_complex_float* q, lapack_int ldq );
```

```
lapack_int LAPACKE_zggsrp( int matrix_layout, char jobu, char jobv, char jobq,
                           lapack_int m, lapack_int p, lapack_int n, lapack_complex_double* a, lapack_int lda,
                           lapack_complex_double* b, lapack_int ldb, double tola, double tolb, lapack_int* k,
                           lapack_int* l, lapack_complex_double* u, lapack_int ldu, lapack_complex_double* v,
                           lapack_int ldv, lapack_complex_double* q, lapack_int ldq );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes orthogonal matrices U , V and Q such that

$$\begin{matrix} \dots & \dots \\ \dots & \dots \end{matrix}$$

$$= \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix}, \quad \text{if } m - k - l < 0$$

$$\begin{matrix} \dots & \dots \\ \dots & \dots \end{matrix}$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m - k - l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal. The sum $k+l$ is equal to the effective numerical rank of the $(m+p)$ -by- n matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine [ggsrp](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobu</i>	CHARACTER*1. Must be 'U' or 'N'.
-------------	----------------------------------

If $\text{jobu} = \text{'U'}$, orthogonal/unitary matrix U is computed.

If $\text{jobu} = \text{'N'}$, U is not computed.

jobv

CHARACTER*1. Must be ' V ' or ' N '.

If $\text{jobv} = \text{'V'}$, orthogonal/unitary matrix V is computed.

If $\text{jobv} = \text{'N'}$, V is not computed.

jobq

CHARACTER*1. Must be ' Q ' or ' N '.

If $\text{jobq} = \text{'Q'}$, orthogonal/unitary matrix Q is computed.

If $\text{jobq} = \text{'N'}$, Q is not computed.

m

INTEGER. The number of rows of the matrix A ($m \geq 0$).

p

INTEGER. The number of rows of the matrix B ($p \geq 0$).

n

INTEGER. The number of columns of the matrices A and B ($n \geq 0$).

$a, b, tau, work$

REAL for sggsvp

DOUBLE PRECISION for dggsvp

COMPLEX for cggsvp

DOUBLE COMPLEX for zggsvp.

Arrays:

$a(l\text{da},*)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$b(l\text{db},*)$ contains the p -by- n matrix B .

The second dimension of b must be at least $\max(1, n)$.

$tau(*)$ is a workspace array.

The dimension of tau must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, 3n, m, p)$.

$l\text{da}$

INTEGER. The leading dimension of a ; at least $\max(1, m)$.

$l\text{db}$

INTEGER. The leading dimension of b ; at least $\max(1, p)$.

$tola, tolb$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

$tola$ and $tolb$ are the thresholds to determine the effective numerical rank of matrix B and a subblock of A . Generally, they are set to

$tola = \max(m, n) * ||A|| * \text{MACHEPS}$,

$tolb = \max(p, n) * ||B|| * \text{MACHEPS}$.

The size of $tola$ and $tolb$ may affect the size of backward errors of the decomposition.

<i>ldu</i>	INTEGER. The leading dimension of the output array u . $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.
<i>ldv</i>	INTEGER. The leading dimension of the output array v . $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.
<i>ldq</i>	INTEGER. The leading dimension of the output array q . $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <code>cggsvp</code> DOUBLE PRECISION for <code>zggsvp</code> . Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	Overwritten by the triangular (or trapezoidal) matrix described in the <i>Description</i> section.
<i>b</i>	Overwritten by the triangular matrix described in the <i>Description</i> section.
<i>k, l</i>	INTEGER. On exit, <i>k</i> and <i>l</i> specify the dimension of subblocks. The sum $k + l$ is equal to effective numerical rank of $(A^H, B^H)^H$.
<i>u, v, q</i>	REAL for <code>sggsvp</code> DOUBLE PRECISION for <code>dggsvp</code> COMPLEX for <code>cggsvp</code> DOUBLE COMPLEX for <code>zggsvp</code> . Arrays: If $jobu = 'U'$, $u(ldu,*)$ contains the orthogonal/unitary matrix U . The second dimension of u must be at least $\max(1, m)$. If $jobu = 'N'$, u is not referenced. If $jobv = 'V'$, $v(ldv,*)$ contains the orthogonal/unitary matrix V . The second dimension of v must be at least $\max(1, m)$. If $jobv = 'N'$, v is not referenced. If $jobq = 'Q'$, $q(ldq,*)$ contains the orthogonal/unitary matrix Q . The second dimension of q must be at least $\max(1, n)$. If $jobq = 'N'$, q is not referenced. <i>info</i> INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggsvp` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>b</i>	Holds the matrix B of size (p,n) .
<i>u</i>	Holds the matrix U of size (m,m) .
<i>v</i>	Holds the matrix V of size (p,m) .
<i>q</i>	Holds the matrix Q of size (n,n) .
<i>jobu</i>	Restored based on the presence of the argument <i>u</i> as follows: <i>jobu</i> = 'U', if <i>u</i> is present, <i>jobu</i> = 'N', if <i>u</i> is omitted.
<i>jobv</i>	Restored based on the presence of the argument <i>v</i> as follows: <i>jobz</i> = 'V', if <i>v</i> is present, <i>jobz</i> = 'N', if <i>v</i> is omitted.
<i>jobq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>jobz</i> = 'Q', if <i>q</i> is present, <i>jobz</i> = 'N', if <i>q</i> is omitted.

?tgsja

Computes the generalized SVD of two upper triangular or trapezoidal matrices.

Syntax

FORTRAN 77:

```
call stgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha, beta,

Description

The routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices A and B . On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine [ggsvp](#) from a general m -by- n matrix A and p -by- n matrix B :

$$A = \begin{matrix} & n - k - l & k & l \\ & k & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix}, & \text{if } m - k - l \geq 0 \\ & l & & \\ m - k - l & & & \end{matrix}$$

.....
.....

...|!||||||| : : : : :

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal.

On exit,

$$U^H A^* Q = D_1^* (0 \ R), \quad V^H B^* Q = D_2^* (0 \ R),$$

where U , V and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 and D_2 are "diagonal" matrices, which are of the following structures:

If $m-k-l \geq 0$,

$$D_1 = \begin{matrix} & k & l \\ \begin{matrix} & k \\ & l \\ m - k - l \end{matrix} & \begin{pmatrix} 0 & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \end{matrix}$$

...|!||||||| : : : :

$$(0 \ R) = \begin{matrix} n - k - l & k & l \\ \begin{matrix} & k \\ & l \end{matrix} & \begin{pmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & R_{22} \end{pmatrix} \end{matrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+1))$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(k+1))$$

$$C^2 + S^2 = I$$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$D_1 = \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m))$,

```
S = diag(beta(K+1), ..., beta(m)),
```

$$C^2 + S^2 = I$$

$$\text{On exit} \quad \begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$$

On exit, R_{22} and R_{23} are stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The computation of the orthogonal

either be formed explicitly, or they *may* be postmultiplied into input matrices U_1 , V_1 , or Q_1 .

The data types are

interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

CHARACTER MUST BE 0, 1, OR N.

If $\text{jobda} = 0$, a must contain an orthogonal/unitary matrix U_1 on entry.

If $\text{jobu} = \text{'T'}$, u is initialized to the unit matrix.

If $\text{Jobu} = \text{'N'}$, u is not computed.

jobv CHARACTER*1. Must be 'V', 'I', or 'N'.

If $\text{jobv} = \text{'V'}$, v must contain an orthogonal/unitary matrix V_1 on entry.

If $\text{jobv} = \text{'I'}$, v is initialized to the unit matrix.

If $\text{jobv} = \text{'N'}$, v is not computed.

jobq

CHARACTER*1. Must be ' Q ', ' I ', or ' N '.

If $\text{jobq} = \text{'Q'}$, q must contain an orthogonal/unitary matrix Q_1 on entry.

If $\text{jobq} = \text{'I'}$, q is initialized to the unit matrix.

If $\text{jobq} = \text{'N'}$, q is not computed.

m

INTEGER. The number of rows of the matrix A ($m \geq 0$).

p

INTEGER. The number of rows of the matrix B ($p \geq 0$).

n

INTEGER. The number of columns of the matrices A and B ($n \geq 0$).

k, l

INTEGER. Specify the subblocks in the input matrices A and B , whose GSVD is computed.

$a, b, u, v, q, work$

REAL for stgsja

DOUBLE PRECISION for dtgsja

COMPLEX for ctgsja

DOUBLE COMPLEX for ztgsja.

Arrays:

$a(lda,*)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$b(lsb,*)$ contains the p -by- n matrix B .

The second dimension of b must be at least $\max(1, n)$.

If $\text{jobu} = \text{'U'}$, $u(ldu,*)$ must contain a matrix U_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).

The second dimension of u must be at least $\max(1, m)$.

If $\text{jobv} = \text{'V'}$, $v(ldv,*)$ must contain a matrix V_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).

The second dimension of v must be at least $\max(1, p)$.

If $\text{jobq} = \text{'Q'}$, $q(ldq,*)$ must contain a matrix Q_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).

The second dimension of q must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, 2n)$.

lda

INTEGER. The leading dimension of a ; at least $\max(1, m)$.

lsb

INTEGER. The leading dimension of b ; at least $\max(1, p)$.

ldu

INTEGER. The leading dimension of the array u .

$lDU \geq \max(1, m)$ if $\text{jobu} = 'U'$; $lDU \geq 1$ otherwise.

ldv

INTEGER. The leading dimension of the array v .

$ldv \geq \max(1, p)$ if $\text{jobv} = 'V'$; $ldv \geq 1$ otherwise.

ldq

INTEGER. The leading dimension of the array q .

$ldq \geq \max(1, n)$ if $\text{jobq} = 'Q'$; $ldq \geq 1$ otherwise.

$tola, tolb$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

$tola$ and $tolb$ are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in ?ggsvp:

$tola = \max(m, n) * |A| * \text{MACHEPS}$,

$tolb = \max(p, n) * |B| * \text{MACHEPS}$.

Output Parameters

a

On exit, $a(n-k+1:n, 1:\min(k+l, m))$ contains the triangular matrix R or part of R .

b

On exit, if necessary, $b(m-k+1:l, n+m-k-l+1:n)$ contains a part of R .

$alpha, beta$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays, DIMENSION at least $\max(1, n)$. Contain the generalized singular value pairs of A and B :

$alpha(1:k) = 1,$

$beta(1:k) = 0,$

and if $m-k-l \geq 0$,

$alpha(k+1:k+1) = \text{diag}(C),$

$beta(k+1:k+1) = \text{diag}(S),$

or if $m-k-l < 0$,

$alpha(k+1:m) = C, alpha(m+1:k+1) = 0$

$beta(K+1:M) = S,$

$beta(m+1:k+1) = 1.$

Furthermore, if $k+l < n$,

$alpha(k+l+1:n) = 0$ and

$beta(k+l+1:n) = 0.$

u

If $\text{jobu} = 'I'$, u contains the orthogonal/unitary matrix U .

If $\text{jobu} = 'U'$, u contains the product U_1^*U .

If $\text{jobu} = 'N'$, u is not referenced.

v

If $\text{jobv} = 'I'$, v contains the orthogonal/unitary matrix U .

	If $jobv = 'V'$, v contains the product V_1^*V .
	If $jobv = 'N'$, v is not referenced.
q	If $jobq = 'I'$, q contains the orthogonal/unitary matrix U .
	If $jobq = 'Q'$, q contains the product Q_1^*Q .
	If $jobq = 'N'$, q is not referenced.
$ncycle$	INTEGER. The number of cycles required for convergence.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the procedure does not converge after MAXIT cycles.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsja` interface are the following:

a	Holds the matrix A of size (m,n) .
b	Holds the matrix B of size (p,n) .
u	Holds the matrix U of size (m,m) .
v	Holds the matrix V of size (p,p) .
q	Holds the matrix Q of size (n,n) .
$alpha$	Holds the vector of length n .
$beta$	Holds the vector of length n .
$jobu$	If omitted, this argument is restored based on the presence of argument u as follows: $jobu = 'U'$, if u is present, $jobu = 'N'$, if u is omitted. If present, $jobu$ must be equal to ' I ' or ' U ' and the argument u must also be present. Note that there will be an error condition if $jobu$ is present and u omitted.
$jobv$	If omitted, this argument is restored based on the presence of argument v as follows: $jobv = 'V'$, if v is present, $jobv = 'N'$, if v is omitted. If present, $jobv$ must be equal to ' I ' or ' V ' and the argument v must also be present.

Note that there will be an error condition if $jobv$ is present and v omitted.

$jobq$ If omitted, this argument is restored based on the presence of argument q as follows:

$jobq = 'Q'$, if q is present,

$jobq = 'N'$, if q is omitted.

If present, $jobq$ must be equal to ' I ' or ' Q ' and the argument q must also be present.

Note that there will be an error condition if $jobq$ is present and q omitted.

Cosine-Sine Decomposition

This section describes LAPACK computational routines for computing the *cosine-sine decomposition* (CS decomposition) of a partitioned unitary/orthogonal matrix. The algorithm computes a complete 2-by-2 CS decomposition, which requires simultaneous diagonalization of all the four blocks of a unitary/orthogonal matrix partitioned into a 2-by-2 block structure.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Computational Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines (FORTRAN 77 interface) that perform CS decomposition of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of an orthogonal/unitary matrix in bidiagonal-block form	bbcisd/bbcisd	bbcisd/bbcisd
Simultaneously bidiagonalize the blocks of a partitioned orthogonal matrix	orbdb unbdb	
Simultaneously bidiagonalize the blocks of a partitioned unitary matrix		orbdb unbdb

- **C:** mkl.h

Description

`mkl_lapack.fi` The routine ?bbcsd computes the CS decomposition of an orthogonal or unitary matrix in bidiagonal-block form:

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 | 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 | 0 & 0 & I \end{pmatrix} = \left(\frac{u_1}{|} \frac{|}{u_2} \right) \begin{pmatrix} C & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \left(\frac{v_1}{|} \frac{|}{v_2} \right)^T$$

or

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 | 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 | 0 & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & & \\ & \vdots & \\ & & u_2 \end{pmatrix} \begin{pmatrix} C & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & & \\ & \vdots & \\ & & v_2 \end{pmatrix}^H$$

respectively.

x is m -by- m with the top-left block p -by- q . Note that q must not be larger than p , $m-p$, or $m-q$. If q is not the smallest index, x must be transposed and/or permuted in constant time using the `trans` option. See `?orcisd/?uncsd` for details.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are represented implicitly by angles `theta(1:q)` and `phi(1:q-1)`.

The orthogonal/unitary matrices u_1 , u_2 , v_1^t , and v_2^t are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>jobu1</code>	CHARACTER. If equals <code>Y</code> , then u_1 is updated. Otherwise, u_1 is not updated.
<code>jobu2</code>	CHARACTER. If equals <code>Y</code> , then u_2 is updated. Otherwise, u_2 is not updated.
<code>jobv1t</code>	CHARACTER. If equals <code>Y</code> , then v_1^t is updated. Otherwise, v_1^t is not updated.
<code>jobv2t</code>	CHARACTER. If equals <code>Y</code> , then v_2^t is updated. Otherwise, v_2^t is not updated.
<code>trans</code>	CHARACTER = <code>'T'</code> : $x, u_1, u_2, v_1^t, v_2^t$ are stored in row-major order. otherwise $x, u_1, u_2, v_1^t, v_2^t$ are stored in column-major order.
<code>m</code>	INTEGER. The number of rows and columns of the orthogonal/unitary matrix X in bidiagonal-block form.
<code>p</code>	INTEGER. The number of rows in the top-left block of x . $0 \leq p \leq m$.
<code>q</code>	INTEGER. The number of columns in the top-left block of x . $0 \leq q \leq \min(p, m-p, m-q)$.
<code>theta</code>	REAL for <code>sbbcsd</code> DOUBLE PRECISION for <code>dbbcsd</code> COMPLEX for <code>cbbcsd</code> DOUBLE COMPLEX for <code>zbbcsd</code> Array, DIMENSION (q).

On entry, the angles $\text{theta}(1), \dots, \text{theta}(q)$ that, along with $\text{phi}(1), \dots, \text{phi}(q-1)$, define the matrix in bidiagonal-block form.

phi REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (q-1).

The angles $\text{phi}(1), \dots, \text{phi}(q-1)$ that, along with $\text{theta}(1), \dots, \text{theta}(q)$, define the matrix in bidiagonal-block form.

u1 REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (ldu1,p).

On entry, an $ldu1$ -by- p matrix.

ldu1 INTEGER. The leading dimension of the array u_1 .

u2 REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (ldu2,m-p).

On entry, an $ldu2$ -by-($m-p$) matrix.

ldu2 INTEGER. The leading dimension of the array u_2 .

v1t REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (ldv1t,q).

On entry, an $ldv1t$ -by- q matrix.

ldv1t INTEGER. The leading dimension of the array $v1t$.

v2t REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (ldv2t,m-q).

On entry, an $ldv2t$ -by- $(m-q)$ matrix.

$ldv2t$ INTEGER. The leading dimension of the array $v2t$.

$work$ REAL for sbbcsd

DOUBLE PRECISION for dbbcsd

COMPLEX for cbbcsd

DOUBLE COMPLEX for zbbcsd

Workspace array, DIMENSION ($\max(1, lwork)$).

$lwork$ INTEGER. The size of the $work$ array. $lwork \geq \max(1, 8*q)$

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

Output Parameters

$theta$ REAL for sbbcsd

DOUBLE PRECISION for dbbcsd

COMPLEX for cbbcsd

DOUBLE COMPLEX for zbbcsd

On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

$u1$ REAL for sbbcsd

DOUBLE PRECISION for dbbcsd

COMPLEX for cbbcsd

DOUBLE COMPLEX for zbbcsd

On exit, $u1$ is postmultiplied by the left singular vector matrix common to $[b11 ; 0]$ and $[b12 \ 0 \ 0 ; 0 \ -I \ 0 \ 0]$.

$u2$ REAL for sbbcsd

DOUBLE PRECISION for dbbcsd

COMPLEX for cbbcsd

DOUBLE COMPLEX for zbbcsd

On exit, $u2$ is postmultiplied by the left singular vector matrix common to $[b21 ; 0]$ and $[b22 \ 0 \ 0 ; 0 \ 0 \ I]$.

$v1t$ REAL for sbbcsd

DOUBLE PRECISION for dbbcsd

COMPLEX for cbbcsd

DOUBLE COMPLEX for zbbcsd

Array, DIMENSION (q).

On exit, $v1t$ is premultiplied by the transpose of the right singular vector matrix common to [$b11 ; 0$] and [$b21 ; 0$].

$v2t$ REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

On exit, $v2t$ is premultiplied by the transpose of the right singular vector matrix common to [$b12 \ 0 \ 0 ; 0 \ -I \ 0$] and [$b22 \ 0 \ 0 ; 0 \ 0 \ I$].

$b11d$ REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (q).

When ?bbcsd converges, $b11d$ contains the cosines of $\theta(1), \dots, \theta(q)$. If ?bbcsd fails to converge, $b11d$ contains the diagonal of the partially reduced top left block.

$b11e$ REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION ($q-1$).

When ?bbcsd converges, $b11e$ contains zeros. If ?bbcsd fails to converge, $b11e$ contains the superdiagonal of the partially reduced top left block.

$b12d$ REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION (q).

When ?bbcsd converges, $b12d$ contains the negative sines of $\theta(1), \dots, \theta(q)$. If ?bbcsd fails to converge, $b12d$ contains the diagonal of the partially reduced top right block.

$b12e$ REAL **for** sbbcsd

DOUBLE PRECISION **for** dbbcsd

COMPLEX **for** cbbcsd

DOUBLE COMPLEX **for** zbbcsd

Array, DIMENSION ($q-1$).

When `?bbcsd` converges, `b12e` contains zeros. If `?bbcsd` fails to converge, `b11e` contains the superdiagonal of the partially reduced top right block.

<code>info</code>	INTEGER. = 0: successful exit < 0: if <code>info = -i</code> , the i -th argument has an illegal value > 0: if <code>?bbcsd</code> did not converge, <code>info</code> specifies the number of nonzero entries in <code>phi</code> , and <code>b11d</code> , <code>b11e</code> , etc. and contains the partially reduced matrix.
-------------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `?bbcsd` interface are as follows:

<code>theta</code>	Holds the vector of length q .
<code>phi</code>	Holds the vector of length $q-1$.
<code>u1</code>	Holds the matrix of size (p,p) .
<code>u2</code>	Holds the matrix of size $(m-p,m-p)$.
<code>v1t</code>	Holds the matrix of size (q,q) .
<code>v2t</code>	Holds the matrix of size $(m-q,m-q)$.
<code>b11d</code>	Holds the vector of length q .
<code>b11e</code>	Holds the vector of length $q-1$.
<code>b12d</code>	Holds the vector of length q .
<code>b12e</code>	Holds the vector of length $q-1$.
<code>b21d</code>	Holds the vector of length q .
<code>b21e</code>	Holds the vector of length $q-1$.
<code>b22d</code>	Holds the vector of length q .
<code>b22e</code>	Holds the vector of length $q-1$.
<code>jobsu1</code>	Indicates whether u_1 is computed. Must be 'Y' or 'O'.
<code>jobsu2</code>	Indicates whether u_2 is computed. Must be 'Y' or 'O'.
<code>jobv1t</code>	Indicates whether v_1^t is computed. Must be 'Y' or 'O'.
<code>jobv2t</code>	Indicates whether v_2^t is computed. Must be 'Y' or 'O'.
<code>trans</code>	Must be 'N' or 'T'.

Description

The routines `?orbdb/?unbdb` simultaneously bidiagonalizes the blocks of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | & \\ & | & p_2 \end{pmatrix} \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 | 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 | 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | & \\ & | & q_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | & \\ & | & p_2 \end{pmatrix} \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 | 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 | 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | & \\ & | & q_2 \end{pmatrix}^H$$

x_{11} is p -by- q . q must not be larger than p , $m-p$, or $m-q$. Otherwise, x must be transposed and/or permuted in constant time using the `trans` and `signs` options. See `?orcisd/?uncsd` for details.

The orthogonal/unitary matrices p_1 , p_2 , q_1 , and q_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. They are represented implicitly by Householder vectors.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are q -by- q bidiagonal matrices represented implicitly by angles `theta(1), ..., theta(q)` and `phi(1), ..., phi(q-1)`. b_{11} and b_{12} are upper bidiagonal, while b_{21} and b_{22} are lower bidiagonal. Every entry in each bidiagonal band is a product of a sine or cosine of `theta` with a sine or cosine of `phi`. See [Sutton09] or description of `?orcisd/?uncsd` for details.

p_1 , p_2 , q_1 , and q_2 are represented as products of elementary reflectors. See description of `?orcisd/?uncsd` for details on generating p_1 , p_2 , q_1 , and q_2 using `?orgqr` and `?orglq`.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>trans</code>	CHARACTER

Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate [computational routines](#).

Driver routines are described in the following sections :

[Linear Least Squares \(LLS\) Problems](#)
[Generalized LLS Problems](#)
[Symmetric Eigenproblems](#)
[Nonsymmetric Eigenproblems](#)
[Singular Value Decomposition](#)
[Cosine-Sine Decomposition](#)
[Generalized Symmetric Definite Eigenproblems](#)
[Generalized Nonsymmetric Eigenproblems](#)

Linear Least Squares (LLS) Problems

This section describes LAPACK driver routines used for solving linear least squares problems. [Table "Driver Routines for Solving LLS Problems"](#) lists all such routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving LLS Problems

Routine Name	Operation performed
gels	Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.
gelsy	Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.
gelss	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.
gelsd	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

?gels

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

FORTRAN 77:

```
call sgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call dgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call cgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call zgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
```

Fortran 95:

```
call gels(a, b [,trans] [,info])
```

C:

```
lapack_int LAPACKE_<?>gels( int matrix_layout, char trans, lapack_int m, lapack_int n,
lapack_int nrhs, <datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix A , or its transpose/ conjugate-transpose, using a QR or LQ factorization of A . It is assumed that A has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$\text{minimize } ||b - A^*x||_2$

-
2. If $\text{trans} = \text{'N'}$ and $m < n$: find the minimum norm solution of an underdetermined system $A^*X = B$.
 3. If $\text{trans} = \text{'T'}$ or 'C' and $m \geq n$: find the minimum norm solution of an undetermined system $A_H^*X = B$.
 4. If $\text{trans} = \text{'T'}$ or 'C' and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$\text{minimize } ||b - A^H X||_2$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- n_{rhs} right hand side matrix B and the n -by- n_{rh} solution matrix X .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

$trans$	CHARACTER*1. Must be ' N ', ' T ', or ' C '. If $trans = \text{'N'}$, the linear system involves matrix A ; If $trans = \text{'T'}$, the linear system involves the transposed matrix A^T (for real flavors only); If $trans = \text{'C'}$, the linear system involves the conjugate-transposed matrix A^H (for complex flavors only).
m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrix A ($n \geq 0$).
n_{rhs}	INTEGER. The number of right-hand sides; the number of columns in B ($n_{rhs} \geq 0$).
$a, b, work$	REAL for sgels DOUBLE PRECISION for dgels COMPLEX for cgels DOUBLE COMPLEX for zgels. Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(lsb,*)$ contains the matrix B of right hand side vectors, stored columnwise; B is m -by- n_{rhs} if $trans = \text{'N'}$, or n -by- n_{rhs} if $trans = \text{'T'}$ or ' C '. The second dimension of b must be at least $\max(1, n_{rhs})$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
lsb	INTEGER. The leading dimension of b ; must be at least $\max(1, m, n)$.

lwork INTEGER. The size of the *work* array; must be at least $\min(m, n) + \max(1, m, n, nrhs)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a On exit, overwritten by the factorization data as follows:
 if $m \geq n$, array *a* contains the details of the QR factorization of the matrix *A* as returned by ?geqrf;
 if $m < n$, array *a* contains the details of the LQ factorization of the matrix *A* as returned by ?gelqf.

b If *info* = 0, *b* overwritten by the solution vectors, stored columnwise:
 if *trans* = 'N' and $m \geq n$, rows 1 to *n* of *b* contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements *n+1* to *m* in that column;
 if *trans* = 'N' and $m < n$, rows 1 to *n* of *b* contain the minimum norm solution vectors;
 if *trans* = 'T' or 'C' and $m \geq n$, rows 1 to *m* of *b* contain the minimum norm solution vectors; if *trans* = 'T' or 'C' and $m < n$, rows 1 to *m* of *b* contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements *m+1* to *n* in that column.

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of the triangular factor of *A* is zero, so that *A* does not have full rank; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gels* interface are the following:

a Holds the matrix *A* of size (m,n) .
b Holds the matrix of size $\max(m,n)$ -by-*nrhs*.
 If *trans* = 'N', then, on entry, the size of *b* is *m*-by-*nrhs*,

If $\text{trans} = \text{'T'}$, then, on entry, the size of b is n -by- $nrhs$,
 trans Must be ' N ' or ' T '. The default value is ' N '.

Application Notes

For better performance, try using $lwork = \min(m, n) + \max(1, m, n, nrhs) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A .

Syntax

FORTRAN 77:

```
call sgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call dgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call cgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork, info)

Description

The ?gelsy routine computes the minimum-norm solution to a real/complex linear least squares problem:

```
minimize ||b - A*x||_2
```

using a complete orthogonal factorization of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The routine first computes a QR factorization with column pivoting:

$$\dots \begin{pmatrix} \dots & \dots & \dots & \dots & \dots \end{pmatrix}$$

with R_{11} defined as the largest leading submatrix whose estimated condition number is less than $1/rcond$. The order of R_{11} , *rank*, is the effective rank of A . Then, R_{22} is considered to be negligible, and R_{12} is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$AP = Q \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^T \begin{pmatrix} T_{11}^{-1} & Q_1^T b \\ 0 & 0 \end{pmatrix} \text{ for real flavors and}$$

$$\dots \begin{pmatrix} \dots & \dots & \dots & \dots & \dots \end{pmatrix}$$

for complex flavors,

where Q_1 consists of the first *rank* columns of Q .

The ?gelsy routine is identical to the original deprecated ?gelsx routine except for the following differences:

- The call to the subroutine ?geqpf has been substituted by the call to the subroutine ?geqp3, which is a BLAS-3 version of the QR factorization with column pivoting.
- The matrix B (the right hand side) is updated with BLAS-3.
- The permutation of the matrix B (the right hand side) is faster and more simple.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a, b, work</i>	<p>REAL for sgelsy DOUBLE PRECISION for dgelsy COMPLEX for cgelsy DOUBLE COMPLEX for zgelsy.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda,*</i>) contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb,*</i>) contains the <i>m</i>-by-<i>nrhs</i> right hand side matrix <i>B</i>. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>jpvt</i>	<p>INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if $jpvt(i) \neq 0$, the <i>i</i>-th column of <i>A</i> is permuted to the front of <i>AP</i>, otherwise the <i>i</i>-th column of <i>A</i> is a free column.</p>
<i>rcond</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of <i>A</i>, which is defined as the order of the largest leading triangular submatrix <i>R</i>₁₁ in the QR factorization with pivoting of <i>A</i>, whose estimated condition number < 1/<i>rcond</i>.</p>
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i>. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>rwork</i>	REAL for cgelsy DOUBLE PRECISION for zgelsy. Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	On exit, overwritten by the details of the complete orthogonal factorization of A .
<i>b</i>	Overwritten by the n -by- $nrhs$ solution matrix X .
<i>jpvt</i>	On exit, if $jpvt(i) = k$, then the i -th column of AP was the k -th column of A .
<i>rank</i>	INTEGER. The effective rank of A , that is, the order of the submatrix R_{11} . This is the same as the order of the submatrix T_{11} in the complete orthogonal factorization of A .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelsy` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>b</i>	Holds the matrix of size $\max(m,n)$ -by- $nrhs$. On entry, contains the m -by- $nrhs$ right hand side matrix B , On exit, overwritten by the n -by- $nrhs$ solution matrix X .
<i>jpvt</i>	Holds the vector of length n . Default value for this element is $jpvt(i) = 0$.
<i>rcond</i>	Default value for this element is $rcond = 100*\text{EPSILON}(1.0_WP)$.

Application Notes

For real flavors:

The unblocked strategy requires that:

$$lwork \geq \max(mn+3n+1, 2*mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork \geq \max(mn+2n+nb*(n+1), 2*mn+nb*nrhs),$$

where nb is an upper bound on the blocksize returned by `ilaenv` for the routines `sgeqp3/dgeqp3, stzrzf/dtzrzf, stzrqf/dtzrqf, sormqr/dormqr, and sormrz/dormrz`.

For complex flavors:

The unblocked strategy requires that:

$$lwork \geq mn + \max(2*mn, n+1, mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork < mn + \max(2*mn, nb*(n+1), mn+mn*nb, mn+ nb*nrhs),$$

where nb is an upper bound on the blocksize returned by [ilaenv](#) for the routines cgeqp3/zgeqp3, ctzrzf/ztzrjf, ctzrqf/ztzrqf, cunmqr/zunmqr, and cunmrz/zunmrz.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelss

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.

Syntax

FORTRAN 77:

```
call sgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call dgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)

Description

The routine computes the minimum norm solution to a real linear least squares problem:

```
minimize ||b - A*x||_2
```

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X . The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
$a, b, work$	<p>REAL for sgels DOUBLE PRECISION for dgels COMPLEX for cgels DOUBLE COMPLEX for zgels.</p> <p>Arrays:</p> <p>$a(lda,*)$ contains the m-by-n matrix A. The second dimension of a must be at least $\max(1, n)$.</p> <p>$b ldb,*)$ contains the m-by-$nrhs$ right hand side matrix B. The second dimension of b must be at least $\max(1, nrhs)$.</p> <p>$work$ is a workspace array, its dimension $\max(1, lwork)$.</p>
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The leading dimension of b ; must be at least $\max(1, m, n)$.
$rcond$	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.</p> <p>$rcond$ is used to determine the effective rank of A. Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond < 0$, machine precision is used instead.</p>
$lwork$	INTEGER. The size of the $work$ array; $lwork \geq 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

$rwork$

REAL for `cgelss`

DOUBLE PRECISION for `zgelss`.

Workspace array used in complex flavors only. DIMENSION at least $\max(1, 5 * \min(m, n))$.

Output Parameters

a

On exit, the first $\min(m, n)$ rows of A are overwritten with its right singular vectors, stored row-wise.

b

Overwritten by the n -by- $nrhs$ solution matrix X .

If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the i -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

s

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$. The singular values of A in decreasing order. The condition number of A in the 2-norm is

$$k_2(A) = s(1) / s(\min(m, n)).$$

$rank$

INTEGER. The effective rank of A , that is, the number of singular values which are greater than $rcond * s(1)$.

$work(1)$

If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm for computing the SVD failed to converge; i indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelss` interface are the following:

a

Holds the matrix A of size (m,n) .

<i>b</i>	Holds the matrix of size $\max(m,n)$ -by- $nrhs$. On entry, contains the m -by- $nrhs$ right hand side matrix B , On exit, overwritten by the n -by- $nrhs$ solution matrix X .
<i>s</i>	Holds the vector of length $\min(m,n)$.
<i>rcond</i>	Default value for this element is $rcond = 100 * \text{EPSILON}(1.0_WP)$.

Application Notes

For real flavors:

$$lwork \geq 3 * \min(m, n) + \max(2 * \min(m, n), \max(m, n), nrhs)$$

For complex flavors:

$$lwork \geq 2 * \min(m, n) + \max(m, n, nrhs)$$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsd

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

Syntax

FORTRAN 77:

```
call sgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)
call dgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes the minimum-norm solution to a real linear least squares problem:

$\text{minimize } \|b - Ax\|_2$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The problem is solved in three steps:

1. Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).
2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

The routine uses auxiliary routines [lals0](#) and [lalsa](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

n INTEGER. The number of columns of the matrix A ($n \geq 0$).

nrhs INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).

a, b, work
REAL for sgelsd
DOUBLE PRECISION for dgelsd
COMPLEX for cgelsd
DOUBLE COMPLEX for zgelsd.

Arrays:

a(*lda,**) contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$b(lDb, *)$ contains the m -by- $nrhs$ right hand side matrix B .

The second dimension of b must be at least $\max(1, nrhs)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The leading dimension of b ; must be at least $\max(1, m, n)$.

$rcond$ REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

$rcond$ is used to determine the effective rank of A . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond \leq 0$, machine precision is used instead.

$lwork$ INTEGER. The size of the $work$ array; $lwork \geq 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the array $work$ and the minimum sizes of the arrays $rwork$ and $iwork$, and returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ is issued by [xerbla](#).

See [Application Notes](#) for the suggested value of $lwork$.

$iwork$ INTEGER. Workspace array. See [Application Notes](#) for the suggested dimension of $iwork$.

$rwork$ REAL for `cgelsd`

DOUBLE PRECISION for `zgelsd`.

Workspace array, used in complex flavors only. See [Application Notes](#) for the suggested dimension of $rwork$.

Output Parameters

a On exit, A has been overwritten.

b Overwritten by the n -by- $nrhs$ solution matrix X .

If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the i -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

s REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$. The singular values of A in decreasing order. The condition number of A in the 2-norm is

$$\kappa^2(A) = s(1) / s(\min(m, n)).$$

$rank$ INTEGER. The effective rank of A , that is, the number of singular values which are greater than $rcond * s(1)$.

<i>work</i> (1)	If $info = 0$, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>rwork</i> (1)	If $info = 0$, on exit, <i>rwork</i> (1) returns the minimum size of the workspace array <i>iwork</i> required for optimum performance.
<i>iwork</i> (1)	If $info = 0$, on exit, <i>iwork</i> (1) returns the minimum size of the workspace array <i>iwork</i> required for optimum performance.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, then the algorithm for computing the SVD failed to converge; i indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelsd` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>b</i>	Holds the matrix of size $\max(m,n)$ -by- $nrhs$. On entry, contains the m -by- $nrhs$ right hand side matrix B , On exit, overwritten by the n -by- $nrhs$ solution matrix X .
<i>s</i>	Holds the vector of length $\min(m,n)$.
<i>rcond</i>	Default value for this element is $rcond = 100 * \text{EPSILON}(1.0_WP)$.

Application Notes

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

The exact minimum amount of workspace needed depends on m , n and $nrhs$. The size *lwork* of the workspace array *work* must be as given below.

For real flavors:

If $m \geq n$,

$$lwork \geq 12n + 2n*smlsiz + 8n*nlvl + n*nrhs + (smlsiz+1)^2;$$

If $m < n$,

$$lwork \geq 12m + 2m*smlsiz + 8m*nlvl + m*nrhs + (smlsiz+1)^2;$$

For complex flavors:

If $m \geq n$,

$$lwork \geq 2n + n*nrhs;$$

If $m < n$,

$$lwork \geq 2m + m*nrhs;$$

where *smlsiz* is returned by *ilaenv* and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and

```
nlvl = INT( log2( min( m, n )/(smlsiz+1) ) ) + 1.
```

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The dimension of the workspace array *iwork* must be at least

$$3*\min(m, n)*nlvl + 11*\min(m, n).$$

The dimension of the workspace array *iwork* (for complex flavors) must be at least *max*(1, *lrwork*).

$$lrwork \geq 10n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m \geq n, \text{ and}$$

$$lrwork \geq 10m + 2m*smlsiz + 8m*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m < n.$$

Generalized LLS Problems

This section describes LAPACK driver routines used for solving generalized linear least squares problems. Table "Driver Routines for Solving Generalized LLS Problems" lists all such routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized LLS Problems

Routine Name	Operation performed
gglse	Solves the linear equality-constrained least squares problem using a generalized RQ factorization.
ggglm	Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

?gglse

Solves the linear equality-constrained least squares problem using a generalized RQ factorization.

Syntax

FORTRAN 77:

```
call sgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call dgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call cgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call zgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
```

Fortran 95:

```
call gglse(a, b, c, d, x [,info])
```

C:

```
lapack_int LAPACKE_<?>gglse( int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
<datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb, <datatype>* c,
<datatype>* d, <datatype>* x );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine solves the linear equality-constrained least squares (LSE) problem:

$\text{minimize } ||c - A^*x||^2 \text{ subject to } B^*x = d$

where A is an m -by- n matrix, B is a p -by- n matrix, c is a given d is a given p -vector. It is assumed that $p \leq n \leq m+p$, and

$$(B^*B)^{-1} B^*A = I_m \quad \text{and} \quad B^*B \text{ is nonsingular}$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

$B = (0 \ R)^* Q, \quad A = Z^* T^* Q$

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

n INTEGER. The number of columns of the matrices A and B ($n \geq 0$).

p INTEGER. The number of rows of the matrix B
($0 \leq p \leq n \leq m+p$).

a, b, c, d, work
REAL for sgglse
DOUBLE PRECISION for dgglse
COMPLEX for cgglse
DOUBLE COMPLEX for zgglse.

Arrays:

a(*lda,**) contains the m -by- n matrix A .

The second dimension of *a* must be at least $\max(1, n)$.

b(*ldb,**) contains the p -by- n matrix B .

The second dimension of *b* must be at least $\max(1, n)$.

c(*), dimension at least max(1, *m*), contains the right hand side vector for the least squares part of the LSE problem.

d(*), dimension at least max(1, *p*), contains the right hand side vector for the constrained equation.

work is a workspace array, its dimension max(1, *lwork*).

lda

INTEGER. The leading dimension of *a*; at least max(1, *m*).

ldb

INTEGER. The leading dimension of *b*; at least max(1, *p*).

lwork

INTEGER. The size of the *work* array;

lwork $\geq \max(1, m+n+p)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

x

REAL for sgglse

b

On exit, the upper triangle of the subarray *b*(1:*p*, *n*-*p*+1:*n*) contains the *p*-by-*p* upper triangular matrix *R*.

d

On exit, *d* is destroyed.

c

On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements *n*-*p*+1 to *m* of vector *c*.

work(1)

If *info* = 0, on exit, *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the upper triangular factor *R* associated with *B* in the generalized RQ factorization of the pair (*B*, *A*) is singular, so that $\text{rank}(B) < P$; the least squares solution could not be computed.

If *info* = 2, the (*n*-*p*)-by- (*n*-*p*) part of the upper trapezoidal factor *T* associated with *A* in the generalized RQ factorization of the pair (*B*, *A*) is singular, so that

$$\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggglm` interface are the following:

- `a` Holds the matrix A of size (m,n) .
- `b` Holds the matrix B of size (p,n) .
- `c` Holds the vector of length (m) .
- `d` Holds the vector of length (p) .
- `x` Holds the vector of length n .

Application Notes

For optimum performance, use

$$lwork \geq p + \min(m, n) + \max(m, n) * nb,$$

where nb is an upper bound for the optimal blocksizes for `?geqrfa`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrg`.

You may set $lwork$ to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

Syntax

FORTRAN 77:

```
call sgglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call dgglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call cgglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call zgglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
```

Fortran 95:

```
call ggglm(a, b, d, x, y [,info])
```

C:

```
lapack_int LAPACKE_<?>ggglm( int matrix_layout, lapack_int n, lapack_int m, lapack_int p, <datatype>* a, lapack_int lda, <datatype>* b, lapack_int ldb, <datatype>* d, <datatype>* x, <datatype>* y );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine solves a general Gauss-Markov linear model (GLM) problem:

$\text{minimize}_x \|y\|_2 \text{ subject to } d = A^*x + B^*y$

where A is an n -by- m matrix, B is an n -by- p matrix, and d is a given n -vector. It is assumed that $m \leq n \leq m+p$, and $\text{rank}(A) = m$ and $\text{rank}(A \ B) = n$.

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y , which is obtained using a generalized QR factorization of the matrices (A, B) given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q^* T^* Z.$$

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$\text{minimize}_x \|B^{-1}(d - A^*x)\|_2$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

n INTEGER. The number of rows of the matrices A and B ($n \geq 0$).

m INTEGER. The number of columns in A ($m \geq 0$).

p INTEGER. The number of columns in B ($p \geq n - m$).

a, b, d, work REAL for sggglm

DOUBLE PRECISION for dggglm

COMPLEX for cggglm

DOUBLE COMPLEX for zggglm.

Arrays:

a(*lda,**) contains the n -by- m matrix A .

The second dimension of *a* must be at least $\max(1, m)$.

b(*ldb,**) contains the n -by- p matrix B .

The second dimension of *b* must be at least $\max(1, p)$.

d(*), dimension at least $\max(1, n)$, contains the left hand side of the GLM equation.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of *b*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array; *lwork* $\geq \max(1, n+m+p)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

x, y

REAL for `sggglm`

DOUBLE PRECISION for `dggglm`

COMPLEX for `cggglm`

DOUBLE COMPLEX for `zggglm`.

Arrays $x(*)$, $y(*)$. DIMENSION at least $\max(1, m)$ for x and at least $\max(1, p)$ for y .

On exit, x and y are the solutions of the GLM problem.

a

On exit, the upper triangular part of the array a contains the m -by- m upper triangular matrix R .

b

On exit, if $n \leq p$, the upper triangle of the subarray $b(1:n, p-n+1:p)$ contains the n -by- n upper triangular matrix T ; if $n > p$, the elements on and above the $(n-p)$ -th subdiagonal contain the n -by- p upper trapezoidal matrix T .

d

On exit, d is destroyed

$work(1)$

If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that $\text{rank}(A) < m$; the least squares solution could not be computed.

If $info = 2$, the bottom $(n-m)$ -by- $(n-m)$ part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that $\text{rank}(A B) < n$; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggglm` interface are the following:

a Holds the matrix A of size (n,m) .

b Holds the matrix B of size (n,p) .

<i>d</i>	Holds the vector of length <i>n</i> .
<i>x</i>	Holds the vector of length (<i>m</i>).
<i>y</i>	Holds the vector of length (<i>p</i>).

Application Notes

For optimum performance, use

$$lwork \geq m + \min(n, p) + \max(n, p) * nb,$$

where *nb* is an upper bound for the optimal blocksizes for ?geqr, ?gerqf, ?ormqr/?unmqr and ?ormrq/?unmrq.

You may set *lwork* to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Symmetric Eigenproblems

This section describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Symmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Symmetric Eigenproblems

Routine Name	Operation performed
syev/heev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix.
syevd/heevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm.
syevx/heevx	Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix.
syevr/heevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations.
spev/hpev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
spevd/hpevd	Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage.
spevx/hpevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
sbev /hbev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
sbevd/hbevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm.
sbevx/hbevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
stev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

Routine Name	Operation performed
stevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.
stevx	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
stevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

?syev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

Syntax**FORTRAN 77:**

```
call ssyev(jobz, uplo, n, a, lda, w, work, lwork, info)
call dsyev(jobz, uplo, n, a, lda, w, work, lwork, info)
```

Fortran 95:

```
call syev(a, w [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>syev( int matrix_layout, char jobz, char uplo, lapack_int n,
<datatype>* a, lapack_int lda, <datatype>* w );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A .

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>jobz</code> <code>uplo</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz</code> = 'N', then only eigenvalues are computed. If <code>jobz</code> = 'V', then eigenvalues and eigenvectors are computed. CHARACTER*1. Must be 'U' or 'L'. If <code>uplo</code> = 'U', <code>a</code> stores the upper triangular part of A . If <code>uplo</code> = 'L', <code>a</code> stores the lower triangular part of A .
--	--

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for ssyev DOUBLE PRECISION for dsyev
	Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint: $lwork \geq \max(1, 3n-1)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix <i>A</i> . If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	REAL for ssyev DOUBLE PRECISION for dsyev Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syev` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>job</code>	Must be ' <code>N</code> ' or ' <code>V</code> '. The default value is ' <code>N</code> '.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For optimum performance set $lwork \geq (nb+2)*n$, where nb is the blocksize for `?sytrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

If $lwork$ has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array on exit. Use this value (`work(1)`) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array `work`. This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?heev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
call zheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
```

Fortran 95:

```
call heev(a, w [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_cheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* w );
```

```
lapack_int LAPACKE_zheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* w );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a</i> , <i>work</i>	COMPLEX for cheev DOUBLE COMPLEX for zheev Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . C onstraint: <i>lwork</i> $\geq \max(1, 2n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

$rwork$

REAL for `cheev`

DOUBLE PRECISION for `zheev`.

Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, array a contains the orthonormal eigenvectors of the matrix A .

If $jobz = 'N'$, then on exit the lower triangle

(if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

w

REAL for `cheev`

DOUBLE PRECISION for `zheev`

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.

$work(1)$

On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heev` interface are the following:

a Holds the matrix A of size (n, n) .

w Holds the vector of length n .

job Must be ' N ' or ' V '. The default value is ' N '.

$uplo$ Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

For optimum performance use

$$lwork \geq (nb+1)*n,$$

where nb is the blocksize for `?hetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?syevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call ssyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
call dsyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevd(a, w [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>syevd( int matrix_layout, char jobz, char uplo, lapack_int n,
<datatype>* a, lapack_int lda, <datatype>* w );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda^* Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. [?syevd](#) requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a</i>	REAL for ssyevd DOUBLE PRECISION for dsyevd Array, DIMENSION (<i>lda</i> , *). <i>a</i> (<i>lدا</i> , *) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lда</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>work</i>	REAL for ssyevd DOUBLE PRECISION for dsyevd . Workspace array, DIMENSION at least <i>lwork</i> .
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: if <i>n</i> \leq 1, then <i>lwork</i> \geq 1; if <i>jobz</i> = 'N' and <i>n</i> $>$ 1, then <i>lwork</i> \geq $2*n + 1$; if <i>jobz</i> = 'V' and <i>n</i> $>$ 1, then <i>lwork</i> \geq $2*n^2 + 6*n + 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the required sizes of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>iwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for `ssyevd`

DOUBLE PRECISION for `dsyevd`

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.
See also $info$.

a

If $jobz = 'V'$, then on exit this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A .

$work(1)$

On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$iwork(1)$

On exit, if $liwork > 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevd` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>jobz</i>	Must be ' N ' or ' V '. The default value is ' N '.
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\varepsilon) * \|T\|_2$, where ε is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [heevd](#)

?heevd

Computes all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call cheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork, liwork, info)
call zheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call heevd(a, w [,job] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_cheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_complex_float* a, lapack_int lda, float* w );
lapack_int LAPACKE_zheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_complex_double* a, lapack_int lda, double* w );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda^* Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace. [?heevd](#) requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be ' <i>N</i> ' or ' <i>V</i> '. If <i>jobz</i> = ' <i>N</i> ', then only eigenvalues are computed. If <i>jobz</i> = ' <i>V</i> ', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '. If <i>uplo</i> = ' <i>U</i> ', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = ' <i>L</i> ', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a</i>	COMPLEX for cheevd DOUBLE COMPLEX for zheevd Array, DIMENSION (<i>lda</i> , *). <i>a</i> (<i>lda</i> , *) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>work</i>	COMPLEX for cheevd DOUBLE COMPLEX for zheevd . Workspace array, DIMENSION $\max(1, lwork)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: if <i>n</i> \leq 1, then <i>lwork</i> \geq 1; if <i>jobz</i> = ' <i>N</i> ' and <i>n</i> $>$ 1, then <i>lwork</i> \geq <i>n</i> +1; if <i>jobz</i> = ' <i>V</i> ' and <i>n</i> $>$ 1, then <i>lwork</i> \geq <i>n</i> ² +2*i <i>n</i> .

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

$rwork$ REAL for `cheevd`

DOUBLE PRECISION for `zheevd`

Workspace array, DIMENSION at least $lrwork$.

$lrwork$ INTEGER.

The dimension of the array $rwork$. Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $job = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $job = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

$iwork$ INTEGER. Workspace array, its dimension $\max(1, liwork)$.

$liwork$ INTEGER.

The dimension of the array $iwork$. Constraints: if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

Output Parameters

w REAL for `cheevd`

DOUBLE PRECISION for `zheevd`

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.
See also $info$.

a If $jobz = 'V'$, then on exit this array is overwritten by the unitary matrix Z which contains the eigenvectors of A .

$work(1)$ On exit, if $lwork > 0$, then the real part of $work(1)$ returns the required minimal size of $lwork$.

<i>rwork</i> (1)	On exit, if <i>lrwork</i> > 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> , and <i>jobz</i> = 'N', then the algorithm failed to converge; <i>i</i> off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if <i>info</i> = <i>i</i> , and <i>jobz</i> = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>info</i> / (n+1) through mod(<i>info</i> , n+1). If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevd` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix *A* + *E* such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set *lwork* = -1 (*liwork* = -1, *lrwork* = -1).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set *lwork* = -1 (*liwork* = -1, *lrwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is `syevd`. See also `hpevd` for matrices held in packed storage, and `hbevd` for banded matrices.

?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax**FORTRAN 77:**

```
call ssyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, iwork, ifail, info)

call dsyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, iwork, ifail, info)
```

Fortran 95:

```
call syevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>syevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, <datatype>* a, lapack_int lda, <datatype> vl, <datatype> vu, lapack_int
il, lapack_int iu, <datatype> abstol, lapack_int* m, <datatype>* w, <datatype>* z,
lapack_int ldz, lapack_int* ifail );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. ?syevx is faster for a few selected eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval $(vl, vu]$ will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, a stores the upper triangular part of A .

If $uplo = 'L'$, a stores the lower triangular part of A .

n

INTEGER. The order of the matrix A ($n \geq 0$).

$a, work$

REAL for ssyevx

DOUBLE PRECISION for dsyevx.

Arrays:

$a(lda,*)$ is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by $uplo$.

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

vl, vu

REAL for ssyevx

DOUBLE PRECISION for dsyevx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if $range = 'A'$ or $'I'$.

il, iu

INTEGER.

If $range = 'I'$, the indices of the smallest and largest eigenvalues to be returned.

Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$;

$il = 1$ and $iu = 0$, if $n = 0$.

Not referenced if $range = 'A'$ or $'V'$.

$abstol$

REAL for ssyevx

DOUBLE PRECISION for dsyevx.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq 1$.

If $jobz = 'V'$, then $ldz \geq \max(1, n)$.

$lwork$

INTEGER.

The dimension of the array $work$.

If $n \leq 1$ then $lwork \geq 1$, otherwise $lwork=8*n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$iwork$

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.
<i>w</i>	REAL for ssyevx DOUBLE PRECISION for dsyevx Array, DIMENSION at least $\max(1, n)$. The first <i>m</i> elements contain the selected eigenvalues of the matrix <i>A</i> in ascending order.
<i>z</i>	REAL for ssyevx DOUBLE PRECISION for dsyevx. Array <i>z</i> (<i>ldz</i> ,*) contains eigenvectors. The second dimension of <i>z</i> must be at least $\max(1, m)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>ifail</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then <i>i</i> eigenvectors failed to converge; their indices are stored in the array <i>ifail</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevx` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>a</code>	Holds the matrix A of size (m, n) .
<code>ifail</code>	Holds the vector of length n .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>vl</code>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<code>vu</code>	Default value for this element is $vu = \text{HUGE}(vl)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0_{\text{WP}}$.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted Note that there will be an error condition if <code>ifail</code> is present and z is omitted.
<code>range</code>	Restored based on the presence of arguments vl , vu , il , iu as follows: $range = 'V'$, if one of or both vl and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of vl , vu , il , iu is present, Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

For optimum performance use $lwork \geq (nb+3) * n$, where nb is the maximum of the blocksize for `?sytrd` and `?ormtr` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If $lwork$ has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array `work`. This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon^* |T|$ is used as tolerance, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2*\text{slamch('S')}$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2*\text{slamch('S')}$.

?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, rwork, iwork, ifail, info)

call zheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, rwork, iwork, ifail, info)
```

Fortran 95:

```
call heevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_cheevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int
il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z,
lapack_int ldz, lapack_int* ifail );

lapack_int LAPACKE_zheevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, double vl, double vu,
lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `heevr` function as its underlying algorithm is faster and uses less workspace. `?heevx` is faster for a few selected eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'.
-------------	----------------------------------

If $jobz = 'N'$, then only eigenvalues are computed.

If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

range

CHARACTER*1. Must be 'A', 'V', or 'I'.

If $range = 'A'$, all eigenvalues will be found.

If $range = 'V'$, all eigenvalues in the half-open interval $(vl, vu]$ will be found.

If $range = 'I'$, the eigenvalues with indices il through iu will be found.

uplo

CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, a stores the upper triangular part of A .

If $uplo = 'L'$, a stores the lower triangular part of A .

n

INTEGER. The order of the matrix A ($n \geq 0$).

a, work

COMPLEX for cheevx

DOUBLE COMPLEX for zheevx.

Arrays:

$a(ilda,*)$ is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by *uplo*.

The second dimension of a must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

vl, vu

REAL for cheevx

DOUBLE PRECISION for zheevx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if $range = 'A'$ or ' I '.

il, iu

INTEGER.

If $range = 'I'$, the indices of the smallest and largest eigenvalues to be returned. Constraints:

$1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if $range = 'A'$ or ' V '.

abstol

REAL for cheevx

DOUBLE PRECISION for zheevx. The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq 1$.

If $jobz = 'V'$, then $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

$lwork \geq 1$ if $n \leq 1$; otherwise at least $2 * n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

$rwork$

REAL for `cheevx`

DOUBLE PRECISION for `zheevx`.

Workspace array, DIMENSION at least $\max(1, 7n)$.

$iwork$

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

m

INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.

w

REAL for `cheevx`

DOUBLE PRECISION for `zheevx`

Array, DIMENSION at least $\max(1, n)$. The first m elements contain the selected eigenvalues of the matrix A in ascending order.

z

COMPLEX for `cheevx`

DOUBLE COMPLEX for `zheevx`.

Array $z(ldz,*)$ contains eigenvectors.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$work(1)$

On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, then $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'V'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevx` interface are the following:

a	Holds the matrix A of size (n, n) .
w	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) .
$ifail$	Holds the vector of length n .
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
vl	Default value for this element is $vl = -\text{HUGE}(v)$.
vu	Default value for this element is $vu = \text{HUGE}(v)$.
il	Default value for this argument is $il = 1$.
iu	Default value for this argument is $iu = n$.
$abstol$	Default value for this element is $abstol = 0.0_{\text{WP}}$.
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted Note that there will be an error condition if $ifail$ is present and z is omitted.
$range$	Restored based on the presence of arguments vl , vu , il , iu as follows: $range = 'V'$, if one of or both vl and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of vl , vu , il , iu is present, Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

For optimum performance use $\text{lwork} \geq (nb+1) * n$, where nb is the maximum of the blocksize for `?hetrd` and `?unmtr` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * \|T\|$ will be used in its place, where $\|T\|$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{slamch('S')}$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{slamch('S')}$.

?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call ssyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, iwork, liwork, info)

call dsyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>syevr( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, <datatype>* a, lapack_int lda, <datatype> vl, <datatype> vu, lapack_int
il, lapack_int iu, <datatype> abstol, lapack_int* m, <datatype>* w, <datatype>* z,
lapack_int ldz, lapack_int* isuppz );
```

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to [sytrd](#). Then, whenever possible, [?syevr](#) calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stemr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block of T :

- a. Compute $T - \sigma^* I = L^* D^* L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b. Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c. For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d. For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine [?syevr](#) calls [stemr](#) when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. [?syevr](#) calls [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Note that [?syevr](#) is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda(i)</i> in the half-open interval: $v1 < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I' and <i>iu-il</i> < <i>n-1</i> , <i>sstebz/dstebz</i> and <i>sstein/dstein</i> are called.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).

a, work

REAL for ssyevr
DOUBLE PRECISION for dsyevr.

Arrays:

a(*lda,**) is an array containing either upper or lower triangular part of the symmetric matrix *A*, as specified by *uplo*.

The second dimension of *a* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array *a*. Must be at least $\max(1, n)$.

vl, vu

REAL for ssyevr
DOUBLE PRECISION for dsyevr.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint:

$1 \leq il \leq iu \leq n$, if $n > 0$;
 $il=1$ and $iu=0$, if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for ssyevr
DOUBLE PRECISION for dsyevr. The absolute error tolerance to which each eigenvalue/eigenvector is required.

If *jobz* = 'V', the eigenvalues and eigenvectors output have residual norms bounded by *abstol*, and the dot products between different eigenvectors are bounded by *abstol*.

If *abstol* < $n * \text{eps} * |T|$, then $n * \text{eps} * |T|$ is used instead, where *eps* is the machine precision, and $|T|$ is the 1-norm of the matrix *T*. The eigenvalues are computed to an accuracy of $\text{eps} * |T|$ irrespective of *abstol*.

If high relative accuracy is important, set *abstol* to ?lamch('S').

ldz

INTEGER. The leading dimension of the output array *z*.

Constraints:

$ldz \geq 1$ and
 $ldz \geq \max(1, n)$ if *jobz* = 'V'.

lwork

INTEGER.

The dimension of the array *work*.

Constraint: $lwork \geq \max(1, 26n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$iwork$ INTEGER. Workspace array, its dimension $\max(1, liwork)$.

$liwork$ INTEGER.

The dimension of the array $iwork$, $lwork \geq \max(1, 10n)$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [xerbla](#).

Output Parameters

a On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

m INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.

w, z REAL for [ssyevr](#)

DOUBLE PRECISION for [dsyevr](#).

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in $w(1)$ to $w(m)$;

$z(ldz, *)$, the second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced. Note that you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$isuppz$ INTEGER.

Array, DIMENSION at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i - 1)$ through $isuppz(2i)$. Referenced only if eigenvectors are needed ($jobz = 'V'$) and all eigenvalues are needed, that is, $range = 'A'$ or $range = 'I'$ and $il = 1$ and $iu = n$.

$work(1)$ On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length (2*m), where the values (2*m) are significant.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<i>vl</i>	Default value for this element is <i>vl</i> = - <code>HUGE(vl)</code> .
<i>vu</i>	Default value for this element is <i>vu</i> = <code>HUGE(vl)</code> .
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = ' <code>V</code> ', if <i>z</i> is present, <i>jobz</i> = ' <code>N</code> ', if <i>z</i> is omitted Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = ' <code>V</code> ', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = ' <code>I</code> ', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = ' <code>A</code> ', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use *lwork* $\geq (nb+6)*n$, where *nb* is the maximum of the blocksize for `?sytrd` and `?ormtr` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call cheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)
call zheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call heevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_cheevr( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int
il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z,
lapack_int ldz, lapack_int* isuppz );
lapack_int LAPACKE_zheevr( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, double vl, double vu,
lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
lapack_complex_double* z, lapack_int ldz, lapack_int* isuppz );
```

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to `hetrd`. Then, whenever possible, `?heevr` calls `stegr` to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the `dqds` algorithm, while orthogonal eigenvectors are computed from various

"good" L^*D*L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of T :

- a. Compute $T - \sigma^* I = L^* D^* L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b. Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c. For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d. For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter `abstol`.

The routine `?heevr` calls `stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `?heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>jobz</code>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. If <code>job</code> = ' <code>N</code> ', then only eigenvalues are computed. If <code>job</code> = ' <code>V</code> ', then eigenvalues and eigenvectors are computed.
<code>range</code>	CHARACTER*1. Must be ' <code>A</code> ' or ' <code>V</code> ' or ' <code>I</code> '. If <code>range</code> = ' <code>A</code> ', the routine computes all eigenvalues. If <code>range</code> = ' <code>V</code> ', the routine computes eigenvalues <code>lambda(i)</code> in the half-open interval: $vl < \lambda(i) \leq vu$. If <code>range</code> = ' <code>I</code> ', the routine computes eigenvalues with indices <code>il</code> to <code>iu</code> . For <code>range</code> = ' <code>V</code> ' or ' <code>I</code> ', <code>sstebz/dstebz</code> and <code>cstein/zstein</code> are called.
<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. If <code>uplo</code> = ' <code>U</code> ', <code>a</code> stores the upper triangular part of <code>A</code> . If <code>uplo</code> = ' <code>L</code> ', <code>a</code> stores the lower triangular part of <code>A</code> .
<code>n</code>	INTEGER. The order of the matrix <code>A</code> ($n \geq 0$).
<code>a, work</code>	COMPLEX for <code>cheevr</code> DOUBLE COMPLEX for <code>zheevr</code> . Arrays: <code>a(lda,*)</code> is an array containing either upper or lower triangular part of the Hermitian matrix <code>A</code> , as specified by <code>uplo</code> .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array a .

Must be at least $\max(1, n)$.

vl, vu

REAL for cheevr

DOUBLE PRECISION for zheevr.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If $range = 'A'$ or ' V' , il and iu are not referenced.

$abstol$

REAL for cheevr

DOUBLE PRECISION for zheevr.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If $jobz = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $abstol$, and the dot products between different eigenvectors are bounded by $abstol$.

If $abstol < n * \text{eps} * |T|$, then $n * \text{eps} * |T|$ will be used in its place, where eps is the machine precision, and $|T|$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\text{eps} * |T|$ irrespective of $abstol$.

If high relative accuracy is important, set $abstol$ to `?lamch('S')`.

ldz

INTEGER. The leading dimension of the output array z . Constraints:

$ldz \geq 1$ if $jobz = 'N'$;

$ldz \geq \max(1, n)$ if $jobz = 'V'$.

$lwork$

INTEGER.

The dimension of the array $work$.

Constraint: $lwork \geq \max(1, 2n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lwork$ or $liwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

rwork REAL for cheevr
 DOUBLE PRECISION for zheevr.
 Workspace array, DIMENSION max(1, *lwork*).

lrwork INTEGER.
 The dimension of the array *rwork*;
 lwork $\geq \max(1, 24n)$.
 If *lrwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

iwork INTEGER. Workspace array, its dimension max(1, *liwork*).

liwork INTEGER.
 The dimension of the array *iwork*,
 lwork $\geq \max(1, 10n)$.
 If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
 If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu*-*il*+1.

w REAL for cheevr
 DOUBLE PRECISION for zheevr.
 Array, DIMENSION at least max(1, *n*), contains the selected eigenvalues in ascending order, stored in *w*(1) to *w*(*m*).

z COMPLEX for cheevr
 DOUBLE COMPLEX for zheevr.
 Array *z*(*ldz*, *); the second dimension of *z* must be at least max(1, *m*).
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If *jobz* = 'N', then *z* is not referenced.

Note: you must ensure that at least $\max(1,m)$ columns are supplied in the array z ; if $\text{range} = \text{'V'}$, the exact value of m is not known in advance and an upper bound must be used.

isuppz

INTEGER.

Array, DIMENSION at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $\text{isuppz}(2i-1)$ through $\text{isuppz}(2i)$. Referenced only if eigenvectors are needed ($\text{jobz} = \text{'V'}$) and all eigenvalues are needed, that is, $\text{range} = \text{'A'}$ or $\text{range} = \text{'I'}$ and $\text{il} = 1$ and $\text{iu} = n$.

work(1)

On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

rwork(1)

On exit, if $\text{info} = 0$, then $\text{rwork}(1)$ returns the required minimal size of lrwork .

iwork(1)

On exit, if $\text{info} = 0$, then $\text{iwork}(1)$ returns the required minimal size of liwork .

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $\text{info} = i$, an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevr` interface are the following:

a

Holds the matrix A of size (n, n) .

w

Holds the vector of length n .

z

Holds the matrix Z of size (n, n) , where the values n and m are significant.

isuppz

Holds the vector of length $(2*n)$, where the values $(2*m)$ are significant.

uplo

Must be '`U`' or '`L`'. The default value is '`U`'.

vl

Default value for this element is $\text{vl} = -\text{HUGE}(\text{vl})$.

vu

Default value for this element is $\text{vu} = \text{HUGE}(\text{vl})$.

il

Default value for this argument is $\text{il} = 1$.

iu

Default value for this argument is $\text{iu} = n$.

abstol

Default value for this element is $\text{abstol} = 0.0_{\text{WP}}$.

<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use *lwork* $\geq (nb+1)*n$, where *nb* is the maximum of the blocksize for ?hetrd and ?unmtr returned by ilaenv.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *lrwork*, or *liwork*) for the first run or set *lwork* = -1 (*lrwork* = -1, *liwork* = -1).

If you choose the first option and set any of admissible *lwork* (or *lrwork*, *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*) on exit. Use this value (*work*(1), *rwork*(1), *iwork*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*lrwork*, *liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of ?steqr may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?spev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspev(jobz, uplo, n, ap, w, z, ldz, work, info)
call dspev(jobz, uplo, n, ap, w, z, ldz, work, info)
```

Fortran 95:

```
call spev(ap, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>spev( int matrix_layout, char jobz, char uplo, lapack_int n,
<datatype>* ap, <datatype>* w, <datatype>* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	REAL for sspev DOUBLE PRECISION for dspev Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of symmetric matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.
<i>work</i>	(*) is a workspace array, DIMENSION at least $\max(1, 3n)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> ≥ 1 ; if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1, n)$.

Output Parameters

<i>w, z</i>	REAL for sspev DOUBLE PRECISION for dspev Arrays: <i>w</i> (*), DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, <i>w</i> contains the eigenvalues of the matrix A in ascending order. <i>z</i> (<i>ldz</i> , *). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix A , with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
-------------	--

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spev` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size (<i>n</i> *(<i>n</i> +1)/2).
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hpev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
call zhpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hpev(ap, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_chpev( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );
lapack_int LAPACKE_zhpev( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_complex_double* ap, double* w, lapack_complex_double* z, lapack_int ldz );
```

Include Files

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	COMPLEX for chpev DOUBLE COMPLEX for zhpev. Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of Hermitian matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. (*) is a workspace array, DIMENSION at least $\max(1, 2n-1)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> ≥ 1 ; if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1, n)$.
<i>rwork</i>	REAL for chpev DOUBLE PRECISION for zhpev. Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

<i>w</i>	REAL for chpev DOUBLE PRECISION for zhpev. Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, <i>w</i> contains the eigenvalues of the matrix A in ascending order.
<i>z</i>	COMPLEX for chpev

DOUBLE COMPLEX for zhpev.

Array z ($ldz, *$).

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the orthonormal eigenvectors of the matrix A , with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced.

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A .

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpev` interface are the following:

ap Holds the array A of size $(n*(n+1)/2)$.

w Holds the vector with the number of elements n .

z Holds the matrix Z of size (n, n) .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

$jobz$ Restored based on the presence of the argument z as follows:

$jobz = 'V'$, if z is present,

$jobz = 'N'$, if z is omitted.

?spevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

FORTRAN 77:

```
call sspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
```

```
call dspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call spevd(ap, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>spevd( int matrix_layout, char jobz, char uplo, lapack_int n,
<datatype>* ap, <datatype>* w, <datatype>* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as:

$$A = Z \Lambda Z^T.$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '.
	If <i>jobz</i> = ' <code>N</code> ', then only eigenvalues are computed.
	If <i>jobz</i> = ' <code>V</code> ', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	If <i>uplo</i> = ' <code>U</code> ', <i>ap</i> stores the packed upper triangular part of A .
	If <i>uplo</i> = ' <code>L</code> ', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap</i> , <i>work</i>	REAL for sspevd DOUBLE PRECISION for dspevd
	Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of symmetric matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be $\max(1, n*(n+1)/2)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> .
	Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;
 if $jobz = 'V'$, then $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

Constraints:

if $n \leq 1$, then $lwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lwork \geq 2*n$;
 if $jobz = 'V'$ and $n > 1$, then
 $lwork \geq n^2 + 6*n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

*iwork*INTEGER. Workspace array, its dimension $\max(1, liwork)$.*liwork*

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w, z

REAL for sspevd

DOUBLE PRECISION for dspevd

Arrays:

w()*, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order.
 See also *info*.

z(ldz,)*.

The second dimension of *z* must be: at least 1 if $jobz = 'N'$; at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*. If $jobz = 'N'$, then *z* is not referenced.

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.
<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required <i>lwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spevd` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = ' <code>V</code> ', if <i>z</i> is present, <i>jobz</i> = ' <code>N</code> ', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\varepsilon) * \|T\|_2$, where ε is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work(1)*, *iwork(1)*) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is `hpevd`.

See also `syevd` for matrices held in full storage, and `sbevd` for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax**FORTRAN 77:**

```
call chpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork,
info)

call zhpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork,
info)
```

Fortran 95:

```
call hpevd(ap, w [,uplo] [,z] [,info])
```

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda^* Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A .

If $uplo = 'L'$, ap stores the packed lower triangular part of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

$ap, work$ COMPLEX for chpevd

DOUBLE COMPLEX for zhpevd

Arrays:

$ap(*)$ contains the packed upper or lower triangle of Hermitian matrix A , as specified by $uplo$.

The dimension of ap must be at least $\max(1, n*(n+1)/2)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldz INTEGER. The leading dimension of the output array z .

Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;

if $jobz = 'V'$, then $ldz \geq \max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$.

Constraints:

if $n \leq 1$, then $lwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

$rwork$ REAL for chpevd

DOUBLE PRECISION for zhpevd

Workspace array, its dimension $\max(1, lrwork)$.

$lrwork$ INTEGER.

The dimension of the array $rwork$. Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

$iwork$ INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

*w*REAL for `chpevd`DOUBLE PRECISION for `zhpevd`Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order.
See also *info*.

*z*COMPLEX for `chpevd`DOUBLE COMPLEX for `zhpevd`Array, DIMENSION (*ldz*,*).The second dimension of *z* must be:at least 1 if $jobz = 'N'$;at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the unitary matrix *Z* which contains the eigenvectors of *A*.

If $jobz = 'N'$, then *z* is not referenced.

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

rwork(1)

On exit, if $info = 0$, then *rwork(1)* returns the required minimal size of *lrwork*.

iwork(1)

On exit, if $info = 0$, then *iwork(1)* returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpевд` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: $jobz = 'V'$, if <code>z</code> is present, $jobz = 'N'$, if <code>z</code> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T + E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [`spevd`](#).

See also [`heevd`](#) for matrices held in full storage, and [`hbевд`](#) for banded matrices.

?spevх

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)

call dspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)
```

Fortran 95:

```

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap</i> , <i>work</i>	REAL for sspevx DOUBLE PRECISION for dspevx Arrays:

ap(*) contains the packed upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.

The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.

work(*) is a workspace array, DIMENSION at least $\max(1, 8n)$.

vl, vu

REAL for sspevx

DOUBLE PRECISION for dspevx

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: *vl* < *vu*.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; *il*=1 and *iu*=0

if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for sspevx

DOUBLE PRECISION for dspevx

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

INTEGER. The leading dimension of the output array *z*.

Constraints:

if *jobz* = 'N', then *ldz* ≥ 1 ;

if *jobz* = 'V', then *ldz* $\geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il+1*.

w, z

REAL for sspevx

DOUBLE PRECISION for dspevx

Arrays:

w(*), DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the selected eigenvalues of the matrix A in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spevxx` interface are the following:

`ap` Holds the array A of size $(n*(n+1)/2)$.

`w` Holds the vector with the number of elements n .

`z` Holds the matrix Z of size (n, n) , where the values n and m are significant.

`ifail` Holds the vector with the number of elements n .

`uplo` Must be '`U`' or '`L`'. The default value is '`U`'.

`vl` Default value for this element is $vl = -\text{HUGE}(vl)$.

`vu` Default value for this element is $vu = \text{HUGE}(vl)$.

<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?\text{lamch}('S')$.

?hpevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
rwork, iwork, ifail, info)

call zhpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpevx(ap, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_chpevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* ap, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz,
lapack_int* ifail );
```

```
lapack_int LAPACKE_zhpevx( int matrix_layout, char jobz, char range, char uplo,
                           lapack_int n, lapack_complex_double* ap, double vl, double vu, lapack_int il,
                           lapack_int iu, double abstol, lapack_int* m, double* w, lapack_complex_double* z,
                           lapack_int ldz, lapack_int* ifail );
```

- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	COMPLEX for chpevx DOUBLE COMPLEX for zhpevx Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of the Hermitian matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> (*) is a workspace array, DIMENSION at least $\max(1, 2n)$.
<i>vl, vu</i>	REAL for chpevx DOUBLE PRECISION for zhpevx

If $\text{range} = \text{'V'}$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $\text{vl} < \text{vu}$.

If $\text{range} = \text{'A'}$ or 'I' , vl and vu are not referenced.

il, iu

INTEGER.

If $\text{range} = \text{'I'}$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq \text{il} \leq \text{iu} \leq n$, if $n > 0$; $\text{il}=1$ and $\text{iu}=0$ if $n = 0$.

If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

abstol

REAL for chpevx

DOUBLE PRECISION for zhpevx

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

INTEGER. The leading dimension of the output array z .

Constraints:

if $\text{jobz} = \text{'N'}$, then $\text{ldz} \geq 1$;

if $\text{jobz} = \text{'V'}$, then $\text{ldz} \geq \max(1, n)$.

rwork

REAL for chpevx

DOUBLE PRECISION for zhpevx

Workspace array, DIMENSION at least $\max(1, 7n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A .

m

INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If $\text{range} = \text{'A'}$, $m = n$, and if $\text{range} = \text{'I'}$, $m = \text{iu}-\text{il}+1$.

w

REAL for chpevx

DOUBLE PRECISION for zhpevx

Array, DIMENSION at least $\max(1, n)$.

If $\text{info} = 0$, contains the selected eigenvalues of the matrix A in ascending order.

z

COMPLEX for chpevx

DOUBLE COMPLEX for zhpevx

Array $\text{z}(\text{ldz}, *)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1,m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpevxx` interface are the following:

ap	Holds the array A of size $(n*(n+1)/2)$.
w	Holds the vector with the number of elements n .
z	Holds the matrix Z of size (n, n) , where the values n and m are significant.
$ifail$	Holds the vector with the number of elements n .
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
vl	Default value for this element is $vl = -\text{HUGE}(vl)$.
vu	Default value for this element is $vu = \text{HUGE}(vl)$.
il	Default value for this argument is $il = 1$.
iu	Default value for this argument is $iu = n$.

<code>abstol</code>	Default value for this element is <code>abstol = 0.0_WP</code> .
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: <code>jobz = 'V'</code> , if <code>z</code> is present, <code>jobz = 'N'</code> , if <code>z</code> is omitted Note that there will be an error condition if <code>ifail</code> is present and <code>z</code> is omitted.
<code>range</code>	Restored based on the presence of arguments <code>vl</code> , <code>vu</code> , <code>il</code> , <code>iu</code> as follows: <code>range = 'V'</code> , if one or both <code>vl</code> and <code>vu</code> are present, <code>range = 'I'</code> , if one or both <code>il</code> and <code>iu</code> are present, <code>range = 'A'</code> , if none of <code>vl</code> , <code>vu</code> , <code>il</code> , <code>iu</code> is present, Note that there will be an error condition if one of or both <code>vl</code> and <code>vu</code> are present and at the same time one of or both <code>il</code> and <code>iu</code> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If `abstol` is less than or equal to zero, then $\varepsilon * \|T\|_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to $2 * ?lamch('S')$.

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
call dsbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
```

Fortran 95:

```
call sbev(ab, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>sbev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, <datatype>* ab, lapack_int ldab, <datatype>* w, <datatype>* z,
lapack_int ldz );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>kd</i> \geq 0).
<i>ab, work</i>	REAL for ssbev DOUBLE PRECISION for dsbev. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3n-2)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least <i>kd</i> + 1.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> \geq 1; if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1, n)$.

Output Parameters

<i>w, z</i>	REAL for ssbev DOUBLE PRECISION for dsbev Arrays: <i>w</i> (*), DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$.
-------------	---

If $jobz = 'V'$, then if $info = 0$, z contains the orthonormal eigenvectors of the matrix A , with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If $uplo = 'U'$, the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows kd and $kd+1$ of ab , and if $uplo = 'L'$, the diagonal and first subdiagonal of T are returned in the first two rows of ab .

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd + 1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> ≥ 1 ;

if $\text{jobz} = \text{'V'}$, then $\text{ldz} \geq \max(1, n)$.

$rwork$

REAL for chbev

DOUBLE PRECISION for zhbev

Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

w

REAL for chbev

DOUBLE PRECISION for zhbev

Array, DIMENSION at least $\max(1, n)$.

If $\text{info} = 0$, contains the eigenvalues in ascending order.

z

COMPLEX for chbev

DOUBLE COMPLEX for zhbev.

Array $z(\text{ldz}, *)$.

The second dimension of z must be at least $\max(1, n)$.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, z contains the orthonormal eigenvectors of the matrix A , with the i -th column of z holding the eigenvector associated with $w(i)$.

If $\text{jobz} = \text{'N'}$, then z is not referenced.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix *A*. In other words, it can compute the spectral factorization of *A* as:

$$A = Z \Lambda Z^T$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
----------------------	---

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab</i> , <i>work</i>	REAL for ssbevd DOUBLE PRECISION for dsbevd. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, \text{lwork})$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least <i>kd</i> +1.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> ≥ 1 ; if <i>jobz</i> = 'V', then <i>ldz</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: if <i>n</i> ≤ 1 , then <i>lwork</i> ≥ 1 ; if <i>jobz</i> = 'N' and <i>n</i> > 1 , then <i>lwork</i> $\geq 2n$; if <i>jobz</i> = 'V' and <i>n</i> > 1 , then <i>lwork</i> $\geq 2*n^2 + 5*n + 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, \text{liwork})$.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i> . Constraints: if <i>n</i> ≤ 1 , then <i>liwork</i> < 1 ; if <i>job</i> = 'N' and <i>n</i> > 1 , then <i>liwork</i> < 1 ; if <i>job</i> = 'V' and <i>n</i> > 1 , then <i>liwork</i> $< 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

Output Parameters

w, z

REAL for ssbevd

DOUBLE PRECISION for dsbevd

Arrays:

$w(*)$, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.
See also $info$.

$z(ldz,*)$.

The second dimension of z must be:

at least 1 if $job = 'N'$;

at least $\max(1, n)$ if $job = 'V'$.

If $job = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A . The i -th column of Z contains the eigenvector which corresponds to the eigenvalue $w(i)$.

If $job = 'N'$, then z is not referenced.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

$work(1)$

On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$iwork(1)$

On exit, if $liwork > 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbevd` interface are the following:

ab

Holds the array A of size $(kd+1,n)$.

w

Holds the vector with the number of elements n .

<i>z</i>	Holds the matrix Z of size (n, n) .
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = ' <i>V</i> ', if <i>z</i> is present, <i>jobz</i> = ' <i>N</i> ', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If any of admissible *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [hbevd](#).

See also [syevd](#) for matrices held in full storage, and [spevd](#) for matrices held in packed storage.

?hbевd

Computes all eigenvalues and (optionally) all eigenvectors of a complex Hermitian band matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call chbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
call zhbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hbевd(ab, w [, uplo] [, z] [, info])
```

C:

```
lapack_int LAPACKE_chbevd( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* w,
                           lapack_complex_float* z, lapack_int ldz );
lapack_int LAPACKE_zhbevd( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* w,
                           lapack_complex_double* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian band matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda^* Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>kd</i> \geq 0).
<i>ab</i> , <i>work</i>	COMPLEX for chbevd DOUBLE COMPLEX for zhbevd. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least <i>kd</i> +1.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then <i>ldz</i> \geq 1;

if $jobz = 'V'$, then $ldz \geq \max(1, n)$.

$lwork$

INTEGER.

The dimension of the array $work$.

Constraints:

if $n \leq 1$, then $lwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n^2$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$rwork$

REAL for chbevd

DOUBLE PRECISION for zhbevd

Workspace array, DIMENSION at least $lrwork$.

$lrwork$

INTEGER.

The dimension of the array $rwork$.

Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER. Workspace array, DIMENSION $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for chbevd

DOUBLE PRECISION for zhbevd

Array, DIMENSION at least max(1, n).

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.
See also $info$.

z

COMPLEX for chbevd

DOUBLE COMPLEX for zhbevd

Array, DIMENSION ($ldz, *$).

The second dimension of z must be:

at least 1 if $jobz = 'N'$;

at least max(1, n) if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the unitary matrix Z which contains the eigenvectors of A . The i -th column of Z contains the eigenvector which corresponds to the eigenvalue $w(i)$.

If $jobz = 'N'$, then z is not referenced.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

$work(1)$

On exit, if $lwork > 0$, then the real part of $work(1)$ returns the required minimal size of $lwork$.

$rwork(1)$

On exit, if $lrwork > 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.

$iwork(1)$

On exit, if $liwork > 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbevd` interface are the following:

ab Holds the array A of size $(kd+1, n)$.

w Holds the vector with the number of elements n .

z Holds the matrix Z of size (n, n) .

$uplo$ Must be '`U`' or '`L`'. The default value is '`U`'.

jobz Restored based on the presence of the argument *z* as follows:
jobz = 'V', if *z* is present,
jobz = 'N', if *z* is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T + E$ such that $\|E\|_2 = O(\epsilon) \|T\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set *lwork* = -1 (*liwork* = -1, *lrwork* = -1).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set *lwork* = -1 (*liwork* = -1, *lrwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [sbevd](#).

See also [heevd](#) for matrices held in full storage, and [hpevd](#) for matrices held in packed storage.

?sbevx

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, iwork, ifail, info)

- Fortran 95: lapack.f90

- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be ' <i>N</i> ' or ' <i>V</i> '. If <i>jobz</i> = ' <i>N</i> ', then only eigenvalues are computed. If <i>jobz</i> = ' <i>V</i> ', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be ' <i>A</i> ' or ' <i>V</i> ' or ' <i>I</i> '. If <i>range</i> = ' <i>A</i> ', the routine computes all eigenvalues. If <i>range</i> = ' <i>V</i> ', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = ' <i>I</i> ', the routine computes eigenvalues in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '. If <i>uplo</i> = ' <i>U</i> ', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = ' <i>L</i> ', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>kd</i> \geq 0).
<i>ab, work</i>	REAL for ssbevx DOUBLE PRECISION for dsbevx. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 7n)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least <i>kd</i> + 1.
<i>vl, vu</i>	REAL for ssbevx DOUBLE PRECISION for dsbevx. If <i>range</i> = ' <i>V</i> ', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: <i>vl</i> < <i>vu</i> .

If $\text{range} = \text{'A'}$ or 'I' , vl and vu are not referenced.

il, iu

INTEGER.

If $\text{range} = \text{'I'}$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq \text{il} \leq \text{iu} \leq n$, if $n > 0$; $\text{il}=1$ and $\text{iu}=0$ if $n = 0$.

If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

abstol

REAL for chpevx

DOUBLE PRECISION for zhpevx

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldq, ldz

INTEGER. The leading dimensions of the output arrays q and z , respectively.

Constraints:

$\text{ldq} \geq 1$, $\text{ldz} \geq 1$;

If $\text{jobz} = \text{'V'}$, then $\text{ldq} \geq \max(1, n)$ and $\text{ldz} \geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

q

REAL for ssbevx DOUBLE PRECISION for dsbevx .

Array, DIMENSION (ldz, n).

If $\text{jobz} = \text{'V'}$, the n -by- n orthogonal matrix is used in the reduction to tridiagonal form.

If $\text{jobz} = \text{'N'}$, the array q is not referenced.

m

INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If $\text{range} = \text{'A'}$, $m = n$, and if $\text{range} = \text{'I'}$, $m = \text{iu}-\text{il}+1$.

w, z

REAL for ssbevx

DOUBLE PRECISION for dsbevx

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$. The first m elements of w contain the selected eigenvalues of the matrix A in ascending order.

$z(\text{ldz}, *)$.

The second dimension of z must be at least $\max(1, m)$.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1,m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If $uplo = 'U'$, the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows kd and $kd+1$ of ab , and if $uplo = 'L'$, the diagonal and first subdiagonal of T are returned in the first two rows of ab .

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbevxx` interface are the following:

ab Holds the array A of size $(kd+1, n)$.

w Holds the vector with the number of elements n .

z Holds the matrix Z of size (n, n) , where the values n and m are significant.

$ifail$ Holds the vector with the number of elements n .

q Holds the matrix Q of size (n, n) .

$uplo$ Must be ' U ' or ' L '. The default value is ' U '.

$v1$ Default value for this element is $v1 = -\text{HUGE}(v1)$.

vu Default value for this element is $vu = \text{HUGE}(v1)$.

il Default value for this argument is $il = 1$.

<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if either <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \varepsilon \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon^* \|T\|_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2^*?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2^*?lamch('S')$.

?hbevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, rwork, iwork, ifail, info)
call zhbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be ' <i>N</i> ' or ' <i>V</i> '. If <i>job</i> = ' <i>N</i> ', then only eigenvalues are computed. If <i>job</i> = ' <i>V</i> ', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be ' <i>A</i> ' or ' <i>V</i> ' or ' <i>I</i> '. If <i>range</i> = ' <i>A</i> ', the routine computes all eigenvalues. If <i>range</i> = ' <i>V</i> ', the routine computes eigenvalues <i>lambda(i)</i> in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = ' <i>I</i> ', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be ' <i>U</i> ' or ' <i>L</i> '. If <i>uplo</i> = ' <i>U</i> ', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = ' <i>L</i> ', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> ≥ 0).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>kd</i> ≥ 0).
<i>ab</i> , <i>work</i>	COMPLEX for chbevx DOUBLE COMPLEX for zhbevx. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array.

The dimension of *work* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of *ab*; must be at least $kd + 1$.

vl, *REAL for chbevx*

DOUBLE PRECISION for zhbevx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu* INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for chbevx

DOUBLE PRECISION for zhbevx.

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldq, *ldz* INTEGER. The leading dimensions of the output arrays *q* and *z*, respectively.

Constraints:

$ldq \geq 1$, $ldz \geq 1$;

If *jobz* = 'V', then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$.

rwork REAL for chbevx

DOUBLE PRECISION for zhbevx

Workspace array, DIMENSION at least $\max(1, 7n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

q COMPLEX for chbevx DOUBLE COMPLEX for zhbevx.

Array, DIMENSION (*ldz*,*n*).

If *jobz* = 'V', the *n*-by-*n* unitary matrix is used in the reduction to tridiagonal form.

If *jobz* = 'N', the array *q* is not referenced.

m INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$.

If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu*-*il*+1.

w REAL for chbevx

DOUBLE PRECISION for zhbevx

Array, DIMENSION at least max(1, n). The first m elements contain the selected eigenvalues of the matrix A in ascending order.

z

COMPLEX for chbevx

DOUBLE COMPLEX for zhbevx.

Array *z*(*ldz*,*).

The second dimension of *z* must be at least max(1, *m*).

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

Note: you must ensure that at least max(1,*m*) columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If *uplo* = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix *T* are returned in rows *kd* and *kd*+1 of *ab*, and if *uplo* = 'L', the diagonal and first subdiagonal of *T* are returned in the first two rows of *ab*.

ifail

INTEGER.

Array, DIMENSION at least max(1, n).

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbevx` interface are the following:

ab

Holds the array *A* of size (*kd*+1, *n*).

<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if either <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to *abstol* + $\varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?lamch('S')$.

?stev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstev(jobz, n, d, e, z, ldz, work, info)
call dstev(jobz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call stev(d, e [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>stev( int matrix_layout, char jobz, lapack_int n, <datatype>* d,
<datatype>* e, <datatype>* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>d, e, work</i>	REAL for ssstev DOUBLE PRECISION for dstev. Arrays: $d(*)$ contains the n diagonal elements of the tridiagonal matrix A . The dimension of d must be at least $\max(1, n)$. $e(*)$ contains the $n-1$ subdiagonal elements of the tridiagonal matrix A . The dimension of e must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace. $work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 2n-2)$. If <i>jobz</i> = 'N', $work$ is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If <i>jobz</i> = 'V' then $ldz \geq \max(1, n)$.

Output Parameters

<i>d</i>	On exit, if <i>info</i> = 0, contains the eigenvalues of the matrix A in ascending order.
<i>z</i>	REAL for ssstev DOUBLE PRECISION for dstev

`Array, DIMENSION (ldz, *).`

The second dimension of *z* must be at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with the eigenvalue returned in *d*(*i*).

If *job* = 'N', then *z* is not referenced.

e

On exit, this array is overwritten with intermediate results.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge;

i elements of *e* did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stev` interface are the following:

d Holds the vector of length *n*.

e Holds the vector of length *n*.

z Holds the matrix *Z* of size (*n*, *n*).

jobz Restored based on the presence of the argument *z* as follows:

jobz = 'V', if *z* is present,

jobz = 'N', if *z* is omitted.

?stevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call sstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
```

```
call dstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call stevd(d, e [, z] [, info])
```

C:

```
lapack_int LAPACKE_<?>stevd( int matrix_layout, char jobz, lapack_int n, <datatype>* d, <datatype>* e, <datatype>* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization of T as: $T = Z^* \Lambda * Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$T^* z_i = \lambda_i * z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

There is no complex analogue of this routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for sstevd DOUBLE PRECISION for dstevd. Arrays: $d(*)$ contains the n diagonal elements of the tridiagonal matrix T . The dimension of d must be at least $\max(1, n)$. $e(*)$ contains the $n-1$ off-diagonal elements of T . The dimension of e must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace. $work(*)$ is a workspace array. The dimension of $work$ must be at least $lwork$.
<i>ldz</i>	INTEGER. The leading dimension of the output array z . Constraints: $ldz \geq 1$ if <i>job</i> = 'N'; $ldz < \max(1, n)$ if <i>job</i> = 'V'.
<i>lwork</i>	INTEGER. The dimension of the array $work$. Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $lwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $lwork \geq n^2 + 4*n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.

The dimension of the array *iwork*.

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

d On exit, if $info = 0$, contains the eigenvalues of the matrix *T* in ascending order.

See also *info*.

z REAL for *sstevd*

DOUBLE PRECISION for *dstevd*

Array, DIMENSION (*ldz*, *).

The second dimension of *z* must be:

at least 1 if $jobz = 'N'$;

at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *T*.

If $jobz = 'N'$, then *z* is not referenced.

e On exit, this array is overwritten with intermediate results.

work(1) On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

iwork(1) On exit, if $liwork > 0$, then *iwork*(1) returns the required minimal size of *liwork*.

info INTEGER.

If $info = 0$, the execution is successful.

If $\text{info} = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stevd` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) .
jobz	Restored based on the presence of the argument z as follows: $\text{jobz} = 'V'$, if z is present, $\text{jobz} = 'N'$, if z is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

If it is not clear how much workspace to supply, use a generous value of lwork (or liwork) for the first run, or set $\text{lwork} = -1$ ($\text{liwork} = -1$).

If lwork (or liwork) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (work , iwork) on exit. Use this value ($\text{work}(1)$, $\text{iwork}(1)$) for subsequent runs.

If $\text{lwork} = -1$ ($\text{liwork} = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (work , iwork). This operation is called a workspace query.

Note that if lwork (liwork) is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stevx

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax**FORTRAN 77:**

```
call sstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work, iwork,
ifail, info)

call dstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work, iwork,
ifail, info)
```

Fortran 95:

```
call stevx(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>stevx( int matrix_layout, char jobz, char range, lapack_int n,
<datatype>* d, <datatype>* e, <datatype> vl, <datatype> vu, lapack_int il, lapack_int
iu, <datatype> abstol, lapack_int* m, <datatype>* w, <datatype>* z, lapack_int ldz,
lapack_int* ifail );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>d, e, work</i>	REAL for sstevx DOUBLE PRECISION for dstevx.

Arrays:

$d(*)$ contains the n diagonal elements of the tridiagonal matrix A .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the $n-1$ subdiagonal elements of A .

The dimension of e must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, 5n)$.

vl, vu

REAL for sstevx

DOUBLE PRECISION for dstevx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If $range = 'A'$ or ' V' , il and iu are not referenced.

$abstol$

REAL for sstevx

DOUBLE PRECISION for dstevx. The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

INTEGER. The leading dimensions of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, then $ldz \geq \max(1, n)$.

$iwork$

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.

w, z

REAL for sstevx

DOUBLE PRECISION for dstevx.

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues of the matrix A in ascending order.

$z(ldz, *)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

d, e

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stevx` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length n .
w	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) , where the values n and m are significant.
$ifail$	Holds the vector of length n .
vl	Default value for this element is $vl = -\text{HUGE}(vl)$.
vu	Default value for this element is $vu = \text{HUGE}(vl)$.
il	Default value for this argument is $il = 1$.

<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * ||A||^1$ is used instead. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch('S')}$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 * ?\text{lamch('S')}$.

?stevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call sstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call dstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)
```

Fortran 95:

```
call stevr(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>stevr( int matrix_layout, char jobz, char range, lapack_int n,
<datatype>* d, <datatype>* e, <datatype> vl, <datatype> vu, lapack_int il, lapack_int
iu, <datatype> abstol, lapack_int* m, <datatype>* w, <datatype>* z, lapack_int ldz,
lapack_int* isuppz );
```

Include Files

- Fortran: mkl.fi

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stegr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T :

- Compute $T - \sigma_i = L_i * D_i * L_i^T$, such that $L_i * D_i * L_i^T$ is a relatively robust representation.
- Compute the eigenvalues, λ_j , of $L_i * D_i * L_i^T$ to high relative accuracy by the *dqds* algorithm.
- If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to Step (a).
- Given the approximate eigenvalue λ_j of $L_i * D_i * L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine [?stevr](#) calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. [?stevr](#) calls [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I' and <i>iu-il</i> < <i>n-1</i> , sstebz/dstebz and sstein/dstein are called.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for sstevr DOUBLE PRECISION for dstevr . Arrays: <i>d</i> (*) contains the n diagonal elements of the tridiagonal matrix T . The dimension of <i>d</i> must be at least $\max(1, n)$.

$e(*)$ contains the $n-1$ subdiagonal elements of A .

The dimension of e must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

vl, vu

REAL for sstevr

DOUBLE PRECISION for dstevr.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If $range = 'A'$ or ' V' , il and iu are not referenced.

$abstol$

REAL for sstevr

DOUBLE PRECISION for dstevr.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If $jobz = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $abstol$, and the dot products between different eigenvectors are bounded by $abstol$. If $abstol < n * \text{eps} * |T|$, then $n * \text{eps} * |T|$ will be used in its place, where eps is the machine precision, and $|T|$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\text{eps} * |T|$ irrespective of $abstol$.

If high relative accuracy is important, set $abstol$ to $?lamch('S')$.

ldz

INTEGER. The leading dimension of the output array z .

Constraints:

$ldz \geq 1$ if $jobz = 'N'$;

$ldz \geq \max(1, n)$ if $jobz = 'V'$.

$lwork$

INTEGER.

The dimension of the array $work$. Constraint:

$lwork \geq \max(1, 20*n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $iwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$,

$iwork \geq \max(1, 10^*n)$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.

w, z

REAL for `sstevr`

DOUBLE PRECISION for `dstevr`.

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues of the matrix T in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1,m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

d, e

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

$isuppz$

INTEGER.

Array, DIMENSION at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i-1)$ through $isuppz(2i)$.

Implemented only for $range = 'A'$ or ' I' and $iu-il = n-1$.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stevr` interface are the following:

<i>d</i>	Holds the vector of length <i>n</i> .
<i>e</i>	Holds the vector of length <i>n</i> .
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length (2*n), where the values (2*m) are significant.
<i>vl</i>	Default value for this element is <i>vl</i> = - <code>HUGE(vl)</code> .
<i>vu</i>	Default value for this element is <i>vu</i> = <code>HUGE(vl)</code> .
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

Normal execution of the routine `?steqr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run, or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work, iwork`) on exit. Use this value (`work(1), iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work, iwork`). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to `-1`, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems.

[Table "Driver Routines for Solving Nonsymmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Nonsymmetric Eigenproblems

Routine Name	Operation performed
<code>gees</code>	Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.
<code>geesx</code>	Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.
<code>geev</code>	Computes the eigenvalues and left and right eigenvectors of a general matrix.
<code>geevx</code>	Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

?gees

Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.

Syntax

FORTRAN 77:

```
call sgees(jobvs, sort, select, n, a, lda, sdim, wr, wi, vs, ldvs, work, lwork, bwork,
info)

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} \cdot & \cdot \\ \cdot & \cdot \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobvs</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed.
<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).
<i>select</i>	LOGICAL FUNCTION of two REAL arguments for real flavors. LOGICAL FUNCTION of one COMPLEX argument for complex flavors. <i>select</i> must be declared EXTERNAL in the calling subroutine. If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form. If <i>sort</i> = 'N', <i>select</i> is not referenced. <i>For real flavors:</i> An eigenvalue $wr(j) + \sqrt{-1} * wi(j)$ is selected if <i>select(wr(j), wi(j))</i> is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy <i>select(wr(j), wi(j))= .TRUE.</i> after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> may be set to <i>n+2</i> (see <i>info</i> below). <i>For complex flavors:</i> An eigenvalue <i>w(j)</i> is selected if <i>select(w(j))</i> is true.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a, work</i>	REAL for sgees DOUBLE PRECISION for dgees COMPLEX for cgees DOUBLE COMPLEX for zgees. <i>Arrays:</i> <i>a(lda,*)</i> is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>ldvs</i>	INTEGER. The leading dimension of the output array <i>vs</i> . Constraints: <i>ldvs</i> ≥ 1 ; <i>ldvs</i> $\geq \max(1, n)$ if <i>jobvs</i> = 'V'.
<i>lwork</i>	INTEGER.

The dimension of the array *work*.

Constraint:

lwork $\geq \max(1, 3n)$ for real flavors;

lwork $\geq \max(1, 2n)$ for complex flavors.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

rwork

REAL for cgees

DOUBLE PRECISION for zgees

Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.

bwork

LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if *sort* = 'N'.

Output Parameters

a

On exit, this array is overwritten by the real-Schur/Schur form *T*.

sdim

INTEGER.

If *sort* = 'N', *sdim* = 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *select* is true.

Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

wr, wi

REAL for sgees

DOUBLE PRECISION for dgees

Arrays, DIMENSION at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form *T*. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for cgees

DOUBLE COMPLEX for zgees.

Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form *T*.

vs

REAL for sgees

DOUBLE PRECISION for dgees

COMPLEX for cgees

DOUBLE COMPLEX for zgees.

Array *vs*(*ldvs*, *); the second dimension of *vs* must be at least $\max(1, n)$.

If $\text{jobvs} = \text{'V'}$, vs contains the orthogonal/unitary matrix Z of Schur vectors.

If $\text{jobvs} = \text{'N'}$, vs is not referenced.

$\text{work}(1)$
On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

info INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i th parameter had an illegal value.

If $\text{info} = i$, and

$i \leq n$:

the QR algorithm failed to compute all the eigenvalues; elements $1:i\text{lo}-1$ and $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged; if $\text{jobvs} = \text{'V'}$, vs contains the matrix which reduces A to its partially converged Schur form;

$i = n+1$:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

$i = n+2$:

after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy $\text{select} = \text{.TRUE.}$. This could also be caused by underflow due to scaling.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gees` interface are the following:

a Holds the matrix A of size (n, n) .

wr Holds the vector of length n . Used in real flavors only.

wi Holds the vector of length n . Used in real flavors only.

w Holds the vector of length n . Used in complex flavors only.

vs Holds the matrix VS of size (n, n) .

jobvs Restored based on the presence of the argument vs as follows:

$\text{jobvs} = \text{'V'}$, if vs is present,

$\text{jobvs} = \text{'N'}$, if vs is omitted.

sort Restored based on the presence of the argument select as follows:

$\text{sort} = \text{'S'}$, if select is present,

$\text{sort} = \text{'N'}$, if select is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geesx

Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.

Syntax

FORTRAN 77:

```
call sgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs, rconde,
rcondv, work, lwork, iwork, liwork, bwork, info)

call dgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs, rconde,
rcondv, work, lwork, iwork, liwork, bwork, info)

call cgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde, rcondv,
work, lwork, rwork, bwork, info)

call zgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde, rcondv,
work, lwork, rwork, bwork, info)
```

Fortran 95:

```
call geesx(a, wr, wi [,vs] [,select] [,sdim] [,rconde] [,rcondv] [,info])
call geesx(a, w [,vs] [,select] [,sdim] [,rconde] [,rcondv] [,info])
```

C:

```
lapack_int LAPACKE_sgeesx( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2
select, char sense, lapack_int n, float* a, lapack_int lda, lapack_int* sdim, float*
wr, float* wi, float* vs, lapack_int ldvs, float* rconde, float* rcondv );

lapack_int LAPACKE_dgeesx( int matrix_layout, char jobvs, char sort, LAPACK_D_SELECT2
select, char sense, lapack_int n, double* a, lapack_int lda, lapack_int* sdim, double*
wr, double* wi, double* vs, lapack_int ldvs, double* rconde, double* rcondv );

lapack_int LAPACKE_cgeesx( int matrix_layout, char jobvs, char sort, LAPACK_C_SELECT1
select, char sense, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int*
sdim, lapack_complex_float* w, lapack_complex_float* vs, lapack_int ldvs, float*
rconde, float* rcondv );

lapack_int LAPACKE_zgeesx( int matrix_layout, char jobvs, char sort, LAPACK_Z_SELECT1
select, char sense, lapack_int n, lapack_complex_double* a, lapack_int lda,
lapack_int* sdim, lapack_complex_double* w, lapack_complex_double* vs, lapack_int ldvs,
double* rconde, double* rcondv );
```

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real-Schur/Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (*rconde*); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (*rcondv*). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers *rconde* and *rcondv*, see [LUG], Section 4.10 (where these quantities are called *s* and *sep* respectively).

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} & \cdots \\ & \vdots \\ & \cdots \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are

$$\lambda_1, \lambda_2, \dots, \lambda_n$$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobvs</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed.
<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).
<i>select</i>	LOGICAL FUNCTION of two REAL arguments for real flavors. LOGICAL FUNCTION of one COMPLEX argument for complex flavors. <i>select</i> must be declared EXTERNAL in the calling subroutine. If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.

If $sort = 'N'$, $select$ is not referenced.

For real flavors:

An eigenvalue $wr(j) + \sqrt{-1} * wi(j)$ is selected if $select(wr(j), wi(j))$ is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that a selected complex eigenvalue may no longer satisfy $select(wr(j), wi(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case $info$ may be set to $n+2$ (see $info$ below).

For complex flavors:

An eigenvalue $w(j)$ is selected if $select(w(j))$ is true.

sense CHARACTER*1. Must be ' N ', ' E ', ' V ', or ' B '. Determines which reciprocal condition number are computed.

If $sense = 'N'$, none are computed;

If $sense = 'E'$, computed for average of selected eigenvalues only;

If $sense = 'V'$, computed for selected right invariant subspace only;

If $sense = 'B'$, computed for both.

If $sense$ is ' E ', ' V ', or ' B ', then $sort$ must equal ' S '.

n INTEGER. The order of the matrix A ($n \geq 0$).

a, work REAL for sgeesx

DOUBLE PRECISION for dgeesx

COMPLEX for cgeesx

DOUBLE COMPLEX for zgeesx.

Arrays:

a($lda, *$) is an array containing the n -by- n matrix A .

The second dimension of *a* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of the array *a*. Must be at least $\max(1, n)$.

ldvs INTEGER. The leading dimension of the output array *vs*. Constraints:

$ldvs \geq 1$;

$ldvs \geq \max(1, n)$ if $jobvs = 'V'$.

lwork INTEGER.

The dimension of the array *work*. Constraint:

$lwork \geq \max(1, 3n)$ for real flavors;

$lwork \geq \max(1, 2n)$ for complex flavors.

Also, if $sense = 'E'$, ' V ', or ' B ', then

$lwork \geq n+2*sdim*(n-sdim)$ for real flavors;

$lwork \geq 2*sdim*(n-sdim)$ for complex flavors;

where $sdim$ is the number of selected eigenvalues computed by this routine.

Note that $2*sdim*(n-sdim) \leq n*n/2$. Note also that an error is only returned if $lwork < \max(1, 2*n)$, but if $sense = 'E'$, or ' ∇ ', or ' B ' this may not be large enough.

For good performance, $lwork$ must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates upper bound on the optimal size of the array $work$, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

$iwork$

INTEGER.

Workspace array, DIMENSION ($liwork$). Used in real flavors only. Not referenced if $sense = 'N'$ or ' E '.

$liwork$

INTEGER.

The dimension of the array $iwork$. Used in real flavors only.

Constraint:

$liwork \geq 1$;

if $sense = 'V'$ or ' B ', $liwork \geq sdim*(n-sdim)$.

$rwork$

REAL for cgeesx

DOUBLE PRECISION for zgeesx

Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.

$bwork$

LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if $sort = 'N'$.

Output Parameters

a

On exit, this array is overwritten by the real-Schur/Schur form T .

$sdim$

INTEGER.

If $sort = 'N'$, $sdim = 0$.

If $sort = 'S'$, $sdim$ is equal to the number of eigenvalues (after sorting) for which $select$ is true.

Note that for real flavors complex conjugate pairs for which $select$ is true for either eigenvalue count as 2.

wr, wi

REAL for sgeesx

DOUBLE PRECISION for dgeesx

Arrays, DIMENSION at least max (1, n) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form T . Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

*w*COMPLEX for `cgeesx`DOUBLE COMPLEX for `zgeesx`.

Array, DIMENSION at least max(1, n). Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form T .

*vs*REAL for `sgeesx`DOUBLE PRECISION for `dgeesx`COMPLEX for `cgeesx`DOUBLE COMPLEX for `zgeesx`.

Array $vs(ldvs,*)$; the second dimension of vs must be at least max(1, n).

If $jobvs = 'V'$, vs contains the orthogonal/unitary matrix Z of Schur vectors.

If $jobvs = 'N'$, vs is not referenced.

rconde, rcondv

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

If $sense = 'E'$ or ' B ', $rconde$ contains the reciprocal condition number for the average of the selected eigenvalues.

If $sense = 'N'$ or ' V ', $rconde$ is not referenced.

If $sense = 'V'$ or ' B ', $rcondv$ contains the reciprocal condition number for the selected right invariant subspace.

If $sense = 'N'$ or ' E ', $rcondv$ is not referenced.

work(1)

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i th parameter had an illegal value.

If $info = i$, and

$i \leq n$:

the QR algorithm failed to compute all the eigenvalues; elements 1: $ilo-1$ and $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged; if $jobvs = 'V'$, vs contains the transformation which reduces A to its partially converged Schur form;

$i = n+1$:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

i = *n*+2:

after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy *select* = .TRUE.. This could also be caused by underflow due to scaling.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geesx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>wr</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>wi</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>w</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>vs</i>	Holds the matrix <i>VS</i> of size (<i>n</i> , <i>n</i>).
<i>jobvs</i>	Restored based on the presence of the argument <i>vs</i> as follows: <i>jobvs</i> = 'V', if <i>vs</i> is present, <i>jobvs</i> = 'N', if <i>vs</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If you choose the first option and set any of admissible *lwork* (or *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geev

Computes the eigenvalues and left and right eigenvectors of a general matrix.

Syntax**FORTRAN 77:**

```
call sgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork, info)
call dgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork, info)

- C: mkl.h

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors. The right eigenvector $v(j)$ of A satisfies

$$A^*v(j) = \lambda(j)^*v(j)$$

where $\lambda(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)^H * A = \lambda(j)^* u(j)^H$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$. The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>jobvl</i>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. If <i>jobvl</i> = ' <code>N</code> ', then left eigenvectors of <i>A</i> are not computed. If <i>jobvl</i> = ' <code>V</code> ', then left eigenvectors of <i>A</i> are computed.
<i>jobvr</i>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. If <i>jobvr</i> = ' <code>N</code> ', then right eigenvectors of <i>A</i> are not computed. If <i>jobvr</i> = ' <code>V</code> ', then right eigenvectors of <i>A</i> are computed.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for <code>sgeev</code> DOUBLE PRECISION for <code>dgeev</code> COMPLEX for <code>cgeev</code> DOUBLE COMPLEX for <code>zgeev</code> . Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least <code>max(1, n)</code> . <i>work</i> is a workspace array, its dimension <code>max(1, lwork)</code> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least <code>max(1, n)</code> .
<i>ldvl, ldvr</i>	INTEGER. The leading dimensions of the output arrays <i>vl</i> and <i>vr</i> , respectively. Constraints: $ldvl \geq 1; ldvr \geq 1$. If <i>jobvl</i> = ' <code>V</code> ', <i>ldvl</i> $\geq \max(1, n)$; If <i>jobvr</i> = ' <code>V</code> ', <i>ldvr</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint for real flavors: $lwork \geq \max(1, 3n)$. If computing eigenvectors (<i>jobvl</i> = ' <code>V</code> ' or <i>jobvr</i> = ' <code>V</code> '), <i>lwork</i> $\geq \max(1, 4n)$. Constraint for complex flavors: $lwork \geq \max(1, 2n)$.

For good performance, $lwork$ must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

$rwork$

REAL for `cgeev`

DOUBLE PRECISION for `zgeev`

Workspace array, size at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

a

On exit, this array is overwritten by intermediate results.

wr, wi

REAL for `sgeev`

DOUBLE PRECISION for `dgeev`

Arrays, size at least $\max(1, n)$ each.

Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for `cgeev`

DOUBLE COMPLEX for `zgeev`.

Array, size at least $\max(1, n)$.

Contains the computed eigenvalues.

vl, vr

REAL for `sgeev`

DOUBLE PRECISION for `dgeev`

COMPLEX for `cgeev`

DOUBLE COMPLEX for `zgeev`.

Arrays:

$vl(ldbl, *)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i * vl(:, j+1)$ and $u(j+1) = vl(:, j) - i * vl(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .

$vr(livr, *)$; the second dimension of vr must be at least $\max(1, n)$.

If $\text{jobvr} = \text{'V'}$, the right eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues.

If $\text{jobvr} = \text{'N'}$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i * vr(:, j+1)$ and $v(j+1) = vr(:, j) - i * vr(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$v(j) = vr(:, j)$, the j -th column of vr .

$\text{work}(1)$

On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i th parameter had an illegal value.

If $\text{info} = i$, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geev` interface are the following:

a Holds the matrix A of size (n, n) .

wr Holds the vector of length n . Used in real flavors only.

wi Holds the vector of length n . Used in real flavors only.

w Holds the vector of length n . Used in complex flavors only.

vl Holds the matrix VL of size (n, n) .

vr Holds the matrix VR of size (n, n) .

jobvl Restored based on the presence of the argument vl as follows:

$\text{jobvl} = \text{'V'}$, if vl is present,

$\text{jobvl} = \text{'N'}$, if vl is omitted.

jobvr Restored based on the presence of the argument vr as follows:

$\text{jobvr} = \text{'V'}$, if vr is present,

$\text{jobvr} = \text{'N'}$, if vr is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine exits immediately with an error and does not provide any information on the recommended workspace.

?geevx

Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

Syntax

FORTRAN 77:

```
call sggevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)
call dgeevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ilo , ihi , $scale$, and $abnrm$), reciprocal condition numbers for the eigenvalues ($rconde$), and reciprocal condition numbers for the right eigenvectors ($rcondv$).

The right eigenvector $v(j)$ of A satisfies

$$A^*v(j) = \lambda(j)^*v(j)$$

where $\lambda(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)^H A = \lambda(j)^* u(j)^H$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$. The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D^*A^*\text{inv}(D)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>balanc</i>	CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. If <i>balanc</i> = 'N', do not diagonally scale or permute; If <i>balanc</i> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; If <i>balanc</i> = 'S', diagonally scale the matrix, i.e. replace A by $D^*A^*\text{inv}(D)$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; If <i>balanc</i> = 'B', both diagonally scale and permute A .
---------------	--

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

jobvl

CHARACTER*1. Must be 'N' or 'V'.

If *jobvl* = 'N', left eigenvectors of *A* are not computed;

If *jobvl* = 'V', left eigenvectors of *A* are computed.

If *sense* = 'E' or 'B', then *jobvl* must be 'V'.

jobvr

CHARACTER*1. Must be 'N' or 'V'.

If *jobvr* = 'N', right eigenvectors of *A* are not computed;

If *jobvr* = 'V', right eigenvectors of *A* are computed.

If *sense* = 'E' or 'B', then *jobvr* must be 'V'.

sense

CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If *sense* = 'N', none are computed;

If *sense* = 'E', computed for eigenvalues only;

If *sense* = 'V', computed for right eigenvectors only;

If *sense* = 'B', computed for eigenvalues and right eigenvectors.

If *sense* is 'E' or 'B', both left and right eigenvectors must also be computed (*jobvl* = 'V' and *jobvr* = 'V').

n

INTEGER. The order of the matrix *A* (*n* \geq 0).

a, work

REAL for sgeevx

DOUBLE PRECISION for dgeevx

COMPLEX for cgeevx

DOUBLE COMPLEX for zgeevx.

Arrays:

a(*lda*,*) is an array containing the *n*-by-*n* matrix *A*.

The second dimension of *a* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array *a*. Must be at least $\max(1, n)$.

ldvl, ldvr

INTEGER. The leading dimensions of the output arrays *vl* and *vr*, respectively.

Constraints:

ldvl \geq 1; *ldvr* \geq 1.

If *jobvl* = 'V', *ldvl* $\geq \max(1, n)$;

If *jobvr* = 'V', *ldvr* $\geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

For real flavors:

If *sense* = 'N' or 'E', *lwork* $\geq \max(1, 2n)$, and if *jobvl* = 'V' or *jobvr* = 'V', *lwork* $\geq 3n$;

If *sense* = 'V' or 'B', *lwork* $\geq n*(n+6)$.

For good performance, *lwork* must generally be larger.

For complex flavors:

If *sense* = 'N' or 'E', *lwork* $\geq \max(1, 2n)$;

If *sense* = 'V' or 'B', *lwork* $\geq n^2 + 2n$. For good performance, *lwork* must generally be larger.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for `cgeevx`

DOUBLE PRECISION for `zgeevx`

Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION at least $\max(1, 2n-2)$. Used in real flavors only. Not referenced if *sense* = 'N' or 'E'.

Output Parameters

a

On exit, this array is overwritten.

If *jobvl* = 'V' or *jobvr* = 'V', it contains the real-Schur/Schur form of the balanced version of the input matrix *A*.

wr, wi

REAL for `sgeevx`

DOUBLE PRECISION for `dgeevx`

Arrays, DIMENSION at least max (1, *n*) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for `cgeevx`

DOUBLE COMPLEX for `zgeevx`.

Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues.

vl, vr

REAL for `sgeevx`

DOUBLE PRECISION for `dgeevx`

COMPLEX for `cgeevx`

DOUBLE COMPLEX for `zgeevx`.

Arrays:

$vl(Idvl,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i * vl(:, j+1)$ and $u(j+1) = vl(:, j) - i * vl(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .

$vr(Idvr,*)$; the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i * vr(:, j+1)$ and $v(j+1) = vr(:, j) - i * vr(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$v(j) = vr(:, j)$, the j -th column of vr .

ilo, ihi

INTEGER. ilo and ihi are integer values determined when A was balanced.

The balanced $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

$scale$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, n)$. Details of the permutations and scaling factors applied when balancing A .

If $P(j)$ is the index of the row and column interchanged with row and column j , and $D(j)$ is the scaling factor applied to row and column j , then

$$\begin{aligned} scale(j) &= P(j), \text{ for } j = 1, \dots, ilo-1 \\ &= D(j), \text{ for } j = ilo, \dots, ihi \\ &= P(j) \text{ for } j = ihi+1, \dots, n. \end{aligned}$$

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

$abnrm$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

rconde, rcondv REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least max(1, *n*) each.

rconde(j) is the reciprocal condition number of the *j*-th eigenvalue.

rcondv(j) is the reciprocal condition number of the *j*-th right eigenvector.

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1: *i/o*-1 and *i+1:n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain eigenvalues which have converged.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geevx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>wr</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>wi</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>w</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).
<i>scale</i>	Holds the vector of length <i>n</i> .
<i>rconde</i>	Holds the vector of length <i>n</i> .
<i>rcondv</i>	Holds the vector of length <i>n</i> .
<i>balanc</i>	Must be 'N', 'B', 'P' or 'S'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows:

	<i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Singular Value Decomposition - LAPACK Driver Routines

[Table "Driver Routines for Singular Value Decomposition"](#) lists the LAPACK driver routines that perform singular value decomposition for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are the same except that the first character is removed.

Driver Routines for Singular Value Decomposition

Routine Name	Operation performed
?gesvd	Computes the singular value decomposition of a general rectangular matrix.
?gesdd	Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.
?gejsv	Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method.
?gesvj	Computes the singular value decomposition of a real matrix using Jacobi plane rotations.
?ggsvd	Computes the generalized singular value decomposition of a pair of general rectangular matrices.

Singular Value Decomposition - LAPACK Computational Routines

?gesvd

Computes the singular value decomposition of a general rectangular matrix.

Syntax

FORTRAN 77:

```

Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written as

$A = U^* \Sigma V^T$ for real routines

$A = U^* \Sigma V^H$ for complex routines

where Σ is an m -by- n matrix which is zero except for its $\min(m,n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m,n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns V^T (for real flavors) or V^H (for complex flavors), not V .

Input Parameters

The data types are given for the Fortran interface, except for *superb*. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

jobu CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix U .

If *jobu* = 'A', all m columns of U are returned in the array *u*;

if *jobu* = 'S', the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the array *u*;

if $\text{jobu} = \text{'O'}$, the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the array a ;

if $\text{jobu} = \text{'N'}$, no columns of U (no left singular vectors) are computed.

jobvt

CHARACTER*1. Must be ' A ', ' S ', ' O ', or ' N '. Specifies options for computing all or part of the matrix V^T/V^H .

If $\text{jobvt} = \text{'A'}$, all n rows of V^T/V^H are returned in the array vt ;

if $\text{jobvt} = \text{'S'}$, the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are returned in the array vt ;

if $\text{jobvt} = \text{'O'}$, the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are overwritten on the array a ;

if $\text{jobvt} = \text{'N'}$, no rows of V^T/V^H (no right singular vectors) are computed.

jobvt and jobu cannot both be ' O '.

m

INTEGER. The number of rows of the matrix A ($m \geq 0$).

n

INTEGER. The number of columns in A ($n \geq 0$).

a, work

REAL for sgesvd

DOUBLE PRECISION for dgesvd

COMPLEX for cgesvd

DOUBLE COMPLEX for zgesvd.

Arrays:

$a(\text{lda},*)$ is an array containing the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array a .

Must be at least $\max(1, m)$.

ldu, ldvt

INTEGER. The leading dimensions of the output arrays u and vt , respectively.

Constraints:

$\text{ldu} \geq 1; \text{ldvt} \geq 1$.

If $\text{jobu} = \text{'S'}$ or ' A ', $\text{ldu} \geq m$;

If $\text{jobvt} = \text{'A'}$, $\text{ldvt} \geq n$;

If $\text{jobvt} = \text{'S'}$, $\text{ldvt} \geq \min(m, n)$.

lwork

INTEGER.

The dimension of the array work .

Constraints:

$\text{lwork} \geq 1$

$\text{lwork} \geq \max(3 * \min(m, n) + \max(m, n), 5 * \min(m, n))$ (for real flavors);

$lwork \geq 2*\min(m, n) + \max(m, n)$ (for complex flavors).

For good performance, $lwork$ must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* for details.

$rwork$

REAL for `cgesvd`

DOUBLE PRECISION for `zgesvd`

Workspace array, DIMENSION at least $\max(1, 5*\min(m, n))$. Used in complex flavors only.

Output Parameters

a

On exit,

If $jobu = 'O'$, a is overwritten with the first $\min(m, n)$ columns of U (the left singular vectors stored columnwise);

If $jobvt = 'O'$, a is overwritten with the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored rowwise);

If $jobu \neq 'O'$ and $jobvt \neq 'O'$, the contents of a are destroyed.

s

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.

u, vt

REAL for `sgesvd`

DOUBLE PRECISION for `dgesvd`

COMPLEX for `cgesvd`

DOUBLE COMPLEX for `zgesvd`.

Arrays:

$u(lu, *)$; the second dimension of u must be at least $\max(1, m)$ if $jobu = 'A'$, and at least $\max(1, \min(m, n))$ if $jobu = 'S'$.

If $jobu = 'A'$, u contains the m -by- m orthogonal/unitary matrix U .

If $jobu = 'S'$, u contains the first $\min(m, n)$ columns of U (the left singular vectors stored column-wise).

If $jobu = 'N'$ or $'O'$, u is not referenced.

$vt(lvvt, *)$; the second dimension of vt must be at least $\max(1, n)$.

If $jobvt = 'A'$, vt contains the n -by- n orthogonal/unitary matrix V^T/V^H .

If $jobvt = 'S'$, vt contains the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored row-wise).

If $jobvt = 'N'$ or $'O'$, vt is not referenced.

$work$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

For real flavors:

If $\text{info} > 0$, $\text{work}(2:\min(m,n))$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = u^* B^* v t$, so it has the same singular values as A , and singular vectors related by u and $v t$.

$rwork$

On exit (for complex flavors), if $\text{info} > 0$, $rwork(1:\min(m,n)-1)$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = u^* B^* v t$, so it has the same singular values as A , and singular vectors related by u and $v t$.

$superb$ (C interface)

On exit, $superb(0:\min(m,n)-2)$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = u^* B^* v t$, so it has the same singular values as A , and singular vectors related by u and $v t$.

$info$

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

If $\text{info} = i$, then if ?bdsqr did not converge, i specifies how many superdiagonals of the intermediate bidiagonal form B did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesvd` interface are the following:

a

Holds the matrix A of size (m, n) .

s

Holds the vector of length $\min(m, n)$.

u

If present and is a square m -by- m matrix, on exit contains the m -by- m orthogonal/unitary matrix U .

Otherwise, if present, on exit contains the first $\min(m, n)$ columns of the matrix U (left singular vectors stored column-wise).

vt

If present and is a square n -by- n matrix, on exit contains the n -by- n orthogonal/unitary matrix V^T/V^H .

Otherwise, if present, on exit contains the first $\min(m, n)$ rows of the matrix V^T/V^H (right singular vectors stored row-wise).

ww

Holds the vector of length $\min(m, n)-1$. ww contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = U^* B^* V T$, so it has the same singular values as A , and singular vectors related by U and $V T$.

job

Must be either '`N`', or '`U`', or '`V`'. The default value is '`N`'.

If $\text{job} = \text{'U'}$, and u is not present, then u is returned in the array a .

If $job = 'V'$, and vt is not present, then vt is returned in the array a .

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gesdd

Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.

Syntax

FORTRAN 77:

```
call sgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)
call dgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)

Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors.

If singular vectors are desired, it uses a divide-and-conquer algorithm. The SVD is written

$A = U \Sigma V'$ for real routines,

$A = U \Sigma \text{conjg}(V')$ for complex routines,

where Σ is an m -by- n matrix which is zero except for its $\min(m,n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m,n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns $vt = V'$ (for real flavors) or $vt = \text{conjg}(V')$ (for complex flavors), not V .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>jobz</i>	<p>CHARACTER*1. Must be '<code>A</code>', '<code>S</code>', '<code>O</code>', or '<code>N</code>'.</p> <p>Specifies options for computing all or part of the matrix U.</p> <p>If $jobz = 'A'$, all m columns of U and all n rows of $V'/\text{conjg}(V)$ are returned in the arrays u and vt;</p> <p>if $jobz = 'S'$, the first $\min(m, n)$ columns of U and the first $\min(m, n)$ rows of $V'/\text{conjg}(V)$ are returned in the arrays u and vt;</p> <p>if $jobz = 'O'$, then</p> <p>if $m \geq n$, the first n columns of U are overwritten in the array a and all rows of $V'/\text{conjg}(V)$ are returned in the array vt;</p> <p>if $m < n$, all columns of U are returned in the array u and the first m rows of $V'/\text{conjg}(V)$ are overwritten in the array a;</p> <p>if $jobz = 'N'$, no columns of U or rows of $V'/\text{conjg}(V)$ are computed.</p>
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	<p>REAL for <code>s gesdd</code></p> <p>DOUBLE PRECISION for <code>d gesdd</code></p> <p>COMPLEX for <code>c gesdd</code></p> <p>DOUBLE COMPLEX for <code>z gesdd</code>.</p> <p>Arrays: $a(lda,*)$ is an array containing the m-by-n matrix A. The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.</p>

<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, m)$.
<i>ldu</i> , <i>ldvt</i>	INTEGER. The leading dimensions of the output arrays <i>u</i> and <i>vt</i> , respectively.
	Constraints:
	<i>ldu</i> ≥ 1 ; <i>ldvt</i> ≥ 1 .
	If <i>jobz</i> = 'S' or 'A', or <i>jobz</i> = 'O' and $m < n$, then <i>ldu</i> $\geq m$;
	If <i>jobz</i> = 'A' or <i>jobz</i> = 'O' and $m \geq n$, then <i>ldvt</i> $\geq n$;
	If <i>jobz</i> = 'S', <i>ldvt</i> $\geq \min(m, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> ; <i>lwork</i> ≥ 1 . If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the <i>work</i> (1), and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for cgesdd DOUBLE PRECISION for zgesdd Workspace array, size at least $\max(1, 5 * \min(m, n))$ if <i>jobz</i> = 'N'. Otherwise, the dimension of <i>rwork</i> must be at least $\max(1, \min(m, n) * \max(5 * \min(m, n) + 7, 2 * \max(m, n) + 2 * \min(m, n) + 1))$. This array is used in complex flavors only.
<i>iwork</i>	INTEGER. Workspace array, size at least $\max(1, 8 * \min(m, n))$.

Output Parameters

<i>a</i>	On exit: If <i>jobz</i> = 'O', then if $m \geq n$, <i>a</i> is overwritten with the first <i>n</i> columns of <i>U</i> (the left singular vectors, stored columnwise). If $m < n$, <i>a</i> is overwritten with the first <i>m</i> rows of <i>V</i> ^T (the right singular vectors, stored rowwise); If <i>jobz</i> ≠ 'O', the contents of <i>a</i> are destroyed.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, size at least $\max(1, \min(m, n))$. Contains the singular values of <i>A</i> sorted so that $s(i) \geq s(i+1)$.
<i>u</i> , <i>vt</i>	REAL for sgesdd DOUBLE PRECISION for dgesdd COMPLEX for cgesdd

DOUBLE COMPLEX for zgesdd.

Arrays:

$u(lu,*)$; the second dimension of u must be at least $\max(1, m)$ if $jobz = 'A'$ or $jobz = 'O'$ and $m < n$.

If $jobz = 'S'$, the second dimension of u must be at least $\max(1, \min(m, n))$.

If $jobz = 'A'$ or $jobz = 'O'$ and $m < n$, u contains the m -by- m orthogonal/unitary matrix U .

If $jobz = 'S'$, u contains the first $\min(m, n)$ columns of U (the left singular vectors, stored columnwise).

If $jobz = 'O'$ and $m \geq n$, or $jobz = 'N'$, u is not referenced.

$vt(lv,*)$; the second dimension of vt must be at least $\max(1, n)$.

If $jobz = 'A'$ or $jobz = 'O'$ and $m \geq n$, vt contains the n -by- n orthogonal/unitary matrix V^T .

If $jobz = 'S'$, vt contains the first $\min(m, n)$ rows of V^T (the right singular vectors, stored rowwise).

If $jobz = 'O'$ and $m < n$, or $jobz = 'N'$, vt is not referenced.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then ?bdsdc did not converge, updating process failed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine gesdd interface are the following:

a Holds the matrix A of size (m, n) .

s Holds the vector of length $\min(m, n)$.

u Holds the matrix U of size

- (m, m) if $jobz = 'A'$ or $jobz = 'O'$ and $m < n$
- $(m, \min(m, n))$ if $jobz = 'S'$

u is not referenced if $jobz$ is not supplied or if $jobz = 'N'$ or $jobz = 'O'$ and $m \geq n$.

vt Holds the matrix VT of size

- (n, n) if $jobz = 'A'$ or $jobz = 'O'$ and $m \geq n$
- $(\min(m, n), n)$ if $jobz = 'S'$

vt is not referenced if *jobz* is not supplied or if *jobz*='N' or *jobz*='O' and *m* < *n*.

job Must be 'N', 'A', 'S', or 'O'. The default value is 'N'.

Application Notes

For real flavors:

If *jobz* = 'N', *lwork* $\geq 3*\min(m, n) + \max(\max(m, n), 6*\min(m, n))$;

If *jobz* = 'O', *lwork* $\geq 3*(\min(m, n))^2 + \max(\max(m, n), 5*(\min(m, n))^2 + 4*\min(m, n))$;

If *jobz* = 'S' or 'A', *lwork* $\geq \min(m, n)*(6 + 4*\min(m, n)) + \max(m, n)$;

For complex flavors:

If *jobz* = 'N', *lwork* $\geq 2*\min(m, n) + \max(m, n)$;

If *jobz* = 'O', *lwork* $\geq 2*(\min(m, n))^2 + \max(m, n) + 2*\min(m, n)$;

If *jobz* = 'S' or 'A', *lwork* $\geq (\min(m, n))^2 + \max(m, n) + 2*\min(m, n)$;

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gejsv

Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method.

Syntax

FORTRAN 77:

```
call sgejsv(job, jobu, jobv, jobr, jobt, jobp, m, n, a, lda, sva, u, ldu, v, ldv,
work, lwork, iwork, info)
```

```
call dgejsv(job, jobu, jobv, jobr, jobt, jobp, m, n, a, lda, sva, u, ldu, v, ldv,
work, lwork, iwork, info)
```

C:

```

jobr, char jobt, char jobp, lapack_int m, lapack_int n, const <datatype>* a,
lapack_int lda, <datatype>* sva, <datatype>* u, lapack_int ldu, <datatype>* v,
lapack_int ldv, <datatype>* stat, lapack_int* istat );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the singular value decomposition (SVD) of a real m -by- n matrix A , where $m \geq n$.

The SVD is written as

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix which is zero except for its n diagonal elements, U is an m -by- n (or m -by- m) orthonormal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array sva .

The routine implements a preconditioned Jacobi SVD algorithm. It uses `?geqp3`, `?geqr`, and `?gelqf` as preprocessors and preconditioners. Optionally, an additional row pivoting can be used as a preprocessor, which in some cases results in much higher accuracy. An example is matrix A with the structure $A = D_1 * C * D_2$, where D_1, D_2 are arbitrarily ill-conditioned diagonal matrices and C is a well-conditioned matrix. In that case, complete pivoting in the first QR factorizations provides accuracy dependent on the condition number of C , and independent of D_1, D_2 . Such higher accuracy is not completely understood theoretically, but it works well in practice.

If A can be written as $A = B*D$, with well-conditioned B and some diagonal D , then the high accuracy is guaranteed, both theoretically and in software independent of D . For more details see [[Drmac08-1](#)], [[Drmac08-2](#)].

The computational range for the singular values can be the full range (`UNDERFLOW`,`OVERFLOW`), provided that the machine arithmetic and the BLAS and LAPACK routines called by `?gejsv` are implemented to work in that range. If that is not the case, the restriction for safe computation with the singular values in the range of normalized IEEE numbers is that the spectral condition number $\kappa(A) = \sigma_{\max}(A) / \sigma_{\min}(A)$ does not overflow. This code (`?gejsv`) is best used in this restricted range, meaning that singular values of magnitude below $\|A\|_2 / \text{slamch('O')}$ (for single precision) or $\|A\|_2 / \text{dlamch('O')}$ (for double precision) are returned as zeros. See `jobr` for details on this.

This implementation is slower than the one described in [[Drmac08-1](#)], [[Drmac08-2](#)] due to replacement of some non-LAPACK components, and because the choice of some tuning parameters in the iterative part (`?gesvj`) is left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: `?geqp3`) should be implemented as in [[Drmac08-3](#)].

If m is much larger than n , it is obvious that the initial QRF with column pivoting can be preprocessed by the QRF without pivoting. That well known trick is not used in `?gejsv` because in some cases heavy row weighting can be treated with complete pivoting. The overhead in cases m much larger than n is then only due to pivoting, but the benefits in accuracy have prevailed. You can incorporate this extra QRF step easily and also improve data movement (matrix transpose, matrix copy, matrix transposed copy) - this implementation of `?gejsv` uses only the simplest, naive data movement.

Input Parameters

The data types are given for the Fortran interface, except for `istat`. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

`joba`

CHARACTER*1. Must be '`C`', '`E`', '`F`', '`G`', '`A`', or '`R`'.

Specifies the level of accuracy:

If `joba = 'C'`, high relative accuracy is achieved if $A = B*D$ with well-conditioned B and arbitrary diagonal matrix D . The accuracy cannot be spoiled by column scaling. The accuracy of the computed output depends on the condition of B , and the procedure aims at the best theoretical

accuracy. The relative error $\max_{i=1:N} |d \sigma_i| / \sigma_i$ is bounded by $f(M, N) * \epsilon \operatorname{cond}(B)$, independent of D . The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of joba . Additional actions are specified as follows:

If $\text{joba} = 'E'$, computation as with ' C ' with an additional estimate of the condition number of B . It provides a realistic error bound.

If $\text{joba} = 'F'$, accuracy higher than in the ' C ' option is achieved, if $A = D1 * C * D2$ with ill-conditioned diagonal scalings $D1, D2$, and a well-conditioned matrix C . This option is advisable, if the structure of the input matrix is not known and relative accuracy is desirable. The input matrix A is preprocessed with QR factorization with full (row and column) pivoting.

If $\text{joba} = 'G'$, computation as with ' F ' with an additional estimate of the condition number of B , where $A = B * D$. If A has heavily weighted rows, using this condition number gives too pessimistic error bound.

If $\text{joba} = 'A'$, small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by $f(m, n) * \epsilon * \|A\|$. The computed SVD $A = U * S * V^T$ restores A up to $f(m, n) * \epsilon * \|A\|$. This enables the procedure to set all singular values below $n * \epsilon * \|A\|$ to zero.

If $\text{joba} = 'R'$, the procedure is similar to the ' A ' option. Rank revealing property of the initial QR factorization is used to reveal (using triangular factor) a gap $\sigma_{r+1} < \epsilon * \sigma_r$, in which case the numerical rank is declared to be r . The SVD is computed with absolute error bounds, but more accurately than with ' A '.

jobu

CHARACTER*1. Must be ' U ', ' F ', ' W ', or ' N '.

Specifies whether to compute the columns of the matrix U :

If $\text{jobu} = 'U'$, n columns of U are returned in the array u .

If $\text{jobu} = 'F'$, a full set of m left singular vectors is returned in the array u .

If $\text{jobu} = 'W'$, u may be used as workspace of length $m * n$. See the description of u .

If $\text{jobu} = 'N'$, u is not computed.

jobv

CHARACTER*1. Must be ' V ', ' J ', ' W ', or ' N '.

Specifies whether to compute the matrix V :

If $\text{jobv} = 'V'$, n columns of V are returned in the array v ; Jacobi rotations are not explicitly accumulated.

If $\text{jobv} = 'J'$, n columns of V are returned in the array v but they are computed as the product of Jacobi rotations. This option is allowed only if $\text{jobu} \neq n$

If $\text{jobv} = 'W'$, v may be used as workspace of length $n * n$. See the description of v .

If $\text{jobv} = 'N'$, v is not computed.

jobr

CHARACTER*1. Must be ' N ' or ' R '.

Specifies the range for the singular values. If small positive singular values are outside the specified range, they may be set to zero. If A is scaled so that the largest singular value of the scaled matrix is around $\text{sqrt}(\text{big})$, $\text{big} = \text{?lamch('O')}$, the function can remove columns of A whose norm in the scaled matrix is less than $\text{sqrt}(\text{?lamch('S')})$ (for $\text{jobr} = 'R'$), or less than $\text{small} = \text{?lamch('S')}/\text{?lamch('E')}$.

If $\text{jobr} = 'N'$, the function does not remove small columns of the scaled matrix. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than big , use `?gesvj`.

If $\text{jobr} = 'R'$, restricted range for singular values of the scaled matrix A is $[\text{sqrt}(\text{?lamch('S')}, \text{sqrt}(\text{big}))]$, roughly as described above. This option is recommended.

For computing the singular values in the full range $[\text{?lamch('S')}, \text{big}]$, use `?gesvj`.

jobt

CHARACTER*1. Must be 'T' or 'N'.

If the matrix is square, the procedure may determine to use a transposed A if A^{**t} seems to be better with respect to convergence. If the matrix is not square, *jobt* is ignored. This is subject to changes in the future.

The decision is based on two values of entropy over the adjoint orbit of $A^{**t} * A$. See the descriptions of `work(6)` and `work(7)`.

If *jobt* = 'T', the function performs transposition if the entropy test indicates possibly faster convergence of the Jacobi process, if A is taken as input. If A is replaced with A^{**t} , the row pivoting is included automatically.

If *jobt* = 'N', the function attempts no speculations. This option can be used to compute only the singular values, or the full SVD (u , σ , and v). For only one set of singular vectors (u or v), the caller should provide both u and v , as one of the matrices is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of u and v .

jobp

CHARACTER*1. Must be 'P' or 'N'.

Enables structured perturbations of denormalized numbers. This option should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence. For details, see [Drmac08-1], [Drmac08-2]. For simplicity, such perturbations are included only when the full SVD or only the singular values are requested. You can add the perturbation for the cases of computing one set of singular vectors.

If *jobp* = 'P', the function introduces perturbation.

If *jobp* = 'N', the function introduces no perturbation.

m

INTEGER. The number of rows of the input matrix A ; $m \geq 0$.

n

INTEGER. The number of columns in the input matrix A ; $n \geq 0$.

a, work, sva, u, v

REAL for `sgejsv`

DOUBLE PRECISION for `dgejsv`.

Array $a(1:\text{da},*)$ is an array containing the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

sva is a workspace array, its dimension is n .

u is a workspace array, its dimension is $(lDU, *)$; the second dimension of u must be at least $\max(1, n)$.

v is a workspace array, its dimension is $(lDV, *)$; the second dimension of v must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array a . Must be at least $\max(1, m)$.

ldu INTEGER. The leading dimension of the array u ; $lDU \geq 1$.

$jobu = 'U'$ or $'F'$ or $'W'$, $lDU \geq m$.

ldv INTEGER. The leading dimension of the array v ; $lDV \geq 1$.

$jobv = 'V'$ or $'J'$ or $'W'$, $lDV \geq n$.

$lwork$ INTEGER.

Length of $work$ to confirm proper allocation of work space. $lwork$ depends on the task performed:

If only σ is needed ($jobu = 'N'$, $jobv = 'N'$) and

- ... no scaled condition estimate is required, then $lwork \geq \max(2*m+n, 4*n+1, 7)$. This is the minimal requirement. For optimal performance (blocked code) the optimal value is $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, 7)$. Here nb is the optimal block size for ?geqp3/?geqrif.

In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(sgeqrif), 7)$ for sgejsv

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dgeqrif), 7)$ for dgejsv

- ... an estimate of the scaled condition number of A is required ($joba = 'E'$, $'G'$). In this case, $lwork$ is the maximum of the above and $n*n + 4*n$, that is, $lwork \geq \max(2*m+n, n*n+4*n, 7)$. For optimal performance (blocked code) the optimal value is $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, n*n+4*n, 7)$.

In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(sgeqrif), n+n*n + lwork(spocon), 7)$ for sgejsv

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dgeqrif), n+n*n + lwork(dpocon), 7)$ for dgejsv

If σ and the right singular vectors are needed ($jobv = 'V'$),

- the minimal requirement is $lwork \geq \max(2*m+n, 4*n+1, 7)$.
- for optimal performance, $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, 7)$, where nb is the optimal block size for ?geqp3, ?geqrif, ?gelqf, ?ormlq.

In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(spocon), n+lwork(sgelqf), 2*n+lwork(sgeqr), n+lwork(sormlq)$ for sgejsv

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dpocon), n+lwork(dgelqf), 2*n+lwork(dgeqr), n+lwork(dormlq)$ for dgejsv

If σ and the left singular vectors are needed

- the minimal requirement is $lwork \geq \max(2*n+m, 4*n+1, 7)$.
- for optimal performance,

```
if jobu = 'U' :: lwork >= max(2*m+n, 3*n+(n+1)*nb, 7),
if jobu = 'F' :: lwork >= max(2*m+n, 3*n+(n+1)*nb, n+m*nb, 7),
where nb is the optimal block size for ?geqp3, ?geqr, ?ormlq . In
general, the optimal length lwork is computed as
```

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(spocon), 2*n+lwork(sgeqr), n+lwork(sormlq)$ for sgejsv

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dpocon), 2*n+lwork(dgeqr), n+lwork(dormlq)$ for dgejsv

Here $lwork(?ormlq)$ equals $n*nb$ (for $jobu = 'U'$) or $m*nb$ (for $jobu = 'F'$)

If full SVD is needed ($jobu = 'U'$ or $'F'$) and

- if $jobv = 'V'$,
the minimal requirement is $lwork \geq \max(2*m+n, 6*n+2*n*n)$
- if $jobv = 'J'$,
the minimal requirement is $lwork \geq \max(2*m+n, 4*n+n*n, 2*n+n*n+6)$
- For optimal performance, $lwork$ should be additionally larger than $n+m*nb$, where nb is the optimal block size for $?ormlq$.

$iwork$

INTEGER. Workspace array, DIMENSION $\max(3, m+3*n)$.

Output Parameters

sva

On exit:

For $work(1)/work(2) = \text{one}$: the singular values of A . During the computation sva contains Euclidean column norms of the iterated matrices in the array a .

For $work(1) \neq work(2)$: the singular values of A are $(work(1)/work(2)) * sva(1:n)$. This factored form is used if $\sigma_{\max}(A)$ overflows or if small singular values have been saved from underflow by scaling the input matrix A .

$jobr = 'R'$, some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

u

On exit:

If $\text{jobu} = \text{'U'}$, contains the m -by- n matrix of the left singular vectors.

If $\text{jobu} = \text{'F'}$, contains the m -by- m matrix of the left singular vectors, including an orthonormal basis of the orthogonal complement of the range of A .

If $\text{jobu} = \text{'W'}$ and $\text{jobv} = \text{'V'}$, $\text{jobt} = \text{'T'}$, and $m = n$, then u is used as workspace if the procedure replaces A with A^{**t} . In that case, v is computed in u as left singular vectors of A^{**t} and copied back to the v array. This ' W ' option is just a reminder to the caller that in this case u is reserved as workspace of length $n*n$.

If $\text{jobu} = \text{'N'}$, u is not referenced.

v

On exit:

If $\text{jobv} = \text{'V'}$ or 'J' , contains the n -by- n matrix of the right singular vectors.

If $\text{jobv} = \text{'W'}$ and $\text{jobv} = \text{'U'}$, $\text{jobt} = \text{'T'}$, and $m = n$, then v is used as workspace if the procedure replaces A with A^{**t} . In that case, u is computed in v as right singular vectors of A^{**t} and copied back to the u array. This ' W ' option is just a reminder to the caller that in this case v is reserved as workspace of length $n*n$.

If $\text{jobv} = \text{'N'}$, v is not referenced.

$work$

On exit,

$work(1) = scale = work(2)/work(1)$ is the scaling factor such that $scale*sva(1:n)$ are the computed singular values of A . See the description of $sva()$.

$work(2) =$ see the description of $work(1)$.

$work(3) = sconda$ is an estimate for the condition number of column equilibrated A . If $\text{joba} = \text{'E'}$ or 'G' , $sconda$ is an estimate of $\sqrt{\|(R^{**t} * R)^{**(-1)}\|_1}$. It is computed using $?pocon$. It holds $n^{**(-1/4)} * sconda \leq \|R^{**(-1)}\|_2 \leq n^{*(1/4)} * sconda$, where R is the triangular factor from the QRF of A . However, if R is truncated and the numerical rank is determined to be strictly smaller than n , $sconda$ is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provided for a user who is familiar with the details of the method.

$work(4) =$ an estimate of the scaled condition number of the triangular factor in the first QR factorization.

$work(5) =$ an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if $\text{jobt} = \text{'T'}$. They are provided for a user who is familiar with the details of the method.

$work(6) =$ the entropy of $A^{**t}*A ::$ this is the Shannon entropy of $\text{diag}(A^{**t}*A) / \text{Trace}(A^{**t}*A)$ taken as point in the probability simplex.

$work(7) =$ the entropy of $A*A^{**t}$.

iwork (Fortran), *istat* (C) INTEGER. On exit,

iwork(1)/*istat*[0] = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of *joba* and *jobr*.

iwork(2)/*istat*[1] = the number of the computed nonzero singular value.

iwork(3)/*istat*[2] = if nonzero, a warning message. If *iwork*(3)/*istat*[2]=1, some of the column norms of *A* were denormalized floats. The requested high accuracy is not warranted by the data.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number of sweeps. The computed values may be inaccurate.

Description

The routine computes the singular value decomposition (SVD) of a real m -by- n matrix *A*, where $m \geq n$.

The SVD of *A* is written as

$$A = U^* \Sigma^* V^*,$$

where Σ is an m -by- n diagonal matrix, U is an m -by- n orthonormal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array sva .

The n -by- n orthogonal matrix V is obtained as a product of Jacobi plane rotations. The rotations are implemented as fast scaled rotations of Anda and Park [AndaPark94]. In the case of underflow of the Jacobi angle, a modified Jacobi transformation of Drmac ([Drmac08-4]) is used. Pivot strategy uses column interchanges of de Rijk ([deRijk98]). The relative accuracy of the computed singular values and the accuracy of the computed singular vectors (in angle metric) is as guaranteed by the theory of Demmel and Veselic [Demmel92]. The condition number that determines the accuracy in the full rank case is essentially

$$(\min_i d_i) \cdot \kappa(A \cdot D)$$

where $\kappa(\cdot)$ is the spectral condition number. The best performance of this Jacobi SVD procedure is achieved if used in an accelerated version of Drmac and Veselic [Drmac08-1], [Drmac08-2]. Some tunning parameters (marked with TP) are available for the implementer.

The computational range for the nonzero singular values is the machine number interval (`UNDERFLOW`, `OVERFLOW`). In extreme cases, even denormalized singular values can be computed with the corresponding gradual loss of accurate digit.

Input Parameters

The data types are given for the Fortran interface, except for `stat`. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>joba</code>	CHARACTER*1. Must be ' <code>L</code> ', ' <code>U</code> ' or ' <code>G</code> '. Specifies the structure of A : If <code>joba</code> = ' <code>L</code> ', the input matrix A is lower triangular. If <code>joba</code> = ' <code>U</code> ', the input matrix A is upper triangular. If <code>joba</code> = ' <code>G</code> ', the input matrix A is a general m -by- n , $m \geq n$.
<code>jobu</code>	CHARACTER*1. Must be ' <code>U</code> ', ' <code>C</code> ' or ' <code>N</code> '. Specifies whether to compute the left singular vectors (columns of U): If <code>jobu</code> = ' <code>U</code> ', the left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A . See more details in the description of <code>a</code> . The default numerical orthogonality threshold is set to approximately <code>TOL=CTOL*EPS</code> , <code>CTOL=sqrt(m)</code> , <code>EPS = ?lamch('E')</code> If <code>jobu</code> = ' <code>C</code> ', analogous to <code>jobu</code> = ' <code>U</code> ', except that you can control the level of numerical orthogonality of the computed left singular vectors. <code>TOL</code> can be set to <code>TOL=CTOL*EPS</code> , where <code>CTOL</code> is given on input in the array <code>work</code> . No <code>CTOL</code> smaller than <code>ONE</code> is allowed. <code>CTOL</code> greater than <code>1 / EPS</code> is meaningless. The option ' <code>C</code> ' can be used if $m * EPS$ is satisfactory orthogonality of the computed left singular vectors, so <code>CTOL=m</code> could save a few sweeps of Jacobi rotations. See the descriptions of <code>a</code> and <code>work(1)</code> . If <code>jobu</code> = ' <code>N</code> ', u is not computed. However, see the description of <code>a</code> .
<code>jobv</code>	CHARACTER*1. Must be ' <code>V</code> ', ' <code>A</code> ' or ' <code>N</code> '.

Specifies whether to compute the right singular vectors, that is, the matrix V :

If $jobv = 'V'$, the matrix V is computed and returned in the array v .

If $jobv = 'A'$, the Jacobi rotations are applied to the mv -by- n array v . In other words, the right singular vector matrix V is not computed explicitly, instead it is applied to an mv -by- n matrix initially stored in the first mv rows of V .

If $jobv = 'N'$, the matrix V is not computed and the array v is not referenced.

m

INTEGER. The number of rows of the input matrix A .

$1/\text{slamch('E')} > m \geq 0$ for `sgesvj`.

$1/\text{dlamch('E')} > m \geq 0$ for `dgesvj`.

n

INTEGER. The number of columns in the input matrix A ; $n \geq 0$.

$a, work, sva, v$

REAL for `sgesvj`

DOUBLE PRECISION for `dgesvj`.

Array $a(1:da,*)$ is an array containing the m -by- n matrix A .

The second dimension of a is $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(4, m+n)$.

If $jobu = 'C'$, $work(1)=\text{CTOL}$, where CTOL defines the threshold for convergence. The process stops if all columns of A are mutually orthogonal up to $\text{CTOL}*\text{EPS}$, $\text{EPS}=\text{lamch('E')}$. It is required that $\text{CTOL} \geq 1$, that is, it is not allowed to force the routine to obtain orthogonality below ϵ .

sva is a workspace array, its dimension is n .

v is a workspace array, its dimension is $(1:dv,*)$; the second dimension of v must be at least $\max(1, n)$.

lda

INTEGER. The leading dimension of the array a . Must be at least $\max(1, m)$.

mv

INTEGER.

$jobv = 'A'$, the product of Jacobi rotations in `gesvj` is applied to the first mv rows of v . See the description of $jobv$.

ldv

INTEGER. The leading dimension of the array v ; $ldv \geq 1$.

$jobv = 'V'$, $ldv \geq \max(1, n)$.

$jobv = 'A'$, $ldv \geq \max(1, mv)$.

$lwork$

INTEGER.

Length of $work$, $work \geq \max(6, m+n)$.

Output Parameters

a

On exit:

If $jobu = 'U'$ or $jobu = 'C'$:

- if $info = 0$, the leading columns of A contain left singular vectors corresponding to the computed singular values of a that are above the underflow threshold $?lamch('S')$, that is, non-zero singular values. The number of the computed non-zero singular values is returned in $work(2)$. Also see the descriptions of sva and $work$. The computed columns of u are mutually numerically orthogonal up to approximately $TOL=\sqrt{m} * EPS$ (default); or $TOL=CTOL*EPS$ $jobu = 'C'$, see the description of $jobu$.
- if $info > 0$, the procedure $?gesvj$ did not converge in the given number of iterations (sweeps). In that case, the computed columns of u may not be orthogonal up to TOL . The output u (stored in a), $sigma$ (given by the computed singular values in $sva(1:n)$) and v is still a decomposition of the input matrix A in the sense that the residual $\|a - scale*u*sigma*v**t\|_2 / \|a\|_2$ is small.

If $jobu = 'N'$:

- if $info = 0$, note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of u is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately $m*EPS$. Thus, on exit, a contains the columns of u scaled with the corresponding singular values.
- if $info > 0$, the procedure $?gesvj$ did not converge in the given number of iterations (sweeps).

sva

On exit:

If $info = 0$, depending on the value $scale = work(1)$, where $scale$ is the scaling factor:

- if $scale = 1$, $sva(1:n)$ contains the computed singular values of a . During the computation, sva contains the Euclidean column norms of the iterated matrices in the array a .
- if $scale \neq 1$, the singular values of a are $scale*sva(1:n)$, and this factored representation is due to the fact that some of the singular values of a might underflow or overflow.

If $info > 0$, the procedure $?gesvj$ did not converge in the given number of iterations (sweeps) and $scale*sva(1:n)$ may not be accurate.

v

On exit:

If $jobv = 'V'$, contains the n -by- n matrix of the right singular vectors.

If $jobv = 'A'$, then v contains the product of the computed right singular vector matrix and the initial matrix in the array v .

If $jobv = 'N'$, v is not referenced.

$work$ (Fortarn), $stat$ (C)

On exit,

$work(1)/stat[0] = scale$ is the scaling factor such that $scale*sva(1:n)$ are the computed singular values of A . See the description of $sva()$.

$work(2)/stat[1]$ is the number of the computed nonzero singular value.

work(3)/*stat*[2] is the number of the computed singular values that are larger than the underflow threshold.

work(4)/*stat*[3] is the number of sweeps of Jacobi rotations needed for numerical convergence.

work(5)/*stat*[4] = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when ?gesvj did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

work(6)/*stat*[5] is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number (30) of sweeps. The output may still be useful. See the description of *work*.

Description

The routine computes the generalized singular value decomposition (GSVD) of an m -by- n real/complex matrix A and p -by- n real/complex matrix B :

$$U'^* A^* Q = D_1 \begin{pmatrix} 0 & R \end{pmatrix}, V'^* B^* Q = D_2 \begin{pmatrix} 0 & R \end{pmatrix},$$

where U , V and Q are orthogonal/unitary matrices and U' , V' mean transpose/conjugate transpose of U and V respectively.

Let $k+l$ = the effective numerical rank of the matrix $(A', B')'$, then R is a $(k+l)$ -by- $(k+l)$ nonsingular upper triangular matrix, D_1 and D_2 are m -by- $(k+l)$ and p -by- $(k+l)$ "diagonal" matrices and of the following structures, respectively:

If $m-k-l \geq 0$,

... 0 0 0 0 0 0 ...

$$D_2 = \begin{matrix} & k & l \\ p - l & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{array}{ccccccccc} & \cdots & & \cdots & & & & & \\ & \vdots & \\ & \cdots & & \cdots & & & & & \end{array}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(K+1))$

$S = \text{diag}(\beta(K+1), \dots, \beta(K+1))$

$C^2 + S^2 = I$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$\begin{array}{ccccccccc} & \cdots & & \cdots & & & & & \\ & \vdots & \\ & \cdots & & \cdots & & & & & \end{array}$$

$$\begin{array}{ccccccccc} & \cdots & & \cdots & & & & & \\ & \vdots & \\ & \cdots & & \cdots & & & & & \end{array}$$

$$(0 \quad R) = \begin{pmatrix} n - k - l & k & m - k & k + l - m \\ & k & R_{11} & R_{12} & R_{13} \\ & m - k & 0 & R_{22} & R_{23} \\ & k + l - m & 0 & 0 & R_{33} \end{pmatrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m))$,

$S = \text{diag}(\beta(K+1), \dots, \beta(m))$,

$C_2 + S_2 = I$

$$\left[\begin{array}{cccccc} & \cdots & & & & & \\ & \vdots & \vdots & \vdots & \vdots & \vdots & \\ & \cdots & & \cdots & & & \end{array} \right]$$

On exit, $\begin{bmatrix} & \cdots & & & & & \\ & \vdots & \vdots & \vdots & \vdots & \vdots & \\ & \cdots & & \cdots & & & \end{bmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The routine computes C , S , R , and optionally the orthogonal/unitary transformation matrices U , V and Q .

In particular, if B is an n -by- n nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A^*B^{-1} :

$$A^*B^{-1} = U^* (D_1^* D_2^{-1}) * V^*.$$

If (A', B') ' has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A'^* A^* x = \lambda * B'^* B^* x.$$

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobu</i>	CHARACTER*1. Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix U is computed. If <i>jobu</i> = 'N', U is not computed.
<i>jobv</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix V is computed. If <i>jobv</i> = 'N', V is not computed.
<i>jobq</i>	CHARACTER*1. Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix Q is computed. If <i>jobq</i> = 'N', Q is not computed.
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix B ($p \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for sggsvd DOUBLE PRECISION for dggsvd COMPLEX for cggsvd DOUBLE COMPLEX for zggsvd. Arrays: <i>a</i> (<i>lda</i> ,*) contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the p -by- n matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(3n, m, p) + n$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, p)$.

<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> . <i>ldu</i> $\geq \max(1, m)$ if <i>jobu</i> = 'U'; <i>ldu</i> ≥ 1 otherwise.
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> . <i>ldv</i> $\geq \max(1, p)$ if <i>jobv</i> = 'V'; <i>ldv</i> ≥ 1 otherwise.
<i>ldq</i>	INTEGER. The leading dimension of the array <i>q</i> . <i>ldq</i> $\geq \max(1, n)$ if <i>jobq</i> = 'Q'; <i>ldq</i> ≥ 1 otherwise.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cggsvd</i> DOUBLE PRECISION for <i>zggsvd</i> . Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>k, l</i>	INTEGER. On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks. The sum <i>k+l</i> is equal to the effective numerical rank of (A', B') .
<i>a</i>	On exit, <i>a</i> contains the triangular matrix <i>R</i> or part of <i>R</i> .
<i>b</i>	On exit, <i>b</i> contains part of the triangular matrix <i>R</i> if $m-k-l < 0$.
<i>alpha, beta</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION at least $\max(1, n)$ each. Contain the generalized singular value pairs of <i>A</i> and <i>B</i> : <i>alpha</i> (1:k) = 1, <i>beta</i> (1:k) = 0, and if $m-k-l \geq 0$, <i>alpha</i> (k+1:k+1) = <i>C</i> , <i>beta</i> (k+1:k+1) = <i>S</i> , or if $m-k-l < 0$, <i>alpha</i> (k+1:m) = <i>C</i> , <i>alpha</i> (m+1:k+1) = 0 <i>beta</i> (k+1:m) = <i>S</i> , <i>beta</i> (m+1:k+1) = 1 and <i>alpha</i> (k+l+1:n) = 0 <i>beta</i> (k+l+1:n) = 0.
<i>u, v, q</i>	REAL for <i>sggsvd</i> DOUBLE PRECISION for <i>dggsvd</i> COMPLEX for <i>cggsvd</i>

DOUBLE COMPLEX for zggsvd.

Arrays:

$u(lu,*)$; the second dimension of u must be at least $\max(1, m)$.

If $jobu = 'U'$, u contains the m -by- m orthogonal/unitary matrix U .

If $jobu = 'N'$, u is not referenced.

$v(lv,*)$; the second dimension of v must be at least $\max(1, p)$.

If $jobv = 'V'$, v contains the p -by- p orthogonal/unitary matrix V .

If $jobv = 'N'$, v is not referenced.

$q(lq,*)$; the second dimension of q must be at least $\max(1, n)$.

If $jobq = 'Q'$, q contains the n -by- n orthogonal/unitary matrix Q .

If $jobq = 'N'$, q is not referenced.

$iwork$ On exit, $iwork$ stores the sorting information.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the Jacobi-type procedure failed to converge. For further details, see subroutine [tgsja](#).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggsvd` interface are the following:

a Holds the matrix A of size (m, n) .

b Holds the matrix B of size (p, n) .

$alpha$ Holds the vector of length n .

$beta$ Holds the vector of length n .

u Holds the matrix U of size (m, m) .

v Holds the matrix V of size (p, p) .

q Holds the matrix Q of size (n, n) .

$iwork$ Holds the vector of length n .

$jobu$ Restored based on the presence of the argument u as follows:

$jobu = 'U'$, if u is present, $jobu = 'N'$, if u is omitted.

$jobv$ Restored based on the presence of the argument v as follows:

$jobz = 'V'$, if v is present,

	<i>jobz</i> = 'N', if <i>v</i> is omitted.
<i>jobq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>jobz</i> = 'Q', if <i>q</i> is present, <i>jobz</i> = 'N', if <i>q</i> is omitted.

Cosine-Sine Decomposition

This section describes LAPACK driver routines for computing the *cosine-sine decomposition* (CS decomposition). You can also call the corresponding computational routines to perform the same task.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

[Table "Driver Routines for Cosine-Sine Decomposition \(CSD\)"](#) lists LAPACK routines (FORTRAN 77 interface) that perform CS decomposition of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of a block-partitioned orthogonal matrix	orcisd uncsd orcisd2by1 uncsd2by1	
Compute the CS decomposition of a block-partitioned unitary matrix		orcisd uncsd

Description

The routines ?orcsd/?uncsd compute the CS decomposition of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | & u_2 \end{pmatrix} \begin{pmatrix} I & 0 & 0|0 & 0 & 0 \\ 0 & C & 0|0 & -S & 0 \\ 0 & 0 & 0|0 & 0 & -I \\ 0 & 0 & 0|I & 0 & 0 \\ 0 & S & 0|0 & C & 0 \\ 0 & 0 & I|0 & 0 & 0 \end{pmatrix} \begin{pmatrix} v_1 & | & v_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & | & u_2 \end{pmatrix} \begin{pmatrix} I & 0 & 0|0 & 0 & 0 \\ 0 & C & 0|0 & -S & 0 \\ 0 & 0 & 0|0 & 0 & -I \\ 0 & 0 & 0|I & 0 & 0 \\ 0 & S & 0|0 & C & 0 \\ 0 & 0 & I|0 & 0 & 0 \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & | & v_2 \end{pmatrix}^H$$

x_{11} is p -by- q . The orthogonal/unitary matrices u_1 , u_2 , v_1 , and v_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobu1</i>	CHARACTER. If equals <i>Y</i> , then u_1 is computed. Otherwise, u_1 is not computed.
<i>jobu2</i>	CHARACTER. If equals <i>Y</i> , then u_2 is computed. Otherwise, u_2 is not computed.
<i>jobv1t</i>	CHARACTER. If equals <i>Y</i> , then v_1^t is computed. Otherwise, v_1^t is not computed.
<i>jobv2t</i>	CHARACTER. If equals <i>Y</i> , then v_2^t is computed. Otherwise, v_2^t is not computed.
<i>trans</i>	CHARACTER = 'T': $x, u_1, u_2, v_1^t, v_2^t$ are stored in row-major order. otherwise $x, u_1, u_2, v_1^t, v_2^t$ are stored in column-major order.
<i>signs</i>	CHARACTER = 'O': The lower-left block is made nonpositive (the "other" convention). otherwise The upper-right block is made nonpositive (the "default" convention).
<i>m</i>	INTEGER. The number of rows and columns of the matrix X .
<i>p</i>	INTEGER. The number of rows in x_{11} and x_{12} . $0 \leq p \leq m$.
<i>q</i>	INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq m$.
<i>x</i>	REAL for <i>sorcisd</i> DOUBLE PRECISION for <i>dorcisd</i>

COMPLEX **for** cuncsd
 DOUBLE COMPLEX **for** zuncsd
Array, DIMENSION (Idx,m).
 On entry, the orthogonal/unitary matrix whose CSD is desired.

lidx INTEGER. The leading dimension of the array X . $lidx \geq \max(1, m)$.

ldu1 INTEGER. The leading dimension of the array u_1 . If $jobu1 = 'Y'$, $ldu1 \geq \max(1, p)$.

ldu2 INTEGER. The leading dimension of the array u_2 . If $jobu2 = 'Y'$, $ldu2 \geq \max(1, m-p)$.

ldv1t INTEGER. The leading dimension of the array $v1t$. If $jobv1t = 'Y'$, $ldv1t \geq \max(1, q)$.

ldv2t INTEGER. The leading dimension of the array $v2t$. If $jobv2t = 'Y'$, $ldv2t \geq \max(1, m-q)$.

work REAL **for** sorcsd
 DOUBLE PRECISION **for** dorcsd
 COMPLEX **for** cuncsd
 DOUBLE COMPLEX **for** zuncsd
Workspace array, DIMENSION ($\max(1, lwork)$).

lwork INTEGER. The size of the *work* array. Constraints:
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.

rwork REAL **for** cuncsd
 DOUBLE PRECISION **for** zuncsd
Workspace array, DIMENSION ($\max(1, lrwork)$).

lrwork INTEGER. The size of the *rwork* array. Constraints:
 If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *rwork* array, returns this value as the first entry of the *rwork* array, and no error message related to *lrwork* is issued by xerbla.

iwork INTEGER. Workspace array, dimension m .

Output Parameters

theta REAL **for** sorcsd

 COMPLEX **for** cuncsd

```

DOUBLE COMPLEX for zuncsd
Array, DIMENSION (r), in which r = min (p, m-p, q, m-q).
C = diag( cos(theta(1)), ..., cos(theta(r)) ), and
S = diag( sin(theta(1)), ..., sin(theta(r)) ).

u1
REAL for sorcsd
DOUBLE PRECISION for dorcsd
COMPLEX for cuncsd
DOUBLE COMPLEX for zuncsd
Array, DIMENSION (p).
If jobu1 = 'Y', u1 contains the p-by-p orthogonal/unitary matrix u1.

u2
REAL for sorcsd
DOUBLE PRECISION for dorcsd
COMPLEX for cuncsd
DOUBLE COMPLEX for zuncsd
Array, DIMENSION (ldu2,m-p).
If jobu2 = 'Y', u2 contains the (m-p)-by-(m-p) orthogonal/unitary matrix
u2.

v1t
REAL for sorcsd
DOUBLE PRECISION for dorcsd
COMPLEX for cuncsd
DOUBLE COMPLEX for zuncsd
Array, DIMENSION (ldv1t,q).
If jobv1t = 'Y', v1t contains the q-by-q orthogonal matrix v1T or unitary
matrix v1H.

v2t
REAL for sorcsd
DOUBLE PRECISION for dorcsd
COMPLEX for cuncsd
DOUBLE COMPLEX for zuncsd
Array, DIMENSION (ldv2t,m-q).
If jobv2t = 'Y', v2t contains the (m-q)-by-(m-q) orthogonal matrix v2T or
unitary matrix v2H.

work
On exit,
If info = 0,      work(1) returns the optimal lwork.
If info > 0,      work(2:r) contains the values phi(1), ...,
phi(r-1) that, together with theta(1), ...,
theta(r) define the matrix in intermediate

```

bidiagonal-block form remaining after nonconvergence. *info* specifies the number of nonzero *phi*'s.

<i>rwork</i>	On exit,	
	If <i>info</i> = 0,	<i>rwork</i> (1) returns the optimal <i>lrwork</i> .
	If <i>info</i> > 0,	<i>rwork</i> (2: <i>r</i>) contains the values <i>phi</i> (1), ..., <i>phi</i> (<i>r</i> -1) that, together with <i>theta</i> (1), ..., <i>theta</i> (<i>r</i>) define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. <i>info</i> specifies the number of nonzero <i>phi</i> 's.
<i>info</i>	INTEGER.	
	= 0: successful exit	
	< 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument has an illegal value	
	> 0: ?bbcisd did not converge. See the description of <i>work</i> above for details.	

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ?orcisd/?uncsd interface are as follows:

<i>x11</i>	Holds the block of matrix <i>X</i> of size (<i>p</i> , <i>q</i>).
<i>x12</i>	Holds the block of matrix <i>X</i> of size (<i>p</i> , <i>m</i> - <i>q</i>).
<i>x21</i>	Holds the block of matrix <i>X</i> of size (<i>m</i> - <i>p</i> , <i>q</i>).
<i>x22</i>	Holds the block of matrix <i>X</i> of size (<i>m</i> - <i>p</i> , <i>m</i> - <i>q</i>).
<i>theta</i>	Holds the vector of length <i>r</i> = min(<i>p</i> , <i>m</i> - <i>p</i> , <i>q</i> , <i>m</i> - <i>q</i>).
<i>u1</i>	Holds the matrix of size (<i>p</i> , <i>p</i>).
<i>u2</i>	Holds the matrix of size (<i>m</i> - <i>p</i> , <i>m</i> - <i>p</i>).
<i>v1t</i>	Holds the matrix of size (<i>q</i> , <i>q</i>).
<i>v2t</i>	Holds the matrix of size (<i>m</i> - <i>q</i> , <i>m</i> - <i>q</i>).
<i>jobsu1</i>	Indicates whether <i>u</i> ₁ is computed. Must be 'Y' or 'O'.
<i>jobsu2</i>	Indicates whether <i>u</i> ₂ is computed. Must be 'Y' or 'O'.
<i>jobv1t</i>	Indicates whether <i>v</i> ₁ ^t is computed. Must be 'Y' or 'O'.
<i>jobv2t</i>	Indicates whether <i>v</i> ₂ ^t is computed. Must be 'Y' or 'O'.
<i>trans</i>	Must be 'N' or 'T'.

signs Must be 'O' or 'D'.

Description

The routines ?orcsd2by1/?uncsd2by1 compute the CS decomposition of an m -by- q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

$$X = \begin{bmatrix} X_{11} \\ X_{21} \end{bmatrix} = \left[\begin{array}{c|c} U_1 & U_2 \end{array} \right] \begin{bmatrix} I & 0 & 0 \\ 0 & C & 0 \\ 0 & 0 & 0 \\ \hline 0 & 0 & 0 \\ 0 & S & 0 \\ 0 & 0 & I \end{bmatrix} V_1^H$$

X_{11} is p -by- q . The orthogonal/unitary matrices U_1 , U_2 , V_1 , and V_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

<i>jobu1</i>	CHARACTER. If equal to 'Y', then u_1 is computed. Otherwise, u_1 is not computed.
<i>jobu2</i>	CHARACTER. If equal to 'Y', then u_2 is computed. Otherwise, u_2 is not computed.
<i>jobv1t</i>	CHARACTER. If equal to 'Y', then v_1^t is computed. Otherwise, v_1^t is not computed.
<i>m</i>	INTEGER. The number of rows and columns of the matrix X .
<i>p</i>	INTEGER. The number of rows in x_{11} . $0 \leq p \leq m$.
<i>q</i>	INTEGER. The number of columns in x_{11} . $0 \leq q \leq m$.
<i>x11</i>	REAL for <i>sorcsd2by1</i> DOUBLE PRECISION for <i>dorcsd2by1</i> COMPLEX for <i>cuncsd2by1</i> DOUBLE COMPLEX for <i>zuncsd2by1</i> Array, size (<i>lidx11,q</i>). On entry, the part of the orthogonal matrix whose CSD is desired.
<i>lidx11</i>	INTEGER. The leading dimension of the array x_{11} . $lidx11 \geq \max(1, p)$.
<i>x21</i>	REAL for <i>sorcsd2by1</i> DOUBLE PRECISION for <i>dorcsd2by1</i> COMPLEX for <i>cuncsd2by1</i> DOUBLE COMPLEX for <i>zuncsd2by1</i> Array, size (<i>lidx21,q</i>). On entry, the part of the orthogonal matrix whose CSD is desired.
<i>lidx21</i>	INTEGER. The leading dimension of the array X . $lidx21 \geq \max(1, m - p)$.
<i>ldu1</i>	INTEGER. The leading dimension of the array u_1 . If $jobu1 = 'Y'$, $ldu1 \geq \max(1, p)$.
<i>ldu2</i>	INTEGER. The leading dimension of the array u_2 . If $jobu2 = 'Y'$, $ldu2 \geq \max(1, m-p)$.
<i>ldv1t</i>	INTEGER. The leading dimension of the array v_1^t . If $jobv1t = 'Y'$, $ldv1t \geq \max(1, q)$.
<i>work</i>	REAL for <i>sorcsd2by1</i> DOUBLE PRECISION for <i>dorcsd2by1</i> COMPLEX for <i>cuncsd2by1</i> DOUBLE COMPLEX for <i>zuncsd2by1</i>

Workspace array, size ($\max(1, lwork)$).

lwork

INTEGER. The size of the *work* array. Constraints:

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

rwork

REAL for *cuncsd2by1*

DOUBLE PRECISION for *zuncsd2by1*

Workspace array, size ($\max(1, lrwork)$).

lrwork

INTEGER. The size of the *rwork* array. Constraints:

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *rwork* array, returns this value as the first entry of the *rwork* array, and no error message related to *lrwork* is issued by *xerbla*.

iwork

INTEGER. Workspace array, dimension $m - \min(p, m - p, q, m - q)$.

Output Parameters

theta

REAL for *sorcsd2by1*

DOUBLE PRECISION for *dorcsd2by1*

COMPLEX for *cuncsd2by1*

DOUBLE COMPLEX for *zuncsd2by1*

Array, size (r), in which $r = \min(p, m-p, q, m-q)$.

$C = \text{diag}(\cos(\theta(1)), \dots, \cos(\theta(r)))$, and

$S = \text{diag}(\sin(\theta(1)), \dots, \sin(\theta(r)))$.

u1

REAL for *sorcsd2by1*

DOUBLE PRECISION for *dorcsd2by1*

COMPLEX for *cuncsd2by1*

DOUBLE COMPLEX for *zuncsd2by1*

Array, size ($ldu1, p$).

If $\text{jobu1} = 'Y'$, *u1* contains the p -by- p orthogonal/unitary matrix U_1 .

u2

REAL for *sorcsd2by1*

DOUBLE PRECISION for *dorcsd2by1*

COMPLEX for *cuncsd2by1*

DOUBLE COMPLEX for *zuncsd2by1*

Array, size ($ldu2, m-p$).

If $\text{jobu2} = 'Y'$, *u2* contains the $(m-p)$ -by- $(m-p)$ orthogonal/unitary matrix U_2 .

<code>v1t</code>	REAL for <code>sorcsd2by1</code> DOUBLE PRECISION for <code>dorcsd2by1</code> COMPLEX for <code>cuncsd2by1</code> DOUBLE COMPLEX for <code>zuncsd2by1</code> Array, size (<code>ldv1t,q</code>). If <code>jobv1t = 'Y'</code> , <code>v1t</code> contains the q -by- q orthogonal matrix v_1^T or unitary matrix v_1^H .
<code>work</code>	On exit, If <code>info = 0</code> , <code>work(1)</code> returns the optimal <code>lwork</code> . If <code>info > 0</code> , <code>work(2:r)</code> contains the values <code>phi(1), ..., phi(r-1)</code> that, together with <code>theta(1), ..., theta(r)</code> define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. <code>info</code> specifies the number of nonzero <code>phi</code> 's.
<code>rwork</code>	On exit, If <code>info = 0</code> , <code>rwork(1)</code> returns the optimal <code>lrwork</code> . If <code>info > 0</code> , <code>rwork(2:r)</code> contains the values <code>phi(1), ..., phi(r-1)</code> that, together with <code>theta(1), ..., theta(r)</code> define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. <code>info</code> specifies the number of nonzero <code>phi</code> 's.
<code>info</code>	INTEGER. = 0: successful exit < 0: if <code>info = -i</code> , the i -th argument has an illegal value > 0: <code>?orcsd2by1/?uncsd2by1</code> did not converge. See the description of <code>work</code> above for details.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `?orcsd2by1/?orcsd2by1` interface are as follows:

<code>x11</code>	Holds the block of matrix X_{11} of size (p, q) .
<code>x21</code>	Holds the block of matrix X_{21} of size $(m-p, q)$.
<code>theta</code>	Holds the vector of length $r = \min(p, m-p, q, m-q)$.
<code>u1</code>	Holds the matrix u_1 of size (p, p) .
<code>u2</code>	Holds the matrix u_2 of size $(m-p, m-p)$.

v_1^t	Holds the matrix v_1^T or v_1^H of size (q,q) .
$jobu1$	Indicates whether u_1 is computed. Must be ' Y ' or ' O '.
$jobu2$	Indicates whether u_2 is computed. Must be ' Y ' or ' O '.
$jobv1t$	Indicates whether v_1^t is computed. Must be ' Y ' or ' O '.

Generalized Symmetric Definite Eigenproblems

This section describes LAPACK driver routines used for solving generalized symmetric definite eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Symmetric Definite Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized Symmetric Definite Eigenproblems

Routine Name	Operation performed
sygv/hegv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
sygvd/hegvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.
sygvx/hegvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
spgv/hpgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
spgvd/hpgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.
spgvx/hpgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
sbgv/hbgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.
sbgvd/hbgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.
sbgvx/hbgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.

?sygv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

FORTRAN 77:

```
call ssygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
call dsygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
```

Fortran 95:

```
call sygv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_<?>sygv( int matrix_layout, lapack_int itype, char jobz, char uplo,

<datatype>* w );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for ssygv DOUBLE PRECISION for dsygv.

Arrays:

$a(lda, *)$ contains the upper or lower triangle of the symmetric matrix A , as specified by $uplo$.

The second dimension of a must be at least $\max(1, n)$.

$b(ldb, *)$ contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by $uplo$.

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb

INTEGER. The leading dimension of b ; at least $\max(1, n)$.

$lwork$

INTEGER.

The dimension of the array $work$;

$lwork \geq \max(1, 3n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, a contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T * B * Z = I$;

if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is destroyed.

b

On exit, if $info \leq n$, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

w

REAL for ssygv

DOUBLE PRECISION for dsygv.

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, [spotrf/dpotrf](#) and [ssyev/dsyev](#) returned an error code:

If $\text{info} = i \leq n$, `ssyev/dsyev` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygv` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>jobz</i>	Must be ' <code>N</code> ' or ' <code>V</code> '. The default value is ' <code>N</code> '.
<i>uplo</i>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For optimum performance use $\text{lwork} \geq (nb+2)*n$, where nb is the blocksize for `ssytrd/dsytrd` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work, iwork`) on exit. Use this value (`work(1), iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work, iwork`). This operation is called a workspace query.

Note that if `work` (`liwork`) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

FORTRAN 77:

```
call chegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
call zhegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
```

Fortran 95:

```
call hegv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_chevg( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,
lapack_int ldb, float* w );

lapack_int LAPACKE_zhegv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb, double* w );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda x, \text{ or } B^*A^*x = \lambda x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

itype INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:

if *itype* = 1, the problem type is $A^*x = \lambda B^*x$;
 if *itype* = 2, the problem type is $A^*B^*x = \lambda x$;
 if *itype* = 3, the problem type is $B^*A^*x = \lambda x$.

jobz CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then compute eigenvalues only.
 If *jobz* = 'V', then compute eigenvalues and eigenvectors.

uplo CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', arrays *a* and *b* store the upper triangles of A and B ;
 If *uplo* = 'L', arrays *a* and *b* store the lower triangles of A and B .

n INTEGER. The order of the matrices A and B ($n \geq 0$).

a, *b*, *work* COMPLEX for chegv

DOUBLE COMPLEX for zhegv.

Arrays:

a(*lda*,*) contains the upper or lower triangle of the Hermitian matrix A , as specified by *uplo*.

The second dimension of *a* must be at least $\max(1, n)$.

$b(lDb, *)$ contains the upper or lower triangle of the Hermitian positive definite matrix B , as specified by $uplo$.

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$; $lwork \geq \max(1, 2n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See [Application Notes](#) for the suggested value of $lwork$.

$rwork$ REAL for [chegv](#)

DOUBLE PRECISION for [zhgsv](#).

Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

a On exit, if $jobz = 'V'$, then if $info = 0$, a contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

```
if  $itype = 1$  or  $2$ ,  $Z^H * B * Z = I$ ;  
if  $itype = 3$ ,  $Z^H * \text{inv}(B) * Z = I$ ;
```

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is destroyed.

b On exit, if $info \leq n$, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.

w REAL for [chegv](#)

DOUBLE PRECISION for [zhgsv](#).

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$work(1)$ On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument has an illegal value.

If $info > 0$, [cpotrf/zpotrf](#) and [cheev/zheev](#) return an error code:

If $\text{info} = i \leq n$, `cheev/zheev` fails to converge, and i off-diagonal elements of an intermediate tridiagonal do not converge to zero;

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B can not be completed and no eigenvalues or eigenvectors are computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegv` interface are the following:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size (n, n) .
w	Holds the vector of length n .
$itype$	Must be 1, 2, or 3. The default value is 1.
$jobz$	Must be ' <code>N</code> ' or ' <code>V</code> '. The default value is ' <code>N</code> '.
$uplo$	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where nb is the blocksize for `chetrd/zhetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call ssygvd( $itype$ ,  $jobz$ ,  $uplo$ ,  $n$ ,  $a$ ,  $lda$ ,  $b$ ,  $ldb$ ,  $w$ ,  $work$ ,  $lwork$ ,  $iwork$ ,  $liwork$ ,  $info$ )
call dsygvd( $itype$ ,  $jobz$ ,  $uplo$ ,  $n$ ,  $a$ ,  $lda$ ,  $b$ ,  $ldb$ ,  $w$ ,  $work$ ,  $lwork$ ,  $iwork$ ,  $liwork$ ,  $info$ )
```

Fortran 95:

```
call sygvd( $a$ ,  $b$ ,  $w$  [ $,itype$ ] [ $,jobz$ ] [ $,uplo$ ] [ $,info$ ])
```

C:

```

- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda*B^*x, \quad A*B^*x = \lambda*x, \quad \text{or} \quad B^*A^*x = \lambda*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda*B^*x$; if <i>itype</i> = 2, the problem type is $A*B^*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for ssygvd DOUBLE PRECISION for dsygvd. Arrays: $a(lda,*)$ contains the upper or lower triangle of the symmetric matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. $b ldb,*)$ contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by <i>uplo</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of *b*; at least $\max(1, n)$.

lwork INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, *lwork* ≥ 1 ;

If *jobz* = 'N' and $n > 1$, *lwork* $< 2n+1$;

If *jobz* = 'V' and $n > 1$, *lwork* $< 2n^2+6n+1$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.

Workspace array, its dimension $\max(1, lwork)$.

liwork INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, *liwork* ≥ 1 ;

If *jobz* = 'N' and $n > 1$, *liwork* ≥ 1 ;

If *jobz* = 'V' and $n > 1$, *liwork* $\geq 5n+3$.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^T * B * Z = I$;

if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;

If *jobz* = 'N', then on exit the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is destroyed.

b On exit, if *info* $\leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

w REAL for ssygvd

DOUBLE PRECISION for `dsygvd`.

`Array`, DIMENSION at least `max(1, n)`.

If `info = 0`, contains the eigenvalues in ascending order.

`work(1)`
On exit, if `info = 0`, then `work(1)` returns the required minimal size of `lwork`.

`iwork(1)`
On exit, if `info = 0`, then `iwork(1)` returns the required minimal size of `liwork`.

`info` INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th argument had an illegal value.

If `info > 0`, an error code is returned as specified below.

- For $info \leq N$:

- If `info = i`, with $i \leq n$, and `jobz = 'N'`, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
- If `jobz = 'V'`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$.

- For $info > N$:

- If `info = n + i`, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygvd` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>jobz</code>	Must be ' <code>N</code> ' or ' <code>V</code> '. The default value is ' <code>N</code> '.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $work$ ($liwork$) is less than the minimal required value and is not equal to -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, lrwork,  
iwork, liwork, info)  
call zhegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, lrwork,  
iwork, liwork, info)
```

Fortran 95:

```
call hegvd(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

C:

```
lapack_int LAPACKE_chegvd( int matrix_layout, lapack_int itype, char jobz, char uplo,  
lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,  
lapack_int ldb, float* w );  
lapack_int LAPACKE_zhegvd( int matrix_layout, lapack_int itype, char jobz, char uplo,  
lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,  
lapack_int ldb, double* w );
```

- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda x, \text{ or } B^*A^*x = \lambda x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	COMPLEX for <code>chegvd</code> DOUBLE COMPLEX for <code>zhegvd</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the upper or lower triangle of the Hermitian positive definite matrix <i>B</i> , as specified by <i>uplo</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$. <i>lda</i> INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$. <i>ldb</i> INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$. <i>lwork</i> INTEGER. The dimension of the array <i>work</i> . Constraints: If $n \leq 1$, <i>lwork</i> ≥ 1 ; If <i>jobz</i> = 'N' and $n > 1$, <i>lwork</i> $\geq n+1$; If <i>jobz</i> = 'V' and $n > 1$, <i>lwork</i> $\geq n^2+2n$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> , <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> , <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lwork</i> or <i>liwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for details.
<i>rwork</i>	REAL for <code>chegvd</code> DOUBLE PRECISION for <code>zhegvd</code> .

Workspace array, DIMENSION max(1, lrwork).

lrwork

INTEGER.

The dimension of the array *rwork*.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, DIMENSION max(1, liwork).

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^H * B * Z = I$;

if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of *A*, including the diagonal, is destroyed.

b

On exit, if $info \leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.

w

REAL for [chegvd](#)

DOUBLE PRECISION for [zhegvd](#).

Array, DIMENSION at least $\max(1, n)$.

If $\text{info} = 0$, contains the eigenvalues in ascending order.

$\text{work}(1)$ On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

$\text{rwork}(1)$ On exit, if $\text{info} = 0$, then $\text{rwork}(1)$ returns the required minimal size of lrwork .

$\text{iwork}(1)$ On exit, if $\text{info} = 0$, then $\text{iwork}(1)$ returns the required minimal size of liwork .

info INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th argument had an illegal value.

If $\text{info} = i$, and $\text{jobz} = \text{'N'}$, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

If $\text{info} = i$, and $\text{jobz} = \text{'V'}$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $\text{info}/(n+1)$ through $\text{mod}(\text{info}, n+1)$.

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegvd` interface are the following:

a Holds the matrix A of size (n, n) .

b Holds the matrix B of size (n, n) .

w Holds the vector of length n .

$itype$ Must be 1, 2, or 3. The default value is 1.

$jobz$ Must be ' N ' or ' V '. The default value is ' N '.

$uplo$ Must be ' U ' or ' L '. The default value is ' U '.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of lwork (liwork or lrwork) for the first run or set $\text{lwork} = -1$ ($\text{liwork} = -1$, $\text{lrwork} = -1$).

If you choose the first option and set any of admissible lwork (liwork or lrwork) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (work , iwork , rwork) on exit. Use this value ($\text{work}(1)$, $\text{iwork}(1)$, $\text{rwork}(1)$) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

FORTRAN 77:

```
call ssygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, iwork, ifail, info)
call dsygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, iwork, ifail, info)
```

Fortran 95:

```
call sygvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

C:

```
lapack_int LAPACKE_<?>sygvx( int matrix_layout, lapack_int itype, char jobz, char
range, char uplo, lapack_int n, <datatype>* a, lapack_int lda, <datatype>* b,
lapack_int ldb, <datatype> vl, <datatype> vu, lapack_int il, lapack_int iu, <datatype>
abstol, lapack_int* m, <datatype>* w, <datatype>* z, lapack_int ldz, lapack_int*
ifail );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 95: `lapack.f90`
- C: `mkl.h`

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>itype</code>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <code>itype = 1</code> , the problem type is $A^*x = \lambda^*B^*x$;
--------------------	--

if $itype = 2$, the problem type is $A^*B^*x = \lambda x$;
 if $itype = 3$, the problem type is $B^*A^*x = \lambda x$.

jobz

CHARACTER*1. Must be 'N' or 'V'.
If $jobz = 'N'$, then compute eigenvalues only.
If $jobz = 'V'$, then compute eigenvalues and eigenvectors.

range

CHARACTER*1. Must be 'A' or 'V' or 'I'.
If $range = 'A'$, the routine computes all eigenvalues.
If $range = 'V'$, the routine computes eigenvalues $\lambda(i)$ in the half-open interval:
 $vl < \lambda(i) \leq vu$.
If $range = 'I'$, the routine computes eigenvalues with indices il to iu .

uplo

CHARACTER*1. Must be 'U' or 'L'.
If $uplo = 'U'$, arrays a and b store the upper triangles of A and B ;
If $uplo = 'L'$, arrays a and b store the lower triangles of A and B .

n

INTEGER. The order of the matrices A and B ($n \geq 0$).

a, b, work

REAL for ssygvx
 DOUBLE PRECISION for dsygvx.
Arrays:

$a(lda, *)$ contains the upper or lower triangle of the symmetric matrix A , as specified by *uplo*.

The second dimension of a must be at least $\max(1, n)$.

$b(ldb, *)$ contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by *uplo*.

The second dimension of b must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb

INTEGER. The leading dimension of b ; at least $\max(1, n)$.

vl, vu

REAL for ssygvx
 DOUBLE PRECISION for dsygvx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$
if $n = 0$.

If $range = 'A'$ or ' V ', il and iu are not referenced.

$abstol$

REAL for ssygvx

DOUBLE PRECISION for dsygvx. The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z . Constraints:

$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

$lwork$

INTEGER.

The dimension of the array $work$;

$lwork < \max(1, 8n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$iwork$

INTEGER.

Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

a

On exit, the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is overwritten.

b

On exit, if $info \leq n$, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$,
 $m = iu - il + 1$.

w, z

REAL for ssygvx

DOUBLE PRECISION for dsygvx.

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:

```
if itype = 1 or 2,  $Z^T * B * Z = I$ ;  
if itype = 3,  $Z^T * \text{inv}(B) * Z = I$ ;
```

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i th argument had an illegal value.

If $info > 0$, *spotrf/dpotrf* and *ssyevx/dsyevx* returned an error code:

If $info = i \leq n$, *ssyevx/dsyevx* failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sygvx* interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>z</i>	Holds the matrix Z of size (n, n) , where the values n and m are significant.

<i>ifail</i>	Holds the vector of length n .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be ' <i>U</i> ' or ' <i>L</i> '. The default value is ' <i>U</i> '.
<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_{\text{WP}}$.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <i>ifail</i> is present and z is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * \|T\|_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0 , indicating that some eigenvectors did not converge, set *abstol* to $2 * ?\text{lamch}('S')$.

For optimum performance use *lwork* $\geq (nb+3)*n$, where *nb* is the blocksize for *ssytrd/dsytrd* returned by *ilaenv*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax**FORTRAN 77:**

```
call chegvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, rwork, iwork, ifail, info)
call zhegvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hegvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

C:

```

- C: mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda * B^*x, \quad A^*B^*x = \lambda * x, \text{ or } B^*A^*x = \lambda * x.$$

Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

itype	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if $itype = 1$, the problem type is $A^*x = \lambda * B^*x$; if $itype = 2$, the problem type is $A^*B^*x = \lambda * x$; if $itype = 3$, the problem type is $B^*A^*x = \lambda * x$.
-------	--

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda(i)</i> in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> (<i>n</i> \geq 0).
<i>a, b, work</i>	COMPLEX for <i>chegvx</i> DOUBLE COMPLEX for <i>zhegvx</i> . Arrays: <i>a</i> (<i>lda,*</i>) contains the upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb,*</i>) contains the upper or lower triangle of the Hermitian positive definite matrix <i>B</i> , as specified by <i>uplo</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, n)$.
<i>vl, vu</i>	REAL for <i>chegvx</i> DOUBLE PRECISION for <i>zhegvx</i> . If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if <i>n</i> > 0; <i>il=1</i> and <i>iu=0</i> if <i>n</i> = 0.

If `range = 'A'` or `'V'`, `il` and `iu` are not referenced.

`abstol`

REAL for `chegvx`

DOUBLE PRECISION for `zhegvx`.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

`ldz`

INTEGER. The leading dimension of the output array `z`. Constraints:

`ldz ≥ 1`; if `jobz = 'V'`, `ldz ≥ max(1, n)`.

`lwork`

INTEGER.

The dimension of the array `work`; `lwork ≥ max(1, 2n)`.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`.

See *Application Notes* for the suggested value of `lwork`.

`rwork`

REAL for `chegvx`

DOUBLE PRECISION for `zhegvx`.

Workspace array, DIMENSION at least `max(1, 7n)`.

`iwork`

INTEGER.

Workspace array, DIMENSION at least `max(1, 5n)`.

Output Parameters

`a`

On exit, the upper triangle (if `uplo = 'U'`) or the lower triangle (if `uplo = 'L'`) of `A`, including the diagonal, is overwritten.

`b`

On exit, if `info ≤ n`, the part of `b` containing the matrix is overwritten by the triangular factor `U` or `L` from the Cholesky factorization $B = U^H * U$ or $B = L^H * L$.

`m`

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If `range = 'A'`, $m = n$, and if `range = 'I'`,

$m = iu - il + 1$.

`w`

REAL for `chegvx`

DOUBLE PRECISION for `zhegvx`.

Array, DIMENSION at least `max(1, n)`.

The first `m` elements of `w` contain the selected eigenvalues in ascending order.

`z`

COMPLEX for `chegvx`

DOUBLE COMPLEX for `zhegvx`.

Array `z(ldz, *)`. The second dimension of `z` must be at least `max(1, m)`.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:

```
if  $\text{itype} = 1$  or  $2$ ,  $Z^H * B * Z = I$ ;  
if  $\text{itype} = 3$ ,  $Z^H * \text{inv}(B) * Z = I$ ;
```

If $\text{jobz} = \text{'N'}$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail .

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $\text{range} = \text{'V'}$, the exact value of m is not known in advance and an upper bound must be used.

$\text{work}(1)$

On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, the first m elements of ifail are zero; if $\text{info} > 0$, the ifail contains the indices of the eigenvectors that failed to converge.

If $\text{jobz} = \text{'N'}$, then ifail is not referenced.

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i th argument had an illegal value.

If $\text{info} > 0$, cpotrf/zpotrf and cheevx/zheevx returned an error code:

If $\text{info} = i \leq n$, cheevx/zheevx failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array ifail ;

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine hegvx interface are the following:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size (n, n) .
w	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) , where the values n and m are significant.

<i>ifail</i>	Holds the vector of length n .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_{\text{WP}}$.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <i>ifail</i> is present and z is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0 , indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?\text{lamch}('S')$.

For optimum performance use *lwork* $\geq (nb+1)*n$, where *nb* is the blocksize for `chetrd/zhetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call sspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
call dspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
```

Fortran 95:

```
call spgv(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>spgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, <datatype>* ap, <datatype>* bp, <datatype>* w, <datatype>* z, lapack_int
ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda*B^*x, A^*B^*x = \lambda*x, \text{ or } B^*A^*x = \lambda*x.$$

Here *A* and *B* are assumed to be symmetric, stored in packed format, and *B* is also positive definite.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

itype INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:

```
if itype = 1, the problem type is A*x = lambda*B*x;
if itype = 2, the problem type is A*B*x = lambda*x;
if itype = 3, the problem type is B*A*x = lambda*x.
```

jobz CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then compute eigenvalues only.

If *jobz* = 'V', then compute eigenvalues and eigenvectors.

uplo CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', arrays *ap* and *bp* store the upper triangles of *A* and *B*;

If $uplo = 'L'$, arrays ap and bp store the lower triangles of A and B .

n

INTEGER. The order of the matrices A and B ($n \geq 0$).

$ap, bp, work$

REAL for sspgv

DOUBLE PRECISION for dspgv.

Arrays:

$ap(*)$ contains the packed upper or lower triangle of the symmetric matrix A , as specified by $uplo$.

The dimension of ap must be at least $\max(1, n*(n+1)/2)$.

$bp(*)$ contains the packed upper or lower triangle of the symmetric matrix B , as specified by $uplo$.

The dimension of bp must be at least $\max(1, n*(n+1)/2)$.

$work(*)$ is a workspace array, DIMENSION at least $\max(1, 3n)$.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

Output Parameters

ap

On exit, the contents of ap are overwritten.

bp

On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as B .

w, z

REAL for sspgv

DOUBLE PRECISION for dspgv.

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T * B * Z = I$;

if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, spptrf/dpptrf and sspev/dspev returned an error code:

If $info = i \leq n$, sspev/dspev failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgv` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: <code>jobz = 'V'</code> , if <code>z</code> is present, <code>jobz = 'N'</code> , if <code>z</code> is omitted.

?hpgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call chpgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
call zhpgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hpgv(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_chpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
                           lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
                           lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
                           lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double* w,
                           lapack_complex_double* z, lapack_int ldz );
```

- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda x, \quad \text{or} \quad B^*A^*x = \lambda x.$$

Here *A* and *B* are assumed to be symmetric, stored in packed format, and *B* is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$;
--------------	--

if $itype = 2$, the problem type is $A^*B^*x = \lambda x$;
 if $itype = 3$, the problem type is $B^*A^*x = \lambda x$.

jobz

CHARACTER*1. Must be 'N' or 'V'.
If $jobz = 'N'$, then compute eigenvalues only.
If $jobz = 'V'$, then compute eigenvalues and eigenvectors.

uplo

CHARACTER*1. Must be 'U' or 'L'.
If $uplo = 'U'$, arrays *ap* and *bp* store the upper triangles of *A* and *B*;
If $uplo = 'L'$, arrays *ap* and *bp* store the lower triangles of *A* and *B*.

n

INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ap, bp, work

REAL **for** sspgvd
 DOUBLE PRECISION **for** dspgvd.

Arrays:

ap(*) contains the packed upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.

The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.

bp(*) contains the packed upper or lower triangle of the symmetric matrix *B*, as specified by *uplo*.

The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.

work is a workspace array, its dimension $\max(1, lwork)$.

ldz

INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lwork \geq 2n$;

If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2 + 6n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, dimension $\max(1, lwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;
 If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
 If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by *xerbla*. See *Application Notes* for details.

Output Parameters

ap

On exit, the contents of *ap* are overwritten.

bp

On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as *B*.

w, z

REAL for sspgv

DOUBLE PRECISION for dspgv.

Arrays:

w(*), DIMENSION at least max(1, *n*).

If *info* = 0, contains the eigenvalues in ascending order.

z(*ldz*,*).

The second dimension of *z* must be at least max(1, *n*).

If $jobz = 'V'$, then if *info* = 0, *z* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^T * B * Z = I$;

if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then *z* is not referenced.

work(1)

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

iwork(1)

On exit, if *info* = 0, then *iwork*(1) returns the required minimal size of *liwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th argument had an illegal value.

If *info* > 0, *spptrf/dpptrf* and *sspevd/dspevd* returned an error code:

If *info* = $i \leq n$, *sspevd/dspevd* failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If *info* = $n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgvd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: $\text{jobz} = \text{'V}'$, if <code>z</code> is present, $\text{jobz} = \text{'N}'$, if <code>z</code> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run, or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`) on exit. Use this value (`work(1)`, `iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hpgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork, lrwork,
iwork, liwork, info)
```

```
call zhpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork, lrwork,
iwork, liwork, info)
```

Fortran 95:

```
call hpgvd(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_chpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double* w,
lapack_complex_double* z, lapack_int ldz );
```

Include Files

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda*B^*x, A^*B^*x = \lambda*x, \text{ or } B^*A^*x = \lambda*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ap</i> , <i>bp</i> , <i>work</i>	COMPLEX for chpgvd DOUBLE COMPLEX for zhpgvd. Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of the Hermitian matrix A , as specified by <i>uplo</i> .

The dimension of ap must be at least $\max(1, n*(n+1)/2)$.

$bp(*)$ contains the packed upper or lower triangle of the Hermitian matrix B , as specified by $uplo$.

The dimension of bp must be at least $\max(1, n*(n+1)/2)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldz INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$rwork$ REAL for `chpgvd`

DOUBLE PRECISION for `zhpgvd`.

Workspace array, its dimension $\max(1, lrwork)$.

$lrwork$ INTEGER.

The dimension of the array $rwork$.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$ INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

$liwork$ INTEGER.

The dimension of the array $iwork$.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
 If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See [Application Notes](#) for details.

Output Parameters

ap	On exit, the contents of ap are overwritten.
bp	On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as B .
w	<p>REAL for chpgvd</p> <p>DOUBLE PRECISION for zhpgvd.</p> <p>Array, DIMENSION at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p>
z	<p>COMPLEX for chpgvd</p> <p>DOUBLE COMPLEX for zhpgvd.</p> <p>Array $z(ldz, *)$.</p> <p>The second dimension of z must be at least $\max(1, n)$.</p> <p>If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:</p> <pre> if $itype = 1$ or 2, $Z^H * B * Z = I$; if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$; </pre> <p>If $jobz = 'N'$, then z is not referenced.</p>
$work(1)$	On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
$rwork(1)$	On exit, if $info = 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.
$iwork(1)$	On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th argument had an illegal value.</p> <p>If $info > 0$, cpptrf/zpptrf and chpevd/zhpevd returned an error code:</p> <p>If $info = i \leq n$, chpevd/zhpevd failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;</p>

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgvd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: <code>jobz</code> = ' <code>V</code> ', if <code>z</code> is present, <code>jobz</code> = ' <code>N</code> ', if <code>z</code> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of lwork (liwork or lrwork) for the first run or set $\text{lwork} = -1$ ($\text{liwork} = -1$, $\text{lrwork} = -1$).

If you choose the first option and set any of admissible lwork (liwork or lrwork) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (work , iwork , rwork) on exit. Use this value ($\text{work}(1)$, $\text{iwork}(1)$, $\text{rwork}(1)$) for subsequent runs.

If you set $\text{lwork} = -1$ ($\text{liwork} = -1$, $\text{lrwork} = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (work , iwork , rwork). This operation is called a workspace query.

Note that if you set lwork (liwork , lrwork) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call sspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, iwork, ifail, info)
```

```
call dspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call spgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

C:

```
lapack_int LAPACKE_<?>spgvx( int matrix_layout, lapack_int itype, char jobz, char
range, char uplo, lapack_int n, <datatype>* ap, <datatype>* bp, <datatype> vl,
<datatype> vu, lapack_int il, lapack_int iu, <datatype> abstol, lapack_int* m,
<datatype>* w, <datatype>* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

itype INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:

```
if itype = 1, the problem type is A*x = lambda*B*x;
if itype = 2, the problem type is A*B*x = lambda*x;
if itype = 3, the problem type is B*A*x = lambda*x.
```

jobz CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then compute eigenvalues only.

If *jobz* = 'V', then compute eigenvalues and eigenvectors.

range CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.

If *range* = 'V', the routine computes eigenvalues *lambda(i)* in the half-open interval:

vl < *lambda(i)* ≤ *vu*.

If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo

CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, arrays ap and bp store the upper triangles of A and B ;
 If $uplo = 'L'$, arrays ap and bp store the lower triangles of A and B .

n

INTEGER. The order of the matrices A and B ($n \geq 0$).

ap, bp, work

REAL for sspgvx

DOUBLE PRECISION for dpgvx.

Arrays:

$ap(*)$ contains the packed upper or lower triangle of the symmetric matrix A , as specified by $uplo$.

The dimension of ap must be at least $\max(1, n*(n+1)/2)$.

$bp(*)$ contains the packed upper or lower triangle of the symmetric matrix B , as specified by $uplo$.

The dimension of bp must be at least $\max(1, n*(n+1)/2)$.

$work(*)$ is a workspace array, DIMENSION at least $\max(1, 8n)$.

vl, vu

REAL for sspgvx

DOUBLE PRECISION for dpgvx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.

If $range = 'A'$ or ' V' , il and iu are not referenced.

abstol

REAL for sspgvx

DOUBLE PRECISION for dpgvx.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z . Constraints:

$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

iwork

INTEGER.

Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap

On exit, the contents of ap are overwritten.

<i>bp</i>	On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as B .
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.
<i>w, z</i>	REAL for sspgvx DOUBLE PRECISION for dspgvx. Arrays: <i>w</i> (*), DIMENSION at least max(1, <i>n</i>). If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (<i>ldz</i> , *). The second dimension of <i>z</i> must be at least max(1, <i>n</i>). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T * B * Z = I$; if <i>itype</i> = 3, $Z^T * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least max(1, <i>m</i>) columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>ifail</i>	INTEGER. Array, DIMENSION at least max(1, <i>n</i>). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>-i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, spptrf/dpptrf and sspevx/dspevx returned an error code: If <i>info</i> = <i>i</i> $\leq n$, sspevx/dspevx failed to converge, and <i>i</i> eigenvectors failed to converge. Their indices are stored in the array <i>ifail</i> ; If <i>info</i> = <i>n</i> + <i>i</i> , for $1 \leq i \leq n$, then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgvx` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<code>ifail</code>	Holds the vector with the number of elements n .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be ' <code>U</code> ' or ' <code>L</code> '. The default value is ' <code>U</code> '.
<code>vl</code>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<code>vu</code>	Default value for this element is $vu = \text{HUGE}(vl)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0_{\text{WP}}$.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <code>ifail</code> is present and z is omitted.
<code>range</code>	Restored based on the presence of arguments vl , vu , il , iu as follows: $range = 'V'$, if one of or both vl and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of vl , vu , il , iu is present. Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\epsilon * \|T\|_1$ is used instead, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when `abstol` is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, set `abstol` to $2 * ?lamch('S')$.

?hpgvx

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax**FORTRAN 77:**

```
call chpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, rwork, iwork, ifail, info)

call zhpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

C:

```
lapack_int LAPACKE_chpgvx( int matrix_layout, lapack_int itype, char jobz, char range,
char uplo, lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float vl,
float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w,
lapack_complex_float* z, lapack_int ldz, lapack_int* ifail );

lapack_int LAPACKE_zhpgvx( int matrix_layout, lapack_int itype, char jobz, char range,
char uplo, lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double vl,
double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

itype	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if $itype = 1$, the problem type is $A^*x = \lambda^*B^*x$; if $itype = 2$, the problem type is $A^*B^*x = \lambda^*x$; if $itype = 3$, the problem type is $B^*A^*x = \lambda^*x$.
-------	---

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> (<i>n</i> \geq 0).
<i>ap</i> , <i>bp</i> , <i>work</i>	COMPLEX for chpgvx DOUBLE COMPLEX for zhpgvx. Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i> (*) contains the packed upper or lower triangle of the Hermitian matrix <i>B</i> , as specified by <i>uplo</i> . The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> (*) is a workspace array, DIMENSION at least $\max(1, 2n)$.
<i>vl</i> , <i>vu</i>	REAL for chpgvx DOUBLE PRECISION for zhpgvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il</i> , <i>iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if <i>n</i> > 0; <i>il</i> =1 and <i>iu</i> =0 if <i>n</i> = 0. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for chpgvx

DOUBLE PRECISION for zhpgvx.

The absolute error tolerance for the eigenvalues.

See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

rwork REAL for chpgvx

DOUBLE PRECISION for zhpgvx.

Workspace array, DIMENSION at least $\max(1, 7n)$.

iwork INTEGER.

Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, the contents of *ap* are overwritten.

bp On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as *B*.

m INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',
 $m = iu - il + 1$.

w REAL for chpgvx

DOUBLE PRECISION for zhpgvx.

Array, DIMENSION at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

z COMPLEX for chpgvx

DOUBLE COMPLEX for zhpgvx.

Array $z(ldz, *)$.

The second dimension of *z* must be at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w(i)*. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^H * B * Z = I$;

if *itype* = 3, $Z^H * \text{inv}(B) * Z = I$;

If *jobz* = 'N', then *z* is not referenced.

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1,m)$ columns are supplied in the array z ; if $\text{range} = \text{'V'}$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, the first m elements of *ifail* are zero; if $\text{info} > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $\text{jobz} = \text{'N'}$, then *ifail* is not referenced.

info

INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the i -th argument had an illegal value.

If $\text{info} > 0$, *cpptrf/zpptrf* and *chpevx/zhpevx* returned an error code:

If $\text{info} = i \leq n$, *chpevx/zhpevx* failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $\text{info} = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hpgvx* interface are the following:

*ap*Holds the array A of size $(n*(n+1)/2)$.*bp*Holds the array B of size $(n*(n+1)/2)$.*w*Holds the vector with the number of elements n .*z*Holds the matrix Z of size (n, n) , where the values n and m are significant.*ifail*Holds the vector with the number of elements n .*itype*

Must be 1, 2, or 3. The default value is 1.

*uplo*Must be '*U*' or '*L*'. The default value is '*U*'.*vl*Default value for this element is $vl = -\text{HUGE}(vl)$.*vu*Default value for this element is $vu = \text{HUGE}(vl)$.*il*Default value for this argument is $il = 1$.*iu*Default value for this argument is $iu = n$.*abstol*Default value for this element is $abstol = 0.0_{\text{WP}}$.

jobz Restored based on the presence of the argument *z* as follows:

jobz = 'V', if *z* is present,
jobz = 'N', if *z* is omitted.

Note that there will be an error condition if *ifail* is present and *z* is omitted.

range Restored based on the presence of arguments *vl*, *vu*, *il*, *iu* as follows:

range = 'V', if one of or both *vl* and *vu* are present,
range = 'I', if one of or both *il* and *iu* are present,
range = 'A', if none of *vl*, *vu*, *il*, *iu* is present,

Note that there will be an error condition if one of or both *vl* and *vu* are present and at the same time one of or both *il* and *iu* are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * \|T\|_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?\text{lamch}('S')$.

?sbgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
call dsbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
```

Fortran 95:

```
call sbgv(ab, bb, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_<?>sbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, <datatype>* ab, lapack_int ldab, <datatype>* bb,
lapack_int ldbb, <datatype>* w, <datatype>* z, lapack_int ldz );
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda * B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
<i>ab</i> , <i>bb</i> , <i>work</i>	REAL for ssbgv DOUBLE PRECISION for dsbgv Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldb</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $\max(1, 3n)$
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1 . If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by pbstf/pbstf .
<i>w</i> , <i>z</i>	REAL for ssbgv

DOUBLE PRECISION for `dsbgv`

Arrays:

`w(*)`, DIMENSION at least $\max(1, n)$.

If `info = 0`, contains the eigenvalues in ascending order.

`z(ldz,*)`.

The second dimension of `z` must be at least $\max(1, n)$.

If `jobz = 'V'`, then if `info = 0`, `z` contains the matrix Z of eigenvectors, with the i -th column of `z` holding the eigenvector associated with `w(i)`. The eigenvectors are normalized so that $Z^T * B * Z = I$.

If `jobz = 'N'`, then `z` is not referenced.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th argument had an illegal value.

If `info > 0`, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if `info = n + i`, for $1 \leq i \leq n$, then `pbstf/pbstf` returned `info = i` and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgv` interface are the following:

`ab` Holds the array A of size $(ka+1, n)$.

`bb` Holds the array B of size $(kb+1, n)$.

`w` Holds the vector with the number of elements n .

`z` Holds the matrix Z of size (n, n) .

`uplo` Must be '`U`' or '`L`'. The default value is '`U`'.

`jobz` Restored based on the presence of the argument `z` as follows:

`jobz = 'V'`, if `z` is present,

`jobz = 'N'`, if `z` is omitted.

?hbgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
call zhbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hbgv(ab, bb, w [,uplo] [,z] [,info])
```

C:

```
lapack_int LAPACKE_chbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab,
                           lapack_complex_float* bb, lapack_int ldbb, float* w, lapack_complex_float* z,
                           lapack_int ldz );

lapack_int LAPACKE_zhbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
                           lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int ldab,
                           lapack_complex_double* bb, lapack_int ldbb, double* w, lapack_complex_double* z,
                           lapack_int ldz );
```

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda * B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
<i>ab</i> , <i>bb</i> , <i>work</i>	REAL for ssbgvd DOUBLE PRECISION for dsbgvd Arrays: <i>ab</i> (<i>ldab,*</i>) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb,*</i>) is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The leading dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1 . If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> .

Constraints:

If $n \leq 1$, $lwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $lwork \geq 3n$;
If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2 + 5n + 1$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

Constraints:

If $n \leq 1$, $liwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab

On exit, the contents of ab are overwritten.

bb

On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by [pbstf/pbstf](#).

w, z

REAL for ssbgvd

DOUBLE PRECISION for dsbgvd

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$z(ldz, *)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.

If $jobz = 'N'$, then z is not referenced.

<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, and if <i>i</i> ≤ <i>n</i> , the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; if <i>info</i> = <i>n</i> + <i>i</i> , for 1 ≤ <i>i</i> ≤ <i>n</i> , then pbstf/pbstf returned <i>info</i> = <i>i</i> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgvd` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>bb</i>	Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work(1)*, *iwork(1)*) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hbгvд

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)
```

```
call zhbqvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, rwork,  
lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hbgvd(ab, bb, w [, uplo] [, z] [, info])
```

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

jobz CHARACTER*1. Must be 'N' or 'V'.

If `jobz = 'N'`, then compute eigenvalues only.

If $jobz = 'v'$, then compute eigenvalues and e

If `uplo = 'U'`, arrays `ab` and `bb` start at `0`.

If $uplo = 'L'$, arrays ab and bb store the lower triangles of A and B .

n INTEGER. The order of the matrices A and B ($n \geq 0$).

ka INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).

kb INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).

$ab, bb, work$ COMPLEX for chbgvd
DOUBLE COMPLEX for zhbgvd

Arrays:

ab ($ldab,*$) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by $uplo$) in band storage format.

The second dimension of the array ab must be at least $\max(1, n)$.

bb ($ldbb,*$) is an array containing either upper or lower triangular part of the Hermitian matrix B (as specified by $uplo$) in band storage format.

The second dimension of the array bb must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

$ldab$ INTEGER. The leading dimension of the array ab ; must be at least $ka+1$.

$ldbb$ INTEGER. The leading dimension of the array bb ; must be at least $kb+1$.

ldz INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$rwork$ REAL for chbgvd

DOUBLE PRECISION for zhbgvd.

Workspace array, DIMENSION $\max(1, lrwork)$.

$lrwork$ INTEGER.

The dimension of the array $rwork$.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;
 If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;
 If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.
 If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$ INTEGER.

Workspace array, DIMENSION $\max(1, liwork)$.

$liwork$ INTEGER.

The dimension of the array $iwork$.

Constraints:

If $n \leq 1$, $lwork \geq 1$;
 If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
 If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab On exit, the contents of ab are overwritten.

bb On exit, contains the factor S from the split Cholesky factorization $B = S^H * S$, as returned by [pbstf/pbstf](#).

w REAL for chbgvd
 DOUBLE PRECISION for zhbgvd.

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

z COMPLEX for chbgvd
 DOUBLE COMPLEX for zhbgvd
 Array $z(Idz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$.

If $jobz = 'N'$, then z is not referenced.

<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i> .
<i>rwork(1)</i>	On exit, if <i>info</i> = 0, then <i>rwork(1)</i> returns the required minimal size of <i>lrwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, and if <i>i</i> ≤ <i>n</i> , the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; if <i>info</i> = <i>n</i> + <i>i</i> , for 1 ≤ <i>i</i> ≤ <i>n</i> , then <i>pbstf/pbstf</i> returned <i>info</i> = <i>i</i> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbqvd* interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>bb</i>	Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set *lwork* = -1 (*liwork* = -1, *lrwork* = -1).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work(1)*, *iwork(1)*, *rwork(1)*) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, iwork, ifail, info)

call dsbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call sbgsvx(ab, bb, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q] [,abstol]
[,info])
```

C:

```
lapack_int LAPACKE_<?>sbgsvx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int ka, lapack_int kb, <datatype>* ab, lapack_int ldab,
<datatype>* bb, lapack_int ldbb, <datatype>* q, lapack_int ldq, <datatype> vl,
<datatype> vu, lapack_int il, lapack_int iu, <datatype> abstol, lapack_int* m,
<datatype>* w, <datatype>* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- C: `mkl.h`

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<code>jobz</code>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '.
	If <code>jobz</code> = ' <code>N</code> ', then compute eigenvalues only.
	If <code>jobz</code> = ' <code>V</code> ', then compute eigenvalues and eigenvectors.

<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> (<i>n</i> \geq 0).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>ka</i> \geq 0).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> (<i>kb</i> \geq 0).
<i>ab</i> , <i>bb</i> , <i>work</i>	REAL for ssbgvx DOUBLE PRECISION for dsbgvx Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldb</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, DIMENSION (7*n).
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least <i>ka</i> +1.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>bb</i> ; must be at least <i>kb</i> +1.
<i>vl</i> , <i>vu</i>	REAL for ssbgvx DOUBLE PRECISION for dsbgvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il</i> , <i>iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if <i>n</i> > 0; <i>il</i> =1 and <i>iu</i> =0 if <i>n</i> = 0.

If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

$abstol$

REAL for ssbgvx

DOUBLE PRECISION for dsbgvx.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $\text{jobz} = \text{'V'}$, $ldz \geq \max(1, n)$.

ldq

INTEGER. The leading dimension of the output array q ; $ldq < 1$.

If $\text{jobz} = \text{'V'}$, $ldq < \max(1, n)$.

$iwork$

INTEGER.

Workspace array, DIMENSION ($5*n$).

Output Parameters

ab

On exit, the contents of ab are overwritten.

bb

On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by [pbstf/pbstf](#).

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If $\text{range} = \text{'A'}$, $m = n$, and if $\text{range} = \text{'I'}$,
 $m = iu - il + 1$.

w, z, q

REAL for ssbgvx

DOUBLE PRECISION for dsbgvx

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $\text{info} = 0$, contains the eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $\text{jobz} = \text{'V'}$, then if $\text{info} = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.

If $\text{jobz} = \text{'N'}$, then z is not referenced.

$q(ldq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $\text{jobz} = \text{'V'}$, then q contains the n -by- n matrix used in the reduction of $A * x = \lambda * B * x$ to standard form, that is, $C * x = \lambda * x$ and consequently C to tridiagonal form.

If $\text{jobz} = \text{'N'}$, then q is not referenced.

$ifail$

INTEGER.

Array, DIMENSION (m).

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then **pbstf/pbstf** returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine **sbgvx** interface are the following:

ab

Holds the array A of size $(ka+1, n)$.

bb

Holds the array B of size $(kb+1, n)$.

w

Holds the vector with the number of elements n .

z

Holds the matrix Z of size (n, n) .

$ifail$

Holds the vector with the number of elements n .

q

Holds the matrix Q of size (n, n) .

$uplo$

Must be ' U ' or ' L '. The default value is ' U '.

vl

Default value for this element is $vl = -\text{HUGE}(v)$.

vu

Default value for this element is $vu = \text{HUGE}(v)$.

il

Default value for this argument is $il = 1$.

iu

Default value for this argument is $iu = n$.

$abstol$

Default value for this element is $abstol = 0.0_{\text{WP}}$.

$jobz$

Restored based on the presence of the argument z as follows:

$jobz = 'V'$, if z is present,

$jobz = 'N'$, if z is omitted.

Note that there will be an error condition if $ifail$ or q is present and z is omitted.

<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present,
Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.	

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?\text{lamch}('S')$.

?hbgyx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)
call zhbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,

Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: <i>vl</i> < <i>lambda</i> (<i>i</i>) ≤ <i i="" vu<="">. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</i>
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> (<i>n</i> ≥ 0).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> (<i>ka</i> ≥ 0).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> (<i>kb</i> ≥ 0).
<i>ab</i> , <i>bb</i> , <i>work</i>	COMPLEX for chbgvx DOUBLE COMPLEX for zhbgvx Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldb</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, DIMENSION at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least <i>ka</i> +1.

lubb INTEGER. The leading dimension of the array *bb*; must be at least $kb+1$.

vl, vu REAL for chbgvx
DOUBLE PRECISION for zhbgvx.
If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: $vl < vu$.
If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; *il*=1 and *iu*=0 if $n = 0$.
If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for chbgvx
DOUBLE PRECISION for zhbgvx.
The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

ldq INTEGER. The leading dimension of the output array *q*; $ldq \geq 1$. If *jobz* = 'V', $ldq \geq \max(1, n)$.

rwork REAL for chbgvx
DOUBLE PRECISION for zhbgvx.
Workspace array, DIMENSION at least $\max(1, 7n)$.

iwork INTEGER.
Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ab On exit, the contents of *ab* are overwritten.

bb On exit, contains the factor *S* from the split Cholesky factorization $B = S^H * S$, as returned by **pbstf/pbstf**.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', *m* = *n*, and if *range* = 'I',
 $m = iu - il + 1$.

w REAL for chbgvx
DOUBLE PRECISION for zhbgvx.

Array $w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

z, q

COMPLEX for chbgvx

DOUBLE COMPLEX for zhbgvx

Arrays:

$z(Idz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B^* Z = I$.

If $jobz = 'N'$, then z is not referenced.

$q(Idq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $jobz = 'V'$, then q contains the n -by- n matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently C to tridiagonal form.

If $jobz = 'N'$, then q is not referenced.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then pbstf/pbstf returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbgyx` interface are the following:

ab

Holds the array A of size $(ka+1, n)$.

<i>bb</i>	Holds the array B of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>ifail</i>	Holds the vector with the number of elements n .
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>uplo</i>	Must be ' U ' or ' L '. The default value is ' U '.
<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_{\text{WP}}$.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon * \max(|a|, |b|)$, where ε is the machine precision.

If *abstol* is less than or equal to zero, then $\varepsilon * \|T\|_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?\text{lamch}('S')$, not zero.

If this routine returns with *info* > 0 , indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?\text{lamch}('S')$.

Generalized Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Nonsymmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

Routine Name	Operation performed
gges	Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.
ggesx	Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.
ggev	Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.
ggevx	Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

?gges

Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.

Syntax**FORTRAN 77:**

Description

The ?gges routine computes the generalized eigenvalues, the generalized real/complex Schur form (S, T), optionally, the left and/or right matrices of Schur vectors (vsl and vsr) for a pair of n -by- n real/complex nonsymmetric matrices (A, B). This gives the generalized Schur factorization

$$(A, B) = (vsl^*S * vsr^H, vsl^*T^* vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

If only the generalized eigenvalues are needed, use the driver [ggev](#) instead, which is faster.

A generalized eigenvalue for a pair of matrices (A, B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - w^*B$ is singular. It is usually represented as the pair (α, β), as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S, T) is in the generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S are "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S, T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

The ?gges routine replaces the deprecated ?gegs routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobvsl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed. If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.
<i>jobvsr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed.

If $\text{jobvsr} = 'V'$, then the right Schur vectors are computed.

sort

CHARACTER*1. Must be ' N ' or ' S '. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

If $\text{sort} = 'N'$, then eigenvalues are not ordered.

If $\text{sort} = 'S'$, eigenvalues are ordered (see selctg).

selctg

LOGICAL FUNCTION of three REAL arguments for real flavors.

LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.

selctg must be declared EXTERNAL in the calling subroutine.

If $\text{sort} = 'S'$, selctg is used to select eigenvalues to sort to the top left of the Schur form.

If $\text{sort} = 'N'$, selctg is not referenced.

For real flavors:

An eigenvalue $(\text{alphar}(j) + \text{alphai}(j))/\text{beta}(j)$ is selected if $\text{selctg}(\text{alphar}(j), \text{alphai}(j), \text{beta}(j))$ is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alphar}(j), \text{alphai}(j), \text{beta}(j)) = .TRUE.$ after ordering. In this case info is set to $n+2$.

For complex flavors:

An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if $\text{selctg}(\text{alpha}(j), \text{beta}(j))$ is true.

Note that a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alpha}(j), \text{beta}(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case info is set to $n+2$ (see info below).

n

INTEGER. The order of the matrices A , B , vsl , and vsr ($n \geq 0$).

a, b, work

REAL for sgges

DOUBLE PRECISION for dgges

COMPLEX for cgges

DOUBLE COMPLEX for zgges.

Arrays:

$a(l\text{da},*)$ is an array containing the n -by- n matrix A (first of the pair of matrices).

The second dimension of a must be at least $\max(1, n)$.

$b(l\text{db},*)$ is an array containing the n -by- n matrix B (second of the pair of matrices).

The second dimension of b must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, l\text{work})$.

$l\text{da}$

INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . Must be at least $\max(1, n)$.
<i>ldvsl, ldvsr</i>	INTEGER. The leading dimensions of the output matrices <i>vsl</i> and <i>vsr</i> , respectively. Constraints: <i>ldvsl</i> ≥ 1 . If <i>jobvsl</i> = 'V', <i>ldvsl</i> $\geq \max(1, n)$. <i>ldvsr</i> ≥ 1 . If <i>jobvsr</i> = 'V', <i>ldvsr</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> $\geq \max(1, 8n+16)$ for real flavors; <i>lwork</i> $\geq \max(1, 2n)$ for complex flavors. For good performance, <i>lwork</i> must generally be larger. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> .
<i>rwork</i>	REAL for <i>cgges</i> DOUBLE PRECISION for <i>zgges</i> Workspace array, DIMENSION at least $\max(1, 8n)$. This array is used in complex flavors only.
<i>bwork</i>	LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if <i>sort</i> = 'N'.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	INTEGER. If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>selctg</i> is true. Note that for real flavors complex conjugate pairs for which <i>selctg</i> is true for either eigenvalue count as 2.
<i>alphar, alphai</i>	REAL for <i>sgges</i> ; DOUBLE PRECISION for <i>dgges</i> . Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	COMPLEX for <i>cgges</i> ;

DOUBLE COMPLEX for zgges.

Array, DIMENSION at least max(1, n). Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for sgges

DOUBLE PRECISION for dgges

COMPLEX for cgges

DOUBLE COMPLEX for zgges.

Array, DIMENSION at least max(1, n).

For real flavors:

On exit, $(\text{alphar}(j) + \text{alphaai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

*alphar(j) + alphaai(j)*i* and *beta(j)*, $j=1, \dots, n$ are the diagonals of the complex Schur form (*S,T*) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (*A,B*) were further reduced to triangular form using complex unitary transformations. If *alphaai(j)* is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j+1*)-st eigenvalues are a complex conjugate pair, with *alphaai(j+1)* negative.

For complex flavors:

On exit, *alpha(j)/beta(j)*, $j=1, \dots, n$, will be the generalized eigenvalues.

alpha(j), $j=1, \dots, n$, and *beta(j)*, $j=1, \dots, n$ are the diagonals of the complex Schur form (*S,T*) output by cgges/zgges. The *beta(j)* will be non-negative real.

See also *Application Notes* below.

vsl, vsr

REAL for sgges

DOUBLE PRECISION for dgges

COMPLEX for cgges

DOUBLE COMPLEX for zgges.

Arrays:

vsl(Idvsl,),* the second dimension of *vs*l must be at least max(1, *n*).

If *jobvsl* = 'V', this array will contain the left Schur vectors.

If *jobvsl* = 'N', *vs*l is not referenced.

vsr(Idvsr,),* the second dimension of *vsr* must be at least max(1, *n*).

If *jobvsr* = 'V', this array will contain the right Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

work(1)

On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$:

the QZ iteration failed. (A, B) is not in Schur form, but $\text{alphar}(j)$, $\text{alphai}(j)$ (for real flavors), or $\text{alpha}(j)$ (for complex flavors), and $\text{beta}(j)$, $j=info+1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in `hgeqz`;

$i = n+2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy $\text{selectg} = .TRUE..$ This could also be caused due to scaling;

$i = n+3$: reordering failed in `tgsen`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gges` interface are the following:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size (n, n) .
alphar	Holds the vector of length n . Used in real flavors only.
alphai	Holds the vector of length n . Used in real flavors only.
alpha	Holds the vector of length n . Used in complex flavors only.
beta	Holds the vector of length n .
vsl	Holds the matrix VSL of size (n, n) .
vsr	Holds the matrix VSR of size (n, n) .
jobvsl	Restored based on the presence of the argument vsl as follows: $\text{jobvsl} = 'V'$, if vsl is present, $\text{jobvsl} = 'N'$, if vsl is omitted.
jobvsr	Restored based on the presence of the argument vsr as follows: $\text{jobvsr} = 'V'$, if vsr is present, $\text{jobvsr} = 'N'$, if vsr is omitted.
sort	Restored based on the presence of the argument select as follows: $\text{sort} = 'S'$, if select is present, $\text{sort} = 'N'$, if select is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of lwork for the first run or set $\text{lwork} = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar(j)/beta(j)* and *alphai(j)/beta(j)* may easily over- or underflow, and *beta(j)* may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

?ggesx

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

Syntax

FORTRAN 77:

```
call sggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim, alphar,
alphai, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, iwork, liwork,

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A, B), the generalized eigenvalues, the generalized real/complex Schur form (S, T), optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A, B) = (vsl^* S * vsr^H, vsl^* T^* vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T ; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ($rcondv$). The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A, B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α, β), as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S, T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S, T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

jobvsl

CHARACTER*1. Must be 'N' or 'V'.

If *jobvsl* = 'N', then the left Schur vectors are not computed.

If $\text{jobvsl} = \text{'V'}$, then the left Schur vectors are computed.

jobvsr

CHARACTER*1. Must be ' N ' or ' V '.

If $\text{jobvsr} = \text{'N'}$, then the right Schur vectors are not computed.

If $\text{jobvsr} = \text{'V'}$, then the right Schur vectors are computed.

sort

CHARACTER*1. Must be ' N ' or ' S '. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

If $\text{sort} = \text{'N'}$, then eigenvalues are not ordered.

If $\text{sort} = \text{'S'}$, eigenvalues are ordered (see selctg).

selctg

LOGICAL FUNCTION of three REAL arguments for real flavors.

LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.

selctg must be declared EXTERNAL in the calling subroutine.

If $\text{sort} = \text{'S'}$, selctg is used to select eigenvalues to sort to the top left of the Schur form.

If $\text{sort} = \text{'N'}$, selctg is not referenced.

For real flavors:

An eigenvalue $(\text{alphar}(j) + \text{alphai}(j))/\text{beta}(j)$ is selected if $\text{selctg}(\text{alphar}(j), \text{alphai}(j), \text{beta}(j))$ is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alpha}(j), \text{beta}(j)) = .\text{TRUE}.$ after ordering. In this case info is set to $n+2$.

For complex flavors:

An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if $\text{selctg}(\text{alpha}(j), \text{beta}(j))$ is true.

Note that a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alpha}(j), \text{beta}(j)) = .\text{TRUE}.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case info is set to $n+2$ (see info below).

sense

CHARACTER*1. Must be ' N ', ' E ', ' V ', or ' B '. Determines which reciprocal condition number are computed.

If $\text{sense} = \text{'N'}$, none are computed;

If $\text{sense} = \text{'E'}$, computed for average of selected eigenvalues only;

If $\text{sense} = \text{'V'}$, computed for selected deflating subspaces only;

If $\text{sense} = \text{'B'}$, computed for both.

If sense is ' E ', ' V ', or ' B ', then sort must equal ' S '.

n

INTEGER. The order of the matrices A , B , vsl , and vsr ($n \geq 0$).

a , b , work

REAL for sggesx

DOUBLE PRECISION for dggesx

COMPLEX for cggesx

DOUBLE COMPLEX for zggesx.

Arrays:

a(*lda*,*) is an array containing the n -by- n matrix *A* (first of the pair of matrices).

The second dimension of *a* must be at least $\max(1, n)$.

b(*ldb*,*) is an array containing the n -by- n matrix *B* (second of the pair of matrices).

The second dimension of *b* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, \ iwork)$.

lda

INTEGER. The leading dimension of the array *a*.

Must be at least $\max(1, n)$.

ldb

INTEGER. The leading dimension of the array *b*.

Must be at least $\max(1, n)$.

ldvsl, ldvsr

INTEGER. The leading dimensions of the output matrices *vsl* and *vsr*, respectively. Constraints:

ldvsl ≥ 1 . If *jobvsl* = 'V', *ldvsl* $\geq \max(1, n)$.

ldvsr ≥ 1 . If *jobvsr* = 'V', *ldvsr* $\geq \max(1, n)$.

iwork

INTEGER.

The dimension of the array *work*.

For real flavors:

If *n*=0 then *iwork* ≥ 1 .

If *n*>0 and *sense* = 'N', then *iwork* $\geq \max(8*n, 6*n+16)$.

If *n*>0 and *sense* = 'E', 'V', or 'B', then *iwork* $\geq \max(8*n, 6*n+16, 2*sdim*(n-sdim))$;

For complex flavors:

If *n*=0 then *iwork* ≥ 1 .

If *n*>0 and *sense* = 'N', then *iwork* $\geq \max(1, 2*n)$;

If *n*>0 and *sense* = 'E', 'V', or 'B', then *iwork* $\geq \max(1, 2*n, 2*sdim*(n-sdim))$.

Note that $2*sdim*(n-sdim) \leq n*n/2$.

An error is only returned if *iwork* $< \max(8*n, 6*n+16)$ for real flavors, and *iwork* $< \max(1, 2*n)$ for complex flavors, but if *sense* = 'E', 'V', or 'B', this may not be large enough.

If *iwork*=-1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *iwork* or *liwork* is issued by xerbla.

rwork

REAL for cggesx

DOUBLE PRECISION for zggesx

Workspace array, DIMENSION at least max(1, 8n).

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION max(1, *liwork*).

liwork

INTEGER.

The dimension of the array *iwork*.

If *sense* = 'N', or *n*=0, then *liwork*≥1,

otherwise *liwork* ≥ (n+6) for real flavors, and *liwork* ≥ (n+2) for complex flavors.

If *liwork*=-1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

bwork

LOGICAL.

Workspace array, DIMENSION at least max(1, *n*).

Not referenced if *sort* = 'N'.

Output Parameters

a

On exit, this array has been overwritten by its generalized Schur form *S*.

b

On exit, this array has been overwritten by its generalized Schur form *T*.

sdim

INTEGER.

If *sort* = 'N', *sdim*= 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *selectg* is true.

Note that for real flavors complex conjugate pairs for which *selectg* is true for either eigenvalue count as 2.

alphar, *alphai*

REAL for sggesx;

DOUBLE PRECISION for dggesx.

Arrays, DIMENSION at least max(1, *n*) each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for cggesx;

DOUBLE COMPLEX for zggesx.

Array, DIMENSION at least max(1, *n*). Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for sggesx

DOUBLE PRECISION for dggesx

COMPLEX for cggesx

DOUBLE COMPLEX for zggesx.

Array, DIMENSION at least max(1, n).

For real flavors:

On exit, (*alphar(j)* + *alphai(j)*i*)/*beta(j)*, j=1,..., n will be the generalized eigenvalues.

alphar(j) + *alphai(j)*i* and *beta(j)*, j=1,..., n are the diagonals of the complex Schur form (*S,T*) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (*A,B*) were further reduced to triangular form using complex unitary transformations. If *alphai(j)* is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with *alphai(j+1)* negative.

For complex flavors:

On exit, *alpha(j)/beta(j)*, j=1,..., n will be the generalized eigenvalues. *alpha(j)*, j=1,..., n, and *beta(j)*, j=1,...,n are the diagonals of the complex Schur form (*S,T*) output by cggesx/zggesx. The *beta(j)* will be non-negative real.

See also *Application Notes* below.

vsl, vsr

REAL for sggesx

DOUBLE PRECISION for dggesx

COMPLEX for cggesx

DOUBLE COMPLEX for zggesx.

Arrays:

vsl(*ldvsl,**), the second dimension of *vsl* must be at least max(1, n).

If *jobvsl* = 'V', this array will contain the left Schur vectors.

If *jobvsl* = 'N', *vsl* is not referenced.

vsr(*ldvsr,**), the second dimension of *vsr* must be at least max(1, n).

If *jobvsr* = 'V', this array will contain the right Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

rconde, rcondv

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION (2) each

If *sense* = 'E' or 'B', *rconde*(1) and *rconde*(2) contain the reciprocal condition numbers for the average of the selected eigenvalues.

Not referenced if *sense* = 'N' or 'V'.

If *sense* = 'V' or 'B', *rcondv*(1) and *rcondv*(2) contain the reciprocal condition numbers for the selected deflating subspaces.

Not referenced if *sense* = 'N' or 'E'.

<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value. If <i>info</i> = <i>i</i> , and <i>i</i> ≤ <i>n</i> : the QZ iteration failed. (<i>A</i> , <i>B</i>) is not in Schur form, but <i>alphar(j)</i> , <i>alphai(j)</i> (for real flavors), or <i>alpha(j)</i> (for complex flavors), and <i>beta(j)</i> , <i>j</i> = <i>info</i> +1, ..., <i>n</i> should be correct. <i>i</i> > <i>n</i> : errors that usually indicate LAPACK problems: <i>i</i> = <i>n</i> +1: other than QZ iteration failed in ?hgeqz; <i>i</i> = <i>n</i> +2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy <i>selctg</i> = .TRUE.. This could also be caused due to scaling; <i>i</i> = <i>n</i> +3: reordering failed in <i>tgsen</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggesx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (<i>n</i> , <i>n</i>).
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (<i>n</i> , <i>n</i>).
<i>rconde</i>	Holds the vector of length (2).
<i>rcondv</i>	Holds the vector of length (2).
<i>jobvsl</i>	Restored based on the presence of the argument <i>vs</i> / <i>l</i> as follows: <i>jobvsl</i> = 'V', if <i>vs</i> / <i>l</i> is present,

	<i>jobvsl</i> = 'N', if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows: <i>jobvsr</i> = 'V', if <i>vsr</i> is present, <i>jobvsr</i> = 'N', if <i>vsr</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Note that there will be an error condition if *rconde* or *rcondv* are present and *select* is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If you choose the first option and set any of admissible *lwork* (or *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar(j)/beta(j)* and *alphai(j)/beta(j)* may easily over- or underflow, and *beta(j)* may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

?ggev

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

Syntax

FORTRAN 77:

```
call sggev(jobvl, jobvr, n, a, lda, b, ldb, alphar, alphai, beta, vl, ldvl, vr, ldvr,
work, lwork, info)

call dggev(jobvl, jobvr, n, a, lda, b, ldb, alphar, alphai, beta, vl, ldvl, vr, ldvr,
work, lwork, info)

call cggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr, work,
lwork, rwork, info)
```

```
call zggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr, work,
lwork, rwork, info)
```

Fortran 95:

```
call ggev(a, b, alphar, alphai, beta [,vl] [,vr] [,info])
call ggev(a, b, alpha, beta [, vl] [,vr] [,info])
```

C:

```
lapack_int LAPACKE_sggev( int matrix_layout, char jobvl, char jobvr, lapack_int n,
float* a, lapack_int lda, float* b, lapack_int ldb, float* alphar, float* alphai,
float* beta, float* vl, lapack_int ldvl, float* vr, lapack_int ldvr );
lapack_int LAPACKE_dggev( int matrix_layout, char jobvl, char jobvr, lapack_int n,

- C: mkl.h

Description

The ?ggev routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of n -by- n real/complex nonsymmetric matrices (A,B).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β), as there is a reasonable interpretation for $\beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies $A^*v(j) = \lambda(j)^*B^*v(j)$.

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H A = \lambda(j)^* u(j)^H B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

The ?ggev routine replaces the deprecated ?gegv routine.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'.
--------------	----------------------------------

If $\text{jobvl} = \text{'N'}$, the left generalized eigenvectors are not computed;
 If $\text{jobvl} = \text{'V'}$, the left generalized eigenvectors are computed.

jobvr
 CHARACTER*1. Must be ' N ' or ' V '.
 If $\text{jobvr} = \text{'N'}$, the right generalized eigenvectors are not computed;
 If $\text{jobvr} = \text{'V'}$, the right generalized eigenvectors are computed.

n
 INTEGER. The order of the matrices A , B , vl , and vr ($n \geq 0$).

a , b , work
 REAL for sggev
 DOUBLE PRECISION for dggev
 COMPLEX for cggev
 DOUBLE COMPLEX for zggev.

Arrays:
 $a(\text{lda},*)$ is an array containing the n -by- n matrix A (first of the pair of matrices).
 The second dimension of a must be at least $\max(1, n)$.
 $b(\text{ldb},*)$ is an array containing the n -by- n matrix B (second of the pair of matrices).
 The second dimension of b must be at least $\max(1, n)$.
 work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda
 INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

ldb
 INTEGER. The leading dimension of the array b . Must be at least $\max(1, n)$.

ldvl , ldvr
 INTEGER. The leading dimensions of the output matrices vl and vr , respectively.

Constraints:
 $\text{ldvl} \geq 1$. If $\text{jobvl} = \text{'V'}$, $\text{ldvl} \geq \max(1, n)$.
 $\text{ldvr} \geq 1$. If $\text{jobvr} = \text{'V'}$, $\text{ldvr} \geq \max(1, n)$.

lwork
 INTEGER.
 The dimension of the array work .
 $\text{lwork} \geq \max(1, 8n+16)$ for real flavors;
 $\text{lwork} \geq \max(1, 2n)$ for complex flavors.
 For good performance, lwork must generally be larger.
 If $\text{lwork} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to lwork is issued by **xerbla**.

rwork
 REAL for cggev
 DOUBLE PRECISION for zggev

Workspace array, DIMENSION at least $\max(1, 8n)$.

This array is used in complex flavors only.

Output Parameters

a, b	On exit, these arrays have been overwritten.
$alphar, alphai$	<p>REAL for sggev;</p> <p>DOUBLE PRECISION for dggev.</p> <p>Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.</p> <p>See <i>beta</i>.</p>
$alpha$	<p>COMPLEX for cggev;</p> <p>DOUBLE COMPLEX for zggev.</p> <p>Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i>.</p>
$beta$	<p>REAL for sggev</p> <p>DOUBLE PRECISION for dggev</p> <p>COMPLEX for cggev</p> <p>DOUBLE COMPLEX for zggev.</p> <p>Array, DIMENSION at least $\max(1, n)$.</p> <p><i>For real flavors:</i></p> <p>On exit, $(alphar(j) + alphai(j)*i)/beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.</p> <p>If $alphai(j)$ is zero, then the j-th eigenvalue is real; if positive, then the j-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $alphai(j+1)$ negative.</p> <p><i>For complex flavors:</i></p> <p>On exit, $alpha(j)/beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.</p> <p>See also <i>Application Notes</i> below.</p>
vl, vr	<p>REAL for sggev</p> <p>DOUBLE PRECISION for dggev</p> <p>COMPLEX for cggev</p> <p>DOUBLE COMPLEX for zggev.</p> <p>Arrays:</p> <p>$vl(Idvl, *)$; the second dimension of vl must be at least $\max(1, n)$.</p> <p>If $jobvl = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of vl, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.</p> <p>If $jobvl = 'N'$, vl is not referenced.</p>

For real flavors:

If the j-th eigenvalue is real, then $u(j) = v1(:,j)$, the j-th column of $v1$.

If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = v1(:,j) + i*v1(:,j+1)$ and $u(j+1) = v1(:,j) - i*v1(:,j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$u(j) = v1(:,j)$, the j-th column of $v1$.

$vr(lvdr,*);$ the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j-th eigenvalue is real, then $v(j) = vr(:,j)$, the j-th column of vr .

If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $v(j) = vr(:,j) + i*vr(:,j+1)$ and $v(j+1) = vr(:,j) - i*vr(:,j+1)$.

For complex flavors:

$v(j) = vr(:,j)$, the j-th column of vr .

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but $alphai(j)$, $alphai(j)$ (for real flavors), or $alpha(j)$ (for complex flavors), and $beta(j)$, $j=info+1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine [ggev](#) interface are the following:

a Holds the matrix A of size (n, n) .

b Holds the matrix B of size (n, n) .

<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alphai</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>vl</i>	Holds the matrix VL of size (n, n) .
<i>vr</i>	Holds the matrix VR of size (n, n) .
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar(j)/beta(j)* and *alphai(j)/beta(j)* may easily over- or underflow, and *beta(j)* may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

?ggevx

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Syntax

FORTRAN 77:

```
call sggevx(balanc, jobvl, jobvr, sense, n, a, lda, b, ldb, alphar, alphai, beta, vl,

- C: mkl.h

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A, B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors ($ilo, ihi, lscale, rscale, abnrm$, and $bbnrm$), reciprocal condition numbers for the eigenvalues ($rconde$), and reciprocal condition numbers for the right eigenvectors ($rcondv$).

A generalized eigenvalue for a pair of matrices (A, B) is a scalar λ or a ratio $\text{alpha} / \text{beta} = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair $(\text{alpha}, \text{beta})$, as there is a reasonable interpretation for $\text{beta}=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$A^*v(j) = \lambda(j)^*B^*v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$u(j)^H A = \lambda(j)^* u(j)^H B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>balanc</i>	CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed. If <i>balanc</i> = 'N', do not diagonally scale or permute; If <i>balanc</i> = 'P', permute only; If <i>balanc</i> = 'S', scale only; If <i>balanc</i> = 'B', both permute and scale. Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.
<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>sense</i>	CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed. If <i>sense</i> = 'N', none are computed; If <i>sense</i> = 'E', computed for eigenvalues only; If <i>sense</i> = 'V', computed for eigenvectors only; If <i>sense</i> = 'B', computed for eigenvalues and eigenvectors.
<i>n</i>	INTEGER. The order of the matrices A , B , vl , and vr ($n \geq 0$).
<i>a, b, work</i>	REAL for sggevx DOUBLE PRECISION for dggevx COMPLEX for cggevx DOUBLE COMPLEX for zggevx.

Arrays:

$a(la,*)$ is an array containing the n -by- n matrix A (first of the pair of matrices).

The second dimension of a must be at least $\max(1, n)$.

$b(lb,*)$ is an array containing the n -by- n matrix B (second of the pair of matrices).

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

la

INTEGER. The leading dimension of the array a .

Must be at least $\max(1, n)$.

lb

INTEGER. The leading dimension of the array b .

Must be at least $\max(1, n)$.

$ldvl, ldvr$

INTEGER. The leading dimensions of the output matrices vl and vr , respectively.

Constraints:

$ldvl \geq 1$. If $jobvl = 'V'$, $ldvl \geq \max(1, n)$.

$ldvr \geq 1$. If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.

$lwork$

INTEGER.

The dimension of the array $work$. $lwork \geq \max(1, 2*n)$;

For real flavors:

If $balanc = 'S'$, or $'B'$, or $jobvl = 'V'$, or $jobvr = 'V'$, then $lwork \geq \max(1, 6*n)$;

if $sense = 'E'$, or $'B'$, then $lwork \geq \max(1, 10*n)$;

if $sense = 'V'$, or $'B'$, $lwork \geq (2n^2 + 8*n + 16)$.

For complex flavors:

if $sense = 'E'$, $lwork \geq \max(1, 4*n)$;

if $sense = 'V'$, or $'B'$, $lwork \geq \max(1, 2*n^2 + 2*n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

$rwork$

REAL for cggevx

DOUBLE PRECISION for zggevx

Workspace array, DIMENSION at least $\max(1, 6*n)$ if $balanc = 'S'$, or $'B'$, and at least $\max(1, 2*n)$ otherwise.

This array is used in complex flavors only.

$iwork$

INTEGER.

Workspace array, DIMENSION at least $(n+6)$ for real flavors and at least $(n+2)$ for complex flavors.

Not referenced if $sense = 'E'$.

bwork

LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$.

Not referenced if $sense = 'N'$.

Output Parameters

a, b

On exit, these arrays have been overwritten.

If $jobvl = 'V'$ or $jobvr = 'V'$ or both, then *a* contains the first part of the real Schur form of the "balanced" versions of the input *A* and *B*, and *b* contains its second part.

alphar, alphai

REAL for sggevx;

DOUBLE PRECISION for dggevx.

Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for cggevx;

DOUBLE COMPLEX for zggevx.

Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for sggevx

DOUBLE PRECISION for dggevx

COMPLEX for cggevx

DOUBLE COMPLEX for zggevx.

Array, DIMENSION at least $\max(1, n)$.

For real flavors:

On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative.

For complex flavors:

On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

See also Application Notes below.

vl, vr

REAL for sggevx

DOUBLE PRECISION for dggevx

COMPLEX for cggevx

DOUBLE COMPLEX for zggevx.

Arrays:

$vl(lv1,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:,j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:,j) + i * vl(:,j+1)$ and $u(j+1) = vl(:,j) - i * vl(:,j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$u(j) = vl(:,j)$, the j -th column of vl .

$vr(lv1,*)$; the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:,j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:,j) + i * vr(:,j+1)$ and $v(j+1) = vr(:,j) - i * vr(:,j+1)$.

For complex flavors:

$v(j) = vr(:,j)$, the j -th column of vr .

ilo, ihi

INTEGER. ilo and ihi are integer values such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

$lscale, rscale$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays, DIMENSION at least $\max(1, n)$ each.

$lscale$ contains details of the permutations and scaling factors applied to the left side of A and B .

If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then

```

 $lscale(j) = PL(j), \text{ for } j = 1, \dots, ilo-1$ 
 $= DL(j), \text{ for } j = ilo, \dots, ihi$ 
 $= PL(j) \text{ for } j = ihi+1, \dots, n.$ 

```

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

rscale contains details of the permutations and scaling factors applied to the right side of *A* and *B*.

If *PR(j)* is the index of the column interchanged with column *j*, and *DR(j)* is the scaling factor applied to column *j*, then

$$\begin{aligned} \text{rscale}(j) &= \text{PR}(j), \text{ for } j = 1, \dots, \text{ilo}-1 \\ &= \text{DR}(j), \text{ for } j = \text{ilo}, \dots, \text{ihi} \\ &= \text{PR}(j) \text{ for } j = \text{ihi}+1, \dots, n. \end{aligned}$$

The order in which the interchanges are made is *n* to *ihi*+1, then 1 to *ilo*-1.

abnrm, *bbnrm*

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

The one-norms of the balanced matrices *A* and *B*, respectively.

rconde, *rcondv*

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least max(1, *n*) each.

If *sense* = 'E', or 'B', *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde(j)*, *rcondv(j)*, and the *j*-th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the *j*-th eigenpair, unless all eigenpairs are selected).

If *sense* = 'N', or 'V', *rconde* is not referenced.

If *sense* = 'V', or 'B', *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.

If the eigenvalues cannot be reordered to compute *rcondv(j)*, *rcondv(j)* is set to 0; this can only occur when the true value would be very small anyway.

If *sense* = 'N', or 'E', *rcondv* is not referenced.

work(1)

On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

i ≤ *n*:

the QZ iteration failed. No eigenvectors have been calculated, but *alphar(j)*, *alphai(j)* (for real flavors), or *alpha(j)* (for complex flavors), and *beta(j)*, *j*=*info*+1, ..., *n* should be correct.

i > *n*: errors that usually indicate LAPACK problems:

i = *n*+1: other than QZ iteration failed in [hgeqz](#);

i = *n*+2: error return from [tgevc](#).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggevx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphaai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).
<i>lscale</i>	Holds the vector of length <i>n</i> .
<i>rscale</i>	Holds the vector of length <i>n</i> .
<i>rconde</i>	Holds the vector of length <i>n</i> .
<i>rcondv</i>	Holds the vector of length <i>n</i> .
<i>balanc</i>	Must be 'N', 'B', or 'P'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar(j)/beta(j)* and *alphai(j)/beta(j)* may easily over- or underflow, and *beta(j)* may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

The table below summarizes information about the available LAPACK auxiliary routines.

LAPACK Auxiliary Routines

Routine Name	Data Types	Description
?lacgv	c, z	Conjugates a complex vector.
?lacrm	c, z	Multiplies a complex matrix by a square real matrix.
?lacrt	c, z	Performs a linear transformation of a pair of complex vectors.
?laesy	c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix.
?rot	c, z	Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.
?spmv	c, z	Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix
?spr	c, z	Performs the symmetrical rank-1 update of a complex symmetric packed matrix.
?syconv	s, c, d, z	Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.
?symv	c, z	Computes a matrix-vector product for a complex symmetric matrix.
?syr	c, z	Performs the symmetric rank-1 update of a complex symmetric matrix.
i?max1	c, z	Finds the index of the vector element whose real part has maximum absolute value.
?sum1	sc, dz	Forms the 1-norm of the complex vector using the true absolute value.
?gbtf2	s, d, c, z	Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.

Routine Name	Data Types	Description
?gebd2	s, d, c, z	Reduces a general matrix to bidiagonal form using an unblocked algorithm.
?gehd2	s, d, c, z	Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.
?gelq2	s, d, c, z	Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.
?geql2	s, d, c, z	Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2	s, d, c, z	Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2p	s, d, c, z	Computes the QR factorization of a general rectangular matrix with non-negative diagonal elements using an unblocked algorithm.
?geqrt2	s, d, c, z	Computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.
?geqrt3	s, d, c, z	Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.
?gerq2	s, d, c, z	Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.
?gesc2	s, d, c, z	Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2.
?getc2	s, d, c, z	Computes the LU factorization with complete pivoting of the general n -by- n matrix.
?getf2	s, d, c, z	Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).
?gtts2	s, d, c, z	Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.
?isnan	s, d,	Tests input for NaN.
?laisnan	s, d,	Tests input for NaN by comparing two arguments for inequality.
?labrd	s, d, c, z	Reduces the first nb rows and columns of a general matrix to a bidiagonal form.
?lacn2	s, d, c, z	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacpy	s, d, c, z	Copies all or part of one two-dimensional array to another.
?ladiv	s, d, c, z	Performs complex division in real arithmetic, avoiding unnecessary overflow.
?lae2	s, d	Computes the eigenvalues of a 2-by-2 symmetric matrix.
?laebz	s, d	Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz.

Routine Name	Data Types	Description
?laed0	s, d, c, z	Used by ?stedc. Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.
?laed1	s, d	Used by ssstedc/dstedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.
?laed2	s, d	Used by ssstedc/dstedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.
?laed3	s, d	Used by ssstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.
?laed4	s, d	Used by ssstedc/dstedc. Finds a single root of the secular equation.
?laed5	s, d	Used by ssstedc/dstedc. Solves the 2-by-2 secular equation.
?laed6	s, d	Used by ssstedc/dstedc. Computes one Newton step in solution of the secular equation.
?laed7	s, d, c, z	Used by ?stedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.
?laed8	s, d, c, z	Used by ?stedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.
?laed9	s, d	Used by ssstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.
?laeda	s, d	Used by ?stedc. Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.
?laein	s, d, c, z	Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.
?laev2	s, d, c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.
?laexc	s, d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
?lag2	s, d	Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.
?lags2	s, d	Computes 2-by-2 orthogonal matrices U , V , and Q , and applies them to matrices A and B such that the rows of the transformed A and B are parallel.
?lagtf	s, d	Computes an LU factorization of a matrix $T - \lambda I$, where T is a general tridiagonal matrix, and λ a scalar, using partial pivoting with row interchanges.
?lagtm	s, d, c, z	Performs a matrix-matrix product of the form $C = \alpha AB + \beta C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.

Routine Name	Data Types	Description
?lagts	s, d	Solves the system of equations $(T - \lambda I)x = y$ or $(T - \lambda I)^T x = y$, where T is a general tridiagonal matrix and λ a scalar, using the LU factorization computed by ?lagtf.
?lagv2	s, d	Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular.
?lahqr	s, d, c, z	Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.
?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?lahr2	s, d, c, z	Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?laic1	s, d, c, z	Applies one step of incremental condition estimation.
?laln2	s, d	Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.
?lals0	s, d, c, z	Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd.
?lalsa	s, d, c, z	Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd.
?lalsd	s, d, c, z	Uses the singular value decomposition of A to solve the least squares problem.
?lamrg	s, d	Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.
?laneg	s, d	Computes the Sturm count.
?langb	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.
?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.
?langt	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.
?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.
?lansb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.

Routine Name	Data Types	Description
?lanhb	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.
?lansp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.
?lanhp	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.
?lanst/?lanht	s, d/c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.
?lansy	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.
?lanhe	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.
?lantb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.
?lantp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.
?lantr	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.
?lanv2	s, d	Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.
?lapll	s, d, c, z	Measures the linear dependence of two vectors.
?lapmr	s, d, c, z	Rearranges rows of a matrix as specified by a permutation vector.
?lapmt	s, d, c, z	Performs a forward or backward permutation of the columns of a matrix.
?lapy2	s, d	Returns $\sqrt{x^2+y^2}$.
?lapy3	s, d	Returns $\sqrt{x^2+y^2+z^2}$.
?laqgb	s, d, c, z	Scales a general band matrix, using row and column scaling factors computed by ?gbequ.
?laqge	s, d, c, z	Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ.
?laqhb	c, z	Scales a Hermitian band matrix, using scaling factors computed by ?pbequ.
?laqp2	s, d, c, z	Computes a QR factorization with column pivoting of the matrix block.

Routine Name	Data Types	Description
?laqps	s, d, c, z	Computes a step of QR factorization with column pivoting of a real m-by-n matrix A by using BLAS level 3.
?laqr0	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr1	s, d, c, z	Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix H and specified shifts.
?laqr2	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr3	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr4	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr5	s, d, c, z	Performs a single small-bulge multi-shift QR sweep.
?laqsb	s, d, c, z	Scales a symmetric/Hermitian band matrix, using scaling factors computed by ?pbequ.
?laqsp	s, d, c, z	Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ.
?laqsy	s, d, c, z	Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ.
?laqtr	s, d	Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.
?lar1v	s, d, c, z	Computes the (scaled) r -th column of the inverse of the submatrix in rows b_1 through b_n of the tridiagonal matrix $LDL^T - \lambda I$.
?lar2v	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.
?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.
?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
?larfgp	s, d, c, z	Generates an elementary reflector (Householder matrix) with non-negative beta.
?larft	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$
?larfx	s, d, c, z	Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order ≤ 10 .
?largv	s, d, c, z	Generates a vector of plane rotations with real cosines and real/complex sines.
?larnv	s, d, c, z	Returns a vector of random numbers from a uniform or normal distribution.

Routine Name	Data Types	Description
?larra	s, d	Computes the splitting points with the specified threshold.
?larrb	s, d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrc	s, d	Computes the number of eigenvalues of the symmetric tridiagonal matrix.
?larrd	s, d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
?larre	s, d	Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.
?larrf	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrj	s, d	Performs refinement of the initial estimates of the eigenvalues of the matrix T .
?larrk	s, d	Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.
?larrr	s, d	Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.
?larrv	s, d, c, z	Computes the eigenvectors of the tridiagonal matrix $T = L D L^T$ given L , D and the eigenvalues of $L D L^T$.
?lartg	s, d, c, z	Generates a plane rotation with real cosine and real/complex sine.
?lartgp	s, d	Generates a plane rotation so that the diagonal is nonnegative.
?lartgs	s, d	Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.
?lartv	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.
?laruv	s, d	Returns a vector of n random real numbers from a uniform distribution.
?larz	s, d, c, z	Applies an elementary reflector (as returned by ?tzrzf) to a general matrix.
?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general matrix.
?larzt	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
?las2	s, d	Computes singular values of a 2-by-2 triangular matrix.
?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .
?lasd0	s, d	Computes the singular values of a real upper bidiagonal n-by-m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc.
?lasd1	s, d	Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by ?bdsdc.

Routine Name	Data Types	Description
?lasd2	s, d	Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.
?lasd3	s, d	Finds all square roots of the roots of the secular equation, as defined by the values in D and Z , and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.
?lasd4	s, d	Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.
?lasd5	s, d	Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.
?lasd6	s, d	Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.
?lasd7	s, d	Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.
?lasd8	s, d	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc.
?lasda	s, d	Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.
?lasdq	s, d	Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.
?lasdt	s, d	Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.
?laset	s, d, c, z	Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.
?lasq1	s, d	Computes the singular values of a real square bidiagonal matrix. Used by ?bdsqr.
?lasq2	s, d	Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd Array Z to high relative accuracy. Used by ?bdsqr and ?stegr.
?lasq3	s, d	Checks for deflation, computes a shift and calls $dqds$. Used by ?bdsqr.
?lasq4	s, d	Computes an approximation to the smallest eigenvalue using values of d from the previous transform. Used by ?bdsqr.
?lasq5	s, d	Computes one $dqds$ transform in ping-pong form. Used by ?bdsqr and ?stegr.
?lasq6	s, d	Computes one dqd transform in ping-pong form. Used by ?bdsqr and ?stegr.
?lasr	s, d, c, z	Applies a sequence of plane rotations to a general rectangular matrix.

Routine Name	Data Types	Description
?lasrt	s, d	Sorts numbers in increasing or decreasing order.
?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
?lasv2	s, d	Computes the singular value decomposition of a 2-by-2 triangular matrix.
?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
?lasy2	s, d	Solves the Sylvester matrix equation where the matrices are of order 1 or 2.
?lasyf	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.
?lasyf_rook	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the bounded Bunch-Kaufman diagonal pivoting method.
?lahef	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.
?lahef_rook	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method.
?latbs	s, d, c, z	Solves a triangular banded system of equations.
?latdf	s, d, c, z	Uses the LU factorization of the n -by- n matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.
?latps	s, d, c, z	Solves a triangular system of equations with the matrix held in packed storage.
?latrd	s, d, c, z	Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
?latrs	s, d, c, z	Solves a triangular system of equations with the scale factor set to prevent overflow.
?latrz	s, d, c, z	Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.
?laau2	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices (unblocked algorithm).
?laum	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices (blocked algorithm).
?orbdb1/?unbdb1	s, d, c, z	Simultaneously bidiagonalizes the blocks of a tall and skinny matrix with orthonormal columns.
?orbdb2/?unbdb2		
?orbdb3/?unbdb3		
?orbdb4/?unbdb4		
?orbdb5/?unbdb5	s, d, c, z	Orthogonalizes a column vector with respect to the orthonormal basis matrix.
?orbdb6/?unbdb6		

Routine Name	Data Types	Description
?org2l/?ung2l	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by ?geqlf (unblocked algorithm).
?org2r/?ung2r	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by ?geqrf (unblocked algorithm).
?orgl2/?ungl2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).
?orgr2/?ungr2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by ?gerqf (unblocked algorithm).
?orm2l/?unm2l	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).
?orm2r/?unm2r	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).
?orml2/?unml2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).
?ormr2/?unmr2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by ?gerqf (unblocked algorithm).
?ormr3/?unmr3	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzrzf (unblocked algorithm).
?pbtf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/ Hermitian positive definite band matrix (unblocked algorithm).
?potf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (unblocked algorithm).
?ptts2	s, d, c, z	Solves a tridiagonal system of the form $AX=B$ using the $L D L^H$ factorization computed by ?pttrf.
?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
?syswapr	s, d, c, z	Applies an elementary permutation on the rows and columns of a symmetric matrix.
?heswapr	c, z	Applies an elementary permutation on the rows and columns of a Hermitian matrix.
?sygs2/?hegs2	s, d/c, z	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).
?sytd2/?hetd2	s, d/c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (unblocked algorithm).
?sytf2	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).
?sytf2_rook	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).
?hetf2	c, z	Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).

Routine Name	Data Types	Description
?hetf2_rook	c, z	Computes the factorization of a complex Hermitian matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).
?tgex2	s, d, c, z	Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.
?tgsy2	s, d, c, z	Solves the generalized Sylvester equation (unblocked algorithm).
?trti2	s, d, c, z	Computes the inverse of a triangular matrix (unblocked algorithm).
clag2z	c → z	Converts a complex single precision matrix to a complex double precision matrix.
dlag2s	d → s	Converts a double precision matrix to a single precision matrix.
slag2d	s → d	Converts a single precision matrix to a double precision matrix.
zlag2c	z → c	Converts a complex double precision matrix to a complex single precision matrix.
?larfp	s, d, c, z	Generates a real or complex elementary reflector.
ila?lc	s, d, c, z	Scans a matrix for its last non-zero column.
ila?lr	s, d, c, z	Scans a matrix for its last non-zero row.
?gsvj0	s, d	Pre-processor for the routine ?gesvj.
?gsvj1	s, d	Pre-processor for the routine ?gesvj, applies Jacobi rotations targeting only particular pivots.
?sfrk	s, d	Performs a symmetric rank-k operation for matrix in RFP format.
?hfrk	c, z	Performs a Hermitian rank-k operation for matrix in RFP format.
?tfsm	s, d, c, z	Solves a matrix equation (one operand is a triangular matrix in RFP format).
?lansf	s, d	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix in RFP format.
?lanhf	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian matrix in RFP format.
?tfttp	s, d, c, z	Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).
?tftrr	s, d, c, z	Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR).
?tpqrt2	s, d, c, z	Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.
?tprfb	s, d, c, z	Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.
?tpptf	s, d, c, z	Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

Routine Name	Data Types	Description
?tpstr	s, d, c, z	Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR).
?trtf	s, d, c, z	Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).
?trtp	s, d, c, z	Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP).
?pstf2	s, d, c, z	Computes the Cholesky factorization with complete pivoting of a real symmetric or complex Hermitian positive semi-definite matrix.
dlat2s	d → s	Converts a double-precision triangular matrix to a single-precision triangular matrix.
zlat2c	z → c	Converts a double complex triangular matrix to a complex triangular matrix.
?lacp2	c, z	Copies all or part of a real two-dimensional array to a complex array.
?la_gbamv	s, d, c, z	Performs a matrix-vector operation to calculate error bounds.
?la_gbrcond	s, d	Estimates the Skeel condition number for a general banded matrix.
?la_gbrcond_c	c, z	Computes the infinity norm condition number of $\text{op}(A)*\text{inv}(\text{diag}(c))$ for general banded matrices.
?la_gbrcond_x	c, z	Computes the infinity norm condition number of $\text{op}(A)*\text{diag}(x)$ for general banded matrices.
?la_gbrfsx_extended	s, d, c, z	Improves the computed solution to a system of linear equations for general banded matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_gbrpvgrw	s, d, c, z	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a general banded matrix.
?la_geamv	s, d, c, z	Computes a matrix-vector product using a general matrix to calculate error bounds.
?la_gercond	s, d	Estimates the Skeel condition number for a general matrix.
?la_gercond_c	c, z	Computes the infinity norm condition number of $\text{op}(A)*\text{inv}(\text{diag}(c))$ for general matrices.
?la_gercond_x	c, z	Computes the infinity norm condition number of $\text{op}(A)*\text{diag}(x)$ for general matrices.
?la_gerfsx_extended	s, d	Improves the computed solution to a system of linear equations for general matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_heamv	c, z	Computes a matrix-vector product using a Hermitian indefinite matrix to calculate error bounds.
?la_hercond_c	c, z	Computes the infinity norm condition number of $\text{op}(A)*\text{inv}(\text{diag}(c))$ for Hermitian indefinite matrices.

Routine Name	Data Types	Description
?la_hercond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) * \text{diag}(x)$ for Hermitian indefinite matrices.
?la_herfsx_extended	c, z	Improves the computed solution to a system of linear equations for Hermitian indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_lin_berr	s, d, c, z	Computes a component-wise relative backward error.
?la_porcond	s, d	Estimates the Skeel condition number for a symmetric positive-definite matrix.
?la_porcond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) * \text{inv}(\text{diag}(c))$ for Hermitian positive-definite matrices.
?la_porcond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) * \text{diag}(x)$ for Hermitian positive-definite matrices.
?la_porfsx_extended	s, d, c, z	Improves the computed solution to a system of linear equations for symmetric or Hermitian positive-definite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_porpvgrow	s, d, c, z	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a symmetric or Hermitian positive-definite matrix.
?laqhe	c, z	Scales a Hermitian matrix.
?laqhp	c, z	Scales a Hermitian matrix stored in packed form.
?larcm	c, z	Copies all or part of a real two-dimensional array to a complex array.
?la_rpvgrw	c, z	Multiplies a square real matrix by a complex matrix.
?larscl2	s, d, c, z	Performs reciprocal diagonal scaling on a vector.
?lascl2	s, d, c, z	Performs diagonal scaling on a vector.
?la_syamv	s, d, c, z	Computes a matrix-vector product using a symmetric indefinite matrix to calculate error bounds.
?la_syrcond	s, d	Estimates the Skeel condition number for a symmetric indefinite matrix.
?la_syrcond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) * \text{inv}(\text{diag}(c))$ for symmetric indefinite matrices.
?la_syrcond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) * \text{diag}(x)$ for symmetric indefinite matrices.
?la_syrfpsx_extended	s, d, c, z	Improves the computed solution to a system of linear equations for symmetric indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_syrvgrw	s, d, c, z	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a symmetric indefinite matrix.
?la_wwaddw	s, d, c, z	Adds a vector into a doubled-single vector.

?lacgv*Conjugates a complex vector.***Syntax**

```
call clacgv( n, x, incx )
```

```
call zlacgv( n, x, incx )
```

C:

```
lapack_int LAPACKE_<?>lacgv (lapack_int n, <datatype> * x, lapack_int incx);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine conjugates a complex vector x of length n and increment $incx$ (see "Vector Arguments in BLAS" in Appendix B).

Input Parameters

The data types are given for the Fortran interface.

n INTEGER. The length of the vector x ($n \geq 0$).

x COMPLEX for clacgv
 DOUBLE COMPLEX for zlacgv.
 Array, dimension $(1+(n-1) * |incx|)$.
 Contains the vector of length n to be conjugated.

incx INTEGER. The spacing between successive elements of x .

Output Parameters

x On exit, overwritten with $\text{conjg}(x)$.

?lacrm*Multiples a complex matrix by a square real matrix.***Syntax**

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

```
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs a simple matrix-matrix multiplication of the form

$C = A^*B$,

where A is m -by- n and complex, B is n -by- n and real, C is m -by- n and complex.

Input Parameters

m	INTEGER. The number of rows of the matrix A and of the matrix C ($m \geq 0$).
n	INTEGER. The number of columns and rows of the matrix B and the number of columns of the matrix C ($n \geq 0$).
a	COMPLEX for <code>clacrm</code> DOUBLE COMPLEX for <code>zlacrm</code> Array, DIMENSION (lda, n). Contains the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a , $lda \geq \max(1, m)$.
b	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Array, DIMENSION (ldb, n). Contains the n -by- n matrix B .
ldb	INTEGER. The leading dimension of the array b , $ldb \geq \max(1, n)$.
ldc	INTEGER. The leading dimension of the output array c , $ldc \geq \max(1, n)$.
$rwork$	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Workspace array, DIMENSION ($2*m*n$).

Output Parameters

c	COMPLEX for <code>clacrm</code> DOUBLE COMPLEX for <code>zlacrm</code> Array, DIMENSION (ldc, n). Contains the m -by- n matrix C .
-----	--

?lacrt

Performs a linear transformation of a pair of complex vectors.

Syntax

```
call clacrt(  $n$ ,  $cx$ ,  $incx$ ,  $cy$ ,  $incy$ ,  $c$ ,  $s$  )
call zlacrt(  $n$ ,  $cx$ ,  $incx$ ,  $cy$ ,  $incy$ ,  $c$ ,  $s$  )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine performs the following transformation

$$\begin{pmatrix} c & s \\ -s & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \Rightarrow \begin{pmatrix} x \\ y \end{pmatrix},$$

where c, s are complex scalars and x, y are complex vectors.

Input Parameters

n	INTEGER. The number of elements in the vectors cx and cy ($n \geq 0$).
cx, cy	COMPLEX for <code>clacrt</code> DOUBLE COMPLEX for <code>zlacrt</code> Arrays, dimension (n). Contain input vectors x and y , respectively.
$incx$	INTEGER. The increment between successive elements of cx .
$incy$	INTEGER. The increment between successive elements of cy .
c, s	COMPLEX for <code>clacrt</code> DOUBLE COMPLEX for <code>zlacrt</code> Complex scalars that define the transform matrix

|
|

Output Parameters

cx	On exit, overwritten with $c*x + s*y$.
cy	On exit, overwritten with $-s*x + c*y$.

?laesy

Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix, and checks that the norm of the matrix of eigenvectors is larger than a threshold value.

Syntax

```
call claesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
call zlaesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix},$$

provided the norm of the matrix of eigenvectors is larger than some threshold value.

$rt1$ is the eigenvalue of larger absolute value, and $rt2$ of smaller absolute value. If the eigenvectors are computed, then on return $(cs1, sn1)$ is the unit eigenvector for $rt1$, hence

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -sn1 \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

Input Parameters

a, b, c	COMPLEX for claesy DOUBLE COMPLEX for zlaesy Elements of the input matrix.
-----------	--

Output Parameters

$rt1, rt2$	COMPLEX for claesy DOUBLE COMPLEX for zlaesy Eigenvalues of larger and smaller modulus, respectively.
$evscal$	COMPLEX for claesy DOUBLE COMPLEX for zlaesy The complex value by which the eigenvector matrix was scaled to make it orthonormal. If $evscal$ is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value $thresh$ (set to 0.1E0).
$cs1, sn1$	COMPLEX for claesy DOUBLE COMPLEX for zlaesy If $evscal$ is not zero, then $(cs1, sn1)$ is the unit right eigenvector for $rt1$.

?rot

Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.

Syntax

```
call crot( n, cx, incx, cy, incy, c, s )
call zrot( n, cx, incx, cy, incy, c, s )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine applies a plane rotation, where the cosine (*c*) is real and the sine (*s*) is complex, and the vectors *cx* and *cy* are complex. This routine has its real equivalents in BLAS (see [?rot](#) in Chapter 2).

Input Parameters

<i>n</i>	INTEGER. The number of elements in the vectors <i>cx</i> and <i>cy</i> .
<i>cx</i> , <i>cy</i>	REAL for srot DOUBLE PRECISION for drot COMPLEX for crot DOUBLE COMPLEX for zrot Arrays of dimension (<i>n</i>), contain input vectors <i>x</i> and <i>y</i> , respectively.
<i>incx</i>	INTEGER. The increment between successive elements of <i>cx</i> .
<i>incy</i>	INTEGER. The increment between successive elements of <i>cy</i> .
<i>c</i>	REAL for crot DOUBLE PRECISION for zrot
<i>s</i>	REAL for srot DOUBLE PRECISION for drot COMPLEX for crot DOUBLE COMPLEX for zrot Values that define a rotation

$$\begin{bmatrix} c & s \\ -\text{conj}(s) & c \end{bmatrix}$$

where $c^*c + s^*\text{conj}(s) = 1.0$.

Output Parameters

<i>cx</i>	On exit, overwritten with $c*x + s*y$.
<i>cy</i>	On exit, overwritten with $-\text{conjg}(s)*x + c*y$.

?spmv

Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix.

Syntax

```
call cspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
call zspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?spmv routines perform a matrix-vector operation defined as

$$y := \alpha * a * x + \beta * y,$$

where:

alpha and *beta* are complex scalars,

x and *y* are *n*-element complex vectors

a is an *n*-by-*n* complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see ?spmv in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i> , <i>beta</i>	COMPLEX for cspmv DOUBLE COMPLEX for zspmv Specify complex scalars <i>alpha</i> and <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>ap</i>	COMPLEX for cspmv

DOUBLE COMPLEX for zspmv

Array, DIMENSION at least $((n*(n + 1))/2)$. Before entry, with $uplo = 'U'$ or ' u ', the array ap must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $A(1, 1)$, $ap(2)$ and $ap(3)$ contain $A(1, 2)$ and $A(2, 2)$ respectively, and so on. Before entry, with $uplo = 'L'$ or ' l ', the array ap must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1, 1)$, $ap(2)$ and $ap(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

x

COMPLEX for cspmv

DOUBLE COMPLEX for zspmv

Array, DIMENSION at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array x must contain the n -element vector x .

incx

INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.

y

COMPLEX for cspmv

DOUBLE COMPLEX for zspmv

Array, DIMENSION at least $(1 + (n - 1)*abs(incy))$. Before entry, the incremented array y must contain the n -element vector y .

incy

INTEGER. Specifies the increment for the elements of y . The value of $incy$ must not be zero.

Output Parameters

y

Overwritten by the updated vector y .

?spr

Performs the symmetrical rank-1 update of a complex symmetric packed matrix.

Syntax

```
call cspr( uplo, n, alpha, x, incx, ap )
call zspr( uplo, n, alpha, x, incx, ap )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?spr routines perform a matrix-vector operation defined as

$$a := \alpha * x * x^H + a,$$

where:

α is a complex scalar

x is an n -element complex vector

a is an n -by- n complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see [?spr](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i> , as follows: If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cspr DOUBLE COMPLEX for zspr Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cspr DOUBLE COMPLEX for zspr Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the n -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>ap</i>	COMPLEX for cspr DOUBLE COMPLEX for zspr Array, DIMENSION at least $((n*(n + 1)) / 2)$. Before entry, with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains $A(1, 1)$, <i>ap</i> (2) and <i>ap</i> (3) contain $A(1, 2)$ and $A(2, 2)$ respectively, and so on. Before entry, with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains $A(1, 1)$, <i>ap</i> (2) and <i>ap</i> (3) contain $A(2, 1)$ and $A(3, 1)$ respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Output Parameters

<i>ap</i>	With <i>uplo</i> = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
-----------	--

With $uplo = 'L'$ or $'U'$, overwritten by the lower triangular part of the updated matrix.

?syconv

Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

Syntax

FORTRAN 77:

```
call ssyconv( uplo, way, n, a, lda, ipiv, work, info )
call dsyconv( uplo, way, n, a, lda, ipiv, work, info )
call csyconv( uplo, way, n, a, lda, ipiv, work, info )
call zsyconv( uplo, way, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call syconv( a[,uplo][,way][,ipiv][,info] )
```

C:

```
lapack_int LAPACKE_<?>syconv (int matrix_layout, char uplo, char way, lapack_int n,
<datatype> * a, lapack_int lda, const lapack_int * ipiv);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine converts matrix A , which results from a triangular matrix factorization, into matrices L and D and vice versa. The routine gets non-diagonalized elements of D returned in the workspace and applies or reverses permutation done with the triangular matrix factorization.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1. Must be ' U ' or ' L '.
	Indicates whether the details of the factorization are stored as an upper or lower triangular matrix: If $uplo = 'U'$: the upper triangular, $A = U*D*U^T$. If $uplo = 'L'$: the lower triangular, $A = L*D*L^T$.
<i>way</i>	CHARACTER*1. Must be ' C ' or ' R '.
	Indicates whether the routine converts or reverts the matrix: $way = 'C'$ means conversion. $way = 'R'$ means reversion.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>a</i>	REAL for ssyconv DOUBLE PRECISION for dsyconv COMPLEX for csyconv DOUBLE COMPLEX for zsyconv Array of DIMENSION (<i>lda,n</i>). The block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?sytrf.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; <i>lda</i> $\geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Details of the interchanges and the block structure of <i>D</i> , as returned by ?sytrf.
<i>work</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i> -th parameter had an illegal value.
-------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syconv` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n, n</i>).
<i>uplo</i>	Must be 'U' or 'L'.
<i>way</i>	Must be 'C' or 'R'.
<i>ipiv</i>	Holds the vector of length <i>n</i> .

See Also

[?sytrf](#)

?symv

Computes a matrix-vector product for a complex symmetric matrix.

Syntax

```
call csymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
call zsymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Include Files

- Fortran: `mkl.fi`

-
- C: mkl.h

Description

The routine performs the matrix-vector operation defined as

$$y := \alpha * a * x + \beta * y,$$

where:

alpha and *beta* are complex scalars

x and *y* are *n*-element complex vectors

a is an *n*-by-*n* symmetric complex matrix.

These routines have their real equivalents in BLAS (see [?symv](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i> , <i>beta</i>	COMPLEX for <code>csymv</code> DOUBLE COMPLEX for <code>zsymv</code> Specify the scalars <i>alpha</i> and <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>a</i>	COMPLEX for <code>csymv</code> DOUBLE COMPLEX for <code>zsymv</code> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>A</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least <code>max(1, n)</code> .
<i>x</i>	COMPLEX for <code>csymv</code> DOUBLE COMPLEX for <code>zsymv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <code>csymv</code>

DOUBLE COMPLEX for zsymv

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .

incy INTEGER. Specifies the increment for the elements of y . The value of *incy* must not be zero.

Output Parameters

y Overwritten by the updated vector y .

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

FORTRAN 77:

```
call csyr( uplo, n, alpha, x, incx, a, lda )
call zsyr( uplo, n, alpha, x, incx, a, lda )
```

C:

```
lapack_int LAPACKE_csy (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float alpha, const lapack_complex_float * x, lapack_int incx,
lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zsy (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double alpha, const lapack_complex_double * x, lapack_int incx,
lapack_complex_double * a, lapack_int lda);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha * x * x^H + a,$$

where:

- α is a complex scalar.
- x is an n -element complex vector.
- a is an n -by- n complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used:
If $uplo = 'U'$ or 'u', then the upper triangular part of the array a is used.

If $uplo = 'L'$ or $'l'$, then the lower triangular part of the array a is used.

n INTEGER. Specifies the order of the matrix a . The value of n must be at least zero.

α COMPLEX for csyr

DOUBLE COMPLEX for zsy r

Specifies the scalar α .

x COMPLEX for csyr

DOUBLE COMPLEX for zsy r

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .

$incx$ INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.

a COMPLEX for csyr

DOUBLE COMPLEX for zsy r

Array, DIMENSION (lda, n). Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced.

Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.

lda INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.

Output Parameters

a With $uplo = 'U'$ or $'u'$, the upper triangular part of the array a is overwritten by the upper triangular part of the updated matrix.

With $uplo = 'L'$ or $'l'$, the lower triangular part of the array a is overwritten by the lower triangular part of the updated matrix.

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

$index = \text{icmax1}(n, cx, incx)$

$index = \text{izmax1}(n, cx, incx)$

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given a complex vector \mathbf{cx} , the $i?max1$ functions return the index of the vector element whose real part has maximum absolute value. These functions are based on the BLAS functions $icamax/izamax$, but using the absolute value of the real part. They are designed for use with $clacon/zlacon$.

Input Parameters

n	INTEGER. Specifies the number of elements in the vector \mathbf{cx} .
\mathbf{cx}	COMPLEX for $icmax1$ DOUBLE COMPLEX for $izmax1$ Array, DIMENSION at least $(1+(n-1)*abs(incx))$. Contains the input vector.
$incx$	INTEGER. Specifies the spacing between successive elements of \mathbf{cx} .

Output Parameters

$index$	INTEGER. Contains the index of the vector element whose real part has maximum absolute value.
---------	---

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
res = scsum1( n, cx, incx )
res = dzsum1( n, cx, incx )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given a complex vector \mathbf{cx} , $scsum1/dzsum1$ functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on $scasum/dzasum$ from Level 1 BLAS, but use the true absolute value and were designed for use with $clacon/zlacon$.

Input Parameters

n	INTEGER. Specifies the number of elements in the vector \mathbf{cx} .
\mathbf{cx}	COMPLEX for $scsum1$ DOUBLE COMPLEX for $dzsum1$ Array, DIMENSION at least $(1+(n-1)*abs(incx))$. Contains the input vector whose elements will be summed.

incx INTEGER. Specifies the spacing between successive elements of *cx* (*incx* > 0).

Output Parameters

<i>res</i>	REAL for <i>sctsum1</i>
	DOUBLE PRECISION for <i>dzsum1</i>
	Contains the sum of absolute values.

?gbtf2

Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.

Syntax

```
call sgbt2( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbt2( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbt2( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbt2( m, n, kl, ku, ab, ldab, ipiv, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine forms the *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* with *kl* sub-diagonals and *ku* super-diagonals. The routine uses partial pivoting with row interchanges and implements the unblocked version of the algorithm, calling Level 2 BLAS. See also [?gbtrf](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> (<i>m</i> ≥ 0).
<i>n</i>	INTEGER. The number of columns in <i>A</i> (<i>n</i> ≥ 0).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> (<i>kl</i> ≥ 0).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> (<i>ku</i> ≥ 0).
<i>ab</i>	REAL for sgbt2 DOUBLE PRECISION for dgbt2 COMPLEX for cgbt2 DOUBLE COMPLEX for zgbt2. Array, DIMENSION (ldab,*). The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Arguments). The second dimension of <i>ab</i> must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $(ldab \geq 2kl + ku + 1)$

Output Parameters

ab Overwritten by details of the factorization. The diagonal and $kl + ku$ super-diagonals of *U* are stored in the first $1 + kl + ku$ rows of *ab*. The multipliers used during the factorization are stored in the next *kl* rows.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, \min(m, n))$.
The pivot indices: row *i* was interchanged with row *ipiv(i)*.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = *-i*, the *i*-th parameter had an illegal value.
If *info* = *i*, u_{ii} is 0. The factorization has been completed, but *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

?gebd2

Reduces a general matrix to bidiagonal form using an unblocked algorithm.

Syntax

```
call sgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call dgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call cgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call zgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces a general *m*-by-*n* matrix *A* to upper or lower bidiagonal form *B* by an orthogonal (unitary) transformation: $Q^T A P = B$ (for real flavors) or $Q^H A P = B$ (for complex flavors).

If *m* \geq *n*, *B* is upper bidiagonal; if *m* < *n*, *B* is lower bidiagonal.

The routine does not form the matrices *Q* and *P* explicitly, but represents them as products of elementary reflectors. If *m* \geq *n*,

$Q = H(1) * H(2) * \dots * H(n)$, and $P = G(1) * G(2) * \dots * G(n-1)$

if *m* < *n*,

$Q = H(1) * H(2) * \dots * H(m-1)$, and $P = G(1) * G(2) * \dots * G(m)$

Each *H(i)* and *G(i)* has the form

$H(i) = I - tauq * v * v^T$ and $G(i) = I - taup * u * u^T$ for real flavors, or

$H(i) = I - \tau_{aq} v^* v^H$ and $G(i) = I - \tau_{ap} u^* u^H$ for complex flavors

where τ_{aq} and τ_{ap} are scalars (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`), and v and u are vectors (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`).

Input Parameters

`m` INTEGER. The number of rows in the matrix A ($m \geq 0$).

`n` INTEGER. The number of columns in A ($n \geq 0$).

`a, work` REAL for `sgebd2`

DOUBLE PRECISION for `dgebd2`

COMPLEX for `cgebd2`

DOUBLE COMPLEX for `zgebd2`.

Arrays:

`a(1da, *)` contains the m -by- n general matrix A to be reduced. The second dimension of `a` must be at least $\max(1, n)$.

`work(*)` is a workspace array, the dimension of `work` must be at least $\max(1, m, n)$.

`lda` INTEGER. The leading dimension of `a`; at least $\max(1, m)$.

Output Parameters

`a` if $m \geq n$, the diagonal and first super-diagonal of `a` are overwritten with the upper bidiagonal matrix B . Elements below the diagonal, with the array `tauq`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the first superdiagonal, with the array `taup`, represent the orthogonal/unitary matrix P as a product of elementary reflectors.

if $m < n$, the diagonal and first sub-diagonal of `a` are overwritten by the lower bidiagonal matrix B . Elements below the first subdiagonal, with the array `tauq`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the diagonal, with the array `taup`, represent the orthogonal/unitary matrix P as a product of elementary reflectors.

`d` REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains the diagonal elements of the bidiagonal matrix B : $d(i) = a(i, i)$.

`e` REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$.

Contains the off-diagonal elements of the bidiagonal matrix B :

if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$;

```

if  $m < n$ ,  $e(i) = a(i+1, i)$  for  $i = 1, 2, \dots, m-1$ .
taug, taup          REAL for sgebd2
                    DOUBLE PRECISION for dgebd2
                    COMPLEX for cgebd2
                    DOUBLE COMPLEX for zgebd2.

Arrays, DIMENSION at least  $\max(1, \min(m, n))$ .
Contain scalar factors of the elementary reflectors which represent
orthogonal/unitary matrices  $Q$  and  $p$ , respectively.

info               INTEGER.
If  $info = 0$ , the execution is successful.
If  $info = -i$ , the  $i$ th parameter had an illegal value.

```

?gehd2

Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.

Syntax

```

call sgehd2(  $n, ilo, ihi, a, lda, tau, work, info$  )
call dgehd2(  $n, ilo, ihi, a, lda, tau, work, info$  )
call cgehd2(  $n, ilo, ihi, a, lda, tau, work, info$  )
call zgehd2(  $n, ilo, ihi, a, lda, tau, work, info$  )

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces a real/complex general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $Q^T A Q = H$ (for real flavors) or $Q^H A Q = H$ (for complex flavors).

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*.

Input Parameters

n	INTEGER The order of the matrix A ($n \geq 0$).
ilo, ihi	INTEGER. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. If A has been output by ?gebal, then ilo and ihi must contain the values returned by that routine. Otherwise they should be set to $ilo = 1$ and $ihi = n$. Constraint: $1 \leq ilo \leq ihi \leq \max(1, n)$.

a, work

REAL for sgehd2
DOUBLE PRECISION for dgehd2
COMPLEX for cgehd2
DOUBLE COMPLEX for zgehd2.

Arrays:

a (*lda, **) contains the n -by- n matrix A to be reduced. The second dimension of *a* must be at least $\max(1, n)$.
work (*n*) is a workspace array.

lda

INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

a

On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See *Application Notes* below.

tau

REAL for sgehd2
DOUBLE PRECISION for dgehd2
COMPLEX for cgehd2
DOUBLE COMPLEX for zgehd2.

Array, DIMENSION at least $\max(1, n-1)$.
Contains the scalar factors of elementary reflectors. See *Application Notes* below.

info

INTEGER.
If *info* = 0, the execution is successful.
If *info* = $-i$, the *i*-th parameter had an illegal value.

Application Notes

The matrix Q is represented as a product of (*ih* - *ilo*) elementary reflectors

$$Q = H(i_0) * H(i_0 + 1) * \dots * H(i_h - 1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau * v * v^H \text{ for complex flavors}$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(i_h + 1:n) = 0$.

On exit, $v(i+2:i_h)$ is stored in *a*(*i*+2:*i_h*, *i*) and τ in *tau*(*i*).

The contents of *a* are illustrated by the following example, with $n = 7$, *ilo* = 2 and *ih* = 6:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v_2 & h & h & h & h & h & h \\ v_2 & v_3 & h & h & h & h & h \\ v_2 & v_3 & v_4 & h & h & h & h \\ a & & & & & & a \end{bmatrix}$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?gelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgelq2( m, n, a, lda, tau, work, info )
call dgelq2( m, n, a, lda, tau, work, info )
call cgelq2( m, n, a, lda, tau, work, info )
call zgelq2( m, n, a, lda, tau, work, info )
```

C:

```
lapack_int LAPACKE_<?>gelq2 (int matrix_layout, lapack_int m, lapack_int n, <datatype>
* a, lapack_int lda, <datatype> * tau);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(k) \dots H(2) H(1)$ (or $Q = H(k)^H \dots H(2)^H H(1)^H$ for complex flavors), where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - tau * v * v^T$ for real flavors, or

$H(i) = I - tau * v * v^H$ for complex flavors,

where tau is a real/complex scalar stored in $tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:n)$ (for real functions) and $\text{conjgv}(i+1:n)$ (for complex functions) are stored in $a(i, i+1:n)$.

Input Parameters

The data types are given for the Fortran interface.

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeql2</code> DOUBLE PRECISION for <code>dgeql2</code> COMPLEX for <code>cgeql2</code> DOUBLE COMPLEX for <code>zgeql2</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $work(m)$ is a workspace array.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a	Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array a contain the m -by- $\min(n,m)$ lower trapezoidal matrix L (L is lower triangular if $n \geq m$); the elements above the diagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of $\min(n,m)$ elementary reflectors.
tau	REAL for <code>sgeql2</code> DOUBLE PRECISION for <code>dgeql2</code> COMPLEX for <code>cgeql2</code> DOUBLE COMPLEX for <code>zgeql2</code> . Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

?geql2

Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeql2( m, n, a, lda, tau, work, info )
call dgeql2( m, n, a, lda, tau, work, info )
```

```
call cgeql2( m, n, a, lda, tau, work, info )
call zgeql2( m, n, a, lda, tau, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes a QL factorization of a real/complex m -by- n matrix A as $A = Q^* L$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$$Q = H(k) * \dots * H(2) * H(1), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v^T \text{ for real flavors, or}$$

$$H(i) = I - tau * v * v^H \text{ for complex flavors}$$

where tau is a real/complex scalar stored in $tau(i)$, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$.

On exit, $v(1:m-k+i-1)$ is stored in $a(1:m-k+i-1, n-k+i)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgeql2

DOUBLE PRECISION for dgeql2

COMPLEX for cgeql2

DOUBLE COMPLEX for zgeql2.

Arrays:

a(*lda*,*) contains the m -by- n matrix A .

The second dimension of *a* must be at least $\max(1, n)$.

work(*m*) is a workspace array.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

Output Parameters

a

Overwritten by the factorization data as follows:

on exit, if $m \geq n$, the lower triangle of the subarray $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular matrix L ; if $m < n$, the elements on and below the $(n-m)$ th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

tau

REAL for sgeql2

DOUBLE PRECISION for dgeql2
 COMPLEX for cgeql2
 DOUBLE COMPLEX for zgeql2.
Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeqr2( m, n, a, lda, tau, work, info )
call dgeqr2( m, n, a, lda, tau, work, info )
call cgeqr2( m, n, a, lda, tau, work, info )
call zgeqr2( m, n, a, lda, tau, work, info )
```

C:

```
lapack_int LAPACKE_<?>geqr2 (int matrix_layout, lapack_int m, lapack_int n, <datatype>
* a, lapack_int lda, <datatype> * tau);
```

Include Files

- C: mkl.h

Description

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q^*R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(1)^*H(2)^* \dots ^*H(k)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - tau*v*v^T$ for real flavors, or

$H(i) = I - tau*v*v^H$ for complex flavors

where tau is a real/complex scalar stored in $tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:m)$ is stored in $a(i+1:m, i)$.

Input Parameters

The data types are given for the Fortran interface.

<i>m</i>	INTEGER. The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i> , <i>work</i>	REAL for sgeqr2 DOUBLE PRECISION for dgeqr2 COMPLEX for cgeqr2 DOUBLE COMPLEX for zgeqr2.
	Arrays: <i>a</i> (<i>lda</i> , *) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (<i>n</i>) is a workspace array.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array <i>a</i> contain the $\min(n,m)$ -by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors.
<i>tau</i>	REAL for sgeqr2 DOUBLE PRECISION for dgeqr2 COMPLEX for cgeqr2 DOUBLE COMPLEX for zgeqr2. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

?geqr2p

Computes the QR factorization of a general rectangular matrix with non-negative diagonal elements using an unblocked algorithm.

Syntax

```
call sgeqr2p( m, n, a, lda, tau, work, info )
call dgeqr2p( m, n, a, lda, tau, work, info )
call cgeqr2p( m, n, a, lda, tau, work, info )
call zgeqr2p( m, n, a, lda, tau, work, info )
```

Include Files

- C: mkl.h

Description

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q^*R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$$Q = H(1)^*H(2)^* \dots ^*H(k), \text{ where } k = \min(m, n)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v^T \text{ for real flavors, or}$$

$$H(i) = I - tau * v * v^H \text{ for complex flavors}$$

where tau is a real/complex scalar stored in $tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:m)$ is stored in $a(i+1:m, i)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgeqr2p

DOUBLE PRECISION for d

COMPLEX for cgeqr2p

DOUBLE COMPLEX for zgeqr2p.

Arrays:

$a(lda, *)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work(n)$ is a workspace array.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:

on exit, the elements on and above the diagonal of the array a contain the $\min(n,m)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

The diagonal elements of the matrix R are non-negative.

tau REAL for sgeqr2p

DOUBLE PRECISION for dgeqr2p

COMPLEX for cgeqr2p

DOUBLE COMPLEX for zgeqr2p.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains scalar factors of the elementary reflectors.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?geqrt2

Computes a QR factorization of a general real or complex matrix using the compact WY representation of Q .

Syntax

FORTRAN 77:

```
call sgeqrt2(m, n, a, lda, t, ldt, info)
call dgeqrt2(m, n, a, lda, t, ldt, info)
call cgeqrt2(m, n, a, lda, t, ldt, info)
call zgeqrt2(m, n, a, lda, t, ldt, info)
```

Fortran 95:

```
call geqrt2(a, t, [info])
```

C:

```

- Fortran 95: lapack.f90
- C: mkl.h

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & \\ v_1 & 1 & \\ v_1 & v_2 & 1 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

where v_i represents one of the vectors that define $H(i)$. The vectors are returned in the lower triangular part of array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$H = I - V^* T^* V^T$ for real flavors, and

$H = I - V^* T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq n$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for sgeqrt2

DOUBLE PRECISION for dgeqrt2

COMPLEX for cgeqrt2

COMPLEX*16 for zgeqrt2.

Arrays: *a* DIMENSION (*lda*, *n*) contains the m -by- n matrix A .

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

ldt INTEGER. The leading dimension of *t*; at least $\max(1, n)$.

Output Parameters

a Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the n -by- n upper triangular matrix R . The elements below the diagonal are the columns of V .

t REAL for sgeqrt2

DOUBLE PRECISION for dgeqrt2

COMPLEX for cgeqrt2

COMPLEX*16 for zgeqrt2.

`Array, DIMENSION (l_{dt} , $\min(m, n)$).`

The n -by- n upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T . The elements below the diagonal are not used.

`info`

INTEGER.

If `info` = 0, the execution is successful.

If `info` < 0 and `info` = $-i$, the i th argument had an illegal value.

?geqrt3

Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q .

Syntax

FORTRAN 77:

```
call sgeqrt3( $m$ ,  $n$ ,  $a$ ,  $lda$ ,  $t$ ,  $l_{dt}$ , info)
call dgeqrt3( $m$ ,  $n$ ,  $a$ ,  $lda$ ,  $t$ ,  $l_{dt}$ , info)
call cgeqrt3( $m$ ,  $n$ ,  $a$ ,  $lda$ ,  $t$ ,  $l_{dt}$ , info)
call zgeqrt3( $m$ ,  $n$ ,  $a$ ,  $lda$ ,  $t$ ,  $l_{dt}$ , info)
```

Fortran 95:

```
call geqrt3( $a$ ,  $t$  [, info])
```

C:

```
lapack_int LAPACKE_sgeqrt3 (int matrix_layout , lapack_int  $m$  , lapack_int  $n$  , float *  $a$  , lapack_int  $lda$  , float *  $t$  , lapack_int  $l_{dt}$  );
lapack_int LAPACKE_dgeqrt3 (int matrix_layout , lapack_int  $m$  , lapack_int  $n$  , double *  $a$  , lapack_int  $lda$  , double *  $t$  , lapack_int  $l_{dt}$  );
lapack_int LAPACKE_cgeqrt3 (int matrix_layout , lapack_int  $m$  , lapack_int  $n$  ,
lapack_complex_float *  $a$  , lapack_int  $lda$  , lapack_complex_float *  $t$  , lapack_int  $l_{dt}$  );
lapack_int LAPACKE_zgeqrt3 (int matrix_layout , lapack_int  $m$  , lapack_int  $n$  ,
lapack_complex_double *  $a$  , lapack_int  $lda$  , lapack_complex_double *  $t$  , lapack_int  $l_{dt}$  );
```

Include Files

$H = I - V^T T^* V^T$ for real flavors, and

$H = I - V^H T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq n$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for sgeqrt3

DOUBLE PRECISION for dgeqrt3

COMPLEX for cgeqrt3

COMPLEX*16 for zgeqrt3.

Arrays: *a* DIMENSION (*lda*, *n*) contains the m -by- n matrix A .

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

ldt INTEGER. The leading dimension of *t*; at least $\max(1, n)$.

Output Parameters

a The elements on and above the diagonal of the array contain the n -by- n upper triangular matrix R . The elements below the diagonal are the columns of V .

t REAL for sgeqrt3

DOUBLE PRECISION for dgeqrt3

COMPLEX for cgeqrt3

COMPLEX*16 for zgeqrt3.

Array, DIMENSION (*ldt*, *n*).

The n -by- n upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T . The elements below the diagonal are not used.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = $-i$, the *i*th argument had an illegal value.

?gerq2

Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgerq2( m, n, a, lda, tau, work, info )
call dgerq2( m, n, a, lda, tau, work, info )
call cgerq2( m, n, a, lda, tau, work, info )
call zgerq2( m, n, a, lda, tau, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes a *RQ* factorization of a real/complex m -by- n matrix A as $A = R*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or

$Q = H(1)^H * H(2)^H * \dots * H(k)^H$ for complex flavors

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - tau * v * v^T$ for real flavors, or

$H(i) = I - tau * v * v^H$ for complex flavors

where tau is a real/complex scalar stored in $tau(i)$, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$.

On exit, $v(1:n-k+i-1)$ is stored in $a(m-k+i, 1:n-k+i-1)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgerq2

DOUBLE PRECISION for dgerq2

COMPLEX for `cgerq2`
 DOUBLE COMPLEX for `zgerq2`.

Arrays:

`a(1da,*)` contains the m -by- n matrix A .
 The second dimension of `a` must be at least `max(1, n)`.
`work(m)` is a workspace array.

`lda` INTEGER. The leading dimension of `a`; at least `max(1, m)`.

Output Parameters

`a` Overwritten by the factorization data as follows:
 on exit, if $m \leq n$, the upper triangle of the subarray `a(1:m, n-m+1:n)` contains the m -by- m upper triangular matrix R ; if $m > n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array `tau`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

`tau` REAL for `sgerq2`
 DOUBLE PRECISION for `dgerq2`
 COMPLEX for `cgerq2`
 DOUBLE COMPLEX for `zgerq2`.
Array, DIMENSION at least `max(1, min(m, n))`.
 Contains scalar factors of the elementary reflectors.

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = -i`, the i -th parameter had an illegal value.

?gesc2

Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2.

Syntax

```
call sgesc2( n, a, lda, rhs, ipiv, jpivot, scale )
call dgesc2( n, a, lda, rhs, ipiv, jpivot, scale )
call cgesc2( n, a, lda, rhs, ipiv, jpivot, scale )
call zgesc2( n, a, lda, rhs, ipiv, jpivot, scale )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine solves a system of linear equations

$$A \cdot X = scale \cdot RHS$$

with a general n -by- n matrix A using the LU factorization with complete pivoting computed by [?getc2](#).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A .
<i>a, rhs</i>	REAL for sgesc2 DOUBLE PRECISION for dgesc2 COMPLEX for cgesc2 DOUBLE COMPLEX for zgesc2. Arrays: $a(1:da, *)$ contains the LU part of the factorization of the n -by- n matrix A computed by ?getc2 : $A = P \cdot L \cdot U \cdot Q.$ The second dimension of a must be at least $\max(1, n)$; $rhs(n)$ contains on entry the right hand side vector for the system of equations.
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row i of the matrix has been interchanged with row $ipiv(i)$.
<i>jpivot</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column j of the matrix has been interchanged with column $jpivot(j)$.

Output Parameters

<i>rhs</i>	On exit, overwritten with the solution vector X .
<i>scale</i>	REAL for sgesc2/cgesc2 DOUBLE PRECISION for dgesc2/zgesc2 Contains the scale factor. <i>scale</i> is chosen in the range $0 \leq scale \leq 1$ to prevent overflow in the solution.

?getc2

Computes the LU factorization with complete pivoting of the general n -by- n matrix.

Syntax

```
call sgetc2( n, a, lda, ipiv, jpivot, info )
call dgetc2( n, a, lda, ipiv, jpivot, info )
call cgetc2( n, a, lda, ipiv, jpivot, info )
call zgetc2( n, a, lda, ipiv, jpivot, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes an *LU* factorization with complete pivoting of the n -by- n matrix A . The factorization has the form $A = P^* L^* U^* Q$, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

The LU factorization computed by this routine is used by [?latdf](#) to compute a contribution to the reciprocal Dif-estimate.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a</i>	REAL for sgetc2 DOUBLE PRECISION for dgetc2 COMPLEX for cgetc2 DOUBLE COMPLEX for zgetc2. Array $a(lda, *)$ contains the n -by- n matrix A to be factored. The second dimension of a must be at least $\max(1, n)$;
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the factors L and U from the factorization $A = P^* L^* U^* Q$; the unit diagonal elements of L are not stored. If $U(k, k)$ appears to be less than $smin$, $U(k, k)$ is given the value of $smin$, that is giving a nonsingular perturbed system.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row i of the matrix has been interchanged with row $ipiv(i)$.
<i>jpivot</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column j of the matrix has been interchanged with column $jpivot(j)$.

info

INTEGER.

If *info* = 0, the execution is successful.If *info* = $k > 0$, $U(k, k)$ is likely to produce overflow if we try to solve for x in $A^*x = b$. So U is perturbed to avoid the overflow.

?getf2

Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
call sgetf2( m, n, a, lda, ipiv, info )
call dgetf2( m, n, a, lda, ipiv, info )
call cgetf2( m, n, a, lda, ipiv, info )
call zgetf2( m, n, a, lda, ipiv, info )
```

C:

```
lapack_int LAPACKE_<?>getf2 (int matrix_layout, lapack_int m, lapack_int n, <datatype>
* a, lapack_int lda, lapack_int * ipiv);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges. The factorization has the form

$$A = P^* L^* U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

The data types are given for the Fortran interface.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for sgetf2

DOUBLE PRECISION for dgetf2

COMPLEX for cgetf2

DOUBLE COMPLEX for zgetf2.

Array, DIMENSION (*lda,**). Contains the matrix A to be factored. The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by L and U . The unit diagonal elements of L are not stored.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, \min(m, n))$.

The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$.

info INTEGER. If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i > 0$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?gtts2

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.

Syntax

```
call sgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call dgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call cgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call zgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine solves for X one of the following systems of linear equations with multiple right hand sides:

$A^*X = B$, $A^T*X = B$, or $A^H*X = B$ (for complex matrices only), with a tridiagonal matrix A using the LU factorization computed by ?gttrf.

Input Parameters

ittrans INTEGER. Must be 0, 1, or 2.

Indicates the form of the equations to be solved:

If $ittrans = 0$, then $A^*X = B$ (no transpose).

If $ittrans = 1$, then $A^T*X = B$ (transpose).

If $ittrans = 2$, then $A^H*X = B$ (conjugate transpose).

n INTEGER. The order of the matrix A ($n \geq 0$).

<i>nrhs</i>	INTEGER. The number of right-hand sides, i.e., the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>d1,d,du,du2,b</i>	<p>REAL for sgtts2 DOUBLE PRECISION for dgts2 COMPLEX for cgts2 DOUBLE COMPLEX for zgts2.</p> <p>Arrays: <i>d1</i>(<i>n</i> - 1), <i>d</i>(<i>n</i>), <i>du</i>(<i>n</i> - 1), <i>du2</i>(<i>n</i> - 2), <i>b</i>(<i>ldb</i>, <i>nrhs</i>).</p> <p>The array <i>d1</i> contains the (<i>n</i> - 1) multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i>.</p> <p>The array <i>d</i> contains the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i>.</p> <p>The array <i>du</i> contains the (<i>n</i> - 1) elements of the first super-diagonal of <i>U</i>.</p> <p>The array <i>du2</i> contains the (<i>n</i> - 2) elements of the second super-diagonal of <i>U</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p>
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; must be $ldb \geq \max(1, n)$.
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>). The pivot indices array, as returned by ?gttrf.</p>

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
----------	---

?isnan

Tests input for NaN.

Syntax

```
val = sisnan( sin )
val = disnan( din )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This logical routine returns .TRUE. if its argument is NaN, and .FALSE. otherwise.

Input Parameters

<i>sin</i>	REAL for sisnan
------------	------------------------

Input to test for NaN.

din DOUBLE PRECISION for disnan
Input to test for NaN.

Output Parameters

val Logical. Result of the test.

?laisnan

Tests input for NaN.

Syntax

```
val = slaisnan( sin1, sin2 )
val = dlaisnan( din1, din2 )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This logical routine checks for NaNs (NaN stands for 'Not A Number') by comparing its two arguments for inequality. NaN is the only floating-point value where $\text{NaN} \neq \text{NaN}$ returns .TRUE.. To check for NaNs, pass the same variable as both arguments.

This routine is not for general use. It exists solely to avoid over-optimization in ?isnan.

Input Parameters

<i>sin1, sin2</i>	REAL for sisnan
	Two numbers to compare for inequality.
<i>din2, din2</i>	DOUBLE PRECISION for disnan
	Two numbers to compare for inequality.

Output Parameters

val Logical. Result of the comparison.

?labrd

Reduces the first *nb* rows and columns of a general matrix to a bidiagonal form.

Syntax

```
call slabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call dlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call clabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

```
call zlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces the first nb rows and columns of a general m -by- n matrix A to upper or lower bidiagonal form by an orthogonal/unitary transformation Q^*A^*P , and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A .

if $m \geq n$, A is reduced to upper bidiagonal form; if $m < n$, to lower bidiagonal form.

The matrices Q and P are represented as products of elementary reflectors: $Q = H(1) * (2) * \dots * H(nb)$, and $P = G(1) * G(2) * \dots * G(nb)$

Each $H(i)$ and $G(i)$ has the form

$H(i) = I - \tau_{aq} v^* v'$ and $G(i) = I - \tau_{ap} u^* u'$

where τ_{aq} and τ_{ap} are scalars, and v and u are vectors.

The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are needed, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $A := A - V^* Y' - X^* U'$.

This is an auxiliary routine called by [?gebrd](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>nb</i>	INTEGER. The number of leading rows and columns of A to be reduced.
<i>a</i>	REAL for slabrd DOUBLE PRECISION for dlabrd COMPLEX for clabrd DOUBLE COMPLEX for zlabrd. Array $a(lda,*)$ contains the matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
<i>ldx</i>	INTEGER. The leading dimension of the output array x ; must beat least $\max(1, m)$.
<i>ldy</i>	INTEGER. The leading dimension of the output array y ; must beat least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the first nb rows and columns of the matrix are overwritten; the rest of the array is unchanged.
----------	---

if $m \geq n$, elements on and below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

if $m < n$, elements below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

d, e

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION (nb) each. The array d contains the diagonal elements of the first nb rows and columns of the reduced matrix:

$d(i) = a(i,i).$

The array e contains the off-diagonal elements of the first nb rows and columns of the reduced matrix.

τ_{aq}, τ_{ap}

REAL for slabrd

DOUBLE PRECISION for dlabrd

COMPLEX for clabrd

DOUBLE COMPLEX for zlabrd.

Arrays, DIMENSION (nb) each. Contain scalar factors of the elementary reflectors which represent the orthogonal/unitary matrices Q and P , respectively.

x, y

REAL for slabrd

DOUBLE PRECISION for dlabrd

COMPLEX for clabrd

DOUBLE COMPLEX for zlabrd.

Arrays, dimension $x(Idx, nb)$, $y(Idy, nb)$.

The array x contains the m -by- nb matrix X required to update the unreduced part of A .

The array y contains the n -by- nb matrix Y required to update the unreduced part of A .

Application Notes

if $m \geq n$, then for the elementary reflectors $H(i)$ and $G(i)$,

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in $a(i:m, i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $a(i, i+1:n)$;

τ_{aq} is stored in $\tau_{aq}(i)$ and τ_{ap} in $\tau_{ap}(i)$.

if $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in $a(i+2:m, i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $a(i, i+1:n)$; τ_{aq} is stored in $\tau_{aq}(i)$ and τ_{ap} in $\tau_{ap}(i)$.

The contents of a on exit are illustrated by the following examples with $nb = 2$:

$m = 6, n = 5 \ (m > n)$

$$\begin{bmatrix} 1 & 1 & u_1 & u_1 & u_1 \\ v_1 & 1 & 1 & u_2 & u_2 \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

$m = 5, n = 6 \ (m < n)$

$$\begin{bmatrix} 1 & u_1 & u_1 & u_1 & u_1 & u_1 \\ 1 & 1 & u_2 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

?lacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

FORTRAN 77:

```
call slacn2( n, v, x, isgn, est, kase, isave )
call dlacn2( n, v, x, isgn, est, kase, isave )
call clacn2( n, v, x, est, kase, isave )
call zlacn2( n, v, x, est, kase, isave )
```

C:

```
lapack_int LAPACKE_slacn2 (lapack_int n, float * v, float * x, lapack_int * isgn, float
* est, lapack_int * kase, lapack_int * isave);
lapack_int LAPACKE_clacn2 (lapack_int n, lapack_complex_float * v, lapack_complex_float
* x, float * est, lapack_int * kase, lapack_int * isave);
lapack_int LAPACKE_dlacn2 (lapack_int n, double * v, double * x, lapack_int * isgn,
double * est, lapack_int * kase, lapack_int * isave);
lapack_int LAPACKE_zlacn2 (lapack_int n, lapack_complex_double * v,
lapack_complex_double * x, double * est, lapack_int * kase, lapack_int * isave);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 1$).
<i>v, x</i>	<p>REAL for <code>slacn2</code></p> <p>DOUBLE PRECISION for <code>dlacn2</code></p> <p>COMPLEX for <code>clacn2</code></p> <p>DOUBLE COMPLEX for <code>zlacn2</code>.</p> <p>Arrays, DIMENSION (n) each.</p> <p><i>v</i> is a workspace array.</p> <p><i>x</i> is used as input after an intermediate return.</p>
<i>isgn</i>	INTEGER.
	Workspace array, DIMENSION (n), used with real flavors only.
<i>est</i>	<p>REAL for <code>slacn2/clacn2</code></p> <p>DOUBLE PRECISION for <code>dlacn2/zlacn2</code></p> <p>On entry with <i>kase</i> set to 1 or 2, and <i>isave</i>(1) = 1, <i>est</i> must be unchanged from the previous call to the routine.</p>
<i>kase</i>	INTEGER.
	On the initial call to the routine, <i>kase</i> must be set to 0.
<i>isave</i>	<p>INTEGER. Array, DIMENSION (3).</p> <p>Contains variables from the previous call to the routine.</p>

Output Parameters

<i>est</i>	An estimate (a lower bound) for $\text{norm}(A)$.
<i>kase</i>	On an intermediate return, <i>kase</i> is set to 1 or 2, indicating whether <i>x</i> is overwritten by A^*x or $A^{T*}x$ for real flavors and A^*x or $A^{H*}x$ for complex flavors.
	On the final return, <i>kase</i> is set to 0.
<i>v</i>	On the final return, <i>v</i> = A^*w , where <i>est</i> = $\text{norm}(v)/\text{norm}(w)$ (<i>w</i> is not returned).
<i>x</i>	<p>On an intermediate return, <i>x</i> is overwritten by</p> <p>A^*x, if <i>kase</i> = 1,</p> <p>$A^{T*}x$, if <i>kase</i> = 2 (for real flavors),</p> <p>$A^{H*}x$, if <i>kase</i> = 2 (for complex flavors),</p> <p>and the routine must be re-called with all the other parameters unchanged.</p>
<i>isave</i>	This parameter is used to save variables between calls to the routine.

?lacon

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacon( n, v, x, isgn, est, kase )
call dlacon( n, v, x, isgn, est, kase )
call clacon( n, v, x, est, kase )
call zlacon( n, v, x, est, kase )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine estimates the 1-norm of a square, real/complex matrix A . Reverse communication is used for evaluating matrix-vector products.

WARNING

The ?lacon routine is not thread-safe. It is deprecated and retained for the backward compatibility only. Use the thread-safe ?lacn2 routine instead.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 1$).
<i>v</i> , <i>x</i>	REAL for slacon DOUBLE PRECISION for dlacon COMPLEX for clacon DOUBLE COMPLEX for zlacon. Arrays, DIMENSION (n) each. <i>v</i> is a workspace array. <i>x</i> is used as input after an intermediate return.
<i>isgn</i>	INTEGER. Workspace array, DIMENSION (n), used with real flavors only.
<i>est</i>	REAL for slacon/clacon DOUBLE PRECISION for dlacon/zlacon An estimate that with $kase=1$ or 2 should be unchanged from the previous call to ?lacon.
<i>kase</i>	INTEGER.

On the initial call to ?lacon, *kase* should be 0.

Output Parameters

<i>est</i>	REAL for slacon/clacon DOUBLE PRECISION for dlacon/zlacon An estimate (a lower bound) for $\text{norm}(A)$.
<i>kase</i>	On an intermediate return, <i>kase</i> will be 1 or 2, indicating whether <i>x</i> should be overwritten by A^*x or $A^{T*}x$ for real flavors and A^*x or $A^{H*}x$ for complex flavors. On the final return from ?lacon, <i>kase</i> will again be 0.
<i>v</i>	On the final return, $v = A^*w$, where <i>est</i> = $\text{norm}(v) / \text{norm}(w)$ (<i>w</i> is not returned).
<i>x</i>	On an intermediate return, <i>x</i> should be overwritten by A^*x , if <i>kase</i> = 1, $A^{T*}x$, if <i>kase</i> = 2 (for real flavors), $A^{H*}x$, if <i>kase</i> = 2 (for complex flavors), and ?lacon must be re-called with all the other parameters unchanged.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call slacpy( uplo, m, n, a, lda, b, ldb )
call dlapcy( uplo, m, n, a, lda, b, ldb )
call clacpy( uplo, m, n, a, lda, b, ldb )
call zlacpy( uplo, m, n, a, lda, b, ldb )
```

C:

```
lapack_int LAPACKE_<?>lacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const <datatype> * a, lapack_int lda, <datatype> * b, lapack_int ldb);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine copies all or part of a two-dimensional matrix *A* to another matrix *B*.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1.
-------------	--------------

Specifies the part of the matrix A to be copied to B .

If $uplo = 'U'$, the upper triangular part of A ;

if $uplo = 'L'$, the lower triangular part of A .

Otherwise, all of the matrix A is copied.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for slacpy

DOUBLE PRECISION for dlacpy

COMPLEX for clacpy

DOUBLE COMPLEX for zlacpy.

Array $a(1:da, :)$, contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

If $uplo = 'U'$, only the upper triangle or trapezoid is accessed; if $uplo = 'L'$, only the lower triangle or trapezoid is accessed.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, m)$.

ldb INTEGER. The leading dimension of the output array b ; $ldb \geq \max(1, m)$.

Output Parameters

b REAL for slacpy

DOUBLE PRECISION for dlacpy

COMPLEX for clacpy

DOUBLE COMPLEX for zlacpy.

Array $b(1:db, :)$, contains the m -by- n matrix B .

The second dimension of b must be at least $\max(1, n)$.

On exit, $B = A$ in the locations specified by $uplo$.

?ladiv

Performs complex division in real arithmetic, avoiding unnecessary overflow.

Syntax

```
call sladiv( a, b, c, d, p, q )
call dladiv( a, b, c, d, p, q )
res = cladiv( x, y )
res = zladiv( x, y )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routines `sladiv/dladiv` perform complex division in real arithmetic as

$$p + iq = \frac{a + ib}{c + id}$$

Complex functions `cladiv/zladiv` compute the result as

$$res = x/y,$$

where x and y are complex. The computation of x / y will not overflow on an intermediary step unless the results overflows.

The algorithm used is due to [Baudin12].

Input Parameters

a, b, c, d	REAL for <code>sladiv</code>
	DOUBLE PRECISION for <code>dladiv</code>
	The scalars a, b, c , and d in the above expression (for real flavors only).
x, y	COMPLEX for <code>cladiv</code>
	DOUBLE COMPLEX for <code>zladiv</code>
	The complex scalars x and y (for complex flavors only).

Output Parameters

p, q	REAL for <code>sladiv</code>
	DOUBLE PRECISION for <code>dladiv</code>
	The scalars p and q in the above expression (for real flavors only).
res	COMPLEX for <code>cladiv</code>
	DOUBLE COMPLEX for <code>zladiv</code>
	Contains the result of division x / y .

?lae2

Computes the eigenvalues of a 2-by-2 symmetric matrix.

Syntax

```
call slae2( a, b, c, rt1, rt2 )
call dlae2( a, b, c, rt1, rt2 )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routines `sla2/dlae2` compute the eigenvalues of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix}$$

On return, $rt1$ is the eigenvalue of larger absolute value, and $rt2$ is the eigenvalue of smaller absolute value.

Input Parameters

a, b, c

REAL for `sla2`
DOUBLE PRECISION for `dlae2`

The elements a, b , and c of the 2-by-2 matrix above.

Output Parameters

$rt1, rt2$

REAL for `sla2`
DOUBLE PRECISION for `dlae2`

The computed eigenvalues of larger and smaller absolute value, respectively.

Application Notes

$rt1$ is accurate to a few ulps barring over/underflow. $rt2$ may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute $rt2$ accurately in all cases.

Overflow is possible only if $rt1$ is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds

$underflow_threshold / \text{macheps}$.

?laebz

Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz.

Syntax

```
call slaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d, e, e2,
nval, ab, c, mout, nab, work, iwork, info )

call dlaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d, e, e2,
nval, ab, c, mout, nab, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laebz contains the iteration loops which compute and use the function $n(w)$, which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w . It performs a choice of two types of loops:

- i_{job} =1, followed by
- i_{job} =2: It takes as input a list of intervals and returns a list of sufficiently small intervals whose union contains the same eigenvalues as the union of the original intervals. The input intervals are $(ab(j,1), ab(j,2))$, $j=1, \dots, minp$. The output interval $(ab(j,1), ab(j,2))$ will contain eigenvalues $nab(j, 1)+1, \dots, nab(j, 2)$, where $1 \leq j \leq mout$.
- i_{job} =3: It performs a binary search in each input interval $(ab(j,1), ab(j,2))$ for a point $w(j)$ such that $n(w(j))=nval(j)$, and uses $c(j)$ as the starting point of the search. If such a $w(j)$ is found, then on output $ab(j,1)=ab(j,2)=w$. If no such $w(j)$ is found, then on output $(ab(j,1), ab(j,2))$ will be a small interval containing the point where $n(w)$ jumps through $nval(j)$, unless that point lies outside the initial interval.

Note that the intervals are in all cases half-open intervals, that is, of the form $(a, b]$, which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than $overflow^{1/2} * overflow^{1/4}$ in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

NOTE

In general, the arguments are not checked for unreasonable values.

Input Parameters

- i_{job} INTEGER. Specifies what is to be done:
- = 1: Compute nab for the initial intervals.
 - = 2: Perform bisection iteration to find eigenvalues of T .
 - = 3: Perform bisection iteration to invert $n(w)$, i.e., to find a point which has a specified number of eigenvalues of T to its left. Other values will cause ?laebz to return with $info=-1$.
- $nitmax$ INTEGER. The maximum number of "levels" of bisection to be performed, i.e., an interval of width W will not be made smaller than $2^{-nitmax}W$. If not all intervals have converged after $nitmax$ iterations, then $info$ is set to the number of non-converged intervals.
- n INTEGER. The dimension n of the tridiagonal matrix T . It must be at least 1.

<i>mmax</i>	INTEGER. The maximum number of intervals. If more than <i>mmax</i> intervals are generated, then ?laebz will quit with <i>info</i> = <i>mmax</i> +1.
<i>minp</i>	INTEGER. The initial number of intervals. It may not be greater than <i>mmax</i> .
<i>nbmin</i>	INTEGER. The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.
<i>abstol</i>	<p>REAL for slaebz</p> <p>DOUBLE PRECISION for dlaebz.</p> <p>The minimum (absolute) width of an interval. When an interval is narrower than <i>abstol</i>, or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.</p>
<i>reltol</i>	<p>REAL for slaebz</p> <p>DOUBLE PRECISION for dlaebz.</p> <p>The minimum relative width of an interval. When an interval is narrower than <i>abstol</i>, or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least <i>radix*machine epsilon</i>.</p>
<i>pivmin</i>	<p>REAL for slaebz</p> <p>DOUBLE PRECISION for dlaebz.</p> <p>The minimum absolute value of a "pivot" in the Sturm sequence loop. This value must be at least ($\max e(j) ^2 * safe_min$) and at least <i>safe_min</i>, where <i>safe_min</i> is at least the smallest number that can divide one without overflow.</p>
<i>d, e, e2</i>	<p>REAL for slaebz</p> <p>DOUBLE PRECISION for dlaebz.</p> <p>Arrays, dimension (<i>n</i>) each. The array <i>d</i> contains the diagonal elements of the tridiagonal matrix <i>T</i>.</p> <p>The array <i>e</i> contains the off-diagonal elements of the tridiagonal matrix <i>T</i> in positions 1 through <i>n</i>-1. <i>e(n)</i> is arbitrary.</p> <p>The array <i>e2</i> contains the squares of the off-diagonal elements of the tridiagonal matrix <i>T</i>. <i>e2(n)</i> is ignored.</p>
<i>nval</i>	<p>INTEGER.</p> <p>Array, dimension (<i>minp</i>).</p> <p>If <i>ijob</i>=1 or 2, not referenced.</p> <p>If <i>ijob</i>=3, the desired values of <i>n(w)</i>.</p>
<i>ab</i>	<p>REAL for slaebz</p> <p>DOUBLE PRECISION for dlaebz.</p> <p>Array, dimension (<i>mmax</i>,2) The endpoints of the intervals. <i>ab(j,1)</i> is <i>a(j)</i>, the left endpoint of the <i>j</i>-th interval, and <i>ab(j,2)</i> is <i>b(j)</i>, the right endpoint of the <i>j</i>-th interval.</p>

c REAL for `slaebz`
 DOUBLE PRECISION for `dlaebz`.
 Array, dimension (*mmax*)
 If *ijob*=1, ignored.
 If *ijob*=2, workspace.
 If *ijob*=3, then on input *c(j)* should be initialized to the first search point in the binary search.

nab INTEGER.
 Array, dimension (*mmax*,2)
 If *ijob*=2, then on input, *nab(i,j)* should be set. It must satisfy the condition:

$$n(ab(i,1)) \leq nab(i,1) \leq nab(i,2) \leq n(ab(i,2)),$$
 which means that in interval *i* only eigenvalues $nab(i,1)+1, \dots, nab(i,2)$ are considered.
 Usually, $nab(i,j)=n(ab(i,j))$, from a previous call to `?laebz` with *ijob*=1.
 If *ijob*=3, normally, *nab* should be set to some distinctive value(s) before `?laebz` is called.

work REAL for `slaebz`
 DOUBLE PRECISION for `dlaebz`.
 Workspace array, dimension (*mmax*).

iwork INTEGER.
 Workspace array, dimension (*mmax*).

Output Parameters

nval The elements of *nval* will be reordered to correspond with the intervals in *ab*. Thus, *nval(j)* on output will not, in general be the same as *nval(j)* on input, but it will correspond with the interval $(ab(j,1), ab(j,2)]$ on output.

ab The input intervals will, in general, be modified, split, and reordered by the calculation.

mout INTEGER.
 If *ijob*=1, the number of eigenvalues in the intervals.
 If *ijob*=2 or 3, the number of intervals output.
 If *ijob*=3, *mout* will equal *minp*.

nab If *ijob*=1, then on output *nab(i,j)* will be set to $N(ab(i,j))$.
 If *ijob*=2, then on output, *nab(i,j)* will contain $\max(na(k, \min(nb(k), N(ab(i,j))))$, where *k* is the index of the input interval that the output interval $(ab(j,1), ab(j,2)]$ came from, and *na(k)* and *nb(k)* are the input values of *nab(k,1)* and *nab(k,2)*.

If $ijob=3$, then on output, $nab(i,j)$ contains $N(ab(i,j))$, unless $N(w) > nval(i)$ for all search points w , in which case $nab(i,1)$ will not be modified, i.e., the output value will be the same as the input value (modulo reorderings, see $nval$ and ab), or unless $N(w) < nval(i)$ for all search points w , in which case $nab(i,2)$ will not be modified.

info

INTEGER.

If $info = 0$ - all intervals convergedIf $info = 1--mmax$ - the last $info$ interval did not converge.If $info = mmax+1$ - more than $mmax$ intervals were generated

Application Notes

This routine is intended to be called only by other LAPACK routines, thus the interface is less user-friendly. It is intended for two purposes:

(a) finding eigenvalues. In this case, $?laebz$ should have one or more initial intervals set up in ab , and $?laebz$ should be called with $ijob=1$. This sets up nab , and also counts the eigenvalues. Intervals with no eigenvalues would usually be thrown out at this point. Also, if not all the eigenvalues in an interval i are desired, $nab(i,1)$ can be increased or $nab(i,2)$ decreased. For example, set $nab(i,1)=nab(i,2)-1$ to get the largest eigenvalue. $?laebz$ is then called with $ijob=2$ and $mmax$ no smaller than the value of $mout$ returned by the call with $ijob=1$. After this ($ijob=2$) call, eigenvalues $nab(i,1)+1$ through $nab(i,2)$ are approximately $ab(i,1)$ (or $ab(i,2)$) to the tolerance specified by $abstol$ and $reftol$.

(b) finding an interval $(a',b']$ containing eigenvalues $w(f), \dots, w(l)$. In this case, start with a Gershgorin interval (a,b) . Set up ab to contain 2 search intervals, both initially (a,b) . One $nval$ element should contain $f-1$ and the other should contain l , while c should contain a and b , respectively. $nab(i,1)$ should be -1 and $nab(i,2)$ should be $n+1$, to flag an error if the desired interval does not lie in (a,b) . $?laebz$ is then called with $ijob=3$. On exit, if $w(f-1) < w(f)$, then one of the intervals $-- j --$ will have $ab(j,1)=ab(j,2)$ and $nab(j,1)=nab(j,2)=f-1$, while if, to the specified tolerance, $w(f-k)=\dots=w(f+r)$, $k > 0$ and $r \geq 0$, then the interval will have $n(ab(j,1))=nab(j,1)=f-k$ and $n(ab(j,2))=nab(j,2)=f+r$. The cases $w(l) < w(l+1)$ and $w(l-r)=\dots=w(l+k)$ are handled similarly.

?laed0

Used by ?stedc. Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.

Syntax

```
call slaed0( icompq, qsiz, n, d, e, q, ldq, qstore, ldqs, work, iwork, info )

Description

Real flavors of this routine compute all eigenvalues and (optionally) corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Complex flavors `claed0/zlaed0` compute all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Input Parameters

<code>icompq</code>	INTEGER. Used with real flavors only. If <code>icompq</code> = 0, compute eigenvalues only. If <code>icompq</code> = 1, compute eigenvectors of original dense symmetric matrix also. On entry, the array q must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. If <code>icompq</code> = 2, compute eigenvalues and eigenvectors of the tridiagonal matrix.
<code>qsiz</code>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <code>icompq</code> = 1).
<code>n</code>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<code>d, e, rwork</code>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: $d(*)$ contains the main diagonal of the tridiagonal matrix. The dimension of d must be at least $\max(1, n)$. $e(*)$ contains the off-diagonal elements of the tridiagonal matrix. The dimension of e must be at least $\max(1, n-1)$. $rwork(*)$ is a workspace array used in complex flavors only. The dimension of $rwork$ must be at least $(1 + 3n + 2n\log_2(n) + 3n^2)$, where $\log_2(n)$ = smallest integer k such that $2^k \geq n$.
<code>q, qstore</code>	REAL for <code>slaed0</code> DOUBLE PRECISION for <code>dlaed0</code> COMPLEX for <code>claed0</code> DOUBLE COMPLEX for <code>zlaed0</code> . Arrays: $q(ldq, *)$, $qstore(ldq, *)$. The second dimension of these arrays must be at least $\max(1, n)$. <i>For real flavors:</i> If <code>icompq</code> = 0, array q is not referenced. If <code>icompq</code> = 1, on entry, q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time.

If $i\text{compq} = 2$, on entry, q will be the identity matrix. The array $qstore$ is a workspace array referenced only when $i\text{compq} = 1$. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

For complex flavors:

On entry, q must contain an $qsiz$ -by- n matrix whose columns are unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix. The array $qstore$ is a workspace array used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

ldq

INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.

$ldqs$

INTEGER. The leading dimension of the array $qstore$; $ldqs \geq \max(1, n)$.

$work$

REAL for `slaed0`

DOUBLE PRECISION for `dlaed0`.

Workspace array, used in real flavors only.

If $i\text{compq} = 0$ or 1 , the dimension of $work$ must be at least $(1 + 3n + 2n\log_2(n) + 3n^2)$, where $\log_2(n) =$ smallest integer k such that $2^k \geq n$.

If $i\text{compq} = 2$, the dimension of $work$ must be at least $(4n + n^2)$.

$iwork$

INTEGER.

Workspace array.

For real flavors, if $i\text{compq} = 0$ or 1 , and for complex flavors, the dimension of $iwork$ must be at least $(6 + 6n + 5n\log_2(n))$.

For real flavors, if $i\text{compq} = 2$, the dimension of $iwork$ must be at least $(3 + 5n)$.

Output Parameters

d

On exit, contains eigenvalues in ascending order.

e

On exit, the array is destroyed.

q

If $i\text{compq} = 2$, on exit, q contains the eigenvectors of the tridiagonal matrix.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i > 0$, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $i/(n+1)$ through $\text{mod}(i, n+1)$.

?laed1

Used by sstedc/dstedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.

Syntax

```
call slaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
call dlaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laed1 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. ?laed7 handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \rho Z * Z^T) * Q^T(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^T(\text{out})$$

where $Z = Q^T u$, u is a vector of length n with ones in the cutpnt and $(\text{cutpnt}+1)$ -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine ?laed2.

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine ?laed4 (as called by ?laed3). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

n INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).

d, q, work REAL for slaed1

DOUBLE PRECISION for dlaed1.

Arrays:

d()* contains the eigenvalues of the rank-1-perturbed matrix. The dimension of *d* must be at least $\max(1, n)$.

*q(ldq, *)* contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of *q* must be at least $\max(1, n)$.

work()* is a workspace array, dimension at least $(4n+n^2)$.

ldq INTEGER. The leading dimension of the array *q*; $ldq \geq \max(1, n)$.

<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order.
<i>rho</i>	REAL for <code>slaed1</code> DOUBLE PRECISION for <code>dlaed1</code> . The subdiagonal entry used to create the rank-1 modification. This parameter can be modified by <code>?laed2</code> , where it is input/output.
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq \text{cutpnt} \leq n/2$.
<i>iwork</i>	INTEGER. Workspace array, dimension (4 <i>n</i>).

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.
<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.
<i>indxq</i>	On exit, contains the permutation which will reintegrate the subproblems back into sorted order, that is, <i>d</i> (<i>indxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed2

Used by `sstedc/dstedc`. Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.

Syntax

```
call slaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc, indxp, coltyp, info )
call dlaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc, indxp, coltyp, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine ?laed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

k	INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation ($0 \leq k \leq n$).
n	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
$n1$	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
d, q, z	REAL for slaed2 DOUBLE PRECISION for dlaed2. Arrays: $d(*)$ contains the eigenvalues of the two submatrices to be combined. The dimension of d must be at least $\max(1, n)$. $q(ldq, *)$ contains the eigenvectors of the two submatrices in the two square blocks with corners at $(1,1), (n1,n1)$ and $(n1+1,n1+1), (n,n)$. The second dimension of q must be at least $\max(1, n)$. $z(*)$ contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). ldq INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$. $indxq$ INTEGER. Array, dimension (n). On entry, the permutation which separately sorts the two subproblems in d into ascending order. Note that elements in the second half of this permutation must first have $n1$ added to their values. rho REAL for slaed2 DOUBLE PRECISION for dlaed2. On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. $indx, indxp$ INTEGER. Workspace arrays, dimension (n) each. Array $indx$ contains the permutation used to sort the contents of d into ascending order. Array $indxp$ contains the permutation used to place deflated values of d at the end of the array. $indx(1:k)$ points to the nondeflated d -values and $indx(k+1:n)$ points to the deflated eigenvalues. $coltyp$ INTEGER. Workspace array, dimension (n). During execution, a label which will indicate which of the following types a column in the $q2$ matrix is:

- 1 : non-zero in the upper half only;
- 2 : dense;
- 3 : non-zero in the lower half only;
- 4 : deflated.

Output Parameters

<i>d</i>	On exit, <i>d</i> contains the trailing ($n-k$) updated eigenvalues (those which were deflated) sorted into increasing order.
<i>q</i>	On exit, <i>q</i> contains the trailing ($n-k$) updated eigenvectors (those which were deflated) in its last $n-k$ columns.
<i>z</i>	On exit, <i>z</i> content is destroyed by the updating process.
<i>indxq</i>	Destroyed on exit.
<i>rho</i>	On exit, <i>rho</i> has been modified to the value required by ?laed3.
<i>dlamda, w, q2</i>	<p>REAL for dlaed2</p> <p>DOUBLE PRECISION for dlaed2.</p> <p>Arrays: <i>dlamda</i>(n), <i>w</i>(n), <i>q2</i>($n1^2 + (n-n1)^2$).</p> <p>The array <i>dlamda</i> contains a copy of the first k eigenvalues which is used by ?laed3 to form the secular equation.</p> <p>The array <i>w</i> contains the first k values of the final deflation-altered <i>z</i>-vector which is passed to ?laed3.</p> <p>The array <i>q2</i> contains a copy of the first k eigenvectors which is used by ?laed3 in a matrix multiply (sgemm/dgemm) to solve for the new eigenvectors.</p>
<i>indxk</i>	INTEGER. Array, dimension (n).
	The permutation used to arrange the columns of the deflated <i>q</i> matrix into three groups: the first group contains non-zero elements only at and above $n1$, the second contains non-zero elements only below $n1$, and the third is dense.
<i>coltyp</i>	On exit, <i>coltyp</i> (<i>i</i>) is the number of columns of type <i>i</i> , for <i>i</i> =1 to 4 only (see the definition of types in the description of <i>coltyp</i> in <i>Input Parameters</i>).
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

?laed3

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.

Syntax

```
call slaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
call dlaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laed3 finds the roots of the secular equation, as defined by the values in d , w , and ρ , between 1 and k .

It makes the appropriate calls to ?laed4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the k -by- k system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but none are known.

Input Parameters

k	INTEGER. The number of terms in the rational function to be solved by ?laed4 ($k \geq 0$).
n	INTEGER. The number of rows and columns in the q matrix. $n \geq k$ (deflation may result in $n > k$).
$n1$	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
q	REAL for slaed3 DOUBLE PRECISION for dlaed3. Array $q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. Initially, the first k columns of this array are used as workspace.
ldq	INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.
ρ	REAL for slaed3 DOUBLE PRECISION for dlaed3. The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
$dlamda, q2, w$	REAL for slaed3 DOUBLE PRECISION for dlaed3. Arrays: $dlamda(k)$, $q2(1:ldq2, *)$, $w(k)$. The first k elements of the array $dlamda$ contain the old roots of the deflated updating problem. These are the poles of the secular equation.

The first k columns of the array $q2$ contain the non-deflated eigenvectors for the split problem. The second dimension of $q2$ must be at least $\max(1, n)$.

The first k elements of the array w contain the components of the deflation-adjusted updating vector.

indx

INTEGER. Array, dimension (n).

The permutation used to arrange the columns of the deflated q matrix into three groups (see ?laed2).

The rows of the eigenvectors found by ?laed4 must be likewise permuted before the matrix multiply can take place.

ctot

INTEGER. Array, dimension (4).

A count of the total number of the various types of columns in q , as described in *indx*. The fourth column type is any column which has been deflated.

s

REAL for slaed3

DOUBLE PRECISION for dlaed3.

Workspace array, dimension $(n1+1)*k$.

Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

Output Parameters

d

REAL for slaed3

DOUBLE PRECISION for dlaed3.

Array, dimension at least $\max(1, n)$.

d(i) contains the updated eigenvalues for $1 \leq i \leq k$.

q

On exit, the columns 1 to k of q contain the updated eigenvectors.

dlambda

May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.

w

Destroyed on exit.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* = 1, an eigenvalue did not converge.

?laed4

Used by sstedc/dstedc. Finds a single root of the secular equation.

Syntax

```
call slaed4( n, i, d, z, delta, rho, dlam, info )
call dlaed4( n, i, d, z, delta, rho, dlam, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine computes the i -th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array d , and that

$D(i) < D(j)$ for $i < j$

and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$\text{diag}(D) + \rho * Z * \text{transpose}(Z)$.

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

n	INTEGER. The length of all arrays.
i	INTEGER. The index of the eigenvalue to be computed; $1 \leq i \leq n$.
d, z	REAL for slaed4 DOUBLE PRECISION for dlaed4 Arrays, dimension (n) each. The array d contains the original eigenvalues. It is assumed that they are in order, $d(i) < d(j)$ for $i < j$. The array z contains the components of the updating vector Z .
ρ	REAL for slaed4 DOUBLE PRECISION for dlaed4 The scalar in the symmetric updating formula.

Output Parameters

δ	REAL for slaed4 DOUBLE PRECISION for dlaed4 Array, dimension (n). If $n \neq 1$, δ contains $(d(j) - \lambda_i)$ in its j -th component. If $n = 1$, then $\delta(1) = 1$. The vector δ contains the information necessary to construct the eigenvectors.
λ	REAL for slaed4 DOUBLE PRECISION for dlaed4

The computed λ_i , the i -th updated eigenvalue.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = 1$, the updating process failed.

?laed5

Used by `sstedc/dstedc`. Solves the 2-by-2 secular equation.

Syntax

```
call slaed5( i, d, z, delta, rho, dlam )
call dlaed5( i, d, z, delta, rho, dlam )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine computes the i -th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(D) + \rho Z * \text{transpose}(Z)$.

The diagonal elements in the array D are assumed to satisfy

$D(i) < D(j)$ for $i < j$.

We also assume $\rho > 0$ and that the Euclidean norm of the vector Z is one.

Input Parameters

i INTEGER. The index of the eigenvalue to be computed;
 $1 \leq i \leq 2$.

d, z REAL for `slaed5`
 DOUBLE PRECISION for `dlaed5`
 Arrays, dimension (2) each. The array d contains the original eigenvalues.
 It is assumed that $d(1) < d(2)$.
 The array z contains the components of the updating vector.

rho REAL for `slaed5`
 DOUBLE PRECISION for `dlaed5`
 The scalar in the symmetric updating formula.

Output Parameters

delta REAL for `slaed5`
 DOUBLE PRECISION for `dlaed5`

Array, dimension (2).

The vector *delta* contains the information necessary to construct the eigenvectors.

dlam REAL for slaed5

DOUBLE PRECISION for dlaed5

The computed *lambda_i*, the *i*-th updated eigenvalue.

?laed6

Used by sstedc/dstedc. Computes one Newton step
in solution of the secular equation.

Syntax

```
call slaed6( kniter, orgati, rho, d, z, finit, tau, info )
call dlaed6( kniter, orgati, rho, d, z, finit, tau, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the positive or negative root (closest to the origin) of

$$f(x) = rho + \frac{z(1)}{d(1) - x} + \frac{z(2)}{d(2) - x} + \frac{z(3)}{d(3) - x}$$

It is assumed that if *orgati* = .TRUE. the root is between *d*(2) and *d*(3); otherwise it is between *d*(1) and *d*(2). This routine is called by ?laed4 when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Input Parameters

kniter

INTEGER.

Refer to ?laed4 for its significance.

orgati

LOGICAL.

If *orgati* = .TRUE., the needed root is between *d*(2) and *d*(3); otherwise it is between *d*(1) and *d*(2). See ?laed4 for further details.

rho

REAL for slaed6

DOUBLE PRECISION for dlaed6

Refer to the equation for *f*(*x*) above.

d, z

REAL for slaed6

DOUBLE PRECISION for dlaed6

Arrays, dimension (3) each.

The array d satisfies $d(1) < d(2) < d(3)$.

Each of the elements in the array z must be positive.

finit

REAL for `slaed6`

DOUBLE PRECISION for `dlaed6`

The value of $f(x)$ at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

Output Parameters

tau

REAL for `slaed6`

DOUBLE PRECISION for `dlaed6`

The root of the equation for $f(x)$.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = 1$, failure to converge.

?laed7

Used by ?stedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.

Syntax

```
call slaed7( icompq, n, qsiz, tlvls, curlvl, curpbm, d, q, ldq, indxq, rho, cutpnt,  

qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info )  

call dlaed7( icompq, n, qsiz, tlvls, curlvl, curpbm, d, q, ldq, indxq, rho, cutpnt,  

qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info )  

call claed7( n, cutpnt, qsiz, tlvls, curlvl, curpbm, d, q, ldq, rho, indxq, qstore,  

qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info )  

call zlaed7( n, cutpnt, qsiz, tlvls, curlvl, curpbm, d, q, ldq, rho, indxq, qstore,  

qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine ?laed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric/Hermitian matrix that has been reduced to tridiagonal form. For real flavors, `slaed1/dlaed1` handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \rho Z^T Z) * Q^T(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^T(\text{out}) \text{ for real flavors, or}$$

$T = Q(\text{in}) * (D(\text{in}) + \rho Z^* Z^H) * Q^H(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^H(\text{out})$ for complex flavors

where $Z = Q^T * u$ for real flavors and $Z = Q^H * u$ for complex flavors, u is a vector of length n with ones in the cutpnt and $(\text{cutpnt} + 1)$ -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `slaed8/dlaed8` (for real flavors) or by the routine `slaed2/dlaed2` (for complex flavors).

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine `?laed4` (as called by `?laed9` or `?laed3`). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>icompq</i>	INTEGER. Used with real flavors only. If <i>icompq</i> = 0, compute eigenvalues only. If <i>icompq</i> = 1, compute eigenvectors of original dense symmetric matrix also. On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq \text{cutpnt} \leq n$.
<i>qsiz</i>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompq</i> = 1).
<i>tlvl</i>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<i>curlvl</i>	INTEGER. The current level in the overall merge routine, $0 \leq \text{curlvl} \leq \text{tlvl}$.
<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>d</i>	REAL for <code>slaed7/claed7</code> DOUBLE PRECISION for <code>dlaed7/zlaed7</code> . Array, dimension at least $\max(1, n)$. Array <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix.
<i>q, work</i>	REAL for <code>slaed7</code> DOUBLE PRECISION for <code>dlaed7</code> COMPLEX for <code>claed7</code>

DOUBLE COMPLEX **for** zlaed7.

Arrays:

q(*ldq*, *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of *q* must be at least $\max(1, n)$.

work(*) is a workspace array, dimension at least $(3n+2*qsiz*n)$ for real flavors and at least $(qsiz*n)$ for complex flavors.

ldq

INTEGER. The leading dimension of the array *q*; $ldq \geq \max(1, n)$.

indxq

INTEGER. Array, dimension (*n*).

Contains the permutation that separately sorts the two sub-problems in *d* into ascending order.

rho

REAL **for** slaed7 /claed7

DOUBLE PRECISION **for** dlaed7/zlaed7.

The subdiagonal element used to create the rank-1 modification.

qstore

REAL **for** slaed7/claed7

DOUBLE PRECISION **for** dlaed7/zlaed7.

Array, dimension (n^2+1). Serves also as output parameter.

Stores eigenvectors of submatrices encountered during divide and conquer, packed together. *qptr* points to beginning of the submatrices.

qptr

INTEGER. Array, dimension (*n*+2). Serves also as output parameter. List of indices pointing to beginning of submatrices stored in *qstore*. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.

prmptr, perm, givptr

INTEGER. Arrays, dimension ($n \log_2 n$) each.

The array *prmptr*(*) contains a list of pointers which indicate where in *perm* a level's permutation is stored. *prmptr*(*i*+1) - *prmptr*(*i*) indicates the size of the permutation and also the size of the full, non-deflated problem.

The array *perm*(*) contains the permutations (from deflation and sorting) to be applied to each eigenblock. This parameter can be modified by ?laed8, where it is output.

The array *givptr*(*) contains a list of pointers which indicate where in *givcol* a level's Givens rotations are stored. *givptr*(*i*+1) - *givptr*(*i*) indicates the number of Givens rotations.

givcol

INTEGER. Array, dimension (2, $n \log_2 n$).

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

givnum

REAL **for** slaed7/claed7

DOUBLE PRECISION **for** dlaed7/zlaed7.

Array, dimension (2, $n \log_2 n$).

Each number indicates the S value to be used in the corresponding Givens rotation.

<i>iwork</i>	INTEGER. Workspace array, dimension ($4n$).
<i>rwork</i>	REAL for <code>claed7</code> DOUBLE PRECISION for <code>zlaed7</code> . Workspace array, dimension ($3n+2qsiz*n$). Used in complex flavors only.

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.
<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.
<i>indxq</i>	INTEGER. Array, dimension (n). Contains the permutation that reintegrates the subproblems back into a sorted order, that is, $d(indxq(i = 1, n))$ will be in the ascending order.
<i>rho</i>	This parameter can be modified by <code>?laed8</code> , where it is input/output.
<i>prmptr, perm, givptr</i>	INTEGER. Arrays, dimension ($n \log_2 n$) each. The array <i>prmptr</i> contains an updated list of pointers. The array <i>perm</i> contains an updated permutation. The array <i>givptr</i> contains an updated list of pointers.
<i>givcol</i>	This parameter can be modified by <code>?laed8</code> , where it is output.
<i>givnum</i>	This parameter can be modified by <code>?laed8</code> , where it is output.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed8

Used by `?stedc`. Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.

Syntax

```
call slaed8( icompq, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda, q2, ldq2, w, perm, givptr, givcol, givnum, indxpx, indx, info )  
call dlaed8( icompq, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda, q2, ldq2, w, perm, givptr, givcol, givnum, indxpx, indx, info )
```

```
call claed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indx, indxq, perm, givptr, givcol, givnum, info )
call zlaed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indx, indxq, perm, givptr, givcol, givnum, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

<i>icompq</i>	INTEGER. Used with real flavors only. If <i>icompq</i> = 0, compute eigenvalues only. If <i>icompq</i> = 1, compute eigenvectors of original dense symmetric matrix also. On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq \text{cutpnt} \leq n$.
<i>qsiz</i>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompq</i> = 1).
<i>d, z</i>	REAL for slaed8/claed8 DOUBLE PRECISION for dlaed8/zlaed8. Arrays, dimension at least $\max(1, n)$ each. The array <i>d</i> (*) contains the eigenvalues of the two submatrices to be combined. On entry, <i>z</i> (*) contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of <i>z</i> are destroyed by the updating process.
<i>q</i>	REAL for slaed8 DOUBLE PRECISION for dlaed8 COMPLEX for claed8 DOUBLE COMPLEX for zlaed8. Array

$q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. On entry, q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems.

For real flavors, If $i_compq = 0$, q is not referenced.

ldq INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.

$ldq2$ INTEGER. The leading dimension of the output array $q2$; $ldq2 \geq \max(1, n)$.

$indxq$ INTEGER. Array, dimension (n).

The permutation that separately sorts the two sub-problems in d into ascending order. Note that elements in the second half of this permutation must first have $cutpt$ added to their values in order to be accurate.

rho REAL for `slaed8/claed8`

DOUBLE PRECISION for `dlaed8/zlaed8`.

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.

Output Parameters

k INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation.

d On exit, contains the trailing $(n-k)$ updated eigenvalues (those which were deflated) sorted into increasing order.

z On exit, the updating process destroys the contents of z .

q On exit, q contains the trailing $(n-k)$ updated eigenvectors (those which were deflated) in its last $(n-k)$ columns.

$indxq$ INTEGER. Array, dimension (n).

The permutation of merged eigenvalues set.

rho On exit, rho has been modified to the value required by `?laed3`.

$dlamda, w$ REAL for `slaed8/claed8`

DOUBLE PRECISION for `dlaed8/zlaed8`.

Arrays, dimension (n) each. The array $dlamda(*)$ contains a copy of the first k eigenvalues which will be used by `?laed3` to form the secular equation.

The array $w(*)$ will hold the first k values of the final deflation-altered z -vector and will be passed to `?laed3`.

$q2$ REAL for `slaed8`

DOUBLE PRECISION for `dlaed8`

COMPLEX for `claed8`

DOUBLE COMPLEX for zlaed8.

Array

$q2(ldq2, *)$. The second dimension of $q2$ must be at least $\max(1, n)$.

Contains a copy of the first k eigenvectors which will be used by slaed7/dlaed7 in a matrix multiply (sgemm/dgemm) to update the new eigenvectors. For real flavors, If $icompq = 0$, $q2$ is not referenced.

$indx_p, indx$

INTEGER. Workspace arrays, dimension (n) each.

The array $indx_p(*)$ will contain the permutation used to place deflated values of d at the end of the array. On output, $indx_p(1:k)$ points to the nondeflated d -values and $indx_p(k+1:n)$ points to the deflated eigenvalues.

The array $indx(*)$ will contain the permutation used to sort the contents of d into ascending order.

$perm$

INTEGER. Array, dimension (n).

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

$givptr$

INTEGER. Contains the number of Givens rotations which took place in this subproblem.

$givcol$

INTEGER. Array, dimension (2, n).

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

$givnum$

REAL for slaed8/claed8

DOUBLE PRECISION for dlaed8/zlaed8.

Array, dimension (2, n).

Each number indicates the S value to be used in the corresponding Givens rotation.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?laed9

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.

Syntax

```
call slaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
call dlaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
```

Include Files

- Fortran: mkl.fi

- C: mkl.h

Description

The routine finds the roots of the secular equation, as defined by the values in d , z , and ρ , between $kstart$ and $kstop$. It makes the appropriate calls to `slaed4/dlaed4` and then stores the new matrix of eigenvectors for use in calculating the next level of z vectors.

Input Parameters

k	INTEGER. The number of terms in the rational function to be solved by <code>slaed4/dlaed4</code> ($k \geq 0$).
$kstart, kstop$	INTEGER. The updated eigenvalues $\lambda(i)$, $kstart \leq i \leq kstop$ are to be computed. $1 \leq kstart \leq kstop \leq k$.
n	INTEGER. The number of rows and columns in the Q matrix. $n \geq k$ (deflation may result in $n > k$).
q	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> . Workspace array, dimension ($ldq, *$). The second dimension of q must be at least $\max(1, n)$.
ldq	INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.
ρ	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
$dlamda, w$	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> Arrays, dimension (k) each. The first k elements of the array $dlamda(*)$ contain the old roots of the deflated updating problem. These are the poles of the secular equation. The first k elements of the array $w(*)$ contain the components of the deflation-adjusted updating vector.
lds	INTEGER. The leading dimension of the output array s ; $lds \geq \max(1, k)$.

Output Parameters

d	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> Array, dimension (n). Elements in $d(i)$ are not referenced for $1 \leq i < kstart$ or $kstop < i \leq n$.
s	REAL for <code>slaed9</code>

DOUBLE PRECISION for `dlaed9`.

`Array, dimension (lds, *)`.

The second dimension of `s` must be at least `max(1, k)`. Will contain the eigenvectors of the repaired matrix which will be stored for subsequent `z` vector calculation and multiplied by the previously accumulated eigenvectors to update the system.

`dlamda`

On exit, the value is modified to make sure all `dlamda(i) - dlamda(j)` can be computed with high relative accuracy, barring overflow and underflow.

`w`

Destroyed on exit.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value. If `info = 1`, the eigenvalue did not converge.

?laeda

Used by ?stedc. Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.

Syntax

```
call slaeda( n, tlvl, curlvl, curpbm, prmprt, perm, givptr, givcol, givnum, q, qptr,
z, ztemp, info )
```

```
call dlaeda( n, tlvl, curlvl, curpbm, prmprt, perm, givptr, givcol, givnum, q, qptr,
z, ztemp, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laeda computes the Z vector corresponding to the merge step in the `curlvl`-th step of the merge process with `tlvl` steps for the `curpbm`-th problem.

Input Parameters

`n` INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).

`tlvl` INTEGER. The total number of merging levels in the overall divide and conquer tree.

`curlvl` INTEGER. The current level in the overall merge routine, $0 \leq curlvl \leq tlvl$.

`curpbm` INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).

*prmptr, perm, givptr*INTEGER. Arrays, dimension ($n \log_2 n$) each.

The array *prmptr*(*) contains a list of pointers which indicate where in *perm* a level's permutation is stored. $\text{prmptr}(i+1) - \text{prmptr}(i)$ indicates the size of the permutation and also the size of the full, non-deflated problem.

The array *perm*(*) contains the permutations (from deflation and sorting) to be applied to each eigenblock.

The array *givptr*(*) contains a list of pointers which indicate where in *givcol* a level's Givens rotations are stored. $\text{givptr}(i+1) - \text{givptr}(i)$ indicates the number of Givens rotations.

*givcol*INTEGER. Array, dimension (2, $n \log_2 n$).

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

*givnum*REAL for *slaeda*DOUBLE PRECISION for *dlaeda*.Array, dimension (2, $n \log_2 n$).

Each number indicates the *S* value to be used in the corresponding Givens rotation.

*q*REAL for *slaeda*DOUBLE PRECISION for *dlaeda*.Array, dimension (n^2).

Contains the square eigenblocks from previous levels, the starting positions for blocks are given by *qptr*.

qptr

INTEGER. Array, dimension ($n+2$). Contains a list of pointers which indicate where in *q* an eigenblock is stored. $\sqrt{\text{qptr}(i+1) - \text{qptr}(i)}$ indicates the size of the block.

*ztemp*REAL for *slaeda*DOUBLE PRECISION for *dlaeda*.Workspace array, dimension (n).

Output Parameters

*z*REAL for *slaeda*DOUBLE PRECISION for *dlaeda*.

Array, dimension (n). Contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

?laein

Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.

Syntax

```
call slaein( rightv, noinit, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3, smlnum,
bignum, info )

call dlaein( rightv, noinit, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3, smlnum,
bignum, info )

call claein( rightv, noinit, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum, info )

call zlaein( rightv, noinit, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (wr,wi) of a real upper Hessenberg matrix H (for real flavors slaein/dlaein) or to the eigenvalue w of a complex upper Hessenberg matrix H (for complex flavors claein/zlaein).

Input Parameters

<i>rightv</i>	LOGICAL.
	If <i>rightv</i> = .TRUE., compute right eigenvector;
	if <i>rightv</i> = .FALSE., compute left eigenvector.
<i>noinit</i>	LOGICAL.
	If <i>noinit</i> = .TRUE., no initial vector is supplied in (vr,vi) or in v (for complex flavors);
	if <i>noinit</i> = .FALSE., initial vector is supplied in (vr,vi) or in v (for complex flavors).
<i>n</i>	INTEGER. The order of the matrix H ($n \geq 0$).
<i>h</i>	REAL for slaein DOUBLE PRECISION for dlaein COMPLEX for claein DOUBLE COMPLEX for zlaein. Array $h(ldh, *)$. The second dimension of h must be at least $\max(1, n)$. Contains the upper Hessenberg matrix H .
<i>ldh</i>	INTEGER. The leading dimension of the array h ; $ldh \geq \max(1, n)$.
<i>wr, wi</i>	REAL for slaein

DOUBLE PRECISION for `dlaein`.

The real and imaginary parts of the eigenvalue of H whose corresponding right or left eigenvector is to be computed (for real flavors of the routine).

w

COMPLEX for `claein`

DOUBLE COMPLEX for `zlaein`.

The eigenvalue of H whose corresponding right or left eigenvector is to be computed (for complex flavors of the routine).

vr, vi

REAL for `slaein`

DOUBLE PRECISION for `dlaein`.

Arrays, dimension (n) each. Used for real flavors only. On entry, if *noinit* = .FALSE. and *wi* = 0.0, *vr* must contain a real starting vector for inverse iteration using the real eigenvalue *wr*;

if *noinit* = .FALSE. and *wi* ≠ 0.0, *vr* and *vi* must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (*wr,wi*); otherwise *vr* and *vi* need not be set.

v

COMPLEX for `claein`

DOUBLE COMPLEX for `zlaein`.

Array, dimension (n). Used for complex flavors only. On entry, if *noinit* = .FALSE., *v* must contain a starting vector for inverse iteration; otherwise *v* need not be set.

b

REAL for `slaein`

DOUBLE PRECISION for `dlaein`

COMPLEX for `claein`

DOUBLE COMPLEX for `zlaein`.

Workspace array *b*(*ldb, **). The second dimension of *b* must be at least $\max(1, n)$.

ldb

INTEGER. The leading dimension of the array *b*;

ldb ≥ *n+1* for real flavors;

ldb ≥ $\max(1, n)$ for complex flavors.

work

REAL for `slaein`

DOUBLE PRECISION for `dlaein`.

Workspace array, dimension (n).

Used for real flavors only.

rwork

REAL for `claein`

DOUBLE PRECISION for `zlaein`.

Workspace array, dimension (n).

Used for complex flavors only.

<i>eps3, smlnum</i>	REAL for slaein/claein DOUBLE PRECISION for dlaein/zlaein. <i>eps3</i> is a small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.
<i>smlnum</i>	A suggested value for <i>smlnum</i> is <i>slamch('s')</i> * (<i>n</i> / <i>slamch('p')</i>) for slaein/claein or <i>dlamch('s')</i> * (<i>n</i> / <i>dlamch('p')</i>) for dlaein/zlaein. See lamch .
<i>bignum</i>	REAL for slaein DOUBLE PRECISION for dlaein. <i>bignum</i> is a machine-dependent value close to overflow threshold. Used for real flavors only. A suggested value for <i>bignum</i> is $1 / \text{slamch('s')}$ for slaein/claein or $1 / \text{dlamch('s')}$ for dlaein/zlaein.

Output Parameters

<i>vr, vi</i>	On exit, if $w_i = 0.0$ (real eigenvalue), <i>vr</i> contains the computed real eigenvector; if $w_i \neq 0.0$ (complex eigenvalue), <i>vr</i> and <i>vi</i> contain the real and imaginary parts of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $ x + y $. <i>vi</i> is not referenced if $w_i = 0.0$.
<i>v</i>	On exit, <i>v</i> contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $ x + y $.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = 1, inverse iteration did not converge. For real flavors, <i>vr</i> is set to the last iterate, and so is <i>vi</i> , if $w_i \neq 0.0$. For complex flavors, <i>v</i> is set to the last iterate.

?laev2

Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.

Syntax

```
call slaev2( a, b, c, rt1, rt2, cs1, sn1 )
call dlaev2( a, b, c, rt1, rt2, cs1, sn1 )
call claev2( a, b, c, rt1, rt2, cs1, sn1 )
call zlaev2( a, b, c, rt1, rt2, cs1, sn1 )
```

Include Files

- Fortran: mkl.fi

- C: mkl.h

Description

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix} \text{ (for } \text{slaev2/dlaev2) or Hermitian matrix } \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix}$$

(for claev2/zlaev2).

On return, $rt1$ is the eigenvalue of larger absolute value, $rt2$ of smaller absolute value, and $(cs1, sn1)$ is the unit right eigenvector for $rt1$, giving the decomposition

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for slaev2/dlaev2),

or

$$\begin{bmatrix} cs1 & \text{conjg}(sn1) \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -\text{conjg}(sn1) \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for claev2/zlaev2).

Input Parameters

a, b, c

- REAL for slaev2
- DOUBLE PRECISION for dlaev2
- COMPLEX for claev2
- DOUBLE COMPLEX for zlaev2.
- Elements of the input matrix.

Output Parameters

$rt1, rt2$

- REAL for slaev2/claeve2
- DOUBLE PRECISION for dlaev2/zlaev2.
- Eigenvalues of larger and smaller absolute value, respectively.

$cs1$

- REAL for slaev2/claeve2
- DOUBLE PRECISION for dlaev2/zlaev2.

$sn1$

- REAL for slaev2
- DOUBLE PRECISION for dlaev2

COMPLEX for `claev2`
 DOUBLE COMPLEX for `zlaev2`.

The vector ($cs1, sn1$) is the unit right eigenvector for $rt1$.

Application Notes

$rt1$ is accurate to a few ulps barring over/underflow. $rt2$ may be inaccurate if there is massive cancellation in the determinant $a*c - b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute $rt2$ accurately in all cases. $cs1$ and $sn1$ are accurate to a few ulps barring over/underflow. Overflow is possible only if $rt1$ is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds `underflow_threshold / macheps`.

?laexc

Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

```
call slaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
call dlaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine swaps adjacent diagonal blocks T_{11} and T_{22} of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

<i>wantq</i>	LOGICAL. If <i>wantq</i> = .TRUE., accumulate the transformation in the matrix Q ; If <i>wantq</i> = .FALSE., do not accumulate the transformation.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>t, q</i>	REAL for <code>slaexc</code> DOUBLE PRECISION for <code>dlaexc</code> Arrays: $t(ldt, *)$ contains on entry the upper quasi-triangular matrix T , in Schur canonical form. The second dimension of t must be at least $\max(1, n)$.

q(1:dg,)* contains on entry, if *wantq* = .TRUE., the orthogonal matrix *Q*. If *wantq* = .FALSE., *q* is not referenced. The second dimension of *q* must be at least $\max(1, n)$.

ldt INTEGER. The leading dimension of *t*; at least $\max(1, n)$.

ldq INTEGER. The leading dimension of *q*;

If *wantq* = .FALSE., then *ldq* ≥ 1 .

If *wantq* = .TRUE., then *ldq* $\geq \max(1, n)$.

j1 INTEGER. The index of the first row of the first block T_{11} .

n1 INTEGER. The order of the first block T_{11}

(*n1* = 0, 1, or 2).

n2 INTEGER. The order of the second block T_{22}

(*n2* = 0, 1, or 2).

work REAL for *slaexc*;

DOUBLE PRECISION for *dlaexc*.

Workspace array, DIMENSION (*n*).

Output Parameters

t On exit, the updated matrix *T*, again in Schur canonical form.

q On exit, if *wantq* = .TRUE., the updated matrix *Q*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = 1, the transformed matrix *T* would be too far from Schur form; the blocks are not swapped and *T* and *Q* are unchanged.

?lag2

Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.

Syntax

```
call slag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
call dlag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the eigenvalues of a 2×2 generalized eigenvalue problem $A - w * B$, with scaling as necessary to avoid over-/underflow. The scaling factor, s , results in a modified eigenvalue equation

$$s^*A = w^*B,$$

where s is a non-negative scaling factor chosen so that w , w^*B , and s^*A do not overflow and, if possible, do not underflow, either.

Input Parameters

a, b	REAL for slag2 DOUBLE PRECISION for dlag2
Arrays:	
$a(1da,2)$	contains, on entry, the 2×2 matrix A . It is assumed that its 1-norm is less than $1/safmin$. Entries less than $\text{sqrt}(safmin) * \text{norm}(A)$ are subject to being treated as zero.
$b(ldb,2)$	contains, on entry, the 2×2 upper triangular matrix B . It is assumed that the one-norm of B is less than $1/safmin$. The diagonals should be at least $\text{sqrt}(safmin)$ times the largest element of B (in absolute value); if a diagonal is smaller than that, then $+/- \text{sqrt}(safmin)$ will be used instead of that diagonal.
$1da$	INTEGER. The leading dimension of a ; $1da \geq 2$.
$1db$	INTEGER. The leading dimension of b ; $1db \geq 2$.
$safmin$	REAL for slag2; DOUBLE PRECISION for dlag2. The smallest positive number such that $1/safmin$ does not overflow. (This should always be $?lamch('S')$ - it is an argument in order to avoid having to call $?lamch$ frequently.)

Output Parameters

$scale1$	REAL for slag2; DOUBLE PRECISION for dlag2.
	A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are $(wr1 +/- wii)/scale1$ (which may lie outside the exponent range of the machine), $scale1=scale2$, and $scale1$ will always be positive. If the eigenvalues are real, then the first (real) eigenvalue is $wr1/scale1$, but this may overflow or underflow, and in fact, $scale1$ may be zero or less than the underflow threshhold if the exact eigenvalue is sufficiently large.
$scale2$	REAL for slag2; DOUBLE PRECISION for dlag2.
	A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then $scale2=scale1$. If the eigenvalues are real, then the second (real)

eigenvalue is $wr2/scale2$, but this may overflow or underflow, and in fact, $scale2$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

wr1 REAL for slag2;

DOUBLE PRECISION for dlag2.

If the eigenvalue is real, then *wr1* is $scale1$ times the eigenvalue closest to the (2,2) element of $A^*inv(B)$.

If the eigenvalue is complex, then *wr1=wr2* is $scale1$ times the real part of the eigenvalues.

wr2 REAL for slag2;

DOUBLE PRECISION for dlag2.

If the eigenvalue is real, then *wr2* is $scale2$ times the other eigenvalue. If the eigenvalue is complex, then *wr1=wr2* is $scale1$ times the real part of the eigenvalues.

wi REAL for slag2;

DOUBLE PRECISION for dlag2.

If the eigenvalue is real, then *wi* is zero. If the eigenvalue is complex, then *wi* is $scale1$ times the imaginary part of the eigenvalues. *wi* will always be non-negative.

?lags2

Computes 2-by-2 orthogonal matrices U , V , and Q , and applies them to matrices A and B such that the rows of the transformed A and B are parallel.

Syntax

```
call slags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
call dlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
call clags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
call zlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
```

Include Files

- Fortran: mkl.fi

Description

For real flavors, the routine computes 2-by-2 orthogonal matrices U , V and Q , such that if *upper* = .TRUE., then

! ! ! ! ! ! ! ! ! ! ! ! ! ! ! !

and

$$V^T * B * Q = V^T * \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if *upper* = .FALSE., then

$$U^T * A * Q = U^T * \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu & csu \end{bmatrix}, V = \begin{bmatrix} csv & snv \\ -snv & csv \end{bmatrix}, Q = \begin{bmatrix} csq & snq \\ -snq & csq \end{bmatrix}$$

Here Z^T denotes the transpose of Z .

For complex flavors, the routine computes 2-by-2 unitary matrices U , V and Q , such that if *upper* = .TRUE., then

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

and

$$V^H * B * Q = V^H * \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if *upper* = .FALSE., then

$$U^H * A * Q = U^H * \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$V^H * B * Q = V^H * \begin{bmatrix} B_1 & 0 \\ B_2 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu^H & csu \end{bmatrix}, \quad V = \begin{bmatrix} csv & snv \\ -snv^H & csv \end{bmatrix}, \quad Q = \begin{bmatrix} csq & snq \\ -snq^H & csq \end{bmatrix}$$

Input Parameters

<i>upper</i>	LOGICAL.
	If <i>upper</i> = .TRUE., the input matrices A and B are upper triangular; If <i>upper</i> = .FALSE., the input matrices A and B are lower triangular.
<i>a1, a3</i>	REAL for slags2 and clags2 DOUBLE PRECISION for dlags2 and zlags2
<i>a2</i>	REAL for slags2 DOUBLE PRECISION for dlags2 COMPLEX for clags2 COMPLEX*16 for zlags2 On entry, <i>a1, a2</i> and <i>a3</i> are elements of the input 2-by-2 upper (lower) triangular matrix A .
<i>b1, b3</i>	REAL for slags2 and clags2 DOUBLE PRECISION for dlags2 and zlags2
<i>b2</i>	REAL for slags2 DOUBLE PRECISION for dlags2 COMPLEX for clags2 COMPLEX*16 for zlags2 On entry, <i>b1, b2</i> and <i>b3</i> are elements of the input 2-by-2 upper (lower) triangular matrix B .

Output Parameters

<i>csu</i>	REAL for slags2 and clags2 DOUBLE PRECISION for dlags2 and zlags2 Element of the desired orthogonal matrix U .
<i>snu</i>	REAL for slags2 DOUBLE PRECISION for dlags2 Element of the desired orthogonal matrix U . COMPLEX for clags2 COMPLEX*16 for zlags2
<i>csv</i>	REAL for slags2 and clags2 DOUBLE PRECISION for dlags2 and zlags2 Element of the desired orthogonal matrix V .
<i>snv</i>	REAL for slags2 DOUBLE PRECISION for dlags2 COMPLEX for clags2 COMPLEX*16 for zlags2 Element of the desired orthogonal matrix V .
<i>csq</i>	REAL for slags2 and clags2 DOUBLE PRECISION for dlags2 and zlags2 Element of the desired orthogonal matrix Q .
<i>sng</i>	REAL for slags2 DOUBLE PRECISION for dlags2 Element of the desired orthogonal matrix Q . COMPLEX for clags2 COMPLEX*16 for zlags2

?lagtf

Computes an LU factorization of a matrix $T - \lambda * I$, where T is a general tridiagonal matrix, and λ is a scalar, using partial pivoting with row interchanges.

Syntax

```
call slagtf( n, a, lambda, b, c, tol, d, in, info )
call dlagtf( n, a, lambda, b, c, tol, d, in, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine factorizes the matrix ($T - \lambda I$), where T is an n -by- n tridiagonal matrix and λ is a scalar, as

$$T - \lambda I = P^* L^* U,$$

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column. The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling. The parameter λ is included in the routine so that ?lagtf may be used, in conjunction with ?lagts, to obtain eigenvectors of T by inverse iteration.

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
a, b, c	REAL for slagtf DOUBLE PRECISION for dlagtf Arrays, dimension $a(n), b(n-1), c(n-1)$: On entry, $a(*)$ must contain the diagonal elements of the matrix T . On entry, $b(*)$ must contain the $(n-1)$ super-diagonal elements of T . On entry, $c(*)$ must contain the $(n-1)$ sub-diagonal elements of T .
tol	REAL for slagtf DOUBLE PRECISION for dlagtf On entry, a relative tolerance used to indicate whether or not the matrix ($T - \lambda I$) is nearly singular. tol should normally be chose as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then tol should be set to about 5×10^{-4} . If tol is supplied as less than eps , where eps is the relative machine precision, then the value eps is used in place of tol .

Output Parameters

a	On exit, a is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .
b	On exit, b is overwritten by the $n-1$ super-diagonal elements of the matrix U of the factorization of T .
c	On exit, c is overwritten by the $n-1$ sub-diagonal elements of the matrix L of the factorization of T .
d	REAL for slagtf DOUBLE PRECISION for dlagtf Array, dimension $(n-2)$. On exit, d is overwritten by the $n-2$ second super-diagonal elements of the matrix U of the factorization of T .
in	INTEGER.

Array, dimension (n).

On exit, in contains details of the permutation matrix p . If an interchange occurred at the k -th step of the elimination, then $in(k) = 1$, otherwise $in(k) = 0$. The element $in(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}((T - \lambda I)(j)) * \text{tol},$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the j -th row of the matrix A .

If no such j exists then $in(n)$ is returned as zero. If $in(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \lambda I)$ is singular or nearly singular.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -k$, the k -th parameter had an illegal value.

?lagtm

Performs a matrix-matrix product of the form $C = \alpha A^*B + \beta C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.

Syntax

```
call slagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call dlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call clagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call zlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs a matrix-vector product of the form:

$$B := \alpha A^*X + \beta B$$

where A is a tridiagonal matrix of order n , B and X are n -by- $nrhs$ matrices, and α and β are real scalars, each of which may be 0., 1., or -1.

Input Parameters

$trans$

CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If $trans = 'N'$, then $B := \alpha A^*X + \beta B$ (no transpose);

If $trans = 'T'$, then $B := \alpha A^T X + \beta B$ (transpose);

If $\text{trans} = \text{'C'}$, then $B := \alpha A^H X + \beta B$ (conjugate transpose)

n INTEGER. The order of the matrix A ($n \geq 0$).

$nrhs$ INTEGER. The number of right-hand sides, i.e., the number of columns in X and B ($nrhs \geq 0$).

α, β REAL for `slagtm/clagtm`

DOUBLE PRECISION for `dlagtm/zlagtm`

Specify the scalars α and β respectively. α must be 0., 1., or -1.; otherwise, it is assumed to be 0. β must be 0., 1., or -1.; otherwise, it is assumed to be 1.

d_l, d, du REAL for `slagtm`

DOUBLE PRECISION for `dlagtm`

COMPLEX for `clagtm`

DOUBLE COMPLEX for `zlagtm`.

Arrays: $d_l(n - 1), d(n), du(n - 1)$.

The array d_l contains the $(n - 1)$ sub-diagonal elements of T .

The array d contains the n diagonal elements of T .

The array du contains the $(n - 1)$ super-diagonal elements of T .

x, b REAL for `slagtm`

DOUBLE PRECISION for `dlagtm`

COMPLEX for `clagtm`

DOUBLE COMPLEX for `zlagtm`.

Arrays:

$x(1:idx, :)$ contains the n -by- $nrhs$ matrix X . The second dimension of x must be at least $\max(1, nrhs)$.

$b(1:db, :)$ contains the n -by- $nrhs$ matrix B . The second dimension of b must be at least $\max(1, nrhs)$.

idx INTEGER. The leading dimension of the array x ; $idx \geq \max(1, n)$.

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the matrix expression $B := \alpha A^H X + \beta B$

?lagts

Solves the system of equations $(T - \lambda I)^T x = y$ or $(T - \lambda I)x = y$, where T is a general tridiagonal matrix and λ is a scalar, using the LU factorization computed by ?lagtf.

Syntax

```
call slagts( job, n, a, b, c, d, in, y, tol, info )
call dlagts( job, n, a, b, c, d, in, y, tol, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine may be used to solve for x one of the systems of equations:

$$(T - \lambda I)x = y \text{ or } (T - \lambda I)^T x = y,$$

where T is an n -by- n tridiagonal matrix, following the factorization of $(T - \lambda I)$ as

$$T - \lambda I = P^* L^* U,$$

computed by the routine [?lagtf](#).

The choice of equation to be solved is controlled by the argument *job*, and in each case there is an option to perturb zero or very small diagonal elements of U , this option being intended for use in applications such as inverse iteration.

Input Parameters

<i>job</i>	INTEGER. Specifies the job to be performed by ?lagts as follows:
= 1:	The equations $(T - \lambda I)x = y$ are to be solved, but diagonal elements of U are not to be perturbed.
= -1:	The equations $(T - \lambda I)x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below.
= 2:	The equations $(T - \lambda I)^T x = y$ are to be solved, but diagonal elements of U are not to be perturbed.
= -2:	The equations $(T - \lambda I)^T x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>c</i> , <i>d</i>	REAL for slagts DOUBLE PRECISION for dlagts Arrays, dimension $a(n)$, $b(n-1)$, $c(n-1)$, $d(n-2)$: On entry, $a(*)$ must contain the diagonal elements of U as returned from ?lagtf . On entry, $b(*)$ must contain the first super-diagonal elements of U as returned from ?lagtf . On entry, $c(*)$ must contain the sub-diagonal elements of L as returned from ?lagtf . On entry, $d(*)$ must contain the second super-diagonal elements of U as returned from ?lagtf .

in INTEGER.
 Array, dimension (*n*).
 On entry, *in*(*) must contain details of the matrix *p* as returned from ?lagtf.

y REAL for slagts
 DOUBLE PRECISION for dlagts
 Array, dimension (*n*). On entry, the right hand side vector *y*.

tol REAL for slagtf
 DOUBLE PRECISION for dlagtf.
 On entry, with *job* < 0, *tol* should be the minimum perturbation to be made to very small diagonal elements of *U*. *tol* should normally be chosen as about *eps**norm(*U*), where *eps* is the relative machine precision, but if *tol* is supplied as non-positive, then it is reset to *eps**max(abs(*u*(*i*,*j*))). If *job* > 0 then *tol* is not referenced.

Output Parameters

y On exit, *y* is overwritten by the solution vector *x*.

tol On exit, *tol* is changed as described in *Input Parameters* section above, only if *tol* is non-positive on entry. Otherwise *tol* is unchanged.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value. If *info* = *i* > 0, overflow would occur when computing the *i*th element of the solution vector *x*. This can only occur when *job* is supplied as positive and either means that a diagonal element of *U* is very small, or that the elements of the right-hand side vector *y* are very large.

?lagv2

Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (*A,B*) where *B* is upper triangular.

Syntax

```
call slagv2( a, lda, b, ldb, alphai, beta, csl, snl, csr, snr )
call dlagv2( a, lda, b, ldb, alphai, beta, csl, snl, csr, snr )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular. The routine computes orthogonal (rotation) matrices given by csl, snl and csr, snr such that:

1) if the pencil (A, B) has two real eigenvalues (include 0/0 or 1/0 types), then

$$\begin{bmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{bmatrix} = \begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

2) if the pencil (A, B) has a pair of complex conjugate eigenvalues, then

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & 0 \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

where $b_{11} \geq b_{22} > 0$.

Input Parameters

a, b	REAL for slagv2 DOUBLE PRECISION for dlagv2
	Arrays: $a(lda,2)$ contains the 2-by-2 matrix A ; $b(ldb,2)$ contains the upper triangular 2-by-2 matrix B .

lda	INTEGER. The leading dimension of the array a ; $lda \geq 2$.
-------	---

ldb	INTEGER. The leading dimension of the array b ; $ldb \geq 2$.
-------	---

Output Parameters

a	On exit, a is overwritten by the "A-part" of the generalized Schur form.
b	On exit, b is overwritten by the "B-part" of the generalized Schur form.
$alphar, alphai, beta$	REAL for slagv2

DOUBLE PRECISION for dlagv2.

Arrays, dimension (2) each.

$(\alpha_{phar}(k) + i * \alpha_{phai}(k)) / \beta(k)$ are the eigenvalues of the pencil (A, B) , $k=1, 2$ and $i = \sqrt{-1}$.

Note that $\beta(k)$ may be zero.

csl, snl

REAL for slagv2

DOUBLE PRECISION for dlagv2

The cosine and sine of the left rotation matrix, respectively.

csr, snr

REAL for slagv2

DOUBLE PRECISION for dlagv2

The cosine and sine of the right rotation matrix, respectively.

?lahqr

Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.

Syntax

```
call slahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, info )
call dlahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, info )
call clahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
call zlahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns ilo to ihi .

Input Parameters

$wantt$

LOGICAL.

If $wantt = .TRUE..$, the full Schur form T is required;

If $wantt = .FALSE..$, eigenvalues only are required.

$wantz$

LOGICAL.

If $wantz = .TRUE..$, the matrix of Schur vectors Z is required;

If $wantz = .FALSE..$, Schur vectors are not required.

n

INTEGER. The order of the matrix H ($n \geq 0$).

ilo, ihi

INTEGER.

It is assumed that h is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $h(ilo, ilo-1) = 0$ (unless $ilo = 1$). The routine ?lahqr works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of h if $wantt = .TRUE..$

Constraints:

$$1 \leq ilo \leq \max(1, ihi); \quad ihi \leq n.$$
h, z

REAL for slahqr

DOUBLE PRECISION for dlahqr

COMPLEX for clahqr

DOUBLE COMPLEX for zlahqr.

Arrays:

 $h(ldh, *)$ contains the upper Hessenberg matrix h .The second dimension of h must be at least $\max(1, n)$. $z(ldz, *)$ If $wantz = .TRUE..$, then, on entry, z must contain the current matrix z of transformations accumulated by ?hseqr.If $wantz = .FALSE..$, then z is not referenced. The second dimension of z must be at least $\max(1, n)$.*ldh*INTEGER. The leading dimension of h ; at least $\max(1, n)$.*ldz*INTEGER. The leading dimension of z ; at least $\max(1, n)$.*iloz, ihiz*INTEGER. Specify the rows of z to which transformations must be applied if $wantz = .TRUE..$

$$1 \leq iloz \leq ilo; \quad ihi \leq ihiz \leq n.$$

Output Parameters

*h*On exit, if $info = 0$ and $wantt = .TRUE..$, then,

- for slahqr/dlahqr, h is upper quasi-triangular in rows and columns $ilo:ihi$ with any 2-by-2 diagonal blocks in standard form.
- for clahqr/zlahqr, h is upper triangular in rows and columns $ilo:ihi$.

If $info = 0$ and $wantt = .FALSE..$, the contents of h are unspecified on exit.If $info$ is positive, see description of $info$ for the output state of h .*wr, wi*

REAL for slahqr

DOUBLE PRECISION for dlahqr

Arrays, DIMENSION at least $\max(1, n)$ each. Used with real flavors only.The real and imaginary parts, respectively, of the computed eigenvalues ilo to ihi are stored in the corresponding elements of wr and wi . If two

eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi(i) > 0$ and $wi(i+1) < 0$.

If $wantt = .TRUE.$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $wr(i) = h(i,i)$, and, if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, $wi(i) = \sqrt{h(i+1,i)*h(i,i+1)}$ and $wi(i+1) = -wi(i)$.

w

COMPLEX for `clahqr`

DOUBLE COMPLEX for `zlahqr`.

Array, DIMENSION at least $\max(1, n)$. Used with complex flavors only. The computed eigenvalues ilo to ih_i are stored in the corresponding elements of w .

If $wantt = .TRUE.$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $w(i) = h(i,i)$.

z

If $wantz = .TRUE.$, then, on exit z has been updated; transformations are applied only to the submatrix $z(iloz:ihiz, ilo:ih_i)$.

info

INTEGER.

If $info = 0$, the execution is successful.

With $info > 0$,

- if $info = i$, `?lahqr` failed to compute all the eigenvalues ilo to ih_i in a total of 30 iterations per eigenvalue; elements $i+1:ih_i$ of wr and wi (for `slahqr/dlahqr`) or w (for `clahqr/zlahqr`) contain those eigenvalues which have been successfully computed.
- if $wantt$ is $.FALSE.$, then on exit the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through $info$ of the final output value of h .
- if $wantt$ is $.TRUE.$, then on exit
 $(\text{initial value of } h)*u = u*(\text{final value of } h)$, (*)
where u is an orthogonal matrix. The final value of h is upper Hessenberg and triangular in rows and columns $info+1$ through ih_i .
- if $wantz$ is $.TRUE.$, then on exit
 $(\text{final value of } z) = (\text{initial value of } z)*u$,
where u is an orthogonal matrix in (*) regardless of the value of $wantt$.

?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .

Syntax

```
call slahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

```
call zlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation $Q^T * A * Q$ for real flavors, or $Q^H * A * Q$ for complex flavors. The routine returns the matrices V and T which determine Q as a block reflector $I - V^* T^* V^T$ (for real flavors) or $I - V^* T^* V^H$ (for complex flavors), and also the matrix $Y = A^* V^* T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v^* v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v^* v^H \text{ for complex flavors, or}$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an obsolete auxiliary routine. Please use the new routine ?lahr2 instead.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>k</i>	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
<i>nb</i>	INTEGER. The number of columns to be reduced.
<i>a</i>	REAL for slahrd DOUBLE PRECISION for dlahrd COMPLEX for clahrd DOUBLE COMPLEX for zlahrd. Array $a(la, n-k+1)$ contains the n -by- $(n-k+1)$ general matrix A to be reduced.
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
<i>ldt</i>	INTEGER. The leading dimension of the output array t ; must be at least $\max(1, nb)$.
<i>ldy</i>	INTEGER. The leading dimension of the output array y ; must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k -th subdiagonal, with the array <i>tau</i> , represent the matrix Q as a product of elementary reflectors. The other columns of <i>a</i> are unchanged. See <i>Application Notes</i> below.
<i>tau</i>	<p>REAL for <code>slahrd</code></p> <p>DOUBLE PRECISION for <code>dlahrd</code></p> <p>COMPLEX for <code>clahrd</code></p> <p>DOUBLE COMPLEX for <code>zlahrd</code>.</p> <p>Array, DIMENSION (nb).</p> <p>Contains scalar factors of the elementary reflectors.</p>
<i>t, y</i>	<p>REAL for <code>slahrd</code></p> <p>DOUBLE PRECISION for <code>dlahrd</code></p> <p>COMPLEX for <code>clahrd</code></p> <p>DOUBLE COMPLEX for <code>zlahrd</code>.</p> <p>Arrays, dimension $t(ldt, nb)$, $y(ldy, nb)$.</p> <p>The array <i>t</i> contains upper triangular matrix T.</p> <p>The array <i>y</i> contains the n-by-nb matrix Y.</p>

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in *a*($i+k+1:n$, *i*) and *tau* is stored in *tau*(*i*).

The elements of the vectors *v* together form the $(n-k+1)$ -by- nb matrix *V* which is needed, with *T* and *Y*, to apply the transformation to the unreduced part of the matrix, using an update of the form:

$A := (I - V^* T^* V^T) * (A - Y^* V^T)$ for real flavors, or

$A := (I - V^* T^* V^H) * (A - Y^* V^H)$ for complex flavors.

The contents of *A* on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?lahr2

?lahr2

Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A.

Syntax

```
call slahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation $Q^T * A * Q$ for real flavors, or $Q^H * A * Q$ for complex flavors. The routine returns the matrices V and T which determine Q as a block reflector $I - V^* T^* V^T$ (for real flavors) or $I - V^* T^* V^H$ (for real flavors), and also the matrix $Y = A^* V^* T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1)^* H(2)^* \dots ^* H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v^* v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v^* v^* v^H \text{ for complex flavors}$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an auxiliary routine called by ?gehrd.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero ($k < n$).
nb	INTEGER. The number of columns to be reduced.
a	REAL for slahr2 DOUBLE PRECISION for dlahr2

COMPLEX for `clahr2`
DOUBLE COMPLEX for `zlahr2`.

Array, DIMENSION ($lda, n-k+1$) contains the n -by- $(n-k+1)$ general matrix A to be reduced.

`lda` INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.

`ldt` INTEGER. The leading dimension of the output array t ; $ldt \geq nb$.

`ldy` INTEGER. The leading dimension of the output array y ; $ldy \geq n$.

Output Parameters

`a` On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k -th subdiagonal, with the array `tau`, represent the matrix Q as a product of elementary reflectors. The other columns of a are unchanged. See *Application Notes* below.

`tau` REAL for `slahr2`
DOUBLE PRECISION for `dlahr2`
COMPLEX for `clahr2`
DOUBLE COMPLEX for `zlahr2`.
Array, DIMENSION (nb).
Contains scalar factors of the elementary reflectors.

`t, y` REAL for `slahr2`
DOUBLE PRECISION for `dlahr2`
COMPLEX for `clahr2`
DOUBLE COMPLEX for `zlahr2`.
Arrays, dimension $t(ldt, nb), y(ldy, nb)$.
The array t contains upper triangular matrix T .
The array y contains the n -by- nb matrix Y .

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0, v(i+k) = 1; v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and `tau` is stored in `tau(i)`.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form:

$A := (I - V^* T^* V^T) * (A - Y^* V^T)$ for real flavors, or

$A := (I - V^* T^* V^H) * (A - Y^* V^H)$ for complex flavors.

The contents of A on exit are illustrated by the following example with $n = 7, k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & a & a & a & a \\ a & a & a & a & a \\ a & a & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?laic1

Applies one step of incremental condition estimation.

Syntax

```
call slaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call dlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call claic1( job, j, x, sest, w, gamma, sestpr, s, c )
call zlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laic1 applies one step of incremental condition estimation in its simplest version.

Let x , $\|x\|_2 = 1$ (where $\|a\|_2$ denotes the 2-norm of a), be an approximate singular vector of an j -by- j lower triangular matrix L , such that

$$\|L^*x\|_2 = sest$$

Then ?laic1 computes $sestpr, s, c$ such that the vector

$$\hat{x} = \begin{bmatrix} s^*x \\ c \end{bmatrix}$$

is an approximate singular vector of

$$\hat{L} = \begin{bmatrix} L & 0 \\ w^T & \gamma \end{bmatrix} \text{ (for complex flavors), or}$$

$$\hat{L} = \begin{bmatrix} L & 0 \\ w^T & \gamma \end{bmatrix} \text{ (for real flavors), in the sense that}$$

$$\|\hat{L}^*\hat{x}\|_2 = sestpr.$$

Depending on job , an estimate for the largest or smallest singular value is computed.

For real flavors, $[s \ c]^T$ and $sestpr^2$ is an eigenpair of the system

$$\text{diag}(sest^*sest, 0) + [\alpha \ \gamma] * \begin{bmatrix} \alpha \\ \gamma \end{bmatrix}$$

where $\alpha = x^T w$.

For complex flavors, $[s \ c]^H$ and $sestpr^2$ is an eigenpair of the system

$$\text{diag}(sest^*sest, 0) + [\alpha \ \gamma] * \begin{bmatrix} \text{conj}(\alpha) \\ \text{conj}(\gamma) \end{bmatrix}$$

where $\alpha = x^H w$.

Input Parameters

<i>job</i>	INTEGER. If <i>job</i> =1, an estimate for the largest singular value is computed; If <i>job</i> =2, an estimate for the smallest singular value is computed;
<i>j</i>	INTEGER. Length of <i>x</i> and <i>w</i> .
<i>x, w</i>	REAL for <i>slaic1</i> DOUBLE PRECISION for <i>dlaic1</i> COMPLEX for <i>claic1</i> DOUBLE COMPLEX for <i>zlaic1</i> . Arrays, dimension (<i>j</i>) each. Contain vectors <i>x</i> and <i>w</i> , respectively.
<i>sest</i>	REAL for <i>slaic1/claic1</i> ; DOUBLE PRECISION for <i>dlaic1/zlaic1</i> . Estimated singular value of <i>j</i> -by- <i>j</i> matrix <i>L</i> .
<i>gamma</i>	REAL for <i>slaic1</i> DOUBLE PRECISION for <i>dlaic1</i> COMPLEX for <i>claic1</i> DOUBLE COMPLEX for <i>zlaic1</i> . The diagonal element <i>gamma</i> .

Output Parameters

<i>sestpr</i>	REAL for <i>slaic1/claic1</i> ; DOUBLE PRECISION for <i>dlaic1/zlaic1</i> . Estimated singular value of (<i>j</i> +1)-by-(<i>j</i> +1) matrix <i>Lhat</i> .
---------------	---

?ln2

Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.

Syntax

```

call slaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx, scale,
xnorm, info )

call dlaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx, scale,
xnorm, info )

```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine solves a system of the form

$$(ca^*A - w^*D)^*X = s^*B, \text{ or } (ca^*A^T - w^*D)^*X = s^*B$$

with possible scaling (s) and perturbation of A .

A is an na -by- na real matrix, *ca* is a real scalar, *D* is an na -by- na real diagonal matrix, *w* is a real or complex value, and *X* and *B* are na -by-1 matrices: real if *w* is real, complex if *w* is complex. The parameter *na* may be 1 or 2.

If w is complex, X and B are represented as na -by-2 matrices, the first column of each being the real part and the second being the imaginary part.

The routine computes the scaling factor s (≤ 1) so chosen that X can be computed without overflow. X is further scaled if necessary to assure that $\text{norm}(ca^*A - w^*D) * \text{norm}(X)$ is less than overflow.

If both singular values of $(ca^*A - w^*D)$ are less than $smin$, $smin*I$ (where I stands for identity) will be used instead of $(ca^*A - w^*D)$. If only one singular value is less than $smin$, one element of $(ca^*A - w^*D)$ will be perturbed enough to make the smallest singular value roughly $smin$.

If both singular values are at least $smin$, $(ca^*A - w^*D)$ will not be perturbed. In any case, the perturbation will be at most some small multiple of $\max(smin, ulp * \text{norm}(ca^*A - w^*D))$.

The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

NOTE

All input quantities are assumed to be smaller than overflow by a reasonable factor (see *bignum*).

Input Parameters

<i>trans</i>	LOGICAL. If <i>trans</i> = .TRUE., <i>A</i> - transpose will be used. If <i>trans</i> = .FALSE., <i>A</i> will be used (not transposed.)
<i>na</i>	INTEGER. The size of the matrix <i>A</i> , possible values 1 or 2.
<i>nw</i>	INTEGER. This parameter must be 1 if <i>w</i> is real, and 2 if <i>w</i> is complex. Possible values 1 or 2.
<i>smin</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . The desired lower bound on the singular values of <i>A</i> . This should be a safe distance away from underflow or overflow, for example, between (<i>underflow/machine_precision</i>) and (<i>machine_precision * overflow</i>). (See <i>bignum</i> and <i>ulp</i>).
<i>ca</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . The coefficient by which <i>A</i> is multiplied.
<i>a</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . Array, DIMENSION (<i>lda,na</i>). The <i>na</i> -by- <i>na</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> . Must be at least <i>na</i> .
<i>d1, d2</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . The (1,1) and (2,2) elements in the diagonal matrix <i>D</i> , respectively. <i>d2</i> is not used if <i>nw</i> = 1.
<i>b</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . Array, DIMENSION (<i>ldb,nw</i>). The <i>na</i> -by- <i>nw</i> matrix <i>B</i> (right-hand side). If <i>nw</i> = 2 (<i>w</i> is complex), column 1 contains the real part of <i>B</i> and column 2 contains the imaginary part.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> . Must be at least <i>na</i> .
<i>wr, wi</i>	REAL for <i>slaln2</i> DOUBLE PRECISION for <i>dlaln2</i> . The real and imaginary part of the scalar <i>w</i> , respectively. <i>wi</i> is not used if <i>nw</i> = 1.

lidx INTEGER. The leading dimension of the output array *x*. Must be at least *na*.

Output Parameters

<i>x</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2. Array, DIMENSION (<i>lidx,nw</i>). The <i>na</i> -by- <i>nw</i> matrix <i>X</i> (unknowns), as computed by the routine. If <i>nw</i> = 2 (<i>w</i> is complex), on exit, column 1 will contain the real part of <i>X</i> and column 2 will contain the imaginary part.
<i>scale</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2. The scale factor that <i>B</i> must be multiplied by to insure that overflow does not occur when computing <i>X</i> . Thus $(ca^*A - w^*D) \cdot X$ will be <i>scale*B</i> , not <i>B</i> (ignoring perturbations of <i>A</i> .) It will be at most 1.
<i>xnorm</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2. The infinity-norm of <i>X</i> , when <i>X</i> is regarded as an <i>na</i> -by- <i>nw</i> real matrix.
<i>info</i>	INTEGER. An error flag. It will be zero if no error occurs, a negative number if an argument is in error, or a positive number if $(ca^*A - w^*D)$ had to be perturbed. The possible values are: If <i>info</i> = 0: no error occurred, and $(ca^*A - w^*D)$ did not have to be perturbed. If <i>info</i> = 1: $(ca^*A - w^*D)$ had to be perturbed to make its smallest (or only) singular value greater than <i>smin</i> .

NOTE

For higher speed, this routine does not check the inputs for errors.

?lals0

Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd.

Syntax

```
call slals0( icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call dlals0( icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call clals0( icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
```

```
call zlals0( icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine applies back the multiplying factors of either the left or right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is $givptr$; the pairs of columns/rows they were applied to are stored in $givcol$; and the c - and s -values of these rotations are stored in $givnum$.

(2L) Permutation. The $(n+1)$ -st row of B is to be moved to the first row, and for $j=2:n$, $perm(j)$ -th row of B is to be moved to the j -th row.

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If $sqre = 1$, one extra Givens rotation to generate the right null space.

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Input Parameters

<i>icompq</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: If <i>icompq</i> = 0: Left singular vector matrix. If <i>icompq</i> = 1: Right singular vector matrix.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. If <i>sqre</i> = 0: the lower block is an nr -by- nr square matrix. If <i>sqre</i> = 1: the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.
<i>nrhs</i>	INTEGER. The number of columns of B and bx . Must be at least 1.
<i>b</i>	REAL for slals0

DOUBLE PRECISION **for** `dlals0`
COMPLEX for `clals0`
DOUBLE COMPLEX for `zlals0.`
Array, DIMENSION (*ldb, nrhs*).

Contains the right hand sides of the least squares problem in rows 1 through *m*.

ldb
INTEGER. The leading dimension of *b*.
Must be at least $\max(1, \max(m, n))$.

bx
REAL for `slals0`
DOUBLE PRECISION for `dlals0`
COMPLEX for `clals0`
DOUBLE COMPLEX for `zlals0.`
Workspace array, DIMENSION (*ldbx, nrhs*).

ldbx
INTEGER. The leading dimension of *bx*.

perm
INTEGER. Array, DIMENSION (*n*).
The permutations (from deflation and sorting) applied to the two blocks.

givptr
INTEGER. The number of Givens rotations which took place in this subproblem.

givcol
INTEGER. Array, DIMENSION (*ldgcol, 2*). Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.

ldgcol
INTEGER. The leading dimension of *givcol*, must be at least *n*.

givnum
REAL for `slals0/clals0`
DOUBLE PRECISION for `dlals0/zlals0`
Array, DIMENSION (*ldgnum, 2*). Each number indicates the *c* or *s* value used in the corresponding Givens rotation.

ldgnum
INTEGER. The leading dimension of arrays *difr*, *poles* and *givnum*, must be at least *k*.

poles
REAL for `slals0/clals0`
DOUBLE PRECISION for `dlals0/zlals0`
Array, DIMENSION (*ldgnum, 2*). On entry, *poles(1:k, 1)* contains the new singular values obtained from solving the secular equation, and *poles(1:k, 2)* is an array containing the poles in the secular equation.

difl
REAL for `slals0/clals0`
DOUBLE PRECISION for `dlals0/zlals0`

Array, DIMENSION (k). On entry, $dif(i)$ is the distance between i -th updated (undeflated) singular value and the i -th (undeflated) old singular value.

difr

REAL for slals0/clals0

DOUBLE PRECISION for dlals0/zlals0

Array, DIMENSION ($ldgnum, 2$). On entry, $difr(i, 1)$ contains the distances between i -th updated (undeflated) singular value and the $i+1$ -th (undeflated) old singular value. And $difr(i, 2)$ is the normalizing factor for the i -th right singular vector.

z

REAL for slals0/clals0

DOUBLE PRECISION for dlals0/zlals0

Array, DIMENSION (k). Contains the components of the deflation-adjusted updating row vector.

K

INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.

c

REAL for slals0/clals0

DOUBLE PRECISION for dlals0/zlals0

Contains garbage if $sqre = 0$ and the c value of a Givens rotation related to the right null space if $sqre = 1$.

s

REAL for slals0/clals0

DOUBLE PRECISION for dlals0/zlals0

Contains garbage if $sqre = 0$ and the s value of a Givens rotation related to the right null space if $sqre = 1$.

work

REAL for slals0

DOUBLE PRECISION for dlals0

Workspace array, DIMENSION (k). Used with real flavors only.

rwork

REAL for clals0

DOUBLE PRECISION for zlals0

Workspace array, DIMENSION ($k*(1+rhs) + 2*rhs$). Used with complex flavors only.

Output Parameters

b

On exit, contains the solution X in rows 1 through n .

info

INTEGER.

If $info = 0$: successful exit.

If $info = -i < 0$, the i -th argument had an illegal value.

?lalsa

Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd.

Syntax

```
call slalsa( icompq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
call dlalsa( icompq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
call clalsa( icompq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork, info )
call zlalsa( icompq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork, info )
```

Description

The routine is an intermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form. The singular vectors are computed as products of simple orthogonal matrices.

If $icompq = 0$, ?lalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if $icompq = 1$, the routine applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in the compact form by ?lalsa.

Input Parameters

<i>icompq</i>	INTEGER. Specifies whether the left or the right singular vector matrix is involved. If <i>icompq</i> = 0: left singular vector matrix is used If <i>icompq</i> = 1: right singular vector matrix is used.
<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The row and column dimensions of the upper bidiagonal matrix.
<i>nrhs</i>	INTEGER. The number of columns of <i>b</i> and <i>bx</i> . Must be at least 1.
<i>b</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa DOUBLE COMPLEX for zlalsa Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). Contains the right hand sides of the least squares problem in rows 1 through <i>m</i> .

<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, \max(m, n))$.
<i>ldbx</i>	INTEGER. The leading dimension of the output array <i>bx</i> .
<i>u</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, smlsiz</i>) . On entry, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>ldu</i>	INTEGER, $ldu \geq n$. The leading dimension of arrays <i>u, vt, difl, difr, poles, givnum</i> , and <i>z</i> .
<i>vt</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, smlsiz +1</i>) . On entry, vt^T (for real flavors) or vt^H (for complex flavors) contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	INTEGER array, DIMENSION (<i>n</i>).
<i>difl</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, nlvl</i>) , where $nlvl = \text{int}(\log_2(n / (smlsiz+1))) + 1$.
<i>difr</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, 2*nlvl</i>) . On entry, <i>difl(*, i)</i> and <i>difr(*, 2<i>i</i>-1)</i> record distances between singular values on the <i>i</i> -th level and singular values on the (<i>i</i> -1)-th level, and <i>difr(*, 2<i>i</i>)</i> record the normalizing factors of the right singular vectors matrices of subproblems on <i>i</i> -th level.
<i>z</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, nlvl</i>) . On entry, <i>z(1, i)</i> contains the components of the deflation- adjusted updating the row vector for subproblems on the <i>i</i> -th level.
<i>poles</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu, 2*nlvl</i>) . On entry, <i>poles(*, 2<i>i</i>-1: 2<i>i</i>)</i> contains the new and old singular values involved in the secular equations on the <i>i</i> -th level.
<i>givptr</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, <i>givptr(i)</i> records the number of Givens rotations performed on the <i>i</i> -th problem on the computation tree.

<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , $2*nvl$). On entry, for each i , <i>givcol</i> (*, $2i-1 : 2i$) records the locations of Givens rotations performed on the i -th level on the computation tree.
<i>ldgcol</i>	INTEGER, <i>ldgcol</i> $\geq n$. The leading dimension of arrays <i>givcol</i> and <i>perm</i> .
<i>perm</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , nvl). On entry, <i>perm</i> (*, i) records permutations done on the i -th level of the computation tree.
<i>givnum</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , $2*nvl$). On entry, <i>givnum</i> (*, $2i-1 : 2i$) records the <i>c</i> and <i>s</i> values of Givens rotations performed on the i -th level on the computation tree.
<i>c</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (n). On entry, if the i -th subproblem is not square, <i>c</i> (i) contains the <i>c</i> value of a Givens rotation related to the right null space of the i -th subproblem.
<i>s</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (n). On entry, if the i -th subproblem is not square, <i>s</i> (i) contains the <i>s</i> -value of a Givens rotation related to the right null space of the i -th subproblem.
<i>work</i>	REAL for slalsa DOUBLE PRECISION for dlalsa Workspace array, DIMENSION at least (n). Used with real flavors only.
<i>rwork</i>	REAL for clalsa DOUBLE PRECISION for zlalsa Workspace array, DIMENSION at least $\max(n, (smlsz+1)*nrhs*3)$. Used with complex flavors only.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least ($3n$).

Output Parameters

<i>b</i>	On exit, contains the solution X in rows 1 through n .
<i>bx</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa DOUBLE COMPLEX for zlalsa

Array, DIMENSION ($ldb, nrhs$). On exit, the result of applying the left or right singular vector matrix to b .

info INTEGER. If $info = 0$: successful exit

If $info = -i < 0$, the i -th argument had an illegal value.

?lalsd

Uses the singular value decomposition of A to solve the least squares problem.

Syntax

```
call slalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork, info )
call dlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork, info )
call clalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork, iwork,
info )

info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A^*X-B , where A is n -by- n upper bidiagonal, and X and B are n -by- $nrhs$. The solution X overwrites B .

The singular values of A smaller than $rcond$ times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in d in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.

It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Input Parameters

<i>uplo</i>	CHARACTER*1. If $uplo = 'U'$, d and e define an upper bidiagonal matrix. If $uplo = 'L'$, d and e define a lower bidiagonal matrix.
<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The dimension of the bidiagonal matrix. $n \geq 0$.

<i>nrhs</i>	INTEGER. The number of columns of <i>B</i> . Must be at least 1.
<i>d</i>	<p>REAL for <i>slalsd/clalsd</i></p> <p>DOUBLE PRECISION for <i>dlalsd/zlalsd</i></p> <p>Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.</p>
<i>e</i>	<p>REAL for <i>slalsd/clalsd</i></p> <p>DOUBLE PRECISION for <i>dlalsd/zlalsd</i></p> <p>Array, DIMENSION (<i>n-1</i>). Contains the super-diagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.</p>
<i>b</i>	<p>REAL for <i>slalsd</i></p> <p>DOUBLE PRECISION for <i>dlalsd</i></p> <p>COMPLEX for <i>clalsd</i></p> <p>DOUBLE COMPLEX for <i>zlalsd</i></p> <p>Array, DIMENSION (<i>ldb,nrhs</i>).</p> <p>On input, <i>b</i> contains the right hand sides of the least squares problem. On output, <i>b</i> contains the solution <i>X</i>.</p>
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, n)$.
<i>rcond</i>	<p>REAL for <i>slalsd/clalsd</i></p> <p>DOUBLE PRECISION for <i>dlalsd/zlalsd</i></p> <p>The singular values of <i>A</i> less than or equal to <i>rcond</i> times the largest singular value are treated as zero in solving the least squares problem. If <i>rcond</i> is negative, machine precision is used instead. For example, for the least squares problem <i>diag(S)*X=B</i>, where <i>diag(S)</i> is a diagonal matrix of singular values, the solution is $X(i)=B(i)/S(i)$ if <i>S(i)</i> is greater than <i>rcond *max(S)</i>, and $X(i)=0$ if <i>S(i)</i> is less than or equal to <i>rcond *max(S)</i>.</p>
<i>rank</i>	INTEGER. The number of singular values of <i>A</i> greater than <i>rcond</i> times the largest singular value.
<i>work</i>	<p>REAL for <i>slalsd</i></p> <p>DOUBLE PRECISION for <i>dlalsd</i></p> <p>COMPLEX for <i>clalsd</i></p> <p>DOUBLE COMPLEX for <i>zlalsd</i></p> <p>Workspace array.</p> <p>DIMENSION for real flavors at least</p> $(9n+2n*smlsiz+8n*nlvl+n*nrhs+(smlsiz+1)^2),$ <p>where</p> <p><i>nlvl</i> = $\max(0, \text{int}(\log_2(n/(smlsiz+1)))) + 1$.</p>

DIMENSION for complex flavors is $(n*nrhs)$.

rwork REAL for clalsd
 DOUBLE PRECISION for zlalsd
 Workspace array, used with complex flavors only.
 DIMENSION at least $(9n + 2n*smlsiz + 8n*nlvl + 3*mlsiz*nrhs + (smlsiz+1)^2)$,
 where
 $nlvl = \max(0, \text{int}(\log_2(\min(m,n)/(smlsiz+1))) + 1)$.
iwork INTEGER.
 Workspace array of DIMENSION $(3n*nlvl + 11n)$.

Output Parameters

d On exit, if $\text{info} = 0$, *d* contains singular values of the bidiagonal matrix.
e On exit, destroyed.
b On exit, *b* contains the solution X .
info INTEGER.
 If $\text{info} = 0$: successful exit.
 If $\text{info} = -i < 0$, the *i*-th argument had an illegal value.
 If $\text{info} > 0$: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns $\text{info}/(n+1)$ through $\text{mod}(\text{info}, n+1)$.

?lamrg

Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.

Syntax

```
call slamrg( n1, n2, a, strd1, strd2, index )
call dlamrg( n1, n2, a, strd1, strd2, index )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine creates a permutation list which will merge the elements of *a* (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Input Parameters

<i>n1, n2</i>	INTEGER. These arguments contain the respective lengths of the two sorted lists to be merged.
<i>a</i>	REAL for slamrg DOUBLE PRECISION for dlamrg. Array, DIMENSION (<i>n1+n2</i>). The first <i>n1</i> elements of <i>a</i> contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final <i>n2</i> elements.
<i>strd1, strd2</i>	INTEGER. These are the strides to be taken through the array <i>a</i> . Allowable strides are 1 and -1. They indicate whether a subset of <i>a</i> is sorted in ascending (<i>strdx</i> = 1) or descending (<i>strdx</i> = -1) order.

Output Parameters

<i>index</i>	INTEGER. Array, DIMENSION (<i>n1+n2</i>). On exit, this array will contain a permutation such that if $b(i) = a(index(i))$ for $i=1, n1+n2$, then <i>b</i> will be sorted in ascending order.
--------------	---

?laneg

Computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T -
 $\sigma * I = L * D * L^T$.

Syntax

```
value = slaneg( n, d, lld, sigma, pivmin, r )
value = dlaneg( n, d, lld, sigma, pivmin, r )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T - $\sigma * I = L * D * L^T$. This implementation works directly on the factors without forming the tridiagonal matrix T . The Sturm count is also the number of eigenvalues of T less than σ . This routine is called from ?larb. The current routine does not use the *pivmin* parameter but rather requires IEEE-754 propagation of infinities and NaNs (NaN stands for 'Not A Number'). This routine also has no input range restrictions but does require default exception handling such that $x/0$ produces Inf when x is non-zero, and Inf/Inf produces NaN. (For more information see [Marques06]).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
----------	-----------------------------------

<i>d</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (n). Contains n diagonal elements of the matrix D .
<i>lld</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (n-1). Contains $(n-1)$ elements $L(i) * L(i) * D(i)$.
<i>sigma</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Shift amount in $T - \sigma I = L^* D^* L^{**} T$.
<i>pivmin</i>	REAL for slaneg DOUBLE PRECISION for dlaneg The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.
<i>r</i>	INTEGER. The twist index for the twisted factorization that is used for the negcount.

Output Parameters

<i>value</i>	INTEGER. The number of negative pivots encountered while factoring.
--------------	---

?langb

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.

Syntax

```
val = slangb( norm, n, kl, ku, ab, ldab, work )
val = dlangb( norm, n, kl, ku, ab, ldab, work )
val = clangb( norm, n, kl, ku, ab, ldab, work )
val = zlangb( norm, n, kl, ku, ab, ldab, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n band matrix A , with kl sub-diagonals and ku super-diagonals.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': <i>val</i> = $\max(A_{ij})$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': <i>val</i> = $\text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': <i>val</i> = $\text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': <i>val</i> = $\text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$. When <i>n</i> = 0, ?langb is set to zero.
<i>kl</i>	INTEGER. The number of sub-diagonals of the matrix <i>A</i> . $kl \geq 0$.
<i>ku</i>	INTEGER. The number of super-diagonals of the matrix <i>A</i> . $ku \geq 0$.
<i>ab</i>	REAL for slangb DOUBLE PRECISION for dlangb COMPLEX for clangb DOUBLE COMPLEX for zlangb Array, DIMENSION (<i>ldab,n</i>). The band matrix <i>A</i> , stored in rows 1 to <i>kl+ku+1</i> . The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows: $ab(ku+1+i-j, j) = a(i, j)$ $\text{for } \max(1, j-ku) \leq i \leq \min(n, j+kl).$
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . $ldab \geq kl+ku+1$.
<i>work</i>	REAL for slangb/clangb DOUBLE PRECISION for dlangb/zlangb Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for slangb/clangb DOUBLE PRECISION for dlangb/zlangb Value returned by the function.
------------	---

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
val = slange( norm, m, n, a, lda, work )
val = dlange( norm, m, n, a, lda, work )
val = clange( norm, m, n, a, lda, work )
val = zlange( norm, m, n, a, lda, work )
```

C:

```
float LAPACKE_slange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
float * a, lapack_int lda);

double LAPACKE_dlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
double * a, lapack_int lda);

float LAPACKE_clange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix A.

Input Parameters

The data types are given for the Fortran interface.

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': val = max(abs(A _{ij})), largest absolute value of the matrix A. = '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum), = 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': val = normF(A), Frobenius norm of the matrix A (square root of sum of squares).
<i>m</i>	INTEGER. The number of rows of the matrix A. <i>m</i> ≥ 0. When <i>m</i> = 0, ?lange is set to zero.
<i>n</i>	INTEGER. The number of columns of the matrix A.

$n \geq 0$. When $n = 0$, ?lange is set to zero.

a REAL for slange

DOUBLE PRECISION for dlange

COMPLEX for clange

DOUBLE COMPLEX for zlange

Array, DIMENSION (*lda,n*).

The *m*-by-*n* matrix *A*.

lda INTEGER. The leading dimension of the array *a*.

lda $\geq \max(m, 1)$.

work REAL for slange and clange.

DOUBLE PRECISION for dlange and zlange.

Workspace array, DIMENSION $\max(1, lwork)$, where $lwork \geq m$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slange/clange

DOUBLE PRECISION for dlange/zlange

Value returned by the function.

?langt

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.

Syntax

val = slangt(*norm*, *n*, *dl*, *d*, *du*)

val = dlangt(*norm*, *n*, *dl*, *d*, *du*)

val = clangt(*norm*, *n*, *dl*, *d*, *du*)

val = zlangt(*norm*, *n*, *dl*, *d*, *du*)

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex tridiagonal matrix *A*.

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': *val* = max(abs(A_{ij})), largest absolute value of the matrix *A*.
= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),
= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),
= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

n INTEGER. The order of the matrix *A*. $n \geq 0$. When *n* = 0, ?langt is set to zero.

dl, d, du

```
REAL for slangt
DOUBLE PRECISION for dlangt
COMPLEX for clangt
DOUBLE COMPLEX for zlangt
```

Arrays: *dl* (*n*-1), *d* (*n*), *du* (*n*-1).
The array *dl* contains the (*n*-1) sub-diagonal elements of *A*.
The array *d* contains the diagonal elements of *A*.
The array *du* contains the (*n*-1) super-diagonal elements of *A*.

Output Parameters

val

```
REAL for slangt/clangt
DOUBLE PRECISION for dlangt/zlangt
```

Value returned by the function.

?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.

Syntax

```
val = slanh( norm, n, a, lda, work )
val = dlanh( norm, n, a, lda, work )
val = clanh( norm, n, a, lda, work )
val = zlanh( norm, n, a, lda, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lanhs returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix *A*.

The value *val* returned by the function is:

```

val = max(abs(Aij)), if norm = 'M' or 'm'
= norm1(A), if norm = '1' or 'O' or 'o'
= normI(A), if norm = 'I' or 'i'
= normF(A), if norm = 'F', 'f', 'E' or 'e'
```

where `norm1` denotes the 1-norm of a matrix (maximum column sum), `normI` denotes the infinity norm of a matrix (maximum row sum) and `normF` denotes the Frobenius norm of a matrix (square root of sum of squares). Note that `max(abs(Aij))` is not a consistent matrix norm.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine as described above.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$. When <i>n</i> = 0, ?lanhs is set to zero.
<i>a</i>	REAL for slanh DOUBLE PRECISION for dlanhs COMPLEX for clanhs DOUBLE COMPLEX for zlanhs Array, DIMENSION (<i>lda,n</i>). The <i>n</i> -by- <i>n</i> upper Hessenberg matrix <i>A</i> ; the part of <i>A</i> below the first sub-diagonal is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(n, 1)$.
<i>work</i>	REAL for slanh and clanhs. DOUBLE PRECISION for dlanhs and zlanhs. Workspace array, DIMENSION ($\max(1, lwork)$), where <i>lwork</i> $\geq n$ when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for slanh/clanh DOUBLE PRECISION for dlanhs/zlanhs Value returned by the function.
------------	---

?lanhs

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.

Syntax

```

val = slansb( norm, uplo, n, k, ab, ldab, work )
val = dlansb( norm, uplo, n, k, ab, ldab, work )
val = clansb( norm, uplo, n, k, ab, ldab, work )
```

```
val = zlansb( norm, uplo, n, k, ab, ldab, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lansb returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real/complex symmetric band matrix A , with k super-diagonals.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm':	<i>val</i> = $\max(A_{ij})$, largest absolute value of the matrix A .
= '1' or 'O' or 'o':	<i>val</i> = $\text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i':	<i>val</i> = $\text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e':	<i>val</i> = $\text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix A is supplied. If <i>uplo</i> = 'U': upper triangular part is supplied; If <i>uplo</i> = 'L': lower triangular part is supplied.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lansb is set to zero.
<i>k</i>	INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A . $k \geq 0$.
<i>ab</i>	REAL for slansb DOUBLE PRECISION for dlansb COMPLEX for clansb DOUBLE COMPLEX for zlansb Array, DIMENSION (<i>ldab,n</i>). The upper or lower triangle of the symmetric band matrix A , stored in the first $k+1$ rows of <i>ab</i> . The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', <i>ab</i> ($k+1+i-j,j$) = <i>a</i> (i,j) for $\max(1,j-k) \leq i \leq j$; if <i>uplo</i> = 'L', <i>ab</i> ($1+i-j,j$) = <i>a</i> (i,j) for $j \leq i \leq \min(n, j+k)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> .

$ldab \geq k+1$.

work

REAL for slansb and clansb.

DOUBLE PRECISION for dlansb and zlansb.

Workspace array, DIMENSION ($\max(1, lwork)$), where

$lwork \geq n$ when $norm = 'I'$ or ' 1 ' or ' O '; otherwise, *work* is not referenced.

Output Parameters

val

REAL for slansb/clansb

DOUBLE PRECISION for dlansb/zlansb

Value returned by the function.

?lanhb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.

Syntax

```
val = clanhb( norm, uplo, n, k, ab, ldab, work )
```

```
val = zlanhb( norm, uplo, n, k, ab, ldab, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n Hermitian band matrix A , with k super-diagonals.

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

- = ' M ' or ' m ': *val* = $\max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
- = ' 1 ' or ' O ' or ' o ': *val* = $\text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
- = ' I ' or ' i ': *val* = $\text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
- = ' F ', ' f ', ' E ' or ' e ': *val* = $\text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the band matrix A is supplied.

If *uplo* = ' U ': upper triangular part is supplied;

If $uplo = 'L'$: lower triangular part is supplied.

n INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lanhb is set to zero.

k INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A .

$k \geq 0$.

ab COMPLEX for clanhb.

DOUBLE COMPLEX for zlanhb.

Array, DIMENSION (l_{daB}, n). The upper or lower triangle of the Hermitian band matrix A , stored in the first $k+1$ rows of ab . The j -th column of A is stored in the j -th column of the array ab as follows:

```
if  $uplo = 'U'$ ,  $ab(k+1+i-j, j) = a(i, j)$ 
for  $\max(1, j-k) \leq i \leq j$ ;
if  $uplo = 'L'$ ,  $ab(1+i-j, j) = a(i, j)$  for  $j \leq i \leq \min(n, j+k)$ .
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

l_{dab} INTEGER. The leading dimension of the array ab . $l_{dab} \geq k+1$.

$work$ REAL for clanhb.

DOUBLE PRECISION for zlanhb.

Workspace array, DIMENSION $\max(1, l_{work})$, where

$l_{work} \geq n$ when $norm = 'I'$ or ' 1 ' or ' O '; otherwise, $work$ is not referenced.

Output Parameters

val REAL for slanhb/clanhb

DOUBLE PRECISION for dlanhb/zlanhb

Value returned by the function.

?lansp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.

Syntax

```
val = slansp( norm, uplo, n, ap, work )
val = dlansp( norm, uplo, n, ap, work )
val = clansp( norm, uplo, n, ap, work )
val = zlansp( norm, uplo, n, ap, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lansp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A , supplied in packed form.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm':	<i>val</i> = $\max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
= '1' or 'O' or 'o':	<i>val</i> = $\text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i':	<i>val</i> = $\text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e':	<i>val</i> = $\text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied. If <i>uplo</i> = 'U': Upper triangular part of A is supplied If <i>uplo</i> = 'L': Lower triangular part of A is supplied.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lansp is set to zero.
<i>ap</i>	REAL for slansp DOUBLE PRECISION for dlansp COMPLEX for clansp DOUBLE COMPLEX for zlansp Array, DIMENSION ($n(n+1)/2$). The upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.
<i>work</i>	REAL for slansp and clansp. DOUBLE PRECISION for dlansp and zlansp. Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.

Output Parameters

`val`

REAL for `slansp/clansp`
DOUBLE PRECISION for `dlansp/zlansp`

Value returned by the function.

?lanhp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.

Syntax

```
val = clanhp( norm, uplo, n, ap, work )
val = zlanhp( norm, uplo, n, ap, work )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function `?lanhp` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A , supplied in packed form.

Input Parameters

`norm`

CHARACTER*1. Specifies the value to be returned by the routine:

- = 'M' or 'm': $val = \max(|A_{ij}|)$, largest absolute value of the matrix A .
- = '1' or 'O' or 'o': $val = \text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
- = 'I' or 'i': $val = \text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
- = 'F', 'f', 'E' or 'e': $val = \text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).

`uplo`

CHARACTER*1.

Specifies whether the upper or lower triangular part of the Hermitian matrix A is supplied.

- If $uplo = 'U'$: Upper triangular part of A is supplied
- If $uplo = 'L'$: Lower triangular part of A is supplied.

`n`

INTEGER. The order of the matrix A .

$n \geq 0$. When $n = 0$, `?lanhp` is set to zero.

`ap`

COMPLEX for `clanhp`.

DOUBLE COMPLEX for `zlanhp`.

Array, DIMENSION ($n(n+1)/2$). The upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:

```
if uplo = 'U', ap(i + (j-1)j/2) = A(i,j) for 1 ≤ i ≤ j;
if uplo = 'L', ap(i + (j-1)(2n-j)/2) = A(i,j) for j ≤ i ≤ n.
```

work

REAL for `clanhp`.

DOUBLE PRECISION for `zlanhp`.

Workspace array, DIMENSION ($\max(1, lwork)$), where

$lwork \geq n$ when $norm = 'I'$ or ' 1 ' or ' O '; otherwise, `work` is not referenced.

Output Parameters

val

REAL for `clanhp`.

DOUBLE PRECISION for `zlanhp`.

Value returned by the function.

?lanst/?lanht

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.

Syntax

```
val = slanst( norm, n, d, e )
val = dlanst( norm, n, d, e )
val = clanht( norm, n, d, e )
val = zlanht( norm, n, d, e )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The functions `?lanst/?lanht` return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or a complex Hermitian tridiagonal matrix A .

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

```
= 'M' or 'm': val = max(abs(Aij)), largest absolute value of the matrix A.
= '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A
(maximum column sum),
```

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),
 = 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

n INTEGER. The order of the matrix *A*.

n ≥ 0. When *n* = 0, ?lanst/?lanht is set to zero.

d REAL for slanst/clanht

DOUBLE PRECISION for dlanst/zlanht

Array, DIMENSION (*n*). The diagonal elements of *A*.

e REAL for slanst

DOUBLE PRECISION for dlanst

COMPLEX for clanht

DOUBLE COMPLEX for zlanht

Array, DIMENSION (*n*-1).

The (*n*-1) sub-diagonal or super-diagonal elements of *A*.

Output Parameters

val REAL for slanst/clanht

DOUBLE PRECISION for dlanst/zlanht

Value returned by the function.

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

val = slansy(*norm*, *uplo*, *n*, *a*, *lda*, *work*)

val = dlansy(*norm*, *uplo*, *n*, *a*, *lda*, *work*)

val = clansy(*norm*, *uplo*, *n*, *a*, *lda*, *work*)

val = zlansy(*norm*, *uplo*, *n*, *a*, *lda*, *work*)

C:

```
float LAPACKE_slansy (int matrix_layout, char norm, char uplo, lapack_int n, const
float * a, lapack_int lda);
```

```
double LAPACKE_dlansy (int matrix_layout, char norm, char uplo, lapack_int n, const
double * a, lapack_int lda);
```

```
float LAPACKE_clansy (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlansy (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lansy returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A .

Input Parameters

The data types are given for the Fortran interface.

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm':	<i>val</i> = $\max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
= '1' or 'O' or 'o':	<i>val</i> = $\text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i':	<i>val</i> = $\text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e':	<i>val</i> = $\text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced. = 'U': Upper triangular part of A is referenced. = 'L': Lower triangular part of A is referenced
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lansy is set to zero.
<i>a</i>	REAL for slansy DOUBLE PRECISION for dlansy COMPLEX for clansy DOUBLE COMPLEX for zlansy Array, DIMENSION (<i>lda,n</i>). The symmetric matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A , and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(n,1)$.
<i>work</i>	REAL for slansy and clansy.

DOUBLE PRECISION for `dlansy` and `zlansy`.
Workspace array, DIMENSION (`max(1,lwork)`), where
 $lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, `work` is not referenced.

Output Parameters

`val` REAL for `slansy/clansy`
 DOUBLE PRECISION for `dlansy/zlansy`
 Value returned by the function.

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

```
val = clanhe( norm, uplo, n, a, lda, work )
val = zlanhe( norm, uplo, n, a, lda, work )
```

C:

```
float LAPACKE_clanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);
double LAPACKE_zlanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A .

Input Parameters

The data types are given for the Fortran interface.

<code>norm</code>	CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm':	<code>val</code> = $\max(A_{ij})$, largest absolute value of the matrix A .
= '1' or 'O' or 'o':	<code>val</code> = $\text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i':	<code>val</code> = $\text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e':	<code>val</code> = $\text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).

<i>uplo</i>	CHARACTER*1.
	Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is to be referenced.
	= 'U': Upper triangular part of <i>A</i> is referenced.
	= 'L': Lower triangular part of <i>A</i> is referenced
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$. When $n = 0$, ?lanhe is set to zero.
<i>a</i>	COMPLEX for clanhe. DOUBLE COMPLEX for zlanhe. Array, DIMENSION (<i>lda,n</i>). The Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(n, 1)$.
<i>work</i>	REAL for clanhe. DOUBLE PRECISION for zlanhe. Workspace array, DIMENSION ($\max(1, lwork)$), where <i>lwork</i> $\geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for clanhe. DOUBLE PRECISION for zlanhe. Value returned by the function.
------------	---

?lantb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.

Syntax

```
val = slantb( norm, uplo, diag, n, k, ab, ldab, work )
val = dlantb( norm, uplo, diag, n, k, ab, ldab, work )
val = clantb( norm, uplo, diag, n, k, ab, ldab, work )
val = zlantb( norm, uplo, diag, n, k, ab, ldab, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lantb returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n triangular band matrix A , with ($k + 1$) diagonals.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm':	<i>val</i> = $\max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
= '1' or 'O' or 'o':	<i>val</i> = $\text{norm}_1(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i':	<i>val</i> = $\text{norm}_I(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e':	<i>val</i> = $\text{norm}_F(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular.
= 'U':	Upper triangular
= 'L':	Lower triangular.
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular.
= 'N':	Non-unit triangular
= 'U':	Unit triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lantb is set to zero.
<i>k</i>	INTEGER. The number of super-diagonals of the matrix A if <i>uplo</i> = 'U', or the number of sub-diagonals of the matrix A if <i>uplo</i> = 'L'. $k \geq 0$.
<i>ab</i>	REAL for slantb DOUBLE PRECISION for dlantb COMPLEX for clantb DOUBLE COMPLEX for zlantb Array, DIMENSION (<i>ldab</i> , <i>n</i>). The upper or lower triangular band matrix A , stored in the first $k+1$ rows of <i>ab</i> . The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', <i>ab</i> ($k+1+i-j,j$) = <i>a</i> (<i>i,j</i>) for $\max(1, j-k) \leq i \leq j$; if <i>uplo</i> = 'L', <i>ab</i> ($1+i-j,j$) = <i>a</i> (<i>i,j</i>) for $j \leq i \leq \min(n, j+k)$.

Note that when $\text{diag} = \text{'U'}$, the elements of the array ab corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

ldab

INTEGER. The leading dimension of the array ab .

$ldab \geq k+1$.

work

REAL for slantb and clantb .

DOUBLE PRECISION for dlantb and zlantb .

Workspace array, DIMENSION ($\max(1, lwork)$), where

$lwork \geq n$ when $\text{norm} = \text{'I'}$; otherwise, work is not referenced.

Output Parameters

val

REAL for $\text{slantb}/\text{clantb}$.

DOUBLE PRECISION for $\text{dlantb}/\text{zlantb}$.

Value returned by the function.

?lantp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.

Syntax

```
val = slantp( norm, uplo, diag, n, ap, work )
val = dlantp( norm, uplo, diag, n, ap, work )
val = clantp( norm, uplo, diag, n, ap, work )
val = zlantp( norm, uplo, diag, n, ap, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lantp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A , supplied in packed form.

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .

= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),
 = 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

uplo CHARACTER*1.

Specifies whether the matrix *A* is upper or lower triangular.

= 'U': Upper triangular

= 'L': Lower triangular.

diag CHARACTER*1.

Specifies whether or not the matrix *A* is unit triangular.

= 'N': Non-unit triangular

= 'U': Unit triangular.

n INTEGER. The order of the matrix *A*.

n ≥ 0. When *n* = 0, ?lantp is set to zero.

ap REAL for slantp

DOUBLE PRECISION for dlantp

COMPLEX for clantp

DOUBLE COMPLEX for zlantp

Array, DIMENSION (*n(n+1)/2*).

The upper or lower triangular matrix *A*, packed columnwise in a linear array. The *j*-th column of *A* is stored in the array *ap* as follows:

if *uplo* = 'U', *AP*(*i* + (*j*-1)*j/2*) = *a*(*i*, *j*) for $1 \leq i \leq j$;

if *uplo* = 'L', *ap*(*i* + (*j*-1)(2*n*-*j*)/2) = *a*(*i*, *j*) for $j \leq i \leq n$.

Note that when *diag* = 'U', the elements of the array *ap* corresponding to the diagonal elements of the matrix *A* are not referenced, but are assumed to be one.

work REAL for slantp and clantp.

DOUBLE PRECISION for dlantp and zlantp.

Workspace array, DIMENSION (max(1, *lwork*)), where *lwork* ≥ *n* when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slantp/clantp.

DOUBLE PRECISION for dlantp/zlantp.

Value returned by the function.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
val = slantr( norm, uplo, diag, m, n, a, lda, work )
val = dlantr( norm, uplo, diag, m, n, a, lda, work )
val = clantr( norm, uplo, diag, m, n, a, lda, work )
val = zlantr( norm, uplo, diag, m, n, a, lda, work )
```

C:

```
float LAPACKE_slantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int
* n, const float * a, lapack_int * lda, float * work);

double LAPACKE_dlantr (char * norm, char * uplo, char * diag, lapack_int * m,
lapack_int * n, const double * a, lapack_int * lda, double * work);

float LAPACKE_clantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int
* n, const lapack_complex_float * a, lapack_int * lda, float * work);

double LAPACKE_zlantr (char * norm, char * uplo, char * diag, lapack_int * m,
lapack_int * n, const lapack_complex_double * a, lapack_int * lda, double * work);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lantr returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A .

Input Parameters

The data types are given for the Fortran interface.

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(A_{ij})$, largest absolute value of the matrix A . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower trapezoidal. = 'U': Upper trapezoidal

= 'L': Lower trapezoidal.

Note that A is triangular instead of trapezoidal if $m = n$.

diag

CHARACTER*1.

Specifies whether or not the matrix A has unit diagonal.

= 'N': Non-unit diagonal

= 'U': Unit diagonal.

m

INTEGER. The number of rows of the matrix A . $m \geq 0$, and if *uplo* = 'U', $m \leq n$.

When $m = 0$, *?lantr* is set to zero.

n

INTEGER. The number of columns of the matrix A . $n \geq 0$, and if *uplo* = 'L', $n \leq m$.

When $n = 0$, *?lantr* is set to zero.

a

REAL for *slantr*

DOUBLE PRECISION for *dlantr*

COMPLEX for *clantr*

DOUBLE COMPLEX for *zlantr*

Array, DIMENSION (*lda,n*).

The trapezoidal matrix A (A is triangular if $m = n$).

If *uplo* = 'U', the leading m -by- n upper trapezoidal part of the array *a* contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced.

If *uplo* = 'L', the leading m -by- n lower trapezoidal part of the array *a* contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when *diag* = 'U', the diagonal elements of A are not referenced and are assumed to be one.

lda

INTEGER. The leading dimension of the array *a*.

lda $\geq \max(m, 1)$.

work

REAL for *slantr/clantrp*.

DOUBLE PRECISION for *dlantr/zlantr*.

Workspace array, DIMENSION ($\max(1, lwork)$), where

lwork $\geq m$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val

REAL for *slantr/clantrp*.

DOUBLE PRECISION for *dlantr/zlantr*.

Value returned by the function.

?lanv2

Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.

Syntax

```

call slanv2( a, b, c, d, rt1r, rt1i, rt2r, rt2i, cs, sn )
call dlanv2( a, b, c, d, rt1r, rt1i, rt2r, rt2i, cs, sn )

```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} cs & -sn \\ sn & cs \end{bmatrix} \begin{bmatrix} aa & bb \\ cc & dd \end{bmatrix} \begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix}$$

where either

- $cc = 0$ so that aa and dd are real eigenvalues of the matrix, or
 - $aa = dd$ and $bb*cc < 0$, so that $aa \pm \sqrt{bb*cc}$ are complex conjugate eigenvalues.

The routine was adjusted to reduce the risk of cancellation errors, when computing real eigenvalues, and to ensure, if possible, that $\text{abs}(rt1r) \geq \text{abs}(rt2r)$.

Input Parameters

Output Parameters

a, b, c, d	On exit, overwritten by the elements of the standardized Schur form.
$rt1r, rt1i, rt2r, rt2i$	REAL for slanv2 DOUBLE PRECISION for dlanv2. The real and imaginary parts of the eigenvalues. If the eigenvalues are a complex conjugate pair, $rt1i > 0$.
cs, sn	REAL for slanv2 DOUBLE PRECISION for dlanv2. Parameters of the rotation matrix.

?lapll

Measures the linear dependence of two vectors.

Syntax

```
call slapll( n, x, incx, Y, incy, ssmin )
call dlapll( n, x, incx, Y, incy, ssmin )
call clapll( n, x, incx, Y, incy, ssmin )
call zlapll( n, x, incx, Y, incy, ssmin )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given two column vectors x and y of length n , let

$A = (x \ y)$ be the n -by-2 matrix.

The routine ?lapll first computes the QR factorization of A as $A = Q^*R$ and then computes the SVD of the 2-by-2 upper triangular matrix R . The smaller singular value of R is returned in $ssmin$, which is used as the measurement of the linear dependency of the vectors x and y .

Input Parameters

n	INTEGER. The length of the vectors x and y .
x	REAL for slapll DOUBLE PRECISION for dlapll COMPLEX for clapll DOUBLE COMPLEX for zlapll Array, DIMENSION ($1+(n-1)incx$). On entry, x contains the n -vector x .
y	REAL for slapll DOUBLE PRECISION for dlapll COMPLEX for clapll DOUBLE COMPLEX for zlapll Array, DIMENSION ($1+(n-1)incy$). On entry, y contains the n -vector y .
$incx$	INTEGER. The increment between successive elements of x ; $incx > 0$.
$incy$	INTEGER. The increment between successive elements of y ; $incy > 0$.

Output Parameters

x	On exit, x is overwritten.
y	On exit, y is overwritten.
$ssmin$	REAL for <code>slapll/clapll</code> DOUBLE PRECISION for <code>dlapll/zlapll</code> The smallest singular value of the n -by-2 matrix $A = (x \ y)$.

?lapmr

Rearranges rows of a matrix as specified by a permutation vector.

Syntax

FORTRAN 77:

```
call slapmr( forwrd, m, n, x, ldx, k )
call dlapmr( forwrd, m, n, x, ldx, k )
call clapmr( forwrd, m, n, x, ldx, k )
call zlapmr( forwrd, m, n, x, ldx, k )
```

Fortran 95:

```
call lapmr( x, k[, forwrd] )
```

C:

```
lapack_int LAPACKE_<?>lapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,  
lapack_int n, <datatype> * x, lapack_int lidx, lapack_int * k);
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?lapmr` routine rearranges the rows of the m -by- n matrix X as specified by the permutation $k(1), k(2), \dots, k(m)$ of the integers $1, \dots, m$.

If *forwrd* = .TRUE., forward permutation:

$X(k(i,*))$ is moved to $X(i,*)$ for $i = 1, 2, \dots, m$.

If *forwrd* = .FALSE., backward permutation:

$X(i,*)$ is moved to $X(k(i,*))$ for $i = 1, 2, \dots, m$.

Input Parameters

The data types are given for the Fortran interface.

<i>forwrd</i>	LOGICAL. If <i>forwrd</i> = .TRUE., forward permutation If <i>forwrd</i> = .FALSE., backward permutation
---------------	--

<i>m</i>	INTEGER. The number of rows of the matrix X . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix X . $n \geq 0$.
<i>x</i>	REAL for <code>slapmr</code> DOUBLE PRECISION for <code>dlapmr</code> COMPLEX for <code>clapmr</code> DOUBLE COMPLEX for <code>zlapmr</code> Array, DIMENSION (<i>lidx,n</i>). On entry, the m -by- n matrix X .
<i>lidx</i>	INTEGER. The leading dimension of the array X , $lidx \geq \max(1,m)$.
<i>k</i>	INTEGER. Array, DIMENSION (<i>m</i>). On entry, <i>k</i> contains the permutation vector and is used as internal workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> contains the permuted matrix X .
<i>k</i>	On exit, <i>k</i> is reset to its original value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `?lapmr` interface are as follows:

<i>x</i>	Holds the matrix X of size (<i>n, n</i>).
<i>k</i>	Holds the vector of length <i>m</i> .
<i>forwrd</i>	Specifies the permutation. Must be ' <code>.TRUE.</code> ' or ' <code>.FALSE.</code> '.

See Also

[?lapmt](#)

Performs a forward or backward permutation of the columns of a matrix.

?lapmt

Performs a forward or backward permutation of the columns of a matrix.

Syntax

```
call slapmt( forwrd, m, n, x, lidx, k )
call dlapmt( forwrd, m, n, x, lidx, k )
call clapmt( forwrd, m, n, x, lidx, k )
call zlapmt( forwrd, m, n, x, lidx, k )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine ?lapmt rearranges the columns of the m -by- n matrix X as specified by the permutation $k(1), k(2), \dots, k(n)$ of the integers $1, \dots, n$.

If $forwrd = .TRUE..$, forward permutation:

$X(*, k(j))$ is moved to $X(*, j)$ for $j=1, 2, \dots, n$.

If $forwrd = .FALSE..$, backward permutation:

$X(*, j)$ is moved to $X(*, k(j))$ for $j = 1, 2, \dots, n$.

Input Parameters

$forwrd$	LOGICAL.
	If $forwrd = .TRUE..$, forward permutation
	If $forwrd = .FALSE..$, backward permutation
m	INTEGER. The number of rows of the matrix X . $m \geq 0$.
n	INTEGER. The number of columns of the matrix X . $n \geq 0$.
x	REAL for slapmt DOUBLE PRECISION for dlapmt COMPLEX for clapmt DOUBLE COMPLEX for zlapmt Array, DIMENSION ($lIdx, n$). On entry, the m -by- n matrix X .
$lIdx$	INTEGER. The leading dimension of the array X , $lIdx \geq \max(1, m)$.
k	INTEGER. Array, DIMENSION (n). On entry, k contains the permutation vector and is used as internal workspace.

Output Parameters

x	On exit, x contains the permuted matrix X .
k	On exit, k is reset to its original value.

See Also

?lapmr

?lapy2

Returns $\sqrt{x^2 + y^2}$.

Syntax

```
val = slapy2( x, y )
val = dlapy2( x, y )
```

C:

```
<datatype> LAPACKE_<?>lapy2 (<datatype> x, <datatype> y);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lapy2 returns $\sqrt{x^2+y^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

The data types are given for the Fortran interface.

<i>x, y</i>	REAL for slapy2 DOUBLE PRECISION for dlapy2
	Specify the input values <i>x</i> and <i>y</i> .

Output Parameters

<i>val</i>	REAL for slapy2 DOUBLE PRECISION for dlapy2.
	Value returned by the function.

?lapy3

Returns $\sqrt{x^2+y^2+z^2}$.

Syntax

```
val = slapy3( x, y, z )
val = dlapy3( x, y, z )
```

C:

```
<datatype> LAPACKE_<?>lapy3 ( <datatype> x, <datatype> y, <datatype> z );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lapy3 returns $\sqrt{x^2+y^2+z^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

The data types are given for the Fortran interface.

<i>x, y, z</i>	REAL for slapy3 DOUBLE PRECISION for dlapy3
	Specify the input values <i>x, y</i> and <i>z</i> .

Output Parameters

val REAL for slapy3
DOUBLE PRECISION for dlapy3.
Value returned by the function.

?laqgb

Scales a general band matrix, using row and column scaling factors computed by ?gbequ.

Syntax

```

call slaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call dlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call claqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call zlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )

```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine equilibrates a general m -by- n band matrix A with k_l subdiagonals and k_u superdiagonals using the row and column scaling factors in the vectors r and c .

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>k1</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> . $k1 \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> . $ku \geq 0$.
<i>ab</i>	REAL for <code>slaqgb</code> DOUBLE PRECISION for <code>dlaqgb</code> COMPLEX for <code>claqgb</code> DOUBLE COMPLEX for <code>zlaqgb</code> <p>Array, DIMENSION (<i>ldab,n</i>). On entry, the matrix <i>A</i> in band storage, in rows 1 to $k1+ku+1$. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows: $ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+k1)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . $lda \geq k1+ku+1$.
<i>amax</i>	REAL for <code>slaqgb/claqgb</code>

	DOUBLE PRECISION for dlaqgb/zlaqgb
	Absolute value of largest matrix entry.
<i>r, c</i>	REAL for slaqgb/claqgb
	DOUBLE PRECISION for dlaqgb/zlaqgb
	Arrays <i>r</i> (<i>m</i>), <i>c</i> (<i>n</i>). Contain the row and column scale factors for <i>A</i> , respectively.
<i>rowcnd</i>	REAL for slaqgb/claqgb
	DOUBLE PRECISION for dlaqgb/zlaqgb
	Ratio of the smallest <i>r</i> (<i>i</i>) to the largest <i>r</i> (<i>i</i>).
<i>colcnd</i>	REAL for slaqgb/claqgb
	DOUBLE PRECISION for dlaqgb/zlaqgb
	Ratio of the smallest <i>c</i> (<i>i</i>) to the largest <i>c</i> (<i>i</i>).

Output Parameters

<i>ab</i>	On exit, the equilibrated matrix, in the same storage format as <i>A</i> . See <i>equed</i> for the form of the equilibrated matrix.
<i>equed</i>	CHARACTER*1. Specifies the form of equilibration that was done. If <i>equed</i> = 'N': No equilibration If <i>equed</i> = 'R': Row equilibration, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> . If <i>equed</i> = 'C': Column equilibration, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> . If <i>equed</i> = 'B': Both row and column equilibration, that is, <i>A</i> has been replaced by <i>diag(r)*A*diag(c)</i> .

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If *rowcnd* < *thresh*, row scaling is done, and if *colcnd* < *thresh*, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, row scaling is done.

?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ.

Syntax

```
call slaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call dlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call claqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
```

```
call zlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine equilibrates a general m -by- n matrix A using the row and column scaling factors in the vectors r and c .

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>a</i>	REAL for slaqge DOUBLE PRECISION for dlagge COMPLEX for claqge DOUBLE COMPLEX for zlagge Array, DIMENSION (<i>lda,n</i>). On entry, the m -by- n matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(m, 1)$.
<i>r</i>	REAL for slanqge/claqge DOUBLE PRECISION for dlagge/zlagge Array, DIMENSION (<i>m</i>). The row scale factors for A .
<i>c</i>	REAL for slanqge/claqge DOUBLE PRECISION for dlagge/zlagge Array, DIMENSION (<i>n</i>). The column scale factors for A .
<i>rowcnd</i>	REAL for slanqge/claqge DOUBLE PRECISION for dlagge/zlagge Ratio of the smallest $r(i)$ to the largest $r(i)$.
<i>colcnd</i>	REAL for slanqge/claqge DOUBLE PRECISION for dlagge/zlagge Ratio of the smallest $c(i)$ to the largest $c(i)$.
<i>amax</i>	REAL for slanqge/claqge DOUBLE PRECISION for dlagge/zlagge Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	On exit, the equilibrated matrix. See <i>equed</i> for the form of the equilibrated matrix.
<i>equed</i>	CHARACTER*1. Specifies the form of equilibration that was done. If <i>equed</i> = 'N': No equilibration If <i>equed</i> = 'R': Row equilibration, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> . If <i>equed</i> = 'C': Column equilibration, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> . If <i>equed</i> = 'B': Both row and column equilibration, that is, <i>A</i> has been replaced by <i>diag(r)*A*diag(c)</i> .

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If *rowcnd* < *thresh*, row scaling is done, and if *colcnd* < *thresh*, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, row scaling is done.

?laqhb

Scales a Hermetian band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call claqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call zlaqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine equilibrates a Hermetian band matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> .

$n \geq 0$.

kd INTEGER. The number of super-diagonals of the matrix A if $uplo = 'U'$, or the number of sub-diagonals if $uplo = 'L'$.

$kd \geq 0$.

ab COMPLEX for `claqhb`

DOUBLE COMPLEX for `zlaghb`

Array, DIMENSION ($ldab, n$). On entry, the upper or lower triangle of the band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array ab as follows:

if $uplo = 'U'$, $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;

if $uplo = 'L'$, $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

$ldab$ INTEGER. The leading dimension of the array ab .

$ldab \geq kd+1$.

$scond$ REAL for `claqsb`

DOUBLE PRECISION for `zlaqsb`

Ratio of the smallest $s(i)$ to the largest $s(i)$.

$amax$ REAL for `claqsb`

DOUBLE PRECISION for `zlaqsb`

Absolute value of largest matrix entry.

Output Parameters

ab On exit, if $info = 0$, the triangular factor U or L from the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ of the band matrix A , in the same storage format as A .

s REAL for `claqsb`

DOUBLE PRECISION for `zlaqsb`

Array, DIMENSION (n). The scale factors for A .

$equed$ CHARACTER*1.

Specifies whether or not equilibration was done.

If $equed = 'N'$: No equilibration.

If $equed = 'Y'$: Equilibration was done, that is, A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters $thresh$, $large$, and $small$, which have the following meaning. $thresh$ is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done.

The values *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, scaling is done.

?laqp2

Computes a QR factorization with column pivoting of the matrix block.

Syntax

```
call slaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call dlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call claqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call zlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes a QR factorization with column pivoting of the block $A(\text{offset}+1:m, 1:n)$. The block $A(1:\text{offset}, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>offset</i>	INTEGER. The number of rows of the matrix A that must be pivoted but not factorized. $\text{offset} \geq 0$.
<i>a</i>	REAL for slaqp2 DOUBLE PRECISION for dlaqp2 COMPLEX for claqp2 DOUBLE COMPLEX for zlaqp2 Array, DIMENSION (<i>lda,n</i>). On entry, the m -by- n matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $\text{lda} \geq \max(1, m)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, if $\text{jpvt}(i) \neq 0$, the <i>i</i> -th column of A is permuted to the front of A^*P (a leading column); if $\text{jpvt}(i) = 0$, the <i>i</i> -th column of A is a free column.
<i>vn1, vn2</i>	REAL for slaqp2/claqp2 DOUBLE PRECISION for dlaqp2/zlaqp2

Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.

work REAL for `slaqp2`
 DOUBLE PRECISION for `dlaqp2`
 COMPLEX for `claqp2`
 DOUBLE COMPLEX for `zlaqp2` Workspace array, DIMENSION (n).

Output Parameters

a On exit, the upper triangle of block $A(\text{offset}+1:m, 1:n)$ is the triangular factor obtained; the elements in block $A(\text{offset}+1:m, 1:n)$ below the diagonal, together with the array *tau*, represent the orthogonal matrix Q as a product of elementary reflectors. Block $A(1:\text{offset}, 1:n)$ has been accordingly pivoted, but not factorized.

jpvt On exit, if $\text{jpvt}(i) = k$, then the i -th column of A^*P was the k -th column of A .

tau REAL for `slaqp2`
 DOUBLE PRECISION for `dlaqp2`
 COMPLEX for `claqp2`
 DOUBLE COMPLEX for `zlaqp2`
 Array, DIMENSION ($\min(m, n)$).
 The scalar factors of the elementary reflectors.

vn1, vn2 Contain the vectors with the partial and exact column norms, respectively.

?laqps

Computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3.

Syntax

```
call slaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call dlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call claqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call zlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3. The routine tries to factorize NB columns from A starting from the row $\text{offset}+1$, and updates all of the matrix with BLAS level 3 routine `?gemm`.

In some cases, due to catastrophic cancellations, ?laqps cannot factorize NB columns. Hence, the actual number of factorized columns is returned in kb .

Block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
$offset$	INTEGER. The number of rows of A that have been factorized in previous steps.
nb	INTEGER. The number of columns to factorize.
a	REAL for <code>slaqps</code> DOUBLE PRECISION for <code>dlaqps</code> COMPLEX for <code>claqps</code> DOUBLE COMPLEX for <code>zlaqps</code> Array, DIMENSION (lda, n) . On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, m)$.
$jpvt$	INTEGER. Array, DIMENSION (n) . If $jpvt(I) = k$ then column k of the full matrix A has been permuted into position i in AP.
$vn1, vn2$	REAL for <code>slaqps/claqps</code> DOUBLE PRECISION for <code>dlaqps/zlaqps</code> Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.
$auxv$	REAL for <code>slaqps</code> DOUBLE PRECISION for <code>dlaqps</code> COMPLEX for <code>claqps</code> DOUBLE COMPLEX for <code>zlaqps</code> Array, DIMENSION (nb) . Auxiliary vector.
f	REAL for <code>slaqps</code> DOUBLE PRECISION for <code>dlaqps</code> COMPLEX for <code>claqps</code> DOUBLE COMPLEX for <code>zlaqps</code> Array, DIMENSION (ldf, nb) . For real flavors, matrix $F^T = L^*Y^T*A$. For complex flavors, matrix $F^H = L^*Y^H*A$.

ldf INTEGER. The leading dimension of the array *f*.
ldf $\geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns actually factorized.

a On exit, block $A(\text{offset}+1:m, 1:kb)$ is the triangular factor obtained and block $A(1:\text{offset}, 1:n)$ has been accordingly pivoted, but not factorized. The rest of the matrix, block $A(\text{offset}+1:m, kb+1:n)$ has been updated.

jpvt INTEGER array, DIMENSION (*n*). If $jpvt(I) = k$ then column *k* of the full matrix *A* has been permuted into position *i* in AP.

tau REAL for *slaqps*
 DOUBLE PRECISION for *dlaqps*
 COMPLEX for *claqps*
 DOUBLE COMPLEX for *zlaqps*
 Array, DIMENSION (*kb*). The scalar factors of the elementary reflectors.

vn1, *vn2* The vectors with the partial and exact column norms, respectively.

auxv Auxiliary vector.

f Matrix $F' = L^*Y^*A$.

?laqr0

Computes the eigenvalues of a Hessenberg matrix,
 and optionally the matrixes from the Schur
 decomposition.

Syntax

```
call slaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )
call dlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )
call claqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )
call zlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^* H^* Q^H = (QZ)^* H^* (QZ)^H$.

Input Parameters

<i>wantt</i>	LOGICAL. If <i>wantt</i> = .TRUE., the full Schur form T is required; If <i>wantt</i> = .FALSE., only eigenvalues are required.
<i>wantz</i>	LOGICAL. If <i>wantz</i> = .TRUE., the matrix of Schur vectors Z is required; If <i>wantz</i> = .FALSE., Schur vectors are not required.
<i>n</i>	INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. It is assumed that H is already upper triangular in rows and columns 1: $ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $H(ilo, ilo-1) = 0$. ilo and ihi are normally set by a previous call to <code>cgebal</code> , and then passed to <code>cgehrd</code> when the matrix output by <code>cgebal</code> is reduced to Hessenberg form. Otherwise, ilo and ihi should be set to 1 and n , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n=0$, then $ilo=1$ and $ihi=0$
<i>h</i>	REAL for <code>slaqr0</code> DOUBLE PRECISION for <code>dlaqr0</code> COMPLEX for <code>claqr0</code> DOUBLE COMPLEX for <code>zlaqr0</code> . Array, DIMENSION (ldh, n), contains the upper Hessenberg matrix H .
<i>ldh</i>	INTEGER. The leading dimension of the array h . $ldh \geq \max(1, n)$.
<i>iloz, ihiz</i>	INTEGER. Specify the rows of Z to which transformations must be applied if <i>wantz</i> is .TRUE., $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.
<i>z</i>	REAL for <code>slaqr0</code> DOUBLE PRECISION for <code>dlaqr0</code> COMPLEX for <code>claqr0</code> DOUBLE COMPLEX for <code>zlaqr0</code> . Array, DIMENSION (ldz, ihi), contains the matrix Z if <i>wantz</i> is .TRUE.. If <i>wantz</i> is .FALSE., z is not referenced.

<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> . If <i>wantz</i> is .TRUE., then <i>ldz</i> $\geq \max(1, ihiz)$. Otherwise, <i>ldz</i> ≥ 1 .
<i>work</i>	REAL for <i>slaqr0</i> DOUBLE PRECISION for <i>dlaqr0</i> COMPLEX for <i>claqr0</i> DOUBLE COMPLEX for <i>zlaqr0</i> . Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> $\geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$. It is recommended to use the workspace query to determine the optimal workspace size. If <i>lwork</i> =-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters <i>n</i> , <i>ilo</i> , and <i>ihiz</i> . The estimate is returned in <i>work</i> (1). No error messages related to the <i>lwork</i> is issued by <i>xerbla</i> . Neither <i>H</i> nor <i>Z</i> are accessed.

Output Parameters

<i>h</i>	If <i>info</i> =0, and <i>wantt</i> is .TRUE., then <i>h</i> contains the upper quasi-triangular/triangular matrix <i>T</i> from the Schur decomposition (the Schur form). If <i>info</i> =0, and <i>wantt</i> is .FALSE., then the contents of <i>h</i> are unspecified on exit. (The output values of <i>h</i> when <i>info</i> > 0 are given under the description of the <i>info</i> parameter below.) The routine may explicitly set <i>h</i> (<i>i</i> , <i>j</i>) for <i>i</i> > <i>j</i> and <i>j</i> =1,2,... <i>ilo</i> -1 or <i>j</i> = <i>ihiz</i> +1, <i>ihiz</i> +2,... <i>n</i> .
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>w</i>	COMPLEX for <i>claqr0</i> DOUBLE COMPLEX for <i>zlaqr0</i> . Arrays, DIMENSION(<i>n</i>). The computed eigenvalues of <i>h</i> (<i>ilo</i> : <i>ihiz</i> , <i>ilo</i> : <i>ihiz</i>) are stored in <i>w</i> (<i>ilo</i> : <i>ihiz</i>). If <i>wantt</i> is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i> , with <i>w</i> (<i>i</i>) = <i>h</i> (<i>i</i> , <i>i</i>).
<i>wr</i> , <i>wi</i>	REAL for <i>slaqr0</i> DOUBLE PRECISION for <i>dlaqr0</i> Arrays, DIMENSION(<i>ihiz</i>) each. The real and imaginary parts, respectively, of the computed eigenvalues of <i>h</i> (<i>ilo</i> : <i>ihiz</i> , <i>ilo</i> : <i>ihiz</i>) are stored in <i>wr</i> (<i>ilo</i> : <i>ihiz</i>) and <i>wi</i> (<i>ilo</i> : <i>ihiz</i>). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)-th, with <i>wi</i> (<i>i</i>)>0 and <i>wi</i> (<i>i</i> +1)<0. If <i>wantt</i> is .TRUE.,

then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $wr(i) = h(i,i)$, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then $wi(i)=\sqrt{(-h(i+1,i)*h(i,i+1))}$.

z
If $wantz$ is .TRUE., then $z(il:ih, iloz:ihiz)$ is replaced by $z(il:ih, iloz:ihiz)*U$, where U is the orthogonal/unitary Schur factor of $h(il:ih, il:ih)$.

If $wantz$ is .FALSE., z is not referenced.

(The output values of z when $info > 0$ are given under the description of the $info$ parameter below.)

$info$
INTEGER.
= 0: the execution is successful.
> 0: if $info = i$, then the routine failed to compute all the eigenvalues. Elements $1:ilo-1$ and $i+1:n$ of wr and wi contain those eigenvalues which have been successfully computed.
> 0: if $wantt$ is .FALSE., then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through $info$ of the final output value of h .
> 0: if $wantt$ is .TRUE., then (initial value of $h)*U = U^*$ (final value of h , where U is an orthogonal/unitary matrix. The final value of h is upper Hessenberg and quasi-triangular/triangular in rows and columns $info+1$ through ih).
> 0: if $wantz$ is .TRUE., then (final value of $z(il:ih, iloz:ihiz))=(initial value of z(il:ih, iloz:ihiz)*U$, where U is the orthogonal/unitary matrix in the previous expression (regardless of the value of $wantt$).
> 0: if $wantz$ is .FALSE., then z is not accessed.

?laqr1

Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix H and specified shifts.

Syntax

```
call slaqr1( n, h, ldh, sr1, sil, sr2, si2, v )
call dlaqr1( n, h, ldh, sr1, sil, sr2, si2, v )
call claqr1( n, h, ldh, s1, s2, v )
call zlaqr1( n, h, ldh, s1, s2, v )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given a 2-by-2 or 3-by-3 matrix H , this routine sets v to a scalar multiple of the first column of the product

$K = (H - s1*I)*(H - s2*I)$, or $K = (H - (sr1 + i*si1)*I)*(H - (sr2 + i*si2)*I)$

scaling to avoid overflows and most underflows.

It is assumed that either 1) $sr1 = sr2$ and $si1 = -si2$, or 2) $si1 = si2 = 0$.

This is useful for starting double implicit shift bulges in the QR algorithm.

Input Parameters

n	INTEGER. The order of the matrix H . n must be equal to 2 or 3.
$sr1, si2, sr2, si2$	REAL for <code>slaqr1</code> DOUBLE PRECISION for <code>dlaqr1</code> Shift values that define K in the formula above.
$s1, s2$	COMPLEX for <code>claqr1</code> DOUBLE COMPLEX for <code>zlaqr1</code> . Shift values that define K in the formula above.
h	REAL for <code>slaqr1</code> DOUBLE PRECISION for <code>dlaqr1</code> COMPLEX for <code>claqr1</code> DOUBLE COMPLEX for <code>zlaqr1</code> . Array, DIMENSION (ldh, n), contains 2-by-2 or 3-by-3 matrix H in the formula above.
ldh	INTEGER. The leading dimension of the array h just as declared in the calling routine. $ldh \geq n$.

Output Parameters

v	REAL for <code>slaqr1</code> DOUBLE PRECISION for <code>dlaqr1</code> COMPLEX for <code>claqr1</code> DOUBLE COMPLEX for <code>zlaqr1</code> . Array with dimension (n) . A scalar multiple of the first column of the matrix K in the formula above.
-----	--

?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```

call slaqqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, ldwv, work, lwork )

call dlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, ldwv, work, lwork )

Description

The routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

This subroutine is identical to ?laqr3 except that it avoids recursion by calling ?lahqr instead of ?laqr4.

Input Parameters

wantt

LOGICAL.

If *wantt* = .TRUE., then the Hessenberg matrix H is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine).

If *wantt* = .FALSE., then only enough of H is updated to preserve the eigenvalues.

wantz

LOGICAL.

If *wantz* = .TRUE., then the orthogonal/unitary matrix Z is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine).

If *wantz* = .FALSE., then Z is not referenced.

n

INTEGER. The order of the Hessenberg matrix H and (if *wantz* = .TRUE.) the order of the orthogonal/unitary matrix Z .

ktop

INTEGER.

It is assumed that either *ktop*=1 or $h(ktop,ktop-1)=0$. *ktop* and *kbot* together determine an isolated block along the diagonal of the Hessenberg matrix.

kbot

INTEGER.

It is assumed without a check that either $kbot=n$ or $h(kbot+1, kbot)=0$. $ktop$ and $kbot$ together determine an isolated block along the diagonal of the Hessenberg matrix.

nw

INTEGER.

Size of the deflation window. $1 \leq nw \leq (kbot-ktop+1)$.*h*REAL **for** slaqr2DOUBLE PRECISION **for** dlaqr2COMPLEX **for** claqr2DOUBLE COMPLEX **for** zlaqr2.Array, DIMENSION ($l dh, n$), on input the initial n -by- n section of *h* stores the Hessenberg matrix *H* undergoing aggressive early deflation.*ldh*INTEGER. The leading dimension of the array *h* just as declared in the calling subroutine. $ldh \geq n$.*iloz, ihiz*INTEGER. Specify the rows of *Z* to which transformations must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ihiz \leq n$.*z*REAL **for** slaqr2DOUBLE PRECISION **for** dlaqr2COMPLEX **for** claqr2DOUBLE COMPLEX **for** zlaqr2.Array, DIMENSION ($l dz, n$), contains the matrix *Z* if *wantz* is .TRUE.. If *wantz* is .FALSE., then *z* is not referenced.*ldz*INTEGER. The leading dimension of the array *z* just as declared in the calling subroutine. $ldz \geq 1$.*v*REAL **for** slaqr2DOUBLE PRECISION **for** dlaqr2COMPLEX **for** claqr2DOUBLE COMPLEX **for** zlaqr2.Workspace array with dimension ($l dv, nw$). An nw -by- nw work array.*ldv*INTEGER. The leading dimension of the array *v* just as declared in the calling subroutine. $ldv \geq nw$.*nh*INTEGER. The number of column of *t*. $nh \geq nw$.*t*REAL **for** slaqr2DOUBLE PRECISION **for** dlaqr2COMPLEX **for** claqr2DOUBLE COMPLEX **for** zlaqr2.Workspace array with dimension ($l dt, nw$).

<i>ldt</i>	INTEGER. The leading dimension of the array <i>t</i> just as declared in the calling subroutine. $ldt \geq nw$.
<i>nv</i>	INTEGER. The number of rows of work array <i>wv</i> available for workspace. $nv \geq nw$.
<i>wv</i>	REAL for <i>slaqr2</i> DOUBLE PRECISION for <i>dlaqr2</i> COMPLEX for <i>claqr2</i> DOUBLE COMPLEX for <i>zlaqr2</i> . Workspace array with dimension $(ldwv, nw)$.
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling subroutine. $ldwv \geq nw$.
<i>work</i>	REAL for <i>slaqr2</i> DOUBLE PRECISION for <i>dlaqr2</i> COMPLEX for <i>claqr2</i> DOUBLE COMPLEX for <i>zlaqr2</i> . Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork=2 * nw$ is sufficient, but for the optimal performance a greater workspace may be required. If <i>lwork=-1</i> , then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters <i>n</i> , <i>nw</i> , <i>ktop</i> , and <i>kbot</i> . The estimate is returned in <i>work(1)</i> . No error messages related to the <i>lwork</i> is issued by <i>xerbla</i> . Neither <i>H</i> nor <i>Z</i> are accessed.

Output Parameters

<i>h</i>	On output <i>h</i> has been transformed by an orthogonal/unitary similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
<i>work(1)</i>	On exit <i>work(1)</i> is set to an estimate of the optimal value of <i>lwork</i> for the given values of the input parameters <i>n</i> , <i>nw</i> , <i>ktop</i> , and <i>kbot</i> .
<i>z</i>	If <i>wantz</i> is .TRUE., then the orthogonal/unitary similarity transformation is accumulated into <i>z(iloz:ihiz, ilo:ichi)</i> from the right. If <i>wantz</i> is .FALSE., then <i>z</i> is unreferenced.
<i>nd</i>	INTEGER. The number of converged eigenvalues uncovered by the routine.
<i>ns</i>	INTEGER. The number of unconverged, that is approximate eigenvalues returned in <i>sr</i> , <i>si</i> or in <i>sh</i> that may be used as shifts by the calling subroutine.
<i>sh</i>	COMPLEX for <i>claqr2</i>

DOUBLE COMPLEX for zlaqr2.

Arrays, DIMENSION (kbot).

The approximate eigenvalues that may be used for shifts are stored in the $sh(kbot-nd-ns+1)$ through the $sh(kbot-nd)$.

The converged eigenvalues are stored in the $sh(kbot-nd+1)$ through the $sh(kbot)$.

sr, si

REAL for slaqr2

DOUBLE PRECISION for dlaqr2

Arrays, DIMENSION (kbot) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the $sr(kbot-nd-ns+1)$ through the $sr(kbot-nd)$, and $si(kbot-nd-ns+1)$ through the $si(kbot-nd)$, respectively.

The real and imaginary parts of converged eigenvalues are stored in the $sr(kbot-nd+1)$ through the $sr(kbot)$, and $si(kbot-nd+1)$ through the $si(kbot)$, respectively.

?laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
call dlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
call claqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
call zlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

The routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

Input Parameters

<i>wantt</i>	LOGICAL. If <i>wantt</i> = .TRUE., then the Hessenberg matrix <i>H</i> is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine). If <i>wantt</i> = .FALSE., then only enough of <i>H</i> is updated to preserve the eigenvalues.
<i>wantz</i>	LOGICAL. If <i>wantz</i> = .TRUE., then the orthogonal/unitary matrix <i>Z</i> is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine). If <i>wantz</i> = .FALSE., then <i>Z</i> is not referenced.
<i>n</i>	INTEGER. The order of the Hessenberg matrix <i>H</i> and (if <i>wantz</i> = .TRUE.) the order of the orthogonal/unitary matrix <i>Z</i> .
<i>ktop</i>	INTEGER. It is assumed that either <i>ktop</i> =1 or <i>h</i> (<i>ktop</i> , <i>ktop</i> -1)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>kbot</i>	INTEGER. It is assumed without a check that either <i>kbot</i> = <i>n</i> or <i>h</i> (<i>kbot</i> +1, <i>kbot</i>)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>nw</i>	INTEGER. Size of the deflation window. $1 \leq nw \leq (kbot - ktop + 1)$.
<i>h</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> DOUBLE COMPLEX for <i>zlaqr3</i> . Array, DIMENSION (<i>ldh</i> , <i>n</i>), on input the initial <i>n</i> -by- <i>n</i> section of <i>h</i> stores the Hessenberg matrix <i>H</i> undergoing aggressive early deflation.
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling subroutine. $ldh \geq n$.
<i>iloz</i> , <i>ihiz</i>	INTEGER. Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> DOUBLE COMPLEX for <i>zlaqr3</i> .

Array, **DIMENSION** (*ldz*, *n*), contains the matrix *Z* if *wantz* is .TRUE.. If *wantz* is .FALSE., then *z* is not referenced.

ldz INTEGER. The leading dimension of the array *z* just as declared in the calling subroutine. *ldz* $\geq 1.$

v REAL **for** *slaqr3*

DOUBLE PRECISION **for** *dlaqr3*

COMPLEX **for** *claqr3*

DOUBLE COMPLEX **for** *zlaqr3*.

Workspace array with dimension (*ldv*, *nw*). An *nw*-by-*nw* work array.

ldv INTEGER. The leading dimension of the array *v* just as declared in the calling subroutine. *ldv* $\geq nw.$

nh INTEGER. The number of column of *t*. *nh* $\geq nw.$

t REAL **for** *slaqr3*

DOUBLE PRECISION **for** *dlaqr3*

COMPLEX **for** *claqr3*

DOUBLE COMPLEX **for** *zlaqr3*.

Workspace array with dimension (*ldt*, *nw*).

ldt INTEGER. The leading dimension of the array *t* just as declared in the calling subroutine. *ldt* $\geq nw.$

nv INTEGER. The number of rows of work array *wv* available for workspace. *nv* $\geq nw.$

wv REAL **for** *slaqr3*

DOUBLE PRECISION **for** *dlaqr3*

COMPLEX **for** *claqr3*

DOUBLE COMPLEX **for** *zlaqr3*.

Workspace array with dimension (*ldwv*, *nw*).

ldwv INTEGER. The leading dimension of the array *wv* just as declared in the calling subroutine. *ldwv* $\geq nw.$

work REAL **for** *slaqr3*

DOUBLE PRECISION **for** *dlaqr3*

COMPLEX **for** *claqr3*

DOUBLE COMPLEX **for** *zlaqr3*.

Workspace array with dimension *lwork*.

lwork INTEGER. The dimension of the array *work*.

`lwork=2*nw`) is sufficient, but for the optimal performance a greater workspace may be required.

If `lwork=-1`, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters `n`, `nw`, `ktop`, and `kbot`. The estimate is returned in `work(1)`. No error messages related to the `lwork` is issued by `xerbla`. Neither `H` nor `Z` are accessed.

Output Parameters

`h`

On output `h` has been transformed by an orthogonal/unitary similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

`work(1)`

On exit `work(1)` is set to an estimate of the optimal value of `lwork` for the given values of the input parameters `n`, `nw`, `ktop`, and `kbot`.

`z`

If `wantz` is .TRUE., then the orthogonal/unitary similarity transformation is accumulated into `z(iloz:ihiz, ilo:ichi)` from the right.

If `wantz` is .FALSE., then `z` is unreferenced.

`nd`

INTEGER. The number of converged eigenvalues uncovered by the routine.

`ns`

INTEGER. The number of unconverged, that is approximate eigenvalues returned in `sr`, `si` or in `sh` that may be used as shifts by the calling subroutine.

`sh`

COMPLEX for `claqr3`

DOUBLE COMPLEX for `zlaqr3`.

Arrays, DIMENSION (`kbot`).

The approximate eigenvalues that may be used for shifts are stored in the `sh(kbot-nd-ns+1)` through the `sh(kbot-nd)`.

The converged eigenvalues are stored in the `sh(kbot-nd+1)` through the `sh(kbot)`.

`sr, si`

REAL for `slaqr3`

DOUBLE PRECISION for `dlaqr3`

Arrays, DIMENSION (`kbot`) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the `sr(kbot-nd-ns+1)` through the `sr(kbot-nd)`, and `si(kbot-nd-ns+1)` through the `si(kbot-nd)`, respectively.

The real and imaginary parts of converged eigenvalues are stored in the `sr(kbot-nd+1)` through the `sr(kbot)`, and `si(kbot-nd+1)` through the `si(kbot)`, respectively.

?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```

call slaqqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )

call dlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )

call claqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )

call zlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^* H^* Q^H = (QZ)^* H^* (QZ)^H$.

This routine implements one level of recursion for ?laqr0. It is a complete implementation of the small bulge multi-shift QR algorithm. It may be called by ?laqr0 and, for large enough deflation window size, it may be called by ?laqr3. This routine is identical to ?laqr0 except that it calls ?laqr2 instead of ?laqr3.

Input Parameters

<code>wantt</code>	LOGICAL. If <code>wantt</code> = .TRUE., the full Schur form T is required; If <code>wantt</code> = .FALSE., only eigenvalues are required.
<code>wantz</code>	LOGICAL. If <code>wantz</code> = .TRUE., the matrix of Schur vectors Z is required; If <code>wantz</code> = .FALSE., Schur vectors are not required.
<code>n</code>	INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).
<code>ilo, ihi</code>	INTEGER. It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $h(ilo, ilo-1) = 0$. <code>ilo</code> and <code>ihi</code> are normally set by a previous call to cgebal, and then passed to cgehrd when the matrix output by cgebal is reduced to Hessenberg form. Otherwise, <code>ilo</code> and <code>ihi</code> should be set to 1 and n , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n=0$, then <code>ilo=1</code> and <code>ihi=0</code>

h REAL for `slaqr4`
 DOUBLE PRECISION for `dlaqr4`
 COMPLEX for `claqr4`
 DOUBLE COMPLEX for `zlaqr4`.
 Array, DIMENSION (*ldh, n*), contains the upper Hessenberg matrix *H*.

ldh INTEGER. The leading dimension of the array *h*. *ldh* $\geq \max(1, n)$.

ilo, ihiz INTEGER. Specify the rows of *Z* to which transformations must be applied if *wantz* is .TRUE., $1 \leq ilo \leq ihi; ihi \leq ihiz \leq n$.

z REAL for `slaqr4`
 DOUBLE PRECISION for `dlaqr4`
 COMPLEX for `claqr4`
 DOUBLE COMPLEX for `zlaqr4`.
 Array, DIMENSION (*ldz, ihi*), contains the matrix *Z* if *wantz* is .TRUE.. If *wantz* is .FALSE., *z* is not referenced.

ldz INTEGER. The leading dimension of the array *z*.
 If *wantz* is .TRUE., then *ldz* $\geq \max(1, ihiz)$. Otherwise, *ldz* ≥ 1 .

work REAL for `slaqr4`
 DOUBLE PRECISION for `dlaqr4`
 COMPLEX for `claqr4`
 DOUBLE COMPLEX for `zlaqr4`.
 Workspace array with dimension *lwork*.

lwork INTEGER. The dimension of the array *work*.
 lwork $\geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$.
 It is recommended to use the workspace query to determine the optimal workspace size. If *lwork=-1*, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters *n, ilo*, and *ihi*. The estimate is returned in *work(1)*. No error messages related to the *lwork* is issued by `xerbla`. Neither *H* nor *Z* are accessed.

Output Parameters

h If *info=0*, and *wantt* is .TRUE., then *h* contains the upper quasi-triangular/triangular matrix *T* from the Schur decomposition (the Schur form).
 If *info=0*, and *wantt* is .FALSE., then the contents of *h* are unspecified on exit.
 (The output values of *h* when *info > 0* are given under the description of the *info* parameter below.)

The routines may explicitly set $h(i,j)$ for $i > j$ and $j=1, 2, \dots, ilo-1$ or $j=ih+1, ih+2, \dots, n$.

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

w

COMPLEX for *claqr4*

DOUBLE COMPLEX for *zlaqr4*.

Arrays, DIMENSION(*n*). The computed eigenvalues of $h(il:ih, il:ih)$ are stored in *w(il:ih)*. If *wantt* is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with $w(i) = h(i,i)$.

wr, wi

REAL for *slaqr4*

DOUBLE PRECISION for *dlaqr4*

Arrays, DIMENSION(*ih*) each. The real and imaginary parts, respectively, of the computed eigenvalues of $h(il:ih, il:ih)$ are stored in the *wr(il:ih)* and *wi(il:ih)*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with *wi(i)* > 0 and *wi(i+1)* < 0. If *wantt* is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *wr(i) = h(i,i)*, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then *wi(i)=sqrt(-h(i+1,i)*h(i,i+1))*.

z

If *wantz* is .TRUE., then $z(il:ih, iloz:ihiz)$ is replaced by $z(il:ih, iloz:ihiz)*U$, where *U* is the orthogonal/unitary Schur factor of $h(il:ih, il:ih)$.

If *wantz* is .FALSE., *z* is not referenced.

(The output values of *z* when *info* > 0 are given under the description of the *info* parameter below.)

info

INTEGER.

= 0: the execution is successful.

> 0: if *info* = *i*, then the routine failed to compute all the eigenvalues.

Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

> 0: if *wantt* is .FALSE., then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is .TRUE., then (initial value of *h*)**U* = *U** (final value of *h*), where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ih*.

> 0: if *wantz* is .TRUE., then (final value of *z(il:ih, iloz:ihiz)*)=(initial value of *z(il:ih, iloz:ihiz)*)**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is .FALSE., then *z* is not accessed.

?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
call slaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz, ihiz,
z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
call dlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz, ihiz,
z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
call claqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz, ihiz, z,

Description

This auxiliary routine called by ?laqr0 performs a single small-bulge multi-shift QR sweep.

Input Parameters

<i>wantt</i>	LOGICAL.
	<i>wantt</i> = .TRUE. if the quasi-triangular/triangular Schur factor is computed.
	<i>wantt</i> is set to .FALSE. otherwise.
<i>wantz</i>	LOGICAL.
	<i>wantz</i> = .TRUE. if the orthogonal/unitary Schur factor is computed.
	<i>wantz</i> is set to .FALSE. otherwise.
<i>kacc22</i>	INTEGER. Possible values are 0, 1, or 2.
	Specifies the computation mode of far-from-diagonal orthogonal updates.
	= 0: the routine does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.
	= 1: the routine accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.
	= 2: the routine accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	INTEGER. The order of the Hessenberg matrix <i>H</i> upon which the routine operates.

<i>ktop, kbot</i>	INTEGER. It is assumed without a check that either <i>ktop</i> =1 or <i>h</i> (<i>ktop</i> , <i>ktop</i> -1)=0, and either <i>kbot</i> = <i>n</i> or <i>h</i> (<i>kbot</i> +1, <i>kbot</i>)=0.
<i>nshfts</i>	INTEGER. Number of simultaneous shifts, must be positive and even.
<i>sr, si</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 Arrays, DIMENSION (<i>nshfts</i>) each. <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.
<i>s</i>	COMPLEX for claqr5 DOUBLE COMPLEX for zlaqr5. Arrays, DIMENSION (<i>nshfts</i>). <i>s</i> contains the shifts of origin that define the multi-shift QR sweep.
<i>h</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 DOUBLE COMPLEX for zlaqr5. Array, DIMENSION (<i>ldh</i> , <i>n</i>), on input contains the Hessenberg matrix.
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling routine. <i>ldh</i> $\geq \max(1, n)$.
<i>iloz, ihiz</i>	INTEGER. Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 DOUBLE COMPLEX for zlaqr5. Array, DIMENSION (<i>ldz</i> , <i>ihi</i>), contains the matrix <i>Z</i> if <i>wantz</i> is .TRUE.. If <i>wantz</i> is .FALSE., then <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling routine. <i>ldz</i> $\geq n$.
<i>v</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 DOUBLE COMPLEX for zlaqr5. Workspace array with dimension (<i>ldv</i> , <i>nshfts</i> /2).

<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling routine. $ldv \geq 3$.
<i>u</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension $(ldu, 3*nshfts-3)$.
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> just as declared in the calling routine. $ldu \geq 3*nshfts-3$.
<i>nh</i>	INTEGER. The number of column in the array <i>wh</i> available for workspace. $nh \geq 1$.
<i>wh</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension $(ldwh, nh)$
<i>ldwh</i>	INTEGER. The leading dimension of the array <i>wh</i> just as declared in the calling routine. $ldwh \geq 3*nshfts-3$
<i>nv</i>	INTEGER. The number of rows of the array <i>wv</i> available for workspace. $nv \geq 1$.
<i>wv</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension $(ldwv, 3*nshfts-3)$.
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling routine. $ldwv \geq nv$.

Output Parameters

<i>sr, si</i>	On output, may be reordered.
<i>h</i>	On output a multi-shift QR Sweep with shifts $sr(j)+i*si(j)$ or $s(j)$ is applied to the isolated diagonal block in rows and columns <i>ktop</i> through <i>kbot</i> .
<i>z</i>	If <i>wantz</i> is .TRUE., then the QR Sweep orthogonal/unitary similarity transformation is accumulated into $z(iloz:ihiz, ilo:ihj)$ from the right. If <i>wantz</i> is .FALSE., then <i>z</i> is unreferenced.

?laqsb

Scales a symmetric band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call slaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call dlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call claqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call zlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Include Files

- Fortran: mkl.fi

Description

The routine equilibrates a symmetric band matrix A using the scaling factors in the vector s .

Input Parameters

uplo CHARACTER*1.
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored.
 If *uplo* = 'U': upper triangular.
 If *uplo* = 'L': lower triangular.

n INTEGER. The order of the matrix A .
 $n \geq 0$.

kd INTEGER. The number of super-diagonals of the matrix A if *uplo* = 'U', or the number of sub-diagonals if *uplo* = 'L'.
 $kd \geq 0$.

ab REAL for slaqsb
 DOUBLE PRECISION for dlaqsb
 COMPLEX for claqsb
 DOUBLE COMPLEX for zlaqsb
 Array, DIMENSION (*ldab,n*). On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array *ab* as follows:
 if *uplo* = 'U', $ab(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) \leq i \leq j$;
 if *uplo* = 'L', $ab(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq kd+1$.

<i>s</i>	REAL for <code>slaqsb/claqsb</code> DOUBLE PRECISION for <code>dlaqsb/zlaqsb</code> Array, DIMENSION (<i>n</i>). The scale factors for <i>A</i> .
<i>scond</i>	REAL for <code>slaqsb/claqsb</code> DOUBLE PRECISION for <code>dlaqsb/zlaqsb</code> Ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for <code>slaqsb/claqsb</code> DOUBLE PRECISION for <code>dlaqsb/zlaqsb</code> Absolute value of largest matrix entry.

Output Parameters

<i>ab</i>	On exit, if <i>info</i> = 0, the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of the band matrix <i>A</i> that can be <i>A</i> = <i>U</i> ^T * <i>U</i> or <i>A</i> = <i>L</i> * <i>L</i> ^T for real flavors and <i>A</i> = <i>U</i> ^H * <i>U</i> or <i>A</i> = <i>L</i> * <i>L</i> ^H for complex flavors, in the same storage format as <i>A</i> .
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i> (<i>s</i>)* <i>A</i> * <i>diag</i> (<i>s</i>).

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqsp

Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ.

Syntax

```
call slaqsp( uplo, n, ap, s, scond, amax, equed )
call dlaqsp( uplo, n, ap, s, scond, amax, equed )
call claqsp( uplo, n, ap, s, scond, amax, equed )
call zlaqsp( uplo, n, ap, s, scond, amax, equed )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine ?laqsp equilibrates a symmetric matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. If $uplo = 'U'$: upper triangular. If $uplo = 'L'$: lower triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>ap</i>	REAL for <code>slaqsp</code> DOUBLE PRECISION for <code>dlaqsp</code> COMPLEX for <code>claqsp</code> DOUBLE COMPLEX for <code>zlaqsp</code> Array, DIMENSION $(n(n+1)/2)$. On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array <i>ap</i> as follows: <code>if uplo = 'U', ap(i + (j-1)j/2) = A(i,j) for 1 ≤ i ≤ j;</code> <code>if uplo = 'L', ap(i + (j-1)(2n-j)/2) = A(i,j) for j≤i≤n.</code>
<i>s</i>	REAL for <code>slaqsp/claqsp</code> DOUBLE PRECISION for <code>dlaqsp/zlaqsp</code> Array, DIMENSION (<i>n</i>). The scale factors for A .
<i>scond</i>	REAL for <code>slaqsp/claqsp</code> DOUBLE PRECISION for <code>dlaqsp/zlaqsp</code> Ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for <code>slaqsp/claqsp</code> DOUBLE PRECISION for <code>dlaqsp/zlaqsp</code> Absolute value of largest matrix entry.

Output Parameters

<i>ap</i>	On exit, the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$, in the same storage format as A .
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If $equed = 'N'$: No equilibration.

If $\text{equed} = \text{'Y'}$: Equilibration was done, that is, A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters thresh , large , and small , which have the following meaning. thresh is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < \text{thresh}$, scaling is done. large and small are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, scaling is done.

?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ.

Syntax

```
call slaqsy( uplo, n, a, lda, s, scond, amax, equed )
call dlaqsy( uplo, n, a, lda, s, scond, amax, equed )
call claqsy( uplo, n, a, lda, s, scond, amax, equed )
call zlaqsy( uplo, n, a, lda, s, scond, amax, equed )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine equilibrates a symmetric matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. If $\text{uplo} = \text{'U'}$: upper triangular. If $\text{uplo} = \text{'L'}$: lower triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	REAL for slaqsy DOUBLE PRECISION for dlaqsy COMPLEX for claqsy DOUBLE COMPLEX for zlaqsy Array, DIMENSION (<i>lda,n</i>). On entry, the symmetric matrix A . If $\text{uplo} = \text{'U'}$, the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of <i>a</i> is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda	INTEGER. The leading dimension of the array a .
	$lda \geq \max(n, 1)$.
s	REAL for <code>slaqsy/claqsy</code> DOUBLE PRECISION for <code>dlaqsy/zlaqsy</code> Array, DIMENSION (n). The scale factors for A .
$scond$	REAL for <code>slaqsy/claqsy</code> DOUBLE PRECISION for <code>dlaqsy/zlaqsy</code> Ratio of the smallest $s(i)$ to the largest $s(i)$.
$amax$	REAL for <code>slaqsy/claqsy</code> DOUBLE PRECISION for <code>dlaqsy/zlaqsy</code> Absolute value of largest matrix entry.

Output Parameters

a	On exit, if $equed = 'Y'$, the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$.
$equed$	CHARACTER*1. Specifies whether or not equilibration was done. If $equed = 'N'$: No equilibration. If $equed = 'Y'$: Equilibration was done, i.e., A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters $thresh$, $large$, and $small$, which have the following meaning. $thresh$ is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done. $large$ and $small$ are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqtr

Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.

Syntax

```
call slaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
call dlaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
```

Include Files

- Fortran: `mkl.fi`

- C: mkl.h

Description

The routine ?laqtr solves the real quasi-triangular system

`op(T) * p = scale*c, if lreal = .TRUE.`

or the complex quasi-triangular systems

`op(T + iB) * (p+iq) = scale*(c+id), if lreal = .FALSE.`

in real arithmetic, where T is upper quasi-triangular.

If `lreal = .FALSE.`, then the first diagonal block of T must be 1-by-1, B is the specially structured matrix

$\text{op}(A) = A \text{ or } A^T$, A^T denotes the transpose of matrix A .

On input,

www.ijerph.org | ISSN: 1660-4601 | DOI: 10.3390/ijerph17030894

This routine is designed for the condition number estimation in routine ?trsna.

Input Parameters

ltran

LOGICAL.

On entry, *Itran* specifies the option of conjugate transpose:

$= .\text{FALSE}., \text{op}(T + iB) = T + iB,$

$$= .\text{TRUE}. , \text{op}(T + iB) = (T + iB)^T.$$

1real

LOGICAL.

On entry, *lreal* specifies the input matrix structure:

`≡ .FALSE., the input is complex`

= TRUE the input is real

n

INTEGER

On entry, n specifies the order of $T + iB$, $n \geq 0$.

七

BEAT for slagter

DOUBLE PRECISION **for** `dlaqtr`

Array, dimension (ldt, n). On entry, t contains a matrix in Schur canonical form. If $lreal = .FALSE.$, then the first diagonal block of t must be 1-by-1.

ldt

INTEGER. The leading dimension of the matrix T .

$ldt \geq \max(1, n)$.

b

REAL **for** `slaqtr`

DOUBLE PRECISION **for** `dlaqtr`

Array, dimension (n). On entry, b contains the elements to form the matrix B as described above. If $lreal = .TRUE.$, b is not referenced.

w

REAL **for** `slaqtr`

DOUBLE PRECISION **for** `dlaqtr`

On entry, w is the diagonal element of the matrix B .

If $lreal = .TRUE.$, w is not referenced.

x

REAL **for** `slaqtr`

DOUBLE PRECISION **for** `dlaqtr`

Array, dimension ($2n$). On entry, x contains the right hand side of the system.

$work$

REAL **for** `slaqtr`

DOUBLE PRECISION **for** `dlaqtr`

Workspace array, dimension (n).

Output Parameters

$scale$

REAL **for** `slaqtr`

DOUBLE PRECISION **for** `dlaqtr`

On exit, $scale$ is the scale factor.

x

On exit, X is overwritten by the solution.

$info$

INTEGER.

If $info = 0$: successful exit.

If $info = 1$: the some diagonal 1-by-1 block has been perturbed by a small number $smin$ to keep nonsingularity.

If $info = 2$: the some diagonal 2-by-2 block has been perturbed by a small number in `?laln2` to keep nonsingularity.

NOTE

For higher speed, this routine does not check the inputs for errors.

?lar1v

Computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of tridiagonal matrix.

Syntax

```
call slar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
call dlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
call clar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
call zlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lar1v computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $L^*D^*L^T - \lambda^*I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude.

The following steps accomplish this computation :

- Stationary qd transform, $L^*D^*L^T - \lambda^*I = L(+)^*D(+)^*L(+)^T$
- Progressive qd transform, $L^*D^*L^T - \lambda^*I = U(-)^*D(-)^*U(-)^T$,
- Computation of the diagonal elements of the inverse of $L^*D^*L^T - \lambda^*I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
- Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix $L^*D^*L^T$.
<i>b1</i>	INTEGER. First index of the submatrix of $L^*D^*L^T$.
<i>bn</i>	INTEGER. Last index of the submatrix of $L^*D^*L^T$.
<i>lambda</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v
	The shift. To compute an accurate eigenvector, <i>lambda</i> should be a good approximation to an eigenvalue of $L^*D^*L^T$.
<i>l</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v

Array, DIMENSION (n-1).

The (n-1) subdiagonal elements of the unit bidiagonal matrix L , in elements 1 to n-1.

d

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

Array, DIMENSION (n).

The n diagonal elements of the diagonal matrix D .

ld

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

Array, DIMENSION (n-1).

The $n-1$ elements $L_i^*D_i$.

lld

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

Array, DIMENSION (n-1).

The $n-1$ elements $L_i^*L_i^*D_i$.

pivmin

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

The minimum pivot in the Sturm sequence.

gaptol

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.

z

REAL for slar1v

DOUBLE PRECISION for dlar1v

COMPLEX for clar1v

DOUBLE COMPLEX for zlar1v

Array, DIMENSION (n). All entries of *z* must be set to 0.

wantnc

LOGICAL.

Specifies whether *negcnt* has to be computed.

r

INTEGER.

The twist index for the twisted factorization used to compute *z*. On input, $0 \leq r \leq n$. If *r* is input as 0, *r* is set to the index where $(L^*D^*L^T - \lambda^*I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, *r* is unchanged.

work

REAL for slar1v/clar1v

DOUBLE PRECISION for dlar1v/zlar1v

Workspace array, DIMENSION (4*n).

Output Parameters

<i>z</i>	REAL for slar1v DOUBLE PRECISION for dlar1v COMPLEX for clar1v DOUBLE COMPLEX for zlar1v Array, DIMENSION (n). The (scaled) <i>r</i> -th column of the inverse. <i>z(r)</i> is returned to be 1.
<i>negcnt</i>	INTEGER. If <i>wantnc</i> is .TRUE. then <i>negcnt</i> = the number of pivots < <i>pivmin</i> in the matrix factorization $L^*D^*L^T$, and <i>negcnt</i> = -1 otherwise.
<i>ztz</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v The square of the 2-norm of <i>z</i> .
<i>mingma</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v The reciprocal of the largest (in magnitude) diagonal element of the inverse of $L^*D^*L^T - \lambda I$.
<i>r</i>	On output, <i>r</i> is the twist index used to compute <i>z</i> . Ideally, <i>r</i> designates the position of the maximum entry in the eigenvector.
<i>isuppz</i>	INTEGER. Array, DIMENSION (2). The support of the vector in <i>Z</i> , that is, the vector <i>z</i> is nonzero only in elements <i>isuppz</i> (1) through <i>isuppz</i> (2).
<i>nrminv</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v Equals $1/\sqrt{ztz}$.
<i>resid</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v The residual of the FP vector. <i>resid</i> = ABS(<i>mingma</i>)/sqrt(<i>ztz</i>).
<i>rqcorr</i>	REAL for slar1v/clar1v DOUBLE PRECISION for dlar1v/zlar1v The Rayleigh Quotient correction to <i>lambda</i> . <i>rqcorr</i> = <i>mingma</i> / <i>ztz</i> .

?lar2v

Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.

Syntax

```
call slar2v( n, x, y, z, incx, c, s, incc )
call dlar2v( n, x, y, z, incx, c, s, incc )
call clar2v( n, x, y, z, incx, c, s, incc )
call zlar2v( n, x, y, z, incx, c, s, incc )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lar2v applies a vector of real/complex plane rotations with real cosines from both sides to a sequence of 2-by-2 real symmetric or complex Hermitian matrices, defined by the elements of the vectors x, y and z. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i & z_i \\ \text{conj}(z_i) & y_i \end{bmatrix} := \begin{bmatrix} c(i) & \text{conj}(s(i)) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i & z_i \\ \text{conj}(z_i) & y_i \end{bmatrix} \begin{bmatrix} c(i) & -\text{conj}(s(i)) \\ s(i) & c(i) \end{bmatrix}$$

Input Parameters

<i>n</i>	INTEGER. The number of plane rotations to be applied.
<i>x, y, z</i>	REAL for slar2v DOUBLE PRECISION for dlar2v COMPLEX for clar2v DOUBLE COMPLEX for zlar2v Arrays, DIMENSION (1+(n-1)*incx) each. Contain the vectors x, y and z, respectively. For all flavors of ?lar2v, elements of x and y are assumed to be real.
<i>incx</i>	INTEGER. The increment between elements of x, y, and z. $incx > 0$.
<i>c</i>	REAL for slar2v/clar2v DOUBLE PRECISION for dlar2v/zlar2v Array, DIMENSION (1+(n-1)*incc). The cosines of the plane rotations.
<i>s</i>	REAL for slar2v DOUBLE PRECISION for dlar2v COMPLEX for clar2v

DOUBLE COMPLEX for zlar2v
Array, DIMENSION (1+(n-1)*incc). The sines of the plane rotations.
incc INTEGER. The increment between elements of *c* and *s*. *incc* > 0.

Output Parameters

<i>x, y, z</i>	Vectors <i>x, y</i> and <i>z</i> , containing the results of transform.
----------------	---

?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call slarf( side, m, n, v, incv, tau, c, ldc, work )
call dlarf( side, m, n, v, incv, tau, c, ldc, work )
call clarf( side, m, n, v, incv, tau, c, ldc, work )
call zlarf( side, m, n, v, incv, tau, c, ldc, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in one of the following forms:

- $H = I - \tau v^* v^T$
where τ is a real scalar and v is a real vector.
If $\tau = 0$, then H is taken to be the unit matrix.
- $H = I - \tau v^* v^H$
where τ is a complex scalar and v is a complex vector.
If $\tau = 0$, then H is taken to be the unit matrix. For clarf/zlarf, to apply H^H (the conjugate transpose of H), supply conjg(τ) instead of τ .

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form $H*C$ If <i>side</i> = 'R': form $C*H$.
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>v</i>	REAL for slarf

DOUBLE PRECISION **for** dlarf
 COMPLEX **for** clarf
 DOUBLE COMPLEX **for** zlarf
Array, DIMENSION
 $(1 + (m-1) * \text{abs}(incv))$ if $\text{side} = 'L'$ or
 $(1 + (n-1) * \text{abs}(incv))$ if $\text{side} = 'R'$. The vector v in the representation of H . v is not used if $\tau = 0$.

incv INTEGER. The increment between elements of v .
 $incv \neq 0$.

tau REAL **for** slarf
 DOUBLE PRECISION **for** dlarf
 COMPLEX **for** clarf
 DOUBLE COMPLEX **for** zlarf
 The value τ in the representation of H .

c REAL **for** slarf
 DOUBLE PRECISION **for** dlarf
 COMPLEX **for** clarf
 DOUBLE COMPLEX **for** zlarf
Array, DIMENSION (ldc, n).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array c .
 $ldc \geq \max(1, m)$.

work REAL **for** slarf
 DOUBLE PRECISION **for** dlarf
 COMPLEX **for** clarf
 DOUBLE COMPLEX **for** zlarf
Workspace array, DIMENSION
 (n) if $\text{side} = 'L'$ or
 (m) if $\text{side} = 'R'$.

Output Parameters

c On exit, C is overwritten by the matrix $H*C$ if $\text{side} = 'L'$, or $C*H$ if $\text{side} = 'R'$.

?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call slarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )

call dlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )

call clarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )

call zlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

C:

```
lapack_int LAPACKE_<?>larfb (int matrix_layout, char side, char trans, char direct,
char storev, lapack_int m, lapack_int n, lapack_int k, const <datatype> * v,
lapack_int ldv, const <datatype> * t, lapack_int ldt, <datatype> * c, lapack_int ldc);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The real flavors of the routine ?larfb apply a real block reflector H or its transpose H^T to a real m -by- n matrix C from either left or right.

The complex flavors of the routine ?larfb apply a complex block reflector H or its conjugate transpose H^H to a complex m -by- n matrix C from either left or right.

Input Parameters

The data types are given for the Fortran interface.

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': apply H or H^T for real flavors and H or H^H for complex flavors from the left. If <i>side</i> = 'R': apply H or H^T for real flavors and H or H^H for complex flavors from the right.
<i>trans</i>	CHARACTER*1. If <i>trans</i> = 'N': apply H (No transpose). If <i>trans</i> = 'C': apply H^H (Conjugate transpose). If <i>trans</i> = 'T': apply H^T (Transpose).
<i>direct</i>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors If <i>direct</i> = 'F': $H = H(1)*H(2)*\dots*H(k)$ (forward)

If `direct = 'B'`: $H = H(k) * \dots * H(2) * H(1)$ (backward)

`storev`

CHARACTER*1.

Indicates how the vectors which define the elementary reflectors are stored:

If `storev = 'C'`: Column-wise

If `storev = 'R'`: Row-wise

`m`

INTEGER. The number of rows of the matrix C .

`n`

INTEGER. The number of columns of the matrix C .

`k`

INTEGER. The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector).

`v`

REAL **for** `slarfb`

DOUBLE PRECISION **for** `dlarfb`

COMPLEX **for** `clarfb`

DOUBLE COMPLEX **for** `zlarfb`

Array, DIMENSION

(ldv, k) if `storev = 'C'`

(ldv, m) if `storev = 'R'` and `side = 'L'`

(ldv, n) if `storev = 'R'` and `side = 'R'`

The matrix v . See *Application Notes* below.

`ldv`

INTEGER. The leading dimension of the array v .

If `storev = 'C'` and `side = 'L'`, $ldv \geq \max(1, m)$;

if `storev = 'C'` and `side = 'R'`, $ldv \geq \max(1, n)$;

if `storev = 'R'`, $ldv \geq k$.

`t`

REAL **for** `slarfb`

DOUBLE PRECISION **for** `dlarfb`

COMPLEX **for** `clarfb`

DOUBLE COMPLEX **for** `zlarfb`

Array, DIMENSION (ldt, k).

Contains the triangular k -by- k matrix T in the representation of the block reflector.

`ldt`

INTEGER. The leading dimension of the array t .

$ldt \geq k$.

`c`

REAL **for** `slarfb`

DOUBLE PRECISION **for** `dlarfb`

COMPLEX **for** `clarfb`

DOUBLE COMPLEX for zlarfb
Array, DIMENSION (*ldc,n*).
 On entry, the *m*-by-*n* matrix *C*.

ldc INTEGER. The leading dimension of the array *c*.
 $ldc \geq \max(1, m)$.

work REAL for slarfb
 DOUBLE PRECISION for dlarfb
 COMPLEX for clarfb
 DOUBLE COMPLEX for zlarfb
Workspace array, DIMENSION (*ldwork, k*).
ldwork INTEGER. The leading dimension of the array *work*.
If *side* = 'L', *ldwork* $\geq \max(1, n)$;
if *side* = 'R', *ldwork* $\geq \max(1, m)$.

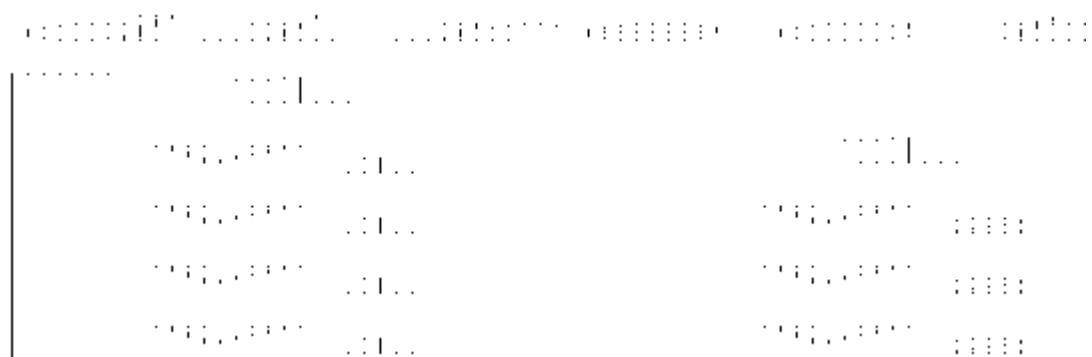

Output Parameters

c On exit, *c* is overwritten by the product of the following:

- H^*C , or H^T*C , or C^*H , or C^*H^T for real flavors
- H^*C , or $H^{H*}C$, or C^*H , or C^*H^H for complex flavors

Application Notes

The shape of the matrix *V* and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with *n* = 5 and *k* = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'B' and storev = 'C': direct = 'B' and storev = 'R':

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 \\ v_2 & v_2 & v_2 & 1 \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call slarfg( n, alpha, x, incx, tau )
call dlarfg( n, alpha, x, incx, tau )
call clarfg( n, alpha, x, incx, tau )
call zlarfg( n, alpha, x, incx, tau )
```

C:

```
lapack_int LAPACKE_<?>larfg (lapack_int n, <datatype> * alpha, <datatype> * x,
lapack_int incx, <datatype> * tau);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larfg generates a real/complex elementary reflector H of order n , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, H^T * H = I, \quad \text{for real flavors and}$$

$$H^X * \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, H^X * H = I, \quad \text{for complex flavors,}$$

where α and β are scalars (with β real for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v' \end{bmatrix} \quad \text{for complex flavors,}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector, respectively. Note that for `clarfg/zlarfg`, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $\text{abs}(\tau - 1) \leq 1$ (for complex flavors).

Input Parameters

The data types are given for the Fortran interface.

<i>n</i>	INTEGER. The order of the elementary reflector.
<i>alpha</i>	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> DOUBLE COMPLEX for <code>zlarfg</code> On entry, the value α .
<i>x</i>	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> DOUBLE COMPLEX for <code>zlarfg</code> Array, DIMENSION $(1+(n-2)*\text{abs}(incx))$. On entry, the vector x .
<i>incx</i>	INTEGER. The increment between elements of x . $incx > 0$.

Output Parameters

<i>alpha</i>	On exit, it is overwritten with the value β .
<i>x</i>	On exit, it is overwritten with the vector v .
<i>tau</i>	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> DOUBLE COMPLEX for <code>zlarfg</code> The value τ .

?larfgp

Generates an elementary reflector (Householder matrix) with non-negative beta .

Syntax

```
call slarfgp( n, alpha, x, incx, tau )
call dlarfgp( n, alpha, x, incx, tau )
call clarfgp( n, alpha, x, incx, tau )
```

```
call zlarfgp( n, alpha, x, incx, tau )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larfgp generates a real/complex elementary reflector H of order n , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, H^T * H = I, \quad \text{for real flavors and}$$

$$H^X * \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, H^X * H = I, \quad \text{for complex flavors,}$$

where α and β are scalars (with β real and non-negative for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \tau * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v' \end{bmatrix} \quad \text{for complex flavors,}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that for c/zlarfgp, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \operatorname{Re}(\tau) \leq 2$ and $\operatorname{abs}(\tau-1) \leq 1$ (for complex flavors).

Input Parameters

n INTEGER. The order of the elementary reflector.

alpha REAL for slarfgp

DOUBLE PRECISION for dlarfgp

COMPLEX for clarfgp

DOUBLE COMPLEX for zlarfgp

On entry, the value alpha.

x REAL for s

DOUBLE PRECISION for dlarfgp

COMPLEX for clarfgp

DOUBLE COMPLEX for zlarfgp

Array, DIMENSION $(1+(n-2)*\operatorname{abs}(incx))$.

On entry, the vector x .

incx INTEGER.

The increment between elements of x . $incx > 0$.

Output Parameters

alpha On exit, it is overwritten with the value *beta*.

x On exit, it is overwritten with the vector v .

tau REAL for slarfpg
DOUBLE PRECISION for dlarfpg
COMPLEX for clarfpg
DOUBLE COMPLEX for zlarfpg
The value *tau*.

?larft

Forms the triangular factor T of a block reflector $H = I - V^*T^*V^{**}H$.

Syntax

```
call slarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
```

C:

```
lapack_int LAPACKE_<?>larft (int matrix_layout, char direct, char storev, lapack_int n,
lapack_int k, const <datatype> * v, lapack_int ldv, const <datatype> * tau, <datatype>
* t, lapack_int ldt);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larft forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If *direct* = 'F', $H = H(1)*H(2)* \dots *H(k)$ and T is upper triangular;

If *direct* = 'B', $H = H(k)* \dots *H(2)*H(1)$ and T is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V^*T^*V^T$ (for real flavors) or $H = I - V^*T^*V^H$ (for complex flavors).

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V^T*T^*V$ (for real flavors) or $H = I - V^H*T^*V$ (for complex flavors).

Input Parameters

The data types are given for the Fortran interface.

<i>direct</i>	CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise.
<i>n</i>	INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.
<i>v</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft DOUBLE COMPLEX for zlarft Array, DIMENSION (<i>ldv</i> , <i>k</i>) if <i>storev</i> = 'C' or (<i>ldv</i> , <i>n</i>) if <i>storev</i> = 'R'. The matrix V .
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> . If <i>storev</i> = 'C', <i>ldv</i> $\geq \max(1, n)$; if <i>storev</i> = 'R', <i>ldv</i> $\geq k$.
<i>tau</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft DOUBLE COMPLEX for zlarft Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$.
<i>ldt</i>	INTEGER. The leading dimension of the output array <i>t</i> . <i>ldt</i> $\geq k$.

Output Parameters

<i>t</i>	REAL for slarft
----------	-----------------

DOUBLE PRECISION for dlarft
 COMPLEX for clarft
 DOUBLE COMPLEX for zlarft
 Array, DIMENSION (*ldt*,*k*). The *k*-by-*k* triangular factor *T* of the block reflector. If *direct* = 'F', *T* is upper triangular; if *direct* = 'B', *T* is lower triangular. The rest of the array is not used.

v The matrix *V*.

Application Notes

The shape of the matrix *V* and the storage of the vectors which define the *H*(*i*) is best illustrated by the following example with *n* = 5 and *k* = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'B' and *storev* = 'C': *direct* = 'B' and *storev* = 'R':

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ 1 & v_3 \\ & 1 \end{bmatrix} \quad \begin{bmatrix} v_1 & v_1 & 1 \\ v_2 & v_2 & v_2 & 1 \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfx

Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order less than or equal to 10.

Syntax

```
call slarfx( side, m, n, v, tau, c, ldc, work )
call dlarfx( side, m, n, v, tau, c, ldc, work )
call clarfx( side, m, n, v, tau, c, ldc, work )
```

```
call zlarfx( side, m, n, v, tau, c, ldc, work )
```

C:

```
lapack_int LAPACKE_<?>larfx (int matrix_layout, char side, lapack_int m, lapack_int n,
const <datatype> * v, <datatype> tau, <datatype> * c, lapack_int ldc, <datatype> *
work);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larfx applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right.

H is represented in the following forms:

- $H = I - \tau u^* v^T$, where τ is a real scalar and v is a real vector.
- $H = I - \tau u^* v^* v^H$, where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then H is taken to be the unit matrix.

Input Parameters

The data types are given for the Fortran interface.

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H .
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>v</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx DOUBLE COMPLEX for zlarfx Array, DIMENSION (<i>m</i>) if <i>side</i> = 'L' or (<i>n</i>) if <i>side</i> = 'R'. The vector <i>v</i> in the representation of H .
<i>tau</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx DOUBLE COMPLEX for zlarfx The value <i>tau</i> in the representation of H .
<i>c</i>	REAL for slarfx

DOUBLE PRECISION **for** dlarfx
 COMPLEX **for** clarfx
 DOUBLE COMPLEX **for** zlarfx

Array, DIMENSION (*ldc,n*). On entry, the *m*-by-*n* matrix *C*.

ldc INTEGER. The leading dimension of the array *c*. *lda* $\geq (1,m).$

work REAL **for** slarfx
 DOUBLE PRECISION **for** dlarfx
 COMPLEX **for** clarfx
 DOUBLE COMPLEX **for** zlarfx

Workspace array, DIMENSION
(n) if *side* = 'L' or
(m) if *side* = 'R'.
work is not referenced if *H* has order < 11.

Output Parameters

c On exit, *C* is overwritten by the matrix *H*C* if *side* = 'L', or *C*H* if *side* = 'R'.

?largv

Generates a vector of plane rotations with real cosines and real/complex sines.

Syntax

```
call slargv( n, x, incx, y, incy, c, incc )
call dlargv( n, x, incx, y, incy, c, incc )
call clargv( n, x, incx, y, incy, c, incc )
call zlargv( n, x, incx, y, incy, c, incc )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine generates a vector of real/complex plane rotations with real cosines, determined by elements of the real/complex vectors *x* and *y*.

For slargv/dlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} a_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

For clargv/zlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -\text{conj}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} r_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

where $c(i)^2 + \text{abs}(s(i))^2 = 1$ and the following conventions are used (these are the same as in clartg/zlartg but differ from the BLAS Level 1 routine crotg/zrotg):

If $y_i = 0$, then $c(i) = 1$ and $s(i) = 0$;

If $x_i = 0$, then $c(i) = 0$ and $s(i)$ is chosen so that r_i is real.

Input Parameters

n INTEGER. The number of plane rotations to be generated.

x, y REAL for slargv

DOUBLE PRECISION for dlargv

COMPLEX for clargv

DOUBLE COMPLEX for zlargv

Arrays, DIMENSION (1+(n-1)*incx) and (1+(n-1)*incy), respectively. On entry, the vectors *x* and *y*.

incx INTEGER. The increment between elements of *x*.

incx > 0.

incy INTEGER. The increment between elements of *y*.

incy > 0.

incc INTEGER. The increment between elements of the output array *c*. *incc* > 0.

Output Parameters

x On exit, *x*(*i*) is overwritten by *a*_{*i*} (for real flavors), or by *r*_{*i*} (for complex flavors), for *i* = 1, ..., *n*.

y On exit, the sines *s*(*i*) of the plane rotations.

c REAL for slargv/clargv

DOUBLE PRECISION for dlargv/zlargv

Array, DIMENSION (1+(n-1)*incc). The cosines of the plane rotations.

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

call slarnv(*idist*, *iseed*, *n*, *x*)

```
call dlarnv( idist, iseed, n, x )
call clarnv( idist, iseed, n, x )
call zlarnv( idist, iseed, n, x )
```

C:

```
lapack_int LAPACKE_<?>larnv (lapack_int idist, lapack_int * iseed, lapack_int n,
<datatype> * x);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larnv returns a vector of *n* random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine ?laruv to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

The data types are given for the Fortran interface.

<i>idist</i>	INTEGER. Specifies the distribution of the random numbers: for slarnv and dlanrv: = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). for clar nv and zlanrv: = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc abs(z) < 1 = 5: uniformly distributed on the circle abs(z) = 1
<i>iseed</i>	INTEGER. Array, DIMENSION (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
<i>n</i>	INTEGER. The number of random numbers to be generated.

Output Parameters

<i>x</i>	REAL for slarnv DOUBLE PRECISION for dlanrv COMPLEX for clar nv DOUBLE COMPLEX for zlanrv
----------	--

Array, DIMENSION (n). The generated random numbers.

iseed On exit, the seed is updated.

?larra

Computes the splitting points with the specified threshold.

Syntax

```
call slarra( n, d, e, e2, spltol, tnrm, nspli, isplit, info )
call dlarra( n, d, e, e2, spltol, tnrm, nspli, isplit, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the splitting points with the specified threshold and sets any "small" off-diagonal elements to zero.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix ($n > 1$).
<i>d</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (n). Contains n diagonal elements of the tridiagonal matrix T .
<i>e</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (n). First $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.
<i>e2</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (n). First $(n-1)$ entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.
<i>spltol</i>	REAL for slarra DOUBLE PRECISION for dlarra

The threshold for splitting. Two criteria can be used: $spltol < 0$: criterion based on absolute off-diagonal value; $spltol > 0$: criterion that preserves relative accuracy.

tnrm REAL **for** slarra
 DOUBLE PRECISION **for** dlarra
 The norm of the matrix.

Output Parameters

e On exit, the entries $e(isplit(i))$, $1 \leq i \leq nsplit$, are set to zero, the other entries of *e* are untouched.

e2 On exit, the entries $e2(isplit(i))$, $1 \leq i \leq nsplit$, are set to zero.

nsplit INTEGER.
 The number of blocks the matrix *T* splits into. $1 \leq nsplit \leq n$

isplit INTEGER.
 Array, DIMENSION (*n*).
 The splitting points, at which *T* breaks up into blocks. The first block consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), and so on, and the *nsplit*-th consists of rows/columns *isplit*(*nsplit*-1)+1 through *isplit*(*nsplit*)=*n*.

info INTEGER.
 = 0: successful exit.

?larrb

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

```
call slarrb( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,  

iwork, pivmin, spdiam, twist, info )  

call dlarrb( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,  

iwork, pivmin, spdiam, twist, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given the relatively robust representation (RRR) $L^*D^*L^T$, the routine does "limited" bisection to refine the eigenvalues of $L^*D^*L^T$, w (*ifirst-offset*) through w (*ilast-offset*), to more accuracy. Initial guesses for these eigenvalues are input in *w*. The corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals $[left, right]$ are maintained by storing their midpoints and semi-widths in the arrays *w* and *werr* respectively.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
<i>d</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix D .
<i>lld</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n-1</i>). The <i>n-1</i> elements $L_i^* L_i^* D_i$.
<i>ifirst</i>	INTEGER. The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rto11, rto12</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Tolerance for the convergence of the bisection intervals. An interval [<i>left</i> , <i>right</i>] has converged if $\text{RIGHT-LEFT.LT.MAX}(\ rto11*\text{gap},\ rto12*\max(\text{left} , \text{right}))$, where <i>gap</i> is the (estimated) distance to the nearest eigenvalue.
<i>offset</i>	INTEGER. Offset for the arrays <i>w</i> , <i>wgap</i> and <i>werr</i> , that is, the <i>ifirst-offset</i> through <i>ilast-offset</i> elements of these arrays are to be used.
<i>w</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i>). On input, <i>w</i> (<i>ifirst-offset</i>) through <i>w</i> (<i>ilast-offset</i>) are estimates of the eigenvalues of $L^*D^*L^T$ indexed <i>ifirst</i> through <i>ilast</i> .
<i>wgap</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n-1</i>). The estimated gaps between consecutive eigenvalues of $L^*D^*L^T$, that is, <i>wgap</i> (<i>i-offset</i>) is the gap between eigenvalues <i>i</i> and <i>i+1</i> . Note that if <i>IFIRST.EQ.ILAST</i> then <i>wgap</i> (<i>ifirst-offset</i>) must be set to 0.
<i>werr</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i>). On input, <i>werr</i> (<i>ifirst-offset</i>) through <i>werr</i> (<i>ilast-offset</i>) are the errors in the estimates of the corresponding elements in <i>w</i> .
<i>work</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Workspace array, DIMENSION ($2*n$).

<i>pivmin</i>	REAL for slarrb DOUBLE PRECISION for dlarrb The minimum pivot in the Sturm sequence.
<i>spdiam</i>	REAL for slarrb DOUBLE PRECISION for dlarrb The spectral diameter of the matrix.
<i>twist</i>	INTEGER. The twist index for the twisted factorization that is used for the negcount. $twist = n$: Compute negcount from $L^* D^* L^T - \lambda * i = L^* D + * L^T$ $twist = n$: Compute negcount from $L^* D^* L^T - \lambda * i = U^* D^- * U^{-T}$ $twist = n$: Compute negcount from $L^* D^* L^T - \lambda * i = N_r^* D^- * N_r$
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (2*n).

Output Parameters

<i>w</i>	On output, the estimates of the eigenvalues are "refined".
<i>wgap</i>	On output, the gaps are refined.
<i>werr</i>	On output, "refined" errors in the estimates of <i>w</i> .
<i>info</i>	INTEGER. Error flag.

?larrc

Computes the number of eigenvalues of the symmetric tridiagonal matrix.

Syntax

```
call slarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
call dlarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine finds the number of eigenvalues of the symmetric tridiagonal matrix T or of its factorization $L^* D^* L^T$ in the specified interval.

Input Parameters

<i>jobt</i>	CHARACTER*1. = 'T': computes Sturm count for matrix T . = 'L': computes Sturm count for matrix $L^*D^*L^T$.
<i>n</i>	INTEGER. The order of the matrix. ($n > 1$).
<i>vl,vu</i>	REAL for slarrc DOUBLE PRECISION for dlarrc The lower and upper bounds for the eigenvalues.
<i>d</i>	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If <i>jobt</i> = 'T': contains the n diagonal elements of the tridiagonal matrix T . If <i>jobt</i> = 'L': contains the n diagonal elements of the diagonal matrix D .
<i>e</i>	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If <i>jobt</i> = 'T': contains the $(n-1)$ offdiagonal elements of the matrix T . If <i>jobt</i> = 'L': contains the $(n-1)$ offdiagonal elements of the matrix L .
<i>pivmin</i>	REAL for slarrc DOUBLE PRECISION for dlarrc The minimum pivot in the Sturm sequence for the matrix T .

Output Parameters

<i>eigcnt</i>	INTEGER. The number of eigenvalues of the symmetric tridiagonal matrix T that are in the half-open interval $(vl, vu]$.
<i>lcnt,rcnt</i>	INTEGER. The left and right negcounts of the interval.
<i>info</i>	INTEGER. Now it is not used and always is set to 0.

?larrd

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
call slarrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplitt,
isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )
```

```
call dlarrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplitt,
isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from ?stemr. The user may ask for all eigenvalues, all eigenvalues in the half-open interval $(vl, vu]$, or the il -th through iu -th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. (For more details see [Kahan66].

Input Parameters

<i>range</i>	CHARACTER. = 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found. = 'I': ("Index") the il -th through iu -th eigenvalues will be found.
<i>order</i>	CHARACTER. = 'B': ("By block") the eigenvalues will be grouped by split-off block (see <i>iblock</i> , <i>isplit</i> below) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.
<i>n</i>	INTEGER. The order of the tridiagonal matrix T ($n \geq 1$).
<i>vl,vu</i>	REAL for slarrd DOUBLE PRECISION for dlarrd If <i>range</i> = 'V': the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , will not be returned. <i>vl</i> < <i>vu</i> . If <i>range</i> = 'A' or 'I': not referenced.
<i>il,iu</i>	INTEGER. If <i>range</i> = 'I': the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$, if $n > 0$; <i>il</i> =1 and <i>iu</i> =0 if $n=0$. If <i>range</i> = 'A' or 'V': not referenced.

<i>gers</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Array, DIMENSION ($2 \times n$). The n Gershgorin intervals (the i -th Gershgorin interval is ($gers(2*i-1)$, $gers(2*i)$)).
<i>reltol</i>	REAL for slarrd DOUBLE PRECISION for dlarrd The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i> .
<i>d</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Array, DIMENSION (n). Contains n diagonal elements of the tridiagonal matrix T .
<i>e</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Array, DIMENSION ($n-1$). Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix T .
<i>e2</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Array, DIMENSION ($n-1$). Contains $(n-1)$ squared off-diagonal elements of the tridiagonal matrix T .
<i>pivmin</i>	REAL for slarrd DOUBLE PRECISION for dlarrd The minimum pivot in the Sturm sequence for the matrix T .
<i>nsplit</i>	INTEGER. The number of diagonal blocks the matrix T . $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Arrays, DIMENSION (n). The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), and so on, and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= n . (Only the first <i>nsplit</i> elements actually is used, but since the user cannot know a priori value of <i>nsplit</i> , n words must be reserved for <i>isplit</i> .)

work REAL for slarrd
 DOUBLE PRECISION for dlarrd
 Workspace array, DIMENSION (4*n).

iwork INTEGER.
 Workspace array, DIMENSION (4*n).

Output Parameters

m INTEGER.
 The actual number of eigenvalues found. $0 \leq m \leq n$. (See also the description of *info=2, 3*.)

w REAL for slarrd
 DOUBLE PRECISION for dlarrd
 Array, DIMENSION (n).
 The first *m* elements of *w* contain the eigenvalue approximations. ?laprd computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue *j*. The eigenvalue approximation is given as the interval midpoint $w(j) = (a_j + b_j)/2$. The corresponding error is bounded by $werr(j) = \text{abs}(a_j - b_j)/2$.

werr REAL for slarrd
 DOUBLE PRECISION for dlarrd
 Array, DIMENSION (n).
 The error bound on the corresponding eigenvalue approximation in *w*.

wl, wu REAL for slarrd
 DOUBLE PRECISION for dlarrd
 The interval $(wl, wu]$ contains all the wanted eigenvalues.
If *range* = 'V': then *wl*=*vl* and *wu*=*vu*.
If *range* = 'A': then *wl* and *wu* are the global Gerschgorin bounds on the spectrum.
If *range* = 'I': then *wl* and *wu* are computed by ?laebz from the index range specified.

iblock INTEGER.
 Array, DIMENSION (n).
At each row/column *j* where $e(j)$ is zero or small, the matrix *T* is considered to split into a block diagonal matrix.
If *info* = 0, then *iblock(i)* specifies to which block (from 1 to the number of blocks) the eigenvalue *w(i)* belongs. (The routine may use the remaining $n-m$ elements as workspace.)

indexw INTEGER.
 Array, DIMENSION (n).

The indices of the eigenvalues within each block (submatrix); for example, $indexw(i) = j$ and $iblock(i)=k$ imply that the i -th eigenvalue $w(i)$ is the j -th eigenvalue in block k .

info

INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument has an illegal value

> 0: some or all of the eigenvalues fail to converge or are not computed:

=1 or 3: bisection fail to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

=2 or 3: *range*='I' only: not all of the eigenvalues *il*:*iu* are found.=4: *range*='I', and the Gershgorin interval initially used is too small. No eigenvalues are computed.

?larre

Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.

Syntax

```
call slarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
call dlarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , the routine sets any "small" off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block spectrum
- the base representation, $T_i - \sigma_i * I = L_i * D_i * L_i^T$, and
- eigenvalues of each $L_i * D_i * L_i^T$.

The representations and eigenvalues found are then used by ?stemr to compute the eigenvectors of a symmetric tridiagonal matrix. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the dqds algorithm (subroutine ?lasq2) to compute all and discard any unwanted one. As an added benefit, ?larre also outputs the n Gerschgorin intervals for the matrices $L_i * D_i * L_i^T$.

Input Parameters

range

CHARACTER.

= 'A': ("All") all eigenvalues will be found.

= 'V': ("Value") all eigenvalues in the half-open interval (vl , vu] will be found.

= 'I': ("Index") the il -th through iu -th eigenvalues of the entire matrix will be found.

n INTEGER. The order of the matrix. $n > 0$.

vl , vu REAL for slarre

DOUBLE PRECISION for dlarre

If $range='V'$, the lower and upper bounds for the eigenvalues.

Eigenvalues less than or equal to vl , or greater than vu , are not returned.
 $vl < vu$.

il , iu INTEGER.

If $range='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$.

d REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION (n).

The n diagonal elements of the diagonal matrices T .

e REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION (n). The first ($n-1$) entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.

$e2$ REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION (n). The first ($n-1$) entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.

$rto11$, $rto12$ REAL for slarre

DOUBLE PRECISION for dlarre

Parameters for bisection. An interval [LEFT,RIGHT] has converged if
 $RIGHT-LEFT.LT.MAX(rto11*gap, rto12*\max(|LEFT|,|RIGHT|))$.

$spltol$ REAL for slarre

DOUBLE PRECISION for dlarre

The threshold for splitting.

$work$ REAL for slarre

DOUBLE PRECISION for dlarre

Workspace array, DIMENSION ($6*n$).

$iwork$ INTEGER.

Workspace array, DIMENSION (5*n).

Output Parameters

<i>vl</i> , <i>vu</i>	On exit, if <i>range</i> ='I' or ='A', contain the bounds on the desired part of the spectrum.
<i>d</i>	On exit, the <i>n</i> diagonal elements of the diagonal matrices D_i .
<i>e</i>	On exit, the subdiagonal elements of the unit bidiagonal matrices L_i . The entries <i>e</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, contain the base points <i>sigma</i> _{<i>i</i>} on output.
<i>e2</i>	On exit, the entries <i>e2</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, have been set to zero.
<i>nsplit</i>	INTEGER. The number of blocks <i>T</i> splits into. $1 \leq nsplit \leq n$.
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc., and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= <i>n</i> .
<i>m</i>	INTEGER. The total number of eigenvalues (of all the $L_i * D_i * L_i^T$) found.
<i>w</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i * D_i * L_i^T$, are sorted in ascending order. The routine may use the remaining <i>n-m</i> elements as workspace.
<i>werr</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (<i>n</i>). The error bound on the corresponding eigenvalue in <i>w</i> .
<i>wgap</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (<i>n</i>). The separation from the right neighbor eigenvalue in <i>w</i> . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block the left gap is stored.
<i>iblock</i>	INTEGER. Array, DIMENSION (<i>n</i>). The indices of the blocks (submatrices) associated with the corresponding eigenvalues in <i>w</i> ; <i>iblock</i> (<i>i</i>)=1 if eigenvalue <i>w</i> (<i>i</i>) belongs to the first block from the top, =2 if <i>w</i> (<i>i</i>) belongs to the second block, etc.
<i>indexw</i>	INTEGER. Array, DIMENSION (<i>n</i>).

The indices of the eigenvalues within each block (submatrix); for example, $\text{indexw}(i)=10$ and $\text{iblock}(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.

gers

REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(\text{gers}(2*i-1), \text{gers}(2*i))$).

pivmin

REAL for slarre

DOUBLE PRECISION for dlarre

The minimum pivot in the Sturm sequence for T .

info

INTEGER.

If $\text{info} = 0$: successful exit

If $\text{info} > 0$: A problem occurred in ?larre. If $\text{info} = 5$, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If $\text{info} < 0$: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter info for further information is required.

- If $\text{info} = -1$, there is a problem in ?larrd
- If $\text{info} = -2$, no base representation could be found in `maxtry` iterations. Increasing `maxtry` and recompilation might be a remedy.
- If $\text{info} = -3$, there is a problem in ?larrb when computing the refined root representation for ?lasq2.
- If $\text{info} = -4$, there is a problem in ?larrb when performing bisection on the desired part of the spectrum.
- If $\text{info} = -5$, there is a problem in ?lasq2.
- If $\text{info} = -6$, there is a problem in ?lasq2.

?larrf

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

```
call slarrf( n, d, l, ld, clstrt, clenld, w, wgap, werr, spdiam, clgap1, clgapr,
pivmin, sigma, dplus, lplus, work, info )
```

```
call dlarrf( n, d, l, ld, clstrt, clenld, w, wgap, werr, spdiam, clgap1, clgapr,
pivmin, sigma, dplus, lplus, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given the initial representation L^*D*L^T and its cluster of close eigenvalues (in a relative measure), $w(clstrt)$, $w(clstrt+1)$, ... $w(clend)$, the routine ?larrf finds a new relatively robust representation

$$L^*D*L^T - \sigma_i * I = L(+) * D(+) * L(+)^T$$

such that at least one of the eigenvalues of $L(+)*D(+)*L(+)^T$ is relatively isolated.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix (subblock, if the matrix is splitted).
<i>d</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements L_i*D_i .
<i>clstrt</i>	INTEGER. The index of the first eigenvalue in the cluster.
<i>clend</i>	INTEGER. The index of the last eigenvalue in the cluster.
<i>w</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION $\geq (clend - clstrt + 1)$. The eigenvalue approximations of L^*D*L^T in ascending order. $w(clstrt)$ through $w(clend)$ form the cluster of relatively close eigenvalues.
<i>wgap</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION $\geq (clend - clstrt + 1)$. The separation from the right neighbor eigenvalue in <i>w</i> .
<i>werr</i>	REAL for slarrf DOUBLE PRECISION for dlarrf

Array, DIMENSION $\geq (clend - clstrt + 1)$. On input, *werr* contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in *w*.

<i>spdiam</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Estimate of the spectral diameter obtained from the Gerschgorin intervals.
<i>clgapl, clgapr</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.
<i>pivmin</i>	REAL for slarrf DOUBLE PRECISION for dlarrf The minimum pivot allowed in the Sturm sequence.
<i>work</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Workspace array, DIMENSION $(2*n)$.

Output Parameters

<i>wgap</i>	On output, the gaps are refined.
<i>sigma</i>	REAL for slarrf DOUBLE PRECISION for dlarrf The shift used to form $L(+)^*D^*(+)^*L(+)^T$.
<i>dplus</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (n) . The n diagonal elements of the diagonal matrix $D(+)$.
<i>lplus</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (n) . The first $(n-1)$ elements of <i>lplus</i> contain the subdiagonal elements of the unit bidiagonal matrix $L(+)^*$.

?larrj

Performs refinement of the initial estimates of the eigenvalues of the matrix *T*.

Syntax

```
call slarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
pivmin, spdiam, info )
```

```
call dlarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
pivmin, spdiam, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Given the initial eigenvalue approximations of T , this routine does bisection to refine the eigenvalues of T , $w(ifirst-offset)$ through $w(ilast-offset)$, to more accuracy. Initial guesses for these eigenvalues are input in w , the corresponding estimate of the error in these guesses in $werr$. During bisection, intervals $[a,b]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T .
<i>d</i>	<p>REAL for slarrj</p> <p>DOUBLE PRECISION for dlarrj</p> <p>Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the matrix T.</p>
<i>e2</i>	<p>REAL for slarrj</p> <p>DOUBLE PRECISION for dlarrj</p> <p>Array, DIMENSION (<i>n-1</i>). Contains (<i>n-1</i>) squared sub-diagonal elements of the T.</p>
<i>ifirst</i>	INTEGER. The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rtol</i>	<p>REAL for slarrj</p> <p>DOUBLE PRECISION for dlarrj</p> <p>Tolerance for the convergence of the bisection intervals. An interval $[a,b]$ is considered to be converged if $(b-a) \leq rtol * \max(a , b)$.</p>
<i>offset</i>	INTEGER. Offset for the arrays w and $werr$, that is the $ifirst-offset$ through $ilast-offset$ elements of these arrays are to be used.
<i>w</i>	<p>REAL for slarrj</p> <p>DOUBLE PRECISION for dlarrj</p> <p>Array, DIMENSION (<i>n</i>). On input, $w(ifirst-offset)$ through $w(ilast-offset)$ are estimates of the eigenvalues of $L^*D^*L^T$ indexed <i>ifirst</i> through <i>ilast</i>.</p>

<i>werr</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (<i>n</i>). On input, <i>werr</i> (<i>ifirst-offset</i>) through <i>werr</i> (<i>ilast-offset</i>) are the errors in the estimates of the corresponding elements in <i>w</i> .
<i>work</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Workspace array, DIMENSION (2*n).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (2*n).
<i>pivmin</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The minimum pivot in the Sturm sequence for the matrix <i>T</i> .
<i>spdiam</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The spectral diameter of the matrix <i>T</i> .

Output Parameters

<i>w</i>	On exit, contains the refined estimates of the eigenvalues.
<i>werr</i>	On exit, contains the refined errors in the estimates of the corresponding elements in <i>w</i> .
<i>info</i>	INTEGER. Now it is not used and always is set to 0.

?larrk

Computes one eigenvalue of a symmetric tridiagonal matrix *T* to suitable accuracy.

Syntax

```
call slarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
call dlarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes one eigenvalue of a symmetric tridiagonal matrix *T* to suitable accuracy. This is an auxiliary code to be called from ?stemr.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. For more details see [Kahan66].

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T . ($n \geq 1$).
<i>iw</i>	INTEGER. The index of the eigenvalue to be returned.
<i>gl, gu</i>	REAL for slarrk DOUBLE PRECISION for dlarrk An upper and a lower bound on the eigenvalue.
<i>d</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
<i>e2</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Array, DIMENSION ($n-1$). Contains $(n-1)$ squared off-diagonal elements of the T .
<i>pivmin</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum pivot in the Sturm sequence for the matrix T .
<i>reltol</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i> .

Output Parameters

<i>w</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the eigenvalue approximation.
<i>werr</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the error bound on the corresponding eigenvalue approximation in <i>w</i> .

<i>info</i>	INTEGER. = 0: Eigenvalue converges = -1: Eigenvalue does not converge
-------------	---

?larrr

Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

```
call slarrr( n, d, e, info )
call dlarrr( n, d, e, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T . ($n > 0$).
<i>d</i>	REAL for slarrr DOUBLE PRECISION for dlarrr Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the matrix T .
<i>e</i>	REAL for slarrr DOUBLE PRECISION for dlarrr Array, DIMENSION (<i>n</i>). The first (<i>n</i> -1) entries contain sub-diagonal elements of the tridiagonal matrix T ; <i>e</i> (<i>n</i>) is set to 0.

Output Parameters

<i>info</i>	INTEGER. = 0: the matrix warrants computations preserving relative accuracy (default value). = -1: the matrix warrants computations guaranteeing only absolute accuracy.
-------------	--

?larrv

*Computes the eigenvectors of the tridiagonal matrix $T = L^*D^*L^T$ given L , D and the eigenvalues of $L^*D^*L^T$.*

Syntax

```
call slarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtoll, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call dlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtoll, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call clarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtoll, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call zlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtoll, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larrv computes the eigenvectors of the tridiagonal matrix $T = L^*D^*L^T$ given L , D and approximations to the eigenvalues of $L^*D^*L^T$.

The input eigenvalues should have been computed by slarre for real flavors (slarrv/clarrv) and by dlarre for double precision flavors (dlarre/zlarre).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix. $n \geq 0$.
<i>vl</i> , <i>vu</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Lower and upper bounds respectively of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range.
<i>d</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). On entry, the <i>n</i> diagonal elements of the diagonal matrix D .
<i>l</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). On entry, the (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix L are contained in elements 1 to <i>n</i> -1 of <i>L</i> if the matrix is not splitted. At the end of each block the corresponding shift is stored as given by slarre for real flavors and by dlarre for double precision flavors.

<i>pivmin</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv The minimum pivot allowed in the Sturm sequence.
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc.
<i>m</i>	INTEGER. The total number of eigenvalues found. $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i> , and if <i>range</i> = 'I', <i>m</i> = <i>iu</i> - <i>il</i> +1.
<i>dol, dou</i>	INTEGER. If you want to compute only selected eigenvectors from all the eigenvalues supplied, specify an index range <i>dol:dou</i> . Or else apply the setting <i>dol</i> =1, <i>dou</i> = <i>m</i> . Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i> . If you want to compute only selected eigenpairs, then the columns <i>dol</i> -1 to <i>dou</i> +1 of the eigenvector space <i>Z</i> contain the computed eigenvectors. All other columns of <i>Z</i> are set to zero.
<i>minrgp, rtol1, rtol2</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(<i>rtol1</i> *gap, <i>rtol2</i> *max(LEFT , RIGHT)).
<i>w</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The first <i>m</i> elements of <i>w</i> contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (the output array <i>w</i> from ?larre is expected here). These eigenvalues are set with respect to the shift of the corresponding root representation for their block.
<i>werr</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in <i>w</i> .
<i>wgap</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The separation from the right neighbor eigenvalue in <i>w</i> .
<i>iblock</i>	INTEGER. Array, DIMENSION (<i>n</i>).

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $=2$ if $w(i)$ belongs to the second block, etc.

*indexw*INTEGER. Array, DIMENSION (n).

The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.

gers

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$). The Gerschgorin intervals should be computed from the original unshifted matrix.

ldz

INTEGER. The leading dimension of the output array Z . $ldz \geq 1$, and if $jobz = 'V'$, $ldz \geq \max(1, n)$.

work

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Workspace array, DIMENSION ($12*n$).*iwork*

INTEGER.

Workspace array, DIMENSION ($7*n$).

Output Parameters

*d*On exit, d may be overwritten.*l*On exit, l is overwritten.*w*On exit, w holds the eigenvalues of the unshifted matrix.*werr*On exit, $werr$ contains refined values of its input approximations.*wgap*

On exit, $wgap$ contains refined values of its input approximations. Very small gaps are changed.

z

REAL for slarrv

DOUBLE PRECISION for dlarrv

COMPLEX for clarrv

DOUBLE COMPLEX for zlarrv

Array, DIMENSION ($ldz, \max(1,m)$).

If $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

NOTE

The user must ensure that at least $\max(1,m)$ columns are supplied in the array z .

isuppz

INTEGER .

Array, DIMENSION ($2 * \max(1, m)$). The support of the eigenvectors in z , that is, the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i-1)$ through $isuppz(2i)$.

info

INTEGER.

If $info = 0$: successful exit

If $info > 0$: A problem occurred in $?larrv$. If $info = 5$, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If $info < 0$: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter $info$ for further information is required.

- If $info = -1$, there is a problem in $?larrb$ when refining a child eigenvalue;
- If $info = -2$, there is a problem in $?larrf$ when computing the relatively robust representation (RRR) of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter $minrgp$ smaller and recompile. However, as the orthogonality of the computed vectors is proportional to $1/minrgp$, you should be aware that you might be trading in precision when you decrease $minrgp$.
- If $info = -3$, there is a problem in $?larrb$ when refining a single eigenvalue after the Rayleigh correction was rejected.

See Also[?larrb](#)[?larre](#)[?larrf](#)**?lartg**

Generates a plane rotation with real cosine and real/complex sine.

Syntax

```
call slartg( f, g, cs, sn, r )
call dlartg( f, g, cs, sn, r )
call clartg( f, g, cs, sn, r )
call zlartg( f, g, cs, sn, r )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -\text{conj}(sn) & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + |sn|^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine [?rotg](#), except for the following differences.

For slartg/dlartg:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$ and $g \neq 0$, then $cs=0$ and $sn=1$ without doing any floating point operations (saves work in [?bdsqr](#) when there are zeros on the diagonal);

If f exceeds g in magnitude, cs will be positive.

For clartg/zlartg:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$, then $cs=0$ and sn is chosen so that r is real.

Input Parameters

f, g	REAL for slartg DOUBLE PRECISION for dlartg COMPLEX for clartg DOUBLE COMPLEX for zlartg
The first and second component of vector to be rotated.	

Output Parameters

cs	REAL for slartg/clartg DOUBLE PRECISION for dlartg/zlartg
The cosine of the rotation.	
sn	REAL for slartg DOUBLE PRECISION for dlartg COMPLEX for clartg DOUBLE COMPLEX for zlartg
The sine of the rotation.	
r	REAL for slartg

DOUBLE PRECISION **for** `dlartg`
 COMPLEX **for** `clartg`
 DOUBLE COMPLEX **for** `zlartg`

The nonzero component of the rotated vector.

?lartgp

Generates a plane rotation so that the diagonal is nonnegative.

Syntax

FORTRAN 77:

```
call slartgp( f, g, cs, sn, r )
call dlartgp( f, g, cs, sn, r )
```

Fortran 95:

```
call lartgp( f, g, cs, sn, r )
```

C:

```
lapack_int LAPACKE_<?>lartgp ( <datatype> f, <datatype> g, <datatype> * cs, <datatype> * sn, <datatype> * r );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + sn^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine `?rotg`, except for the following differences:

- f and g are unchanged on return.
- If $g=0$, then $cs=(+/-)1$ and $sn=0$.
- If $f=0$ and $g \neq 0$, then $cs=0$ and $sn=(+/-)1$.

The sign is chosen so that $r \geq 0$.

Input Parameters

The data types are given for the Fortran interface.

f, g	REAL for <code>slartgp</code>
	DOUBLE PRECISION for <code>dlartgp</code>

The first and second component of the vector to be rotated.

Output Parameters

<i>cs</i>	REAL for slartgp DOUBLE PRECISION for dlartgp
The cosine of the rotation.	
<i>sn</i>	REAL for slartgp DOUBLE PRECISION for dlartgp
The sine of the rotation.	
<i>r</i>	REAL for slartgp DOUBLE PRECISION for dlartgp
The nonzero component of the rotated vector.	

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ?lartgp interface are as follows:

<i>f</i>	Holds the first component of the vector to be rotated.
<i>g</i>	Holds the second component of the vector to be rotated.
<i>cs</i>	Holds the cosine of the rotation.
<i>sn</i>	Holds the sine of the rotation.
<i>r</i>	Holds the nonzero component of the rotated vector.

[?lartgs](#)

?lartgs

Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Syntax

FORTRAN 77:

```
call slartgs( x, y, sigma, cs, sn )
call dlartgs( x, y, sigma, cs, sn )
```

Fortran 95:

```
call lartgs( x,y,sigma,cs,sn )
```

C:

```
lapack_int LAPACKE_<?>lartgs (<datatype> x, <datatype> y, <datatype> sigma, <datatype>
* cs, <datatype> * sn);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. x and y are the top-row entries, and σ is the shift. The computed cs and sn define a plane rotation that satisfies the following:

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} x^2 - \sigma \\ x * y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

with r nonnegative.

If $x^2 - \sigma$ and $x * y$ are 0, the rotation is by $\pi/2$.

Input Parameters

The data types are given for the Fortran interface.

x, y	REAL for slartgs DOUBLE PRECISION for dlartgs
The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively.	
σ	REAL for slartgs DOUBLE PRECISION for dlartgs
	Shift

Output Parameters

cs	REAL for slartgs DOUBLE PRECISION for dlartgs
The cosine of the rotation.	
sn	REAL for slartgs DOUBLE PRECISION for dlartgs
	The sine of the rotation.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ?lartgs interface are as follows:

<i>x</i>	Holds the (1,1) entry of an upper diagonal matrix.
<i>y</i>	Holds the (1,2) entry of an upper diagonal matrix.
<i>sigma</i>	Holds the shift.
<i>cs</i>	Holds the cosine of the rotation.
<i>sn</i>	Holds the sine of the rotation.

[?lartg](#)
[?lartgp](#)

?lartv

Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.

Syntax

```
call slartv( n, x, incx, y, incy, c, s, incc )
call dlartv( n, x, incx, y, incy, c, s, incc )
call clartv( n, x, incx, y, incy, c, s, incc )
call zlartv( n, x, incx, y, incy, c, s, incc )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine applies a vector of real/complex plane rotations with real cosines to elements of the real/complex vectors *x* and *y*. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} := \begin{bmatrix} c(i) & s(i) \\ -\text{conj}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

Input Parameters

<i>n</i>	INTEGER. The number of plane rotations to be applied.
<i>x</i> , <i>y</i>	REAL for slartv DOUBLE PRECISION for dlartv COMPLEX for clartv DOUBLE COMPLEX for zlartv
	Arrays, DIMENSION (1+(<i>n</i> -1)* <i>incx</i>) and (1+(<i>n</i> -1)* <i>incy</i>), respectively. The input vectors <i>x</i> and <i>y</i> .

<i>incx</i>	INTEGER. The increment between elements of <i>x</i> . <i>incx</i> > 0.
<i>incy</i>	INTEGER. The increment between elements of <i>y</i> . <i>incy</i> > 0.
<i>c</i>	REAL for slartv/clartv DOUBLE PRECISION for dlartv/zlartv Array, DIMENSION (1+(<i>n</i> -1)* <i>incc</i>). The cosines of the plane rotations.
<i>s</i>	REAL for slartv DOUBLE PRECISION for dlartv COMPLEX for clartv DOUBLE COMPLEX for zlartv Array, DIMENSION (1+(<i>n</i> -1)* <i>incc</i>). The sines of the plane rotations.
<i>incc</i>	INTEGER. The increment between elements of <i>c</i> and <i>s</i> . <i>incc</i> > 0.

Output Parameters

<i>x, y</i>	The rotated vectors <i>x</i> and <i>y</i> .
-------------	---

?laruv

Returns a vector of *n* random real numbers from a uniform distribution.

Syntax

```
call slaruv( iseed, n, x )
call dlaruv( iseed, n, x )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laruv returns a vector of *n* random real numbers from a uniform (0,1) distribution (*n* ≤ 128).

This is an auxiliary routine called by ?larnv.

Input Parameters

<i>iseed</i>	INTEGER. Array, DIMENSION (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
<i>n</i>	INTEGER. The number of random numbers to be generated. <i>n</i> ≤ 128.

Output Parameters

<i>x</i>	REAL for slaruv DOUBLE PRECISION for dlaruv Array, DIMENSION (<i>n</i>). The generated random numbers.
<i>seed</i>	On exit, the seed is updated.

?larz

Applies an elementary reflector (as returned by ?tzrzf) to a general matrix.

Syntax

```
call slarz( side, m, n, l, v, incv, tau, c, ldc, work )
call dlarz( side, m, n, l, v, incv, tau, c, ldc, work )
call clarz( side, m, n, l, v, incv, tau, c, ldc, work )
call zlarz( side, m, n, l, v, incv, tau, c, ldc, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?larz applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the forms

$H = I - \tau u^* v^* v^T$ for real flavors and $H = I - \tau u^* v^* v^H$ for complex flavors,

where τ is a real/complex scalar and v is a real/complex vector, respectively.

If $\tau = 0$, then H is taken to be the unit matrix.

For complex flavors, to apply H^H (the conjugate transpose of H), supply `conjg(tau)` instead of τ .

H is a product of k elementary reflectors as returned by ?tzrzf.

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form $H*C$ If <i>side</i> = 'R': form $C*H$
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>l</i>	INTEGER. The number of entries of the vector v containing the meaningful part of the Householder vectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$.

v

REAL for slarz
DOUBLE PRECISION for dlarz
COMPLEX for clarz
DOUBLE COMPLEX for zlarz
Array, DIMENSION (1+(*l*-1)*abs(*incv*)).
The vector *v* in the representation of *H* as returned by ?tzrzf.
v is not used if *tau* = 0.

incv

INTEGER. The increment between elements of *v*.
incv ≠ 0.

tau

REAL for slarz
DOUBLE PRECISION for dlarz
COMPLEX for clarz
DOUBLE COMPLEX for zlarz
The value *tau* in the representation of *H*.

c

REAL for slarz
DOUBLE PRECISION for dlarz
COMPLEX for clarz
DOUBLE COMPLEX for zlarz
Array, DIMENSION (*ldc,n*).
On entry, the *m*-by-*n* matrix *C*.

ldc

INTEGER. The leading dimension of the array *c*.
ldc ≥ max(1, *m*).

work

REAL for slarz
DOUBLE PRECISION for dlarz
COMPLEX for clarz
DOUBLE COMPLEX for zlarz
Workspace array, DIMENSION
(*n*) if *side* = 'L' or
(*m*) if *side* = 'R'.

Output Parameters

c On exit, *C* is overwritten by the matrix *H*C* if *side* = 'L', or *C*H* if *side* = 'R'.

?larzb

Applies a block reflector or its transpose/conjugate-transpose to a general matrix.

Syntax

```
call slarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )

call dlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )

call clarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )

call zlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine applies a real/complex block reflector H or its transpose H^T (or the conjugate transpose H^H for complex flavors) to a real/complex distributed m -by- n matrix C from the left or the right. Currently, only $storev = 'R'$ and $direct = 'B'$ are supported.

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': apply H or H^T/H^H from the left If <i>side</i> = 'R': apply H or H^T/H^H from the right
<i>trans</i>	CHARACTER*1. If <i>trans</i> = 'N': apply H (No transpose) If <i>trans</i> ='C': apply H^H (conjugate transpose) If <i>trans</i> ='T': apply H^T (transpose transpose)
<i>direct</i>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors = 'F': $H = H(1)*H(2)*\dots*H(k)$ (forward, not supported) = 'B': $H = H(k)*\dots*H(2)*H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Indicates how the vectors which define the elementary reflectors are stored: = 'C': Column-wise (not supported) = 'R': Row-wise.

m INTEGER. The number of rows of the matrix *C*.

n INTEGER. The number of columns of the matrix *C*.

k INTEGER. The order of the matrix *T* (equal to the number of elementary reflectors whose product defines the block reflector).

l INTEGER. The number of columns of the matrix *V* containing the meaningful part of the Householder reflectors.

If *side* = 'L', $m \geq l \geq 0$, if *side* = 'R', $n \geq l \geq 0$.

v REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
DOUBLE COMPLEX for zlarzb
Array, DIMENSION (*ldv*, *nv*).
If *storev* = 'C', *nv* = *k*;
if *storev* = 'R', *nv* = *l*.

ldv INTEGER. The leading dimension of the array *v*.
If *storev* = 'C', *ldv* $\geq l$; if *storev* = 'R', *ldv* $\geq k$.

t REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
DOUBLE COMPLEX for zlarzb
Array, DIMENSION (*ldt*, *k*). The triangular *k*-by-*k* matrix *T* in the representation of the block reflector.

ldt INTEGER. The leading dimension of the array *t*.
ldt $\geq k$.

c REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
DOUBLE COMPLEX for zlarzb
Array, DIMENSION (*ldc*, *n*). On entry, the *m*-by-*n* matrix *C*.

ldc INTEGER. The leading dimension of the array *c*.
ldc $\geq \max(1, m)$.

work REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
DOUBLE COMPLEX for zlarzb

Workspace array, DIMENSION (*ldwork*, *k*).

ldwork INTEGER. The leading dimension of the array *work*.
If *side* = 'L', *ldwork* $\geq \max(1, n)$;
if *side* = 'R', *ldwork* $\geq \max(1, m)$.

Output Parameters

c On exit, *C* is overwritten by H^*C , or H^T/H^H*C , or C^*H , or C^*H^T/H^H .

?larzt

Forms the triangular factor *T* of a block reflector $H = I - V*T^*V^H$

Syntax

```
call slarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine forms the triangular factor *T* of a real/complex block reflector *H* of order $> n$, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', $H = H(1)*H(2)*\dots*H(k)$, and *T* is upper triangular.

If *direct* = 'B', $H = H(k)*\dots*H(2)*H(1)$, and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th column of the array *v*, and $H = I - V*T^*V^T$ (for real flavors) or $H = I - V*T^*V^H$ (for complex flavors).

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th row of the array *v*, and $H = I - V^T*T^*V$ (for real flavors) or $H = I - V^{H^T}*T^*V$ (for complex flavors).

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

direct CHARACTER*1.

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

If *direct* = 'F': $H = H(1)*H(2)*\dots*H(k)$ (forward, not supported)

If *direct* = 'B': $H = H(k)*\dots*H(2)*H(1)$ (backward)

storev CHARACTER*1.

Specifies how the vectors which define the elementary reflectors are stored (see also *Application Notes* below):

If $storev = 'C'$: column-wise (not supported)

If $storev = 'R'$: row-wise

n INTEGER. The order of the block reflector H . $n \geq 0$.

k INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.

v REAL for `slarzt`

DOUBLE PRECISION for `dlarzt`

COMPLEX for `clarzt`

DOUBLE COMPLEX for `zlarzt`

Array, DIMENSION

(ldv, k) if $storev = 'C'$

(ldv, n) if $storev = 'R'$ The matrix V .

ldv INTEGER. The leading dimension of the array v .

If $storev = 'C'$, $ldv \geq \max(1, n)$;

if $storev = 'R'$, $ldv \geq k$.

τ REAL for `slarzt`

DOUBLE PRECISION for `dlarzt`

COMPLEX for `clarzt`

DOUBLE COMPLEX for `zlarzt`

Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$.

ldt INTEGER. The leading dimension of the output array t .

$ldt \geq k$.

Output Parameters

t REAL for `slarzt`

DOUBLE PRECISION for `dlarzt`

COMPLEX for `clarzt`

DOUBLE COMPLEX for `zlarzt`

Array, DIMENSION (ldt, k). The k -by- k triangular factor T of the block reflector. If $direct = 'F'$, T is upper triangular; if $direct = 'B'$, T is lower triangular. The rest of the array is not used.

v The matrix V . See *Application Notes* below.

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and storev = 'C': direct = 'F' and storev = 'R':

$$V = \begin{bmatrix} v_1 & v_2 & v_3 \\ \vdots & \ddots & \vdots \\ \vdots & \ddots & \vdots \\ 1 & \ddots & \vdots \\ 1 & \ddots & \vdots \\ 1 & & \end{bmatrix}$$

 V
/ \

$$\begin{bmatrix} v_1 & v_2 & v_3 & v_1 & v_2 & v_3 & \cdots & \cdots & \cdots & 1 \\ v_1 & v_2 & v_3 & v_1 & v_2 & v_3 & \cdots & \cdots & \cdots & 1 \\ v_3 & v_2 & v_1 & v_3 & v_2 & v_1 & \cdots & \cdots & \cdots & 1 \end{bmatrix}$$

direct = 'B' and storev = 'C': direct = 'B' and storev = 'R':

$$V = \begin{bmatrix} \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ 1 & \cdot & \cdot \\ 1 & & \end{bmatrix}$$

 V
/ \

$$\begin{bmatrix} 1 & \cdot & \cdot & \cdot & \cdot & v_1 & v_2 & v_3 & v_4 & v_5 \\ \cdot & 1 & \cdot & \cdot & \cdot & v_1 & v_2 & v_3 & v_4 & v_5 \\ \cdot & \cdot & 1 & \cdot & \cdot & v_2 & v_3 & v_4 & v_5 & v_5 \end{bmatrix}$$

$$V = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

?las2

Computes singular values of a 2-by-2 triangular matrix.

Syntax

```
call slas2( f, g, h, ssmin, ssmax )
call dlas2( f, g, h, ssmin, ssmax )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?las2 computes the singular values of the 2-by-2 matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, *ssmin* is the smaller singular value and *SSMAX* is the larger singular value.

Input Parameters

<i>f, g, h</i>	REAL for slas2 DOUBLE PRECISION for dlas2
	The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.

Output Parameters

<i>ssmin, ssmax</i>	REAL for slas2 DOUBLE PRECISION for dlas2
	The smaller and the larger singular values, respectively.

Application Notes

Barring over/underflow, all output quantities are correct to within a few units in the last place (*ulps*), even in the absence of a guard digit in addition/subtraction. In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows, or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?lascl

Multiples a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .

Syntax

```
call slascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
```

```
call dlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call clascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call zlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lascl multiplies the m -by- n real/complex matrix A by the real scalar $c_{\text{to}}/c_{\text{from}}$. The operation is performed without over/underflow as long as the final result $c_{\text{to}} \cdot A(i, j) / c_{\text{from}}$ does not over/underflow.

type specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

<i>type</i>	CHARACTER*1. This parameter specifies the storage type of the input matrix.
= 'G'	: A is a full matrix.
= 'L'	: A is a lower triangular matrix.
= 'U'	: A is an upper triangular matrix.
= 'H'	: A is an upper Hessenberg matrix.
= 'B'	: A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the lower half stored
= 'Q'	: A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the upper half stored.
= 'Z'	: A is a band matrix with lower bandwidth kl and upper bandwidth ku . See description of the ?gbtrf function for storage details.
<i>kl</i>	INTEGER. The lower bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>ku</i>	INTEGER. The upper bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>cfrom, cto</i>	REAL for slascl/clascl DOUBLE PRECISION for dlascl/zlascl The matrix A is multiplied by $cto/cfrom$. $A(i, j)$ is computed without over/underflow if the final result $cto \cdot A(i, j) / cfrom$ can be represented without over/underflow. <i>cfrom</i> must be nonzero.
<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>a</i>	REAL for slascl DOUBLE PRECISION for dlascl COMPLEX for clascl

DOUBLE COMPLEX for zlascl
 Array, DIMENSION (lda, n). The matrix to be multiplied by $cto/cfrom$. See type for the storage type.

lda INTEGER. The leading dimension of the array a .
 $lda \geq \max(1, m)$.

Output Parameters

a The multiplied matrix A .
 $info$ INTEGER.
 If $info = 0$ - successful exit
 If $info = -i < 0$, the i -th argument had an illegal value.

See Also

?gbtrf

?lasd0

Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasd0(  $n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info$  )
call dlasd0(  $n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info$  )
```

- C: mkl.h

Description

Using a divide and conquer approach, the routine ?lasd0 computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and offdiagonal e , where $m = n + sqre$.

The algorithm computes orthogonal matrices U and VT such that $B = U^* S^* VT$. The singular values S are overwritten on d .

The related subroutine ?lasda computes only the singular values, and optionally, the singular vectors in compact form.

Input Parameters

n INTEGER. On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array d .
 $sqre$ INTEGER. Specifies the column dimension of the bidiagonal matrix.
 If $sqre = 0$: the bidiagonal matrix has column dimension $m = n$.
 If $sqre = 1$: the bidiagonal matrix has column dimension $m = n+1$.

<i>d</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION (<i>m</i> -1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. On entry, leading dimension of the output array <i>u</i> .
<i>ldvt</i>	INTEGER. On entry, leading dimension of the output array <i>vt</i> .
<i>smlsiz</i>	INTEGER. On entry, maximum size of the subproblems at the bottom of the computation tree.
<i>iwork</i>	INTEGER. Workspace array, dimension must be at least (8 <i>n</i>).
<i>work</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Workspace array, dimension must be at least (3 <i>m</i> ² +2 <i>m</i>).

Output Parameters

<i>d</i>	On exit <i>d</i> , If <i>info</i> = 0, contains singular values of the bidiagonal matrix.
<i>u</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least (<i>ldq</i> , <i>n</i>). On exit, <i>u</i> contains the left singular vectors.
<i>vt</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least (<i>ldvt</i> , <i>m</i>). On exit, <i>vt</i> ^T contains the right singular vectors.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value. If <i>info</i> = 1, a singular value did not converge.

?lasd1

Computes the SVD of an upper bidiagonal matrix *B* of the specified size. Used by ?bdsdc.

Syntax

```
call slasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork, work, info )
call dlasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the SVD of an upper bidiagonal n -by- m matrix B , where $n = nl + nr + 1$ and $m = n + sqre$.

The routine ?lasd1 is called from ?lasd0.

A related subroutine ?asd7 handles the case in which the singular values (and the singular vectors in factored form) are desired.

?lasd1 computes the SVD as follows:

$$VT = U(in)^* \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1^T & a & Z2^T & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) \ 0) * VT(out)$$

where $Z^T = (Z1^T \ a \ Z2^T \ b) = u^T * VT^T$, and u is a vector of dimension m with *alpha* and *beta* in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry *b* is empty if *sqre* = 0.

The left singular vectors of the original matrix are stored in *u*, and the transpose of the right singular vectors are stored in *vt*, and the singular values are in *d*. The algorithm consists of three stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the *Z* vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine ?asd2.
2. The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine ?asd4 (as called by ?asd3). This routine also calculates the singular vectors of the current problem.
3. The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

Input Parameters

nl INTEGER. The row dimension of the upper block.

$$nl \geq 1.$$

nr INTEGER. The row dimension of the lower block.

$$nr \geq 1.$$

sqre INTEGER.

If *sqre* = 0: the lower block is an *nr*-by-*nr* square matrix.

If $sqre = 1$: the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.

d

REAL for slasd1

DOUBLE PRECISION for dlasd1

Array, DIMENSION ($nl+nr+1$). $n = nl+nr+1$. On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block; and $d(nl+2:n)$ contains the singular values of the lower block.

alpha

REAL for slasd1

DOUBLE PRECISION for dlasd1

Contains the diagonal element associated with the added row.

beta

REAL for slasd1

DOUBLE PRECISION for dlasd1

Contains the off-diagonal element associated with the added row.

u

REAL for slasd1

DOUBLE PRECISION for dlasd1

Array, DIMENSION (lDU, n). On entry $u(1:nl, 1:nl)$ contains the left singular vectors of the upper block; $u(nl+2:n, nl+2:n)$ contains the left singular vectors of the lower block.

*ldu*INTEGER. The leading dimension of the array U .

$lDU \geq \max(1, n)$.

vt

REAL for slasd1

DOUBLE PRECISION for dlasd1

Array, DIMENSION ($lDVT, m$), where $m = n + sqre$.

On entry $vt(1:nl+1, 1:nl+1)^T$ contains the right singular vectors of the upper block; $vt(nl+2:m, nl+2:m)^T$ contains the right singular vectors of the lower block.

*ldvt*INTEGER. The leading dimension of the array vt .

$lDVT \geq \max(1, M)$.

iwork

INTEGER.

Workspace array, DIMENSION ($4n$).

work

REAL for slasd1

DOUBLE PRECISION for dlasd1

Workspace array, DIMENSION ($3m_2 + 2m$).

Output Parameters

d

On exit $d(1:n)$ contains the singular values of the modified matrix.

<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I)))$, $I = 1, n$.
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I)))$, $I = 1, n$.
<i>u</i>	On exit <i>u</i> contains the left singular vectors of the bidiagonal matrix.
<i>vt</i>	On exit vt^T contains the right singular vectors of the bidiagonal matrix.
<i>idxq</i>	INTEGER Array, DIMENSION (<i>n</i>). Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(idxq(i = 1, n))$ will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = $-i < 0$, the <i>i</i> -th argument had an illegal value. If <i>info</i> = 1, a singular value did not converge.

?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

Syntax

```
call slasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma, u2, ldu2,  

vt2, ldvt2, idxp, idxp, idxq, coltyp, info )  
  
call dlasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma, u2, ldu2,  

vt2, ldvt2, idxp, idxp, idxq, coltyp, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

The routine ?lasd2 is called from ?lasd1.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block.

$nr \geq 1$.

sqre

INTEGER.

If $sqre = 0$): the lower block is an nr -by- nr square matrix

If $sqre = 1$): the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.

d

REAL for slasd2

DOUBLE PRECISION for dlasd2

Array, DIMENSION (n). On entry *d* contains the singular values of the two submatrices to be combined.

alpha

REAL for slasd2

DOUBLE PRECISION for dlasd2

Contains the diagonal element associated with the added row.

beta

REAL for slasd2

DOUBLE PRECISION for dlasd2

Contains the off-diagonal element associated with the added row.

u

REAL for slasd2

DOUBLE PRECISION for dlasd2

Array, DIMENSION (lDU, n). On entry *u* contains the left singular vectors of two submatrices in the two square blocks with corners at $(1,1)$, (nl, nl) , and $(nl+2, nl+2)$, (n,n) .

ldu

INTEGER. The leading dimension of the array *u*.

$ldu \geq n$.

ldu2

INTEGER. The leading dimension of the output array *u2*. $ldu2 \geq n$.

vt

REAL for slasd2

DOUBLE PRECISION for dlasd2

Array, DIMENSION ($ldvt, m$). On entry, vt^T contains the right singular vectors of two submatrices in the two square blocks with corners at $(1,1)$, $(nl+1, nl+1)$, and $(nl+2, nl+2)$, (m, m) .

ldvt

INTEGER. The leading dimension of the array *vt*. $ldvt \geq m$.

ldvt2

INTEGER. The leading dimension of the output array *vt2*. $ldvt2 \geq m$.

idxp

INTEGER.

Workspace array, DIMENSION (n). This will contain the permutation used to place deflated values of *D* at the end of the array. On output *idxp*($2:k$) points to the nondeflated *d*-values and *idxp*($k+1:n$) points to the deflated singular values.

idx

INTEGER.

Workspace array, DIMENSION (n). This will contain the permutation used to sort the contents of d into ascending order.

coltyp

INTEGER.

Workspace array, DIMENSION (n). As workspace, this array contains a label that indicates which of the following types a column in the $u2$ matrix or a row in the $vt2$ matrix is:

- 1 : non-zero in the upper half only
- 2 : non-zero in the lower half only
- 3 : dense
- 4 : deflated.

idxq

INTEGER. Array, DIMENSION (n). This parameter contains the permutation that separately sorts the two sub-problems in D in the ascending order. Note that entries in the first half of this permutation must first be moved one position backwards and entries in the second half must have $nl+1$ added to their values.

Output Parameters

k

INTEGER. Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. $1 \leq k \leq n$.

d

On exit D contains the trailing ($n-k$) updated singular values (those which were deflated) sorted into increasing order.

u

On exit u contains the trailing ($n-k$) updated left singular vectors (those which were deflated) in its last $n-k$ columns.

*z*REAL for `slasd2`DOUBLE PRECISION for `dlasd2`

Array, DIMENSION (n). On exit, z contains the updating row vector in the secular equation.

*dsigma*REAL for `slasd2`DOUBLE PRECISION for `dlassd2`

Array, DIMENSION (n). Contains a copy of the diagonal elements ($k-1$ singular values and one zero) in the secular equation.

*u2*REAL for `slasd2`DOUBLE PRECISION for `dlassd2`

Array, DIMENSION ($lDU2, n$). Contains a copy of the first $k-1$ left singular vectors which will be used by `?lasd3` in a matrix multiply (`?gemm`) to solve for the new left singular vectors. $u2$ is arranged into four blocks. The first block contains a column with 1 at $nl+1$ and zero everywhere else; the second block contains non-zero entries only at and above nl ; the third contains non-zero entries only below $nl+1$; and the fourth is dense.

<i>vt</i>	On exit, vt^T contains the trailing $(n-k)$ updated right singular vectors (those which were deflated) in its last $n-k$ columns. In case $sqre = 1$, the last row of <i>vt</i> spans the right null space.
<i>vt2</i>	<pre>REAL for slasd2 DOUBLE PRECISION for dlasd2</pre> <p>Array, DIMENSION ($ldvt2, n$). $vt2^T$ contains a copy of the first k right singular vectors which will be used by ?lasd3 in a matrix multiply (?gemm) to solve for the new right singular vectors. <i>vt2</i> is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in <i>sigma</i>; the second block contains non-zeros only at and before $nl + 1$; the third block contains non-zeros only at and after $nl + 2$.</p>
<i>idxc</i>	INTEGER. Array, DIMENSION (n). This will contain the permutation used to arrange the columns of the deflated <i>u</i> matrix into three groups: the first group contains non-zero entries only at and above nl , the second contains non-zero entries only below $nl+2$, and the third is dense.
<i>coltyp</i>	On exit, it is an array of dimension 4, with $coltyp(i)$ being the dimension of the i -th type columns.
<i>info</i>	<pre>INTEGER. If info = 0): successful exit If info = -i < 0, the i-th argument had an illegal value.</pre>

?lasd3

Finds all square roots of the roots of the secular equation, as defined by the values in *D* and *Z*, and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.

Syntax

```
call slasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt, vt2,
ldvt2, idxc, ctot, z, info )
call dlasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt, vt2,
ldvt2, idxc, ctot, z, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd3 finds all the square roots of the roots of the secular equation, as defined by the values in *D* and *Z*.

It makes the appropriate calls to ?lasd4 and then updates the singular vectors by matrix multiplication.

The routine ?lasd3 is called from ?lasd1.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1.$
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1.$
<i>sqrre</i>	INTEGER. If <i>sqrre</i> = 0): the lower block is an <i>nr</i> -by- <i>nr</i> square matrix. If <i>sqrre</i> = 1): the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqrre \geq n$ columns.
<i>k</i>	INTEGER. The size of the secular equation, $1 \leq k \leq n.$
<i>q</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Workspace array , DIMENSION at least (<i>ldq</i> , <i>k</i>).
<i>ldq</i>	INTEGER. The leading dimension of the array <i>Q</i> . $ldq \geq k.$
<i>dsigma</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array , DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> . $ldu \geq n.$
<i>u2</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array , DIMENSION (<i>ldu2</i> , <i>n</i>). The first <i>k</i> columns of this matrix contain the non-deflated left singular vectors for the split problem.
<i>ldu2</i>	INTEGER. The leading dimension of the array <i>u2</i> . $ldu2 \geq n.$
<i>ldvt</i>	INTEGER. The leading dimension of the array <i>vt</i> . $ldvt \geq n.$
<i>vt2</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array , DIMENSION (<i>ldvt2</i> , <i>n</i>).

The first k columns of $vt2'$ contain the non-deflated right singular vectors for the split problem.

ldvt2

INTEGER. The leading dimension of the array $vt2$.

$ldvt2 \geq n$.

idxc

INTEGER. Array, DIMENSION (n).

The permutation used to arrange the columns of u (and rows of vt) into three groups: the first group contains non-zero entries only at and above (or before) $n_1 + 1$; the second contains non-zero entries only at and below (or after) $n_1 + 2$; and the third is dense. The first column of u and the row of vt are treated separately, however. The rows of the singular vectors found by ?lasd4 must be likewise permuted before the matrix multiplies can take place.

ctot

INTEGER. Array, DIMENSION (4). A count of the total number of the various types of columns in u (or rows in vt), as described in *idxc*.

The fourth column type is any column which has been deflated.

z

REAL for slasd3

DOUBLE PRECISION for dlasd3

Array, DIMENSION (k). The first k elements of this array contain the components of the deflation-adjusted updating row vector.

Output Parameters

d

REAL for slasd3

DOUBLE PRECISION for dlasd3

Array, DIMENSION (k). On exit the square roots of the roots of the secular equation, in ascending order.

u

REAL for slasd3

DOUBLE PRECISION for dlasd3

Array, DIMENSION (lDU, n).

The last $n - k$ columns of this matrix contain the deflated left singular vectors.

vt

REAL for slasd3

DOUBLE PRECISION for dlasd3

Array, DIMENSION ($ldvt, m$).

The last $m - k$ columns of vt' contain the deflated right singular vectors.

vt2

Destroyed on exit.

z

Destroyed on exit.

info

INTEGER.

If $info = 0$): successful exit.

If $\text{info} = -i < 0$, the i -th argument had an illegal value.
 If $\text{info} = 1$, an singular value did not converge.

Application Notes

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

?lasd4

Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd4( n, i, d, z, delta, rho, sigma, work, info)
call dlasd4( n, i, d, z, delta, rho, sigma, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array d , and that $0 \leq d(i) < d(j)$ for $i < j$ and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T,$$

where the Euclidean norm of Z is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

n	INTEGER. The length of all arrays.
i	INTEGER. The index of the eigenvalue to be computed. $1 \leq i \leq n$.
d	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (n). The original eigenvalues. They must be in order, $0 \leq d(i) < d(j)$ for $i < j$.
z	REAL for slasd4 DOUBLE PRECISION for dlasd4

Array, DIMENSION (n).

The components of the updating vector.

rho REAL for slasd4

DOUBLE PRECISION for dlasd4

The scalar in the symmetric updating formula.

work REAL for slasd4

DOUBLE PRECISION for dlasd4

Workspace array, DIMENSION (n).

If $n \neq 1$, *work* contains $(d(j) + \sigma_i)$ in its j -th component.

If $n = 1$, then *work(1)* = 1.

Output Parameters

delta REAL for slasd4

DOUBLE PRECISION for dlasd4

Array, DIMENSION (n).

If $n \neq 1$, *delta* contains $(d(j) - \sigma_i)$ in its j -th component.

If $n = 1$, then *delta (1)* = 1. The vector *delta* contains the information necessary to construct the (singular) eigenvectors.

sigma REAL for slasd4

DOUBLE PRECISION for dlasd4

The computed σ_i , the i -th updated eigenvalue.

info INTEGER.

= 0: successful exit

> 0: If *info* = 1, the updating process failed.

?lasd5

Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd5( i, d, z, delta, rho, dsigma, work )
call dlasd5( i, d, z, delta, rho, dsigma, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(d) * \text{diag}(d) + rho * Z * Z^T$

The diagonal entries in the array d must satisfy $0 \leq d(i) < d(j)$ for $i < i$, rho must be greater than 0, and that the Euclidean norm of the vector Z is equal to 1.

Input Parameters

i	INTEGER. The index of the eigenvalue to be computed. $i = 1$ or $i = 2$.
d	REAL for slasd5 DOUBLE PRECISION for dlasd5 Array , dimension (2). The original eigenvalues, $0 \leq d(1) < d(2)$.
z	REAL for slasd5 DOUBLE PRECISION for dlasd5 Array , dimension (2). The components of the updating vector.
rho	REAL for slasd5 DOUBLE PRECISION for dlasd5 The scalar in the symmetric updating formula.
$work$	REAL for slasd5 DOUBLE PRECISION for dlasd5. Workspace array, dimension (2). Contains $(d(j) + sigma_i)$ in its j -th component.

Output Parameters

$delta$	REAL for slasd5 DOUBLE PRECISION for dlasd5. Array , dimension (2). Contains $(d(j) - sigma_i)$ in its j -th component. The vector $delta$ contains the information necessary to construct the eigenvectors.
$dsigma$	REAL for slasd5 DOUBLE PRECISION for dlasd5. The computed $sigma_i$, the i -th updated eigenvalue.

?lasd6

Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.

Syntax

```
call slasd6( icompq, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr, givcol,  
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork, info )
```

```
call dlasd6( icompq, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr, givcol,  
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd6 computes the *SVD* of an updated upper bidiagonal matrix *B* obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. *B* is an *n*-by-*m* matrix with *n* = *nl* + *nr* + 1 and *m* = *n* + *sqre*. A related subroutine, ?lasd1, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. ?lasd6 computes the *SVD* as follows:

$$B = U(in)^* \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ z1' & a & z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out)^* (D(out))^* VT(out)$$

where $Z' = (Z1' \ a \ Z2' \ b) = u^* VT'$, and *u* is a vector of dimension *m* with *alpha* and *beta* in the *nl*+1 and *nl*+2-th entries and zeros elsewhere; and the entry *b* is empty if *sqre* = 0.

The singular values of *B* can be computed using *D1*, *D2*, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in *vf* and *vl*, respectively, in ?lasd6. Hence *U* and *VT* are not explicitly referenced.

The singular values are stored in *D*. The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the *Z* vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine ?lasd7.
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine ?lasd4 (as called by ?lasd8). This routine also updates *vf* and *vl* and computes the distances between the updated singular values and the old singular values. ?lasd6 is called from ?lasda.

Input Parameters

<i>icompq</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only = 1: Compute singular vectors in factored form as well.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.

nr INTEGER. The row dimension of the lower block.
 $nr \geq 1$.

sqre INTEGER .
= 0: the lower block is an nr -by- nr square matrix.
= 1: the lower block is an nr -by- $(nr+1)$ rectangular matrix.
The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.

d REAL for slasd6
DOUBLE PRECISION for dlasd6
Array, dimension ($nl + nr + 1$). On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block, and $d(nl+2:n)$ contains the singular values of the lower block.

vf REAL for slasd6
DOUBLE PRECISION for dlasd6
Array, dimension (m).
On entry, $vf(1:nl+1)$ contains the first components of all right singular vectors of the upper block; and $vf(nl+2:m)$ contains the first components of all right singular vectors of the lower block.

vl REAL for slasd6
DOUBLE PRECISION for dlasd6
Array, dimension (m).
On entry, $vl(1:nl+1)$ contains the last components of all right singular vectors of the upper block; and $vl(nl+2:m)$ contains the last components of all right singular vectors of the lower block.

alpha REAL for slasd6
DOUBLE PRECISION for dlasd6
Contains the diagonal element associated with the added row.

beta REAL for slasd6
DOUBLE PRECISION for dlasd6
Contains the off-diagonal element associated with the added row.

ldgcol INTEGER. The leading dimension of the output array *givcol*, must be at least n .

ldgnum INTEGER.
The leading dimension of the output arrays *givnum* and *poles*, must be at least n .

work REAL for slasd6
DOUBLE PRECISION for dlasd6

Workspace array, dimension ($4m$).

iwork INTEGER.

Workspace array, dimension ($3n$).

Output Parameters

d On exit $d(1:n)$ contains the singular values of the modified matrix.

vf On exit, *vf* contains the first components of all right singular vectors of the bidiagonal matrix.

vl On exit, *vl* contains the last components of all right singular vectors of the bidiagonal matrix.

alpha On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I)))$, $I = 1, n$.

beta On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I)))$, $I = 1, n$.

idxq INTEGER.

Array, dimension (n). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(\text{idxq}(i = 1, n))$ will be in ascending order.

perm INTEGER.

Array, dimension (n). The permutations (from deflation and sorting) to be applied to each block. Not referenced if *icompq* = 0.

givptr INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if *icompq* = 0.

givcol INTEGER.

Array, dimension ($ldgcol, 2$). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if *icompq* = 0.

givnum REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension ($ldgnum, 2$). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if *icompq* = 0.

poles REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension ($ldgnum, 2$). On exit, *poles*($1,*$) is an array containing the new singular values obtained from solving the secular equation, and *poles*($2,*$) is an array containing the poles in the secular equation. Not referenced if *icompq* = 0.

difl REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension (n). On exit, $difl(i)$ is the distance between i -th updated (undeflated) singular value and the i -th (undeflated) old singular value.

difr

REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension ($ldgnum, 2$) if $icompq = 1$ and dimension (n) if $icompq = 0$.

On exit, $difr(i, 1)$ is the distance between i -th updated (undeflated) singular value and the $i+1$ -th (undeflated) old singular value. If $icompq = 1$, $difr(1: k, 2)$ is an array containing the normalizing factors for the right singular vector matrix.

See ?lasd8 for details on *difl* and *difr*.

z

REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension (m).

The first elements of this array contain the components of the deflation-adjusted updating row vector.

k

INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.

c

REAL for slasd6

DOUBLE PRECISION for dlasd6

c contains garbage if $sqre = 0$ and the C-value of a Givens rotation related to the right null space if $sqre = 1$.

s

REAL for slasd6

DOUBLE PRECISION for dlasd6

s contains garbage if $sqre = 0$ and the S-value of a Givens rotation related to the right null space if $sqre = 1$.

info

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0: if $info = 1$, an singular value did not converge

?lasd7

Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

Syntax

```
call slasd7( icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta, dsigma,
idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s, info )
```

```
call dlasd7( icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta, dsigma,
idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd7 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one. ?lasd7 is called from ?lasd6.

Input Parameters

<i>icompq</i>	INTEGER. Specifies whether singular vectors are to be computed in compact form, as follows:
	= 0: Compute singular values only.
	= 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>nl</i>	INTEGER. The row dimension of the upper block.
	<i>nl</i> \geq 1.
<i>nr</i>	INTEGER. The row dimension of the lower block.
	<i>nr</i> \geq 1.
<i>sqre</i>	INTEGER.
	= 0: the lower block is an <i>nr</i> -by- <i>nr</i> square matrix.
	= 1: the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has <i>n</i> = <i>nl</i> + <i>nr</i> + 1 rows and <i>m</i> = <i>n</i> + <i>sqre</i> \geq <i>n</i> columns.
<i>d</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>n</i>). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>zw</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). Workspace for <i>z</i> .
<i>vf</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). On entry, <i>vf</i> (1: <i>nl</i> +1) contains the first components of all right singular vectors of the upper block; and <i>vf</i> (<i>nl</i> +2: <i>m</i>) contains the first components of all right singular vectors of the lower block.

<i>vfw</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlassd7</code> Array, DIMENSION (<i>m</i>). Workspace for <i>vf</i> .
<i>vl</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlassd7</code> Array, DIMENSION (<i>m</i>). On entry, <i>vl</i> (1: <i>n</i> l+1) contains the last components of all right singular vectors of the upper block; and <i>vl</i> (<i>n</i> l+2: <i>m</i>) contains the last components of all right singular vectors of the lower block.
<i>VLW</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlassd7</code> Array, DIMENSION (<i>m</i>). Workspace for <i>VL</i> .
<i>alpha</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlassd7</code> . Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlassd7</code> Contains the off-diagonal element associated with the added row.
<i>idx</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>idxp</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>d</i> at the end of the array.
<i>idxq</i>	INTEGER. Array, DIMENSION (<i>n</i>). This contains the permutation which separately sorts the two sub-problems in <i>d</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have <i>n</i> l+1 added to their values.
<i>ldgcol</i>	INTEGER. The leading dimension of the output array <i>givcol</i> , must be at least <i>n</i> .
<i>ldgnum</i>	INTEGER. The leading dimension of the output array <i>givnum</i> , must be at least <i>n</i> .

Output Parameters

<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. $1 \leq k \leq n$.
<i>d</i>	On exit, <i>d</i> contains the trailing ($n-k$) updated singular values (those which were deflated) sorted into increasing order.
<i>z</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>m</i>). On exit, <i>Z</i> contains the updating row vector in the secular equation.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>dsigma</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>n</i>). Contains a copy of the diagonal elements ($k-1$ singular values and one zero) in the secular equation.
<i>idxp</i>	On output, <i>idxp</i> ($2:k$) points to the nondeflated <i>d</i> -values and <i>idxp</i> ($k+1:n$) points to the deflated singular values.
<i>perm</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if <i>icompq</i> = 0.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompq</i> = 0.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>givnum</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>ldgnum</i> , 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>c</i>	REAL for slasd7. DOUBLE PRECISION for dlasd7.

If $sqre = 0$, then c contains garbage, and if $sqre = 1$, then c contains C -value of a Givens rotation related to the right null space.

s REAL for slasd7.

DOUBLE PRECISION for dlasd7.

If $sqre = 0$, then s contains garbage, and if $sqre = 1$, then s contains S -value of a Givens rotation related to the right null space.

$info$ INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

?lasd8

Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc.

Syntax

```
call slasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info )
call dlasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd8 finds the square roots of the roots of the secular equation, as defined by the values in $dsigma$ and z . It makes the appropriate calls to ?lasd4, and stores, for each element in d , the distance to its two nearest poles (elements in $dsigma$). It also updates the arrays vf and vl , the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd8 is called from ?lasd6.

Input Parameters

$icompq$

INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine:

= 0: Compute singular values only.

= 1: Compute singular vectors in factored form as well.

k

INTEGER. The number of terms in the rational function to be solved by ?lasd4. $k \geq 1$.

z

REAL for slasd8

DOUBLE PRECISION for dlasd8.

Array, DIMENSION (k).

The first k elements of this array contain the components of the deflation-adjusted updating row vector.

vf REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array, DIMENSION (*k*).
 On entry, *vf* contains information passed through dbede8.

vl REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array, DIMENSION (*k*). On entry, *vl* contains information passed through dbede8.

lddifr INTEGER. The leading dimension of the output array *difr*, must be at least *k*.

dsigma REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array, DIMENSION (*k*).
 The first *k* elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

work REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Workspace array, DIMENSION at least (3*k*).

Output Parameters

d REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array, DIMENSION (*k*).
 On output, *D* contains the updated singular values.

z Updated on exit.

vf On exit, *vf* contains the first *k* components of the first components of all right singular vectors of the bidiagonal matrix.

vl On exit, *vl* contains the first *k* components of the last components of all right singular vectors of the bidiagonal matrix.

difl REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array, DIMENSION (*k*). On exit, *difl(i) = d(i) - dsigma(i).*

difr REAL for slasd8
 DOUBLE PRECISION for dlasd8.
 Array,
 DIMENSION (*lddifr*, 2) if *icompq* = 1 and

DIMENSION (k) if $icompq = 0$.

On exit, $difr(i,1) = d(i) - dsigma(i+1)$, $difr(k,1)$ is not defined and will not be referenced. If $icompq = 1$, $difr(1:k,2)$ is an array containing the normalizing factors for the right singular vector matrix.

$dsigma$

The elements of this array may be very slightly altered in value.

$info$

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0: If $info = 1$, a singular value did not converge.

?lasd9

Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc.

Syntax

```
call slasd9( icompq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
call dlasd9( icompq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasd9 finds the square roots of the roots of the secular equation, as defined by the values in $dsigma$ and z . It makes the appropriate calls to ?lasd4, and stores, for each element in d , the distance to its two nearest poles (elements in $dsigma$). It also updates the arrays vf and vl , the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd9 is called from ?lasd7.

Input Parameters

$icompq$ INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine:

If $icompq = 0$, compute singular values only;

If $icompq = 1$, compute singular vector matrices in factored form also.

k INTEGER. The number of terms in the rational function to be solved by slasd4. $k \geq 1$.

$dsigma$ REAL for slasd9

DOUBLE PRECISION for dlasd9.

Array, DIMENSION(k).

The first k elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

z REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array, DIMENSION (k). The first k elements of this array contain the components of the deflation-adjusted updating row vector.

vf REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array, DIMENSION(k). On entry, *vf* contains information passed through *sbede8*.

vl REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array, DIMENSION(k). On entry, *vl* contains information passed through *sbede8*.

work REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Workspace array, DIMENSION at least (3k).

Output Parameters

d REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array, DIMENSION(k). *d(i)* contains the updated singular values.

vf On exit, *vf* contains the first k components of the first components of all right singular vectors of the bidiagonal matrix.

vl On exit, *vl* contains the first k components of the last components of all right singular vectors of the bidiagonal matrix.

difl REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array, DIMENSION (k).
 On exit, *difl(i) = d(i) - dsigma(i)*.

difr REAL for slasd9
 DOUBLE PRECISION for dlasd9.
 Array,
 DIMENSION (*ldu*, 2) if *icompq* = 1 and
 DIMENSION (k) if *icompq* = 0.
 On exit, *difr(i, 1) = d(i) - dsigma(i+1)*, *difr(k, 1)* is not defined and will not be referenced.
 If *icompq* = 1, *difr(1:k, 2)* is an array containing the normalizing factors for the right singular vector matrix.

info INTEGER.
 = 0: successful exit.
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value.
 > 0: If *info* = 1, an singular value did not converge

?lasda

Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal *d* and off-diagonal *e*. Used by ?bdsdc.

Syntax

```
call slasda( icompq, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z, poles,  

givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )  

call dlasda( icompq, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z, poles,  

givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal *n*-by-*m* matrix *B* with diagonal *d* and off-diagonal *e*, where *m* = *n* + *sqre*.

The algorithm computes the singular values in the SVD $B = U^* S^* V^T$. The orthogonal matrices *U* and *VT* are optionally computed in compact form. A related subroutine ?laasd0 computes the singular values and the singular vectors in explicit form.

Input Parameters

icompq INTEGER.
 Specifies whether singular vectors are to be computed in compact form, as follows:
 = 0: Compute singular values only.
 = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

smlsiz INTEGER.
 The maximum size of the subproblems at the bottom of the computation tree.

n INTEGER. The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array *d*.

sqre INTEGER. Specifies the column dimension of the bidiagonal matrix.
 If *sqre* = 0: the bidiagonal matrix has column dimension *m* = *n*
 If *sqre* = 1: the bidiagonal matrix has column dimension *m* = *n* + 1.

<i>d</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>m</i> - 1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> . <i>ldu</i> $\geq n$.
<i>ldgcol</i>	INTEGER. The leading dimension of arrays <i>givcol</i> and <i>perm</i> . <i>ldgcol</i> $\geq n$.
<i>work</i>	REAL for slasda DOUBLE PRECISION for dlasda. Workspace array, DIMENSION $(6n + (smlsiz+1)^2)$.
<i>iwork</i>	INTEGER. Workspace array, Dimension must be at least $(7n)$.

Output Parameters

<i>d</i>	On exit <i>d</i> , if <i>info</i> = 0, contains the singular values of the bidiagonal matrix.
<i>u</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i>) if <i>icompq</i> = 1. Not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>vt</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i> +1) if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>vt</i> ' contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	INTEGER. Array, DIMENSION (<i>n</i>) if <i>icompq</i> = 1 and DIMENSION (1) if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>k</i> (<i>i</i>) is the dimension of the <i>i</i> -th secular equation on the computation tree.
<i>difl</i>	REAL for slasda

DOUBLE PRECISION for dlasda.

Array, DIMENSION (*lDU*, *nLVL*),

where $n\text{lvl} = \text{floor}(\log_2(n/\text{smlsiz}))$.

difr

REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (lDU , $2 \cdot nvl$) if $icompq = 1$ and

DIMENSION (n) if $icompq = 0$.

If $icompq = 1$, on exit, $difl(1:n, i)$ and $difr(1:n, 2i - 1)$ record distances between singular values on the i -th level and singular values on the $(i - 1)$ -th level, and $difr(1:n, 2i)$ contains the normalizing factors for the right singular vector matrix. See ?lasd8 for details.

z

REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (*ldu*, *nlvl*) if *icomprg* = 1 and

DIMENSION (n) if $icompq = 0$. The first k elements of $z(1, i)$ contain the components of the deflation-adjusted updating row vector for subproblems on the i -th level.

poles

REAL for slasda

DOUBLE PRECISION for dlasda

Array, DIMENSION (lDU , $2 * nLV1$)

if $icompq = 1$, and not referenced if $icompq = 0$. If $icompq = 1$, on exit, $\text{poles}(1, 2i - 1)$ and $\text{poles}(1, 2i)$ contain the new and old singular values involved in the secular equations on the i -th level.

givptr

INTEGER. Array, DIMENSION (n) if $icompq = 1$, and not referenced if $icompq = 0$. If $icompq = 1$, on exit, $givptr(i)$ records the number of Givens rotations performed on the i -th problem on the computation tree.

givcol

INTEGER.

Array, DIMENSION ($1dgcol$, $2*nlvl$) if $icompq = 1$, and not referenced if $icompq = 0$. If $icompq = 1$, on exit, for each i , $givcol(1, 2 i - 1)$ and $givcol(1, 2 i)$ record the locations of Givens rotations performed on the i -th level on the computation tree.

perm

INTEGER . Array, DIMENSION ($ldgcol$, $nlvl$) if $icompq = 1$, and not referenced if $icompq = 0$. If $icompq = 1$, on exit, $perm(1, i)$ records permutations done on the i -th level of the computation tree.

givnum

REAL for slasda

DOUBLE PRECISION for dlasda.

Array DIMENSION (*ldu*, $2*nvl$) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, for each *i*, *givnum*(1, 2 *i* - 1) and *givnum*(1, 2 *i*) record the *C*- and *S*-values of Givens rotations performed on the *i*-th level on the computation tree.

c REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (*n*) if *icompq* = 1, and

DIMENSION (1) if *icompq* = 0.

If *icompq* = 1 and the *i*-th subproblem is not square, on exit, *c*(*i*) contains the *C*-value of a Givens rotation related to the right null space of the *i*-th subproblem.

s REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (*n*) *icompq* = 1, and

DIMENSION (1) if *icompq* = 0.

If *icompq* = 1 and the *i*-th subproblem is not square, on exit, *s*(*i*) contains the *S*-value of a Givens rotation related to the right null space of the *i*-th subproblem.

info INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: If *info* = 1, an singular value did not converge

?lasdq

Computes the SVD of a real bidiagonal matrix with diagonal *d* and off-diagonal *e*. Used by ?bdsdc.

Syntax

```
call slasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work, info )
```

```
call dlasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine `?lasdq` computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal d and off-diagonal e , accumulating the transformations if desired. If B is the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that $B = Q^* S^* P^T$. The singular values S are overwritten on d .

The input matrix U is changed to $U^* Q$ if desired.

The input matrix VT is changed to $P^T * VT$ if desired.

The input matrix C is changed to $Q^T * C$ if desired.

Input Parameters

<code>uplo</code>	CHARACTER*1. On entry, <code>uplo</code> specifies whether the input bidiagonal matrix is upper or lower bidiagonal. If <code>uplo</code> = 'U' or 'u', B is upper bidiagonal; If <code>uplo</code> = 'L' or 'l', B is lower bidiagonal.
<code>sqre</code>	INTEGER. = 0: then the input matrix is n -by- n . = 1: then the input matrix is n -by- $(n+1)$ if <code>uplu</code> = 'U' and $(n+1)$ -by- n if <code>uplu</code> = 'L'. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<code>n</code>	INTEGER. On entry, <code>n</code> specifies the number of rows and columns in the matrix. <code>n</code> must be at least 0.
<code>ncvt</code>	INTEGER. On entry, <code>ncvt</code> specifies the number of columns of the matrix VT . <code>ncvt</code> must be at least 0.
<code>nru</code>	INTEGER. On entry, <code>nru</code> specifies the number of rows of the matrix U . <code>nru</code> must be at least 0.
<code>ncc</code>	INTEGER. On entry, <code>ncc</code> specifies the number of columns of the matrix C . <code>ncc</code> must be at least 0.
<code>d</code>	REAL for <code>slasdq</code> DOUBLE PRECISION for <code>dlassdq</code> . Array, DIMENSION (n). On entry, d contains the diagonal entries of the bidiagonal matrix.
<code>e</code>	REAL for <code>slasdq</code> DOUBLE PRECISION for <code>dlassdq</code> . Array, DIMENSION is $(n-1)$ if <code>sqre</code> = 0 and n if <code>sqre</code> = 1. On entry, the entries of e contain the off-diagonal entries of the bidiagonal matrix.
<code>vt</code>	REAL for <code>slasdq</code> DOUBLE PRECISION for <code>dlassdq</code> .

Array, DIMENSION (*ldvt, ncvt*). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension n -by- $ncvt$ if *sqre* = 0 and $(n+1)$ -by- $ncvt$ if *sqre* = 1 (not referenced if *ncvt*=0).

ldvt INTEGER. On entry, *ldvt* specifies the leading dimension of *vt* as declared in the calling (sub) program. *ldvt* must be at least 1. If *ncvt* is nonzero, *ldvt* must also be at least *n*.

u REAL for *slasdq*

DOUBLE PRECISION for *dlassdq*.

Array, DIMENSION (*ldu, n*). On entry, contains a matrix which on exit has been postmultiplied by *Q*, dimension *nru*-by-*n* if *sqre* = 0 and *nru*-by- $(n+1)$ if *sqre* = 1 (not referenced if *nru*=0).

ldu INTEGER. On entry, *ldu* specifies the leading dimension of *u* as declared in the calling (sub) program. *ldu* must be at least $\max(1, nru)$.

c REAL for *slasdq*

DOUBLE PRECISION for *dlassdq*.

Array, DIMENSION (*ldc, ncc*). On entry, contains an *n*-by-*ncc* matrix which on exit has been premultiplied by *Q'*, dimension *n*-by-*ncc* if *sqre* = 0 and $(n+1)$ -by-*ncc* if *sqre* = 1 (not referenced if *ncc*=0).

ldc INTEGER. On entry, *ldc* specifies the leading dimension of *C* as declared in the calling (sub) program. *ldc* must be at least 1. If *ncc* is non-zero, *ldc* must also be at least *n*.

work REAL for *slasdq*

DOUBLE PRECISION for *dlassdq*.

Array, DIMENSION (4*n*). This is a workspace array. Only referenced if one of *ncvt*, *nru*, or *ncc* is nonzero, and if *n* is at least 2.

Output Parameters

d On normal exit, *d* contains the singular values in ascending order.

e On normal exit, *e* will contain 0. If the algorithm does not converge, *d* and *e* will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.

vt On exit, the matrix has been premultiplied by *P'*.

u On exit, the matrix has been postmultiplied by *Q*.

c On exit, the matrix has been premultiplied by *Q'*.

info INTEGER. On exit, a value of 0 indicates a successful exit. If *info* < 0, argument number -*info* is illegal. If *info* > 0, the algorithm did not converge, and *info* specifies how many superdiagonals did not converge.

?lasdt

Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.

Syntax

```
call slasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
call dlasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine creates a tree of subproblems for bidiagonal divide and conquer.

Input Parameters

<i>n</i>	INTEGER. On entry, the number of diagonal elements of the bidiagonal matrix.
<i>msub</i>	INTEGER. On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Output Parameters

<i>lvl</i>	INTEGER. On exit, the number of levels on the computation tree.
<i>nd</i>	INTEGER. On exit, the number of nodes on the tree.
<i>inode</i>	INTEGER. Array, DIMENSION (<i>n</i>). On exit, centers of subproblems.
<i>ndiml</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of left children.
<i>ndimr</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of right children.

?laset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
call slaset( uplo, m, n, alpha, beta, a, lda )
call dlaset( uplo, m, n, alpha, beta, a, lda )
call claset( uplo, m, n, alpha, beta, a, lda )
call zlaset( uplo, m, n, alpha, beta, a, lda )
```

C:

```
lapack_int LAPACKE_<?>laset (int matrix_layout, char uplo, lapack_int m, lapack_int n,
<datatype> alpha, <datatype> beta, <datatype> * a, lapack_int lda);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine initializes an m -by- n matrix A to β on the diagonal and α on the off-diagonals.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix A to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of A is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of A is not changed. Otherwise: All of the matrix A is set.
<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>alpha, beta</i>	REAL for slaset DOUBLE PRECISION for dlaset COMPLEX for claset DOUBLE COMPLEX for zlaset. The constants to which the off-diagonal and diagonal elements are to be set, respectively.
<i>a</i>	REAL for slaset DOUBLE PRECISION for dlaset COMPLEX for claset DOUBLE COMPLEX for zlaset. Array, DIMENSION (<i>lda, n</i>). On entry, the m -by- n matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1,m)$.

Output Parameters

a On exit, the leading m -by- n submatrix of A is set as follows:

```

if uplo = 'U', A(i,j) = alpha, 1≤i≤j-1, 1≤j≤n,
if uplo = 'L', A(i,j) = alpha, j+1≤i≤m, 1≤j≤n,
otherwise, A(i,j) = alpha, 1≤i≤m, 1≤j≤n, i ≠ j,
and, for all uplo, A(i,i) = beta, 1≤i≤min(m, n).

```

?lasq1

Computes the singular values of a real square bidiagonal matrix. Used by ?bdsqr.

Syntax

```

call slasq1( n, d, e, work, info )
call dlasq1( n, d, e, work, info )

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasq1 computes the singular values of a real n -by- n bidiagonal matrix Z with diagonal d and off-diagonal e . The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

Input Parameters

<i>n</i>	INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
<i>d</i>	REAL for slasq1 DOUBLE PRECISION for dlasq1. Array, DIMENSION (n). On entry, d contains the diagonal elements of the bidiagonal matrix whose SVD is desired.
<i>e</i>	REAL for slasq1 DOUBLE PRECISION for dlasq1. Array, DIMENSION (n). On entry, elements $e(1:n-1)$ contain the off-diagonal elements of the bidiagonal matrix whose SVD is desired.
<i>work</i>	REAL for slasq1 DOUBLE PRECISION for dlasq1. Workspace array, DIMENSION ($4n$).

Output Parameters

<i>d</i>	On normal exit, d contains the singular values in decreasing order.
----------	---

<i>e</i>	On exit, <i>e</i> is overwritten.
<i>info</i>	INTEGER. = 0: successful exit; < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value; > 0: the algorithm failed: = 1, a split was marked by a positive value in <i>e</i> ; = 2, current block of <i>Z</i> not diagonalized after $100n$ iterations (in inner while loop) - on exit the current contents of <i>d</i> and <i>e</i> represent a matrix with the same singular values as the matrix with which ?lasq1 was originally called, and which the calling subroutine could use to finish the computation, or even feed back into ?lasq1; = 3, termination criterion of outer while loop not met (program created more than <i>n</i> unreduced blocks).

?lasq2

Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the quotient difference array z to high relative accuracy.
Used by ?bdsqr and ?steqr.

Syntax

```
call slasq2( n, z, info )
call dlasq2( n, z, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasq2 computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the quotient difference array *z* to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of *z* to the tridiagonal matrix, let *L* be a unit lower bidiagonal matrix with subdiagonals *z*(2,4,6,...) and let *U* be an upper bidiagonal matrix with 1's above and diagonal *z*(1,3,5,...). The tridiagonal is *LU* or, if you prefer, the symmetric tridiagonal to which it is similar.

Input Parameters

<i>n</i>	INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
<i>z</i>	REAL for slasq2 DOUBLE PRECISION for dlasq2. Array, DIMENSION (4 * <i>n</i>). On entry, <i>z</i> holds the quotient difference array.

Output Parameters

<i>z</i>	On exit, entries 1 to n hold the eigenvalues in decreasing order, $z(2n+1)$ holds the trace, and $z(2n+2)$ holds the sum of the eigenvalues. If $n > 2$, then $z(2n+3)$ holds the iteration count, $z(2n+4)$ holds $\text{ndivs}/\text{nint}^2$, and $z(2n+5)$ holds the percentage of shifts that failed.
<i>info</i>	<p>INTEGER.</p> <p>= 0: successful exit;</p> <p>< 0: if the i-th argument is a scalar and had an illegal value, then $info = -i$, if the i-th argument is an array and the j-entry had an illegal value, then $info = -(i*100 + j)$;</p> <p>> 0: the algorithm failed;</p> <p>= 1, a split was marked by a positive value in <i>e</i>;</p> <p>= 2, current block of <i>z</i> not diagonalized after $100*n$ iterations (in inner while loop) - On exit <i>z</i> holds a quotient difference array with the same eigenvalues as the <i>z</i> array on entry;</p> <p>= 3, termination criterion of outer while loop not met (program created more than n unreduced blocks).</p>

Application Notes

The routine `?lasq2` defines a logical variable, *ieee*, which is `.TRUE.` on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs, and `.FALSE.` otherwise. This variable is passed to `?lasq3`.

`?lasq3`

Checks for deflation, computes a shift and calls dqds.
Used by ?bdsqr.

Syntax

```
call slasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee, ttype,
dmin1, dmin2, dn, dn1, dn2, g, tau )
call dlasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee, ttype,
dmin1, dmin2, dn, dn1, dn2, g, tau )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine `?lasq3` checks for deflation, computes a shift *tau*, and calls *dqds*. In case of failure, it changes shifts, and tries again until output is positive.

Input Parameters

<i>i0</i>	INTEGER. First index.
-----------	-----------------------

<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Array, DIMENSION ($4n$). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong. <i>pp</i> =2 indicates that flipping was applied to the <i>Z</i> array and that the initial tests for deflation should not be performed.
<i>desig</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Lower order part of <i>sigma</i> .
<i>qmax</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Maximum value of <i>q</i> .
<i>ieee</i>	LOGICAL. Flag for <i>ieee</i> or non- <i>ieee</i> arithmetic (passed to <code>?lasq5</code>).
<i>ttype</i>	INTEGER. Shift type.
<i>dmin1, dmin2, dn, dn1, dn2, g</i>	REAL for <code>slasq3</code>
<i>tau</i>	DOUBLE PRECISION for <code>dlasq3</code> . These scalars are passed as arguments in order to save their values between calls to <code>?lasq3</code> .

Output Parameters

<i>dmin</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Minimum value of <i>d</i> .
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong. <i>pp</i> =2 indicates that flipping was applied to the <i>Z</i> array and that the initial tests for deflation should not be performed.
<i>sigma</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Sum of shifts used in the current segment.
<i>desig</i>	Lower order part of <i>sigma</i> .
<i>nfail</i>	INTEGER. Number of times shift was too big.
<i>iter</i>	INTEGER. Number of iterations.

<i>ndiv</i>	INTEGER. Number of divisions.
<i>ttype</i>	INTEGER. Shift type.
<i>dmin1, dmin2, dn, dn1, dn2, g</i>	REAL for <code>slasq3</code>
<i>tau</i>	DOUBLE PRECISION for <code>dlasq3</code> .
These scalars are passed as arguments in order to save their values between calls to <code>?lasq3</code> .	

?lasq4

Computes an approximation to the smallest eigenvalue using values of *d* from the previous transform. Used by `?bdsqr`.

Syntax

```
call slasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype, g )
call dlasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype, g )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine computes an approximation *tau* to the smallest eigenvalue using values of *d* from the previous transform.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Array, DIMENSION ($4n$). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp=0</i> for ping, <i>pp=1</i> for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of <code>eigtest</code> .
<i>dmin</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for <code>slasq4</code>

	DOUBLE PRECISION for dlasq4.
	Minimum value of d , excluding $d(n0)$.
$dmin2$	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of d , excluding $d(n0)$ and $d(n0-1)$.
dn	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains $d(n)$.
$dn1$	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains $d(n-1)$.
$dn2$	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains $d(n-2)$.
g	REAL for slasq4 DOUBLE PRECISION for dlasq4. A scalar passed as an argument in order to save its value between calls to ?lasq4.

Output Parameters

τ	REAL for slasq4 DOUBLE PRECISION for dlasq4. Shift.
$ttype$	INTEGER. Shift type.
g	REAL for slasq4 DOUBLE PRECISION for dlasq4. A scalar passed as an argument in order to save its value between calls to ?lasq4.

?lasq5

Computes one dqds transform in ping-pong form.

Used by ?bdsqr and ?stegr.

Syntax

```
call slasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
call dlasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes one dqds transform in ping-pong form: one version for ieee machines, another for non-ieee machines.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Array, DIMENSION ($4n$). <i>z</i> holds the <i>qd</i> array. <i>emin</i> is stored in <i>z</i> ($4*n0$) to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>tau</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . This is the shift.
<i>ieee</i>	LOGICAL. Flag for IEEE or non-IEEE arithmetic.

Output Parameters

<i>dmin</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Minimum value of <i>d</i> , excluding <i>d(n0)</i> .
<i>dmin2</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Minimum value of <i>d</i> , excluding <i>d(n0)</i> and <i>d(n0-1)</i> .
<i>dn</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Contains <i>d(n0)</i> , the last value of <i>d</i> .
<i>dnlm1</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Contains <i>d(n0-1)</i> .
<i>dnlm2</i>	REAL for <code>slasq5</code> DOUBLE PRECISION for <code>dlasq5</code> . Contains <i>d(n0-2)</i> .

?lasq6

Computes one *dqd* transform in ping-pong form. Used by ?bdsqr and ?stegr.

Syntax

```
call slasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
call dlasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasq6 computes one *dqd* (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Input Parameters

i0 INTEGER. First index.

n0 INTEGER. Last index.

z REAL for slasq6
 DOUBLE PRECISION for dlasq6.
 Array, DIMENSION ($4n$). *Z* holds the *qd* array. *emin* is stored in *z*($4*n0$) to avoid an extra argument.

pp INTEGER. *pp*=0 for ping, *pp*=1 for pong.

Output Parameters

dmin REAL for slasq6
 DOUBLE PRECISION for dlasq6.
 Minimum value of *d*.

dmin1 REAL for slasq6
 DOUBLE PRECISION for dlasq6.
 Minimum value of *d*, excluding *d(n0)*.

dmin2 REAL for slasq6
 DOUBLE PRECISION for dlasq6.
 Minimum value of *d*, excluding *d(n0)* and *d(n0-1)*.

dn REAL for slasq6
 DOUBLE PRECISION for dlasq6. Contains *d(n0)*, the last value of *d*.

dnm1 REAL for slasq6

DOUBLE PRECISION for dlasq6. Contains $d(n0-1)$.

?lasr

Applies a sequence of plane rotations to a general rectangular matrix.

Syntax

```
call slasr( side, pivot, direct, m, n, c, s, a, lda )
call dlasr( side, pivot, direct, m, n, c, s, a, lda )
call clasr( side, pivot, direct, m, n, c, s, a, lda )
call zlasr( side, pivot, direct, m, n, c, s, a, lda )
```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine applies a sequence of plane rotations to a real/complex matrix A , from the left or the right.

$A := P^* A$, when *side* = 'L' (Left-hand side)

A := *A***P'*, when *side* = 'R' (Right-hand side)

where P is an orthogonal matrix consisting of a sequence of plane rotations with $z = m$ when `side = 'L'` and $z = n$ when `side = 'R'`.

When `direct = 'F'` (Forward sequence), then

$$P = P(z-1) * \dots * P(2) * P(1),$$

and when `direct = 'B'` (Backward sequence), then

$$P = P(1) * P(2) * \dots * P(z-1),$$

where $P(k)$ is a plane rotation matrix defined by the 2-by-2 plane rotation:

... (1999) 111

When `pivot = 'v'` (Variable pivot), the rotation is performed for the plane $(k, k + 1)$, that is, $P(k)$ has the form

$$P(k) = \begin{bmatrix} 1 & & & & \\ & \dots & & & \\ & & 1 & & \\ & & & c(k) s(k) & \\ & & & -s(k) c(k) & \\ & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears as a rank-2 modification to the identity matrix in rows and columns k and $k+1$.

When $pivot = 'T'$ (Top pivot), the rotation is performed for the plane $(1, k+1)$, so $P(k)$ has the form

$$P(k) = \begin{bmatrix} c(k) & & s(k) & & \\ & 1 & & & \\ & & \dots & & \\ & & & 1 & \\ & -s(k) & & & c(k) \\ & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and $k+1$.

Similarly, when $pivot = 'B'$ (Bottom pivot), the rotation is performed for the plane (k, z) , giving $P(k)$ the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & & s(k) \\ & & & & 1 & \\ & & & & & \dots \\ & & & & & & 1 \\ & & & -s(k) & & & c(k) \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and z . The rotations are performed without ever forming $P(k)$ explicitly.

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether the plane rotation matrix P is applied to A on the left or the right. = 'L': left, compute $A := P*A$ = 'R': right, compute $A:= A*P'$
<i>direct</i>	CHARACTER*1. Specifies whether P is a forward or backward sequence of plane rotations. = 'F': forward, $P = P(z-1)*...*P(2)*P(1)$ = 'B': backward, $P = P(1)*P(2)*...*P(z-1)$
<i>pivot</i>	CHARACTER*1. Specifies the plane for which $P(k)$ is a plane rotation matrix. = 'V': Variable pivot, the plane $(k, k+1)$ = 'T': Top pivot, the plane $(1, k+1)$ = 'B': Bottom pivot, the plane (k, z)
<i>m</i>	INTEGER. The number of rows of the matrix A . If $m \leq 1$, an immediate return is effected.
<i>n</i>	INTEGER. The number of columns of the matrix A . If $n \leq 1$, an immediate return is effected.
<i>c, s</i>	REAL for slasr/clasr DOUBLE PRECISION for dlasr/zlasr. Arrays, DIMENSION ($m-1$) if <i>side</i> = 'L', ($n-1$) if <i>side</i> = 'R'. <i>c(k)</i> and <i>s(k)</i> contain the cosine and sine of the plane rotations respectively that define the 2-by-2 plane rotation part ($R(k)$) of the $P(k)$ matrix as described above in <i>Description</i> .
<i>a</i>	REAL for slasr DOUBLE PRECISION for dlasr COMPLEX for clasr DOUBLE COMPLEX for zlasr. Array, DIMENSION (<i>lda, n</i>). The m -by- n matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.

Output Parameters

a On exit, *A* is overwritten by P^*A if *side* = 'R', or by A^*P if *side* = 'L'.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt( id, n, d, info )
```

```
call dlasrt( id, n, d, info )
```

C:

```
lapack_int LAPACKE_<?>lasrt (char id, lapack_int n, <datatype> * d);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasrt sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of stack limits *n* to about 2^{32} .

Input Parameters

The data types are given for the Fortran interface.

<i>id</i>	CHARACTER*1. = 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order.
-----------	--

<i>n</i>	INTEGER. The length of the array <i>d</i> .
----------	---

<i>d</i>	REAL for slasrt DOUBLE PRECISION for dlasrt. On entry, the array to be sorted.
----------	--

Output Parameters

<i>d</i>	On exit, <i>d</i> has been sorted into increasing order ($d(1) \leq \dots \leq d(n)$) or into decreasing order ($d(1) \geq \dots \geq d(n)$), depending on <i>id</i> .
----------	--

<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.
-------------	--

?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call slassq( n, x, incx, scale, sumsq )
call dlassq( n, x, incx, scale, sumsq )
call classq( n, x, incx, scale, sumsq )
call zlassq( n, x, incx, scale, sumsq )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The real routines slassq/dlassq return the values *scl* and *smsq* such that

$$scl^2 * smsq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = x(1 + (i - 1) * incx)$.

The value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(x(i))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *smsq* are overwritten on *scale* and *sumsq*, respectively.

The complex routines classq/zlassq return the values *scl* and *ssq* such that

$$scl^2 * ssq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{abs}(x(1 + (i - 1) * incx))$.

The value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy $1.0 \leq ssq \leq sumsq + 2n$

scale is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{aimag}(x(i)))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *ssq* are overwritten on *scale* and *sumsq*, respectively.

All routines ?lassq make only one pass through the vector *x*.

Input Parameters

n INTEGER. The number of elements to be used from the vector *x*.

x REAL for slassq

DOUBLE PRECISION for dlassq

COMPLEX for classq

DOUBLE COMPLEX for zlassq.

The vector for which a scaled sum of squares is computed: $x(i) = x(1 + (i-1) * incx), 1 \leq i \leq n$.

<i>incx</i>	INTEGER. The increment between successive values of the vector <i>x</i> . <i>incx</i> > 0.
<i>scale</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	On exit, <i>scale</i> is overwritten with <i>sc</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	For real flavors: On exit, <i>sumsq</i> is overwritten with the value <i>smsq</i> in the equation above. For complex flavors: On exit, <i>sumsq</i> is overwritten with the value <i>ssq</i> in the equation above.

?lasv2

Computes the singular value decomposition of a 2-by-2 triangular matrix.

Syntax

```
call slasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
call dlasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasv2 computes the singular value decomposition of a 2-by-2 triangular matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, $\text{abs}(\text{ssmax})$ is the larger singular value, $\text{abs}(\text{ssmin})$ is the smaller singular value, and (csl, snl) and (csr, snr) are the left and right singular vectors for $\text{abs}(\text{ssmax})$, giving the decomposition

$$\begin{bmatrix} \text{csl} & \text{snl} \\ -\text{snl} & \text{csl} \end{bmatrix} \begin{bmatrix} f & g \\ 0 & h \end{bmatrix} \begin{bmatrix} \text{csr} & -\text{snr} \\ \text{snr} & \text{csr} \end{bmatrix} = \begin{bmatrix} \text{ssmax} & 0 \\ 0 & \text{ssmin} \end{bmatrix}$$

Input Parameters

f, g, h

REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.

Output Parameters

ssmin, ssmax

REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
 $\text{abs}(ssmin)$ and $\text{abs}(ssmax)$ is the smaller and the larger singular value, respectively.

snl, csl

REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
The vector (*csl, snl*) is a unit left singular vector for the singular value $\text{abs}(ssmax)$.

snr, csr

REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
The vector (*csr, snr*) is a unit right singular vector for the singular value $\text{abs}(ssmax)$.

Application Notes

Any input parameter may be aliased with any output parameter.

Barring over/underflow and assuming a guard digit in subtraction, all output quantities are correct to within a few units in the last place (ulp).

In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call slaswp( n, a, lda, k1, k2, ipiv, incx )
call dlaswp( n, a, lda, k1, k2, ipiv, incx )
call claswp( n, a, lda, k1, k2, ipiv, incx )
call zlaswp( n, a, lda, k1, k2, ipiv, incx )
```

C:

```
lapack_int LAPACKE_<?>laswp (int matrix_layout, lapack_int n, <datatype> * a,
lapack_int lda, lapack_int k1, lapack_int k2, const lapack_int * ipiv, lapack_int
incx);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine performs a series of row interchanges on the matrix A . One row interchange is initiated for each of rows $k1$ through $k2$ of A .

Input Parameters

The data types are given for the Fortran interface.

<i>n</i>	INTEGER. The number of columns of the matrix A .
<i>a</i>	REAL for slaswp DOUBLE PRECISION for dlaswp COMPLEX for claswp DOUBLE COMPLEX for zlaswp. Array, DIMENSION (<i>lda, n</i>). On entry, the matrix of column dimension <i>n</i> to which the row interchanges will be applied.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> .
<i>k1</i>	INTEGER. The first element of <i>ipiv</i> for which a row interchange will be done.
<i>k2</i>	INTEGER. The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	INTEGER. Array, DIMENSION ($k2 \times incx $). The vector of pivot indices. Only the elements in positions $k1$ through $k2$ of <i>ipiv</i> are accessed. $ipiv(k) = l$ implies rows k and l are to be interchanged.
<i>incx</i>	INTEGER. The increment between successive values of <i>ipiv</i> . If <i>ipiv</i> is negative, the pivots are applied in reverse order.

Output Parameters

<i>a</i>	On exit, the permuted matrix.
----------	-------------------------------

?lasy2

Solves the Sylvester matrix equation where the matrices are of order 1 or 2.

Syntax

```
call slasy2( ltranl, ltranr, isgn, n1, n2, tl, ldltl, tr, ldtr, b, ldb, scale, x, ldx,
xnorm, info )
```

```
call dlasly2( ltranl, ltranr, isgn, n1, n2, tl, ldltl, tr, ldtr, b, ldb, scale, x, ldx,
xnorm, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine solves for the $n1$ -by- $n2$ matrix X , $1 \leq n1, n2 \leq 2$, in

$$\text{op}(TL) * X + isgn * X * \text{op}(TR) = scale * B,$$

where

TL is $n1$ -by- $n1$,

TR is $n2$ -by- $n2$,

B is $n1$ -by- $n2$,

and $isgn = 1$ or -1 . $\text{op}(T) = T$ or T^T , where T^T denotes the transpose of T .

Input Parameters

ltranl

LOGICAL.

On entry, *ltranl* specifies the $\text{op}(TL)$:

- = .FALSE., $\text{op}(TL) = TL$,
- = .TRUE., $\text{op}(TL) = (TL)^T$.

ltranr

LOGICAL.

On entry, *ltranr* specifies the $\text{op}(TR)$:

- = .FALSE., $\text{op}(TR) = TR$,
- = .TRUE., $\text{op}(TR) = (TR)^T$.

isgn

INTEGER. On entry, *isgn* specifies the sign of the equation as described before. *isgn* may only be 1 or -1.

n1

INTEGER. On entry, *n1* specifies the order of matrix TL .

n1 may only be 0, 1 or 2.

n2

INTEGER. On entry, *n2* specifies the order of matrix TR .

n2 may only be 0, 1 or 2.

tl

REAL for slasy2

DOUBLE PRECISION for dlasly2.

Array, DIMENSION (*ldtl*,2).

On entry, *tl* contains an $n1$ -by- $n1$ matrix TL .

<i>ldt1</i>	INTEGER. The leading dimension of the matrix <i>TL</i> . $ldt1 \geq \max(1, n1).$
<i>tr</i>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlassy2</code> . Array, DIMENSION (<i>ldtr</i> ,2). On entry, <i>tr</i> contains an n_2 -by- n_2 matrix <i>TR</i> .
<i>ldtr</i>	INTEGER. The leading dimension of the matrix <i>TR</i> . $ldtr \geq \max(1, n2).$
<i>b</i>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlassy2</code> . Array, DIMENSION (<i>ldb</i> ,2). On entry, the n_1 -by- n_2 matrix <i>B</i> contains the right-hand side of the equation.
<i>ldb</i>	INTEGER. The leading dimension of the matrix <i>B</i> . $ldb \geq \max(1, n1).$
<i>idx</i>	INTEGER. The leading dimension of the output matrix <i>X</i> . $idx \geq \max(1, n1).$

Output Parameters

<i>scale</i>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlassy2</code> . On exit, <i>scale</i> contains the scale factor. <i>scale</i> is chosen less than or equal to 1 to prevent the solution overflowing.
<i>x</i>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlassy2</code> . Array, DIMENSION (<i>idx</i> ,2). On exit, <i>x</i> contains the n_1 -by- n_2 solution.
<i>xnorm</i>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlassy2</code> . On exit, <i>xnorm</i> is the infinity-norm of the solution.
<i>info</i>	INTEGER. On exit, <i>info</i> is set to 0: successful exit. 1: <i>TL</i> and <i>TR</i> have too close eigenvalues, so <i>TL</i> or <i>TR</i> is perturbed to get a nonsingular equation.

NOTE

For higher speed, this routine does not check the inputs for errors.

?lasyf

Computes a partial factorization of a symmetric matrix, using the diagonal pivoting method.

Syntax

```
call slasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lasyf computes a partial factorization of a symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

If $uplo = 'U'$:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{22}' \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

$uplo = 'L'$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

This is an auxiliary routine called by ?sytrf. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

$uplo$

CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

- = 'U': Upper triangular
- = 'L': Lower triangular

n

INTEGER. The order of the matrix A . $n \geq 0$.

nb

INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.

a REAL for `slasyf`
 DOUBLE PRECISION for `dlassyf`
 COMPLEX for `clasyf`
 DOUBLE COMPLEX for `zlassyf`.
 Array, DIMENSION (lda, n). If $uplo = 'U'$, the leading n -by- n upper triangular part of *a* contains the upper triangular part of the matrix A , and the strictly lower triangular part of *a* is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of *a* contains the lower triangular part of the matrix A , and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

w REAL for `slasyf`
 DOUBLE PRECISION for `dlassyf`
 COMPLEX for `clasyf`
 DOUBLE COMPLEX for `zlassyf`.
 Workspace array, DIMENSION (ldw, nb).

ldw INTEGER. The leading dimension of the array *w*. $ldw \geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns of A that were actually factored *kb* is either $nb-1$ or nb , or n if $n \leq nb$.

a On exit, *a* contains details of the partial factorization.

ipiv INTEGER. Array, DIMENSION (n). Details of the interchanges and the block structure of D .

If $uplo = 'U'$, only the last *kb* elements of *ipiv* are set;

if $uplo = 'L'$, only the first *kb* elements are set.

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lasyf_rook

Computes a partial factorization of a complex symmetric matrix, using the bounded Bunch-Kaufman diagonal pivoting method.

Syntax

```
call slasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine `?lasyf_rook` computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

$$\begin{aligned} A &= \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{22}' \end{bmatrix} \text{ if } \text{uplo} = 'U', \text{ or} \\ A &= \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } \text{uplo} = 'L' \end{aligned}$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

This is an auxiliary routine called by `?sytrf_rook`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $\text{uplo} = 'U'$) or A_{22} (if $\text{uplo} = 'L'$).

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$.
<code>nb</code>	INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.
<code>a</code>	REAL for <code>slasyf_rook</code>

DOUBLE PRECISION for `dlasyf_rook`
 COMPLEX for `clasyf_rook`
 DOUBLE COMPLEX for `zlassyf_rook`.

Array, DIMENSION (lda, n). If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

w REAL for `slasyf_rook`
 DOUBLE PRECISION for `dlasyf_rook`
 COMPLEX for `clasyf_rook`
 DOUBLE COMPLEX for `zlassyf_rook`.
Workspace array, DIMENSION (ldw, nb).

ldw INTEGER. The leading dimension of the array w . $ldw \geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns of A that were actually factored kb is either $nb-1$ or nb , or n if $n \leq nb$.

a On exit, a contains details of the partial factorization.

$ipiv$ INTEGER. Array, DIMENSION (n). Details of the interchanges and the block structure of D .

If $uplo = 'U'$, only the last kb elements of $ipiv$ are set;

if $uplo = 'L'$, only the first kb elements are set.

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

$info$ INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lahef

Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.

Syntax

```
call clahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lahef computes a partial factorization of a complex Hermitian matrix A , using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

If $uplo = 'U'$:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}^H & U_{22}^H \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

If $uplo = 'U'$:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

Note that U^H denotes the conjugate transpose of U .

This is an auxiliary routine called by ?hetrf. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

$uplo$

CHARACTER*1.

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

- = 'U': upper triangular
- = 'L': lower triangular

n

INTEGER. The order of the matrix A . $n \geq 0$.

nb

INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.

a COMPLEX for `clahef`
 DOUBLE COMPLEX for `zlahef`.
 Array, DIMENSION (*lda, n*).
 On entry, the Hermitian matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *A* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *A* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *A* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *A* is not referenced.

lda INTEGER. The leading dimension of the array *a*. *lda* $\geq \max(1, n)$.

w COMPLEX for `clahef`
 DOUBLE COMPLEX for `zlahef`.
 Workspace array, DIMENSION (*ldw, nb*).

ldw INTEGER. The leading dimension of the array *w*. *ldw* $\geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns of *A* that were actually factored *kb* is either *nb*-1 or *nb*, or *n* if *n* $\leq nb$.

a On exit, *A* contains details of the partial factorization.

ipiv INTEGER.
 Array, DIMENSION (*n*). Details of the interchanges and the block structure of *D*.
 If *uplo* = 'U', only the last *kb* elements of *ipiv* are set;
 if *uplo* = 'L', only the first *kb* elements are set.
 If *ipiv*(*k*) > 0, then rows and columns *k* and *ipiv*(*k*) are interchanged and *D*(*k, k*) is a 1-by-1 diagonal block.
 If *uplo* = 'U' and *ipiv*(*k*) = *ipiv*(*k*-1) < 0, then rows and columns *k*-1 and -*ipiv*(*k*) are interchanged and *D*(*k*-1:k, *k*-1:k) is a 2-by-2 diagonal block.
 If *uplo* = 'L' and *ipiv*(*k*) = *ipiv*(*k*+1) < 0, then rows and columns *k*+1 and -*ipiv*(*k*) are interchanged and *D*(*k*:*k*+1, *k*:*k*+1) is a 2-by-2 diagonal block.

info INTEGER.
 = 0: successful exit
 > 0: if *info* = *k*, *D*(*k, k*) is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular.

?lahef_rook

 = 0: successful exit
 > 0: if *info* = *k*, *D*(*k*, *k*) is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular.

?latbs

Solves a triangular banded system of equations.

Syntax

```
call slatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
call dlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
call clatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
call zlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine solves one of the triangular systems

$$A^*x = s^*b, \text{ or } A^T*x = s^*b, \text{ or } A^H*x = s^*b \text{ (for complex flavors)}$$

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ?tbsv is called. If the matrix A is singular ($A(j, j)=0$ for some j), then s is set to 0 and a non-trivial solution to $A^*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A^*x = s^*b$ (no transpose) = 'T': solve $A^T*x = s^*b$ (transpose) = 'C': solve $A^H*x = s^*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether $cnorm$ is set. = 'Y': $cnorm$ contains the column norms on entry;

= 'N': *cnorm* is not set on entry. On exit, the norms are computed and stored in *cnorm*.

n INTEGER. The order of the matrix *A*. $n \geq 0$.

kd INTEGER. The number of subdiagonals or superdiagonals in the triangular matrix *A*. $kb \geq 0$.

ab REAL for *slatbs*

DOUBLE PRECISION for *dlatbs*

COMPLEX for *clatbs*

DOUBLE COMPLEX for *zlatbs*.

Array, DIMENSION (*ldab*, *n*).

The upper or lower triangular band matrix *A*, stored in the first $kb+1$ rows of the array. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:

```
if uplo = 'U', ab(kd+1+i -j, j) = A(i, j) for  $\max(1, j-kd) \leq i \leq j$ ;  
if uplo = 'L', ab(1+i -j, j) = A(i, j) for  $j \leq i \leq \min(n, j+kd)$ .
```

ldab INTEGER. The leading dimension of the array *ab*. $ldab \geq kb+1$.

x REAL for *slatbs*

DOUBLE PRECISION for *dlatbs*

COMPLEX for *clatbs*

DOUBLE COMPLEX for *zlatbs*.

Array, DIMENSION (*n*).

On entry, the right hand side *b* of the triangular system.

cnorm REAL for *slatbs/clatbs*

DOUBLE PRECISION for *dlatbs/zlatbs*.

Array, DIMENSION (*n*).

If *NORMIN* = 'Y', *cnorm* is an input argument and *cnorm(j)* contains the norm of the off-diagonal part of the *j*-th column of *A*.

If *trans* = 'N', *cnorm(j)* must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm(j)* must be greater than or equal to the 1-norm.

Output Parameters

scale REAL for *slatbs/clatbs*

DOUBLE PRECISION for *dlatbs/zlatbs*.

The scaling factor *s* for the triangular system as described above. If *scale* = 0, the matrix *A* is singular or badly scaled, and the vector *x* is an exact or approximate solution to *Ax* = 0.

<i>cnorm</i>	If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm(j)</i> returns the 1-norm of the off-diagonal part of the <i>j</i> -th column of <i>A</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th argument had an illegal value

?latdf

Uses the LU factorization of the *n*-by-*n* matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.

Syntax

```
call slatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpivot )
call dlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpivot )
call clatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpivot )
call zlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpivot )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?latdf uses the LU factorization of the *n*-by-*n* matrix *Z* computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate by solving $Z^*x = b$ for *x*, and choosing the right-hand side *b* such that the norm of *x* is as large as possible. On entry *rhs* = *b* holds the contribution from earlier solved subsystems, and on return *rhs* = *x*.

The factorization of *Z* returned by ?getc2 has the form $Z = P^*L^*U^*Q$, where *P* and *Q* are permutation matrices. *L* is lower triangular with unit diagonal elements and *U* is upper triangular.

Input Parameters

<i>ijob</i>	INTEGER. <i>ijob</i> = 2: First compute an approximative null-vector <i>e</i> of <i>Z</i> using ?gecon, <i>e</i> is normalized, and solve for $Z^*x = \pm e - f$ with the sign giving the greater value of 2-norm(<i>x</i>). This option is about 5 times as expensive as default. <i>ijob</i> ≠ 2 (default): Local look ahead strategy where all entries of the right-hand side <i>b</i> is chosen as either +1 or -1 .
<i>n</i>	INTEGER. The number of columns of the matrix <i>Z</i> .
<i>z</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. Array, DIMENSION (<i>ldz</i> , <i>n</i>)

On entry, the *LU* part of the factorization of the n -by- n matrix Z computed by ?getc2: $Z = P^* L^* U^* Q$.

ldz INTEGER. The leading dimension of the array Z . $lda \geq \max(1, n)$.

rhs REAL for slatdf/clatdf

DOUBLE PRECISION for dlatdf/zlatdf.

Array, DIMENSION (n).

On entry, *rhs* contains contributions from other subsystems.

rdsum REAL for slatdf/clatdf

DOUBLE PRECISION for dlatdf/zlatdf.

On entry, the sum of squares of computed contributions to the *Dif*-estimate under computation by ?tgsvL, where the scaling factor *rdscal* has been factored out. If *trans* = 'T', *rdsum* is not touched.

Note that *rdsum* only makes sense when ?tgsv2 is called by ?tgsvL.

rdscal REAL for slatdf/clatdf

DOUBLE PRECISION for dlatdf/zlatdf.

On entry, scaling factor used to prevent overflow in *rdsum*.

If *trans* = 'T', *rdscal* is not touched.

Note that *rdscal* only makes sense when ?tgsv2 is called by ?tgsvL.

ipiv INTEGER.

Array, DIMENSION (n).

The pivot indices; for $1 \leq i \leq n$, row i of the matrix has been interchanged with row *ipiv*(i).

jpivot INTEGER.

Array, DIMENSION (n).

The pivot indices; for $1 \leq j \leq n$, column j of the matrix has been interchanged with column *jpivot*(j).

Output Parameters

rhs

On exit, *rhs* contains the solution of the subsystem with entries according to the value of *ijob*.

rdsum

On exit, the corresponding sum of squares updated with the contributions from the current sub-system.

If *trans* = 'T', *rdsum* is not touched.

rdscal

On exit, *rdscal* is updated with respect to the current contributions in *rdsum*.

If *trans* = 'T', *rdscal* is not touched.

?latps

Solves a triangular system of equations with the matrix held in packed storage.

Syntax

```
call slatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call dlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call clatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call zlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?latps solves one of the triangular systems

$A^*x = s^*b$, or $A^T*x = s^*b$, or $A^H*x = s^*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem does not cause overflow, the Level 2 BLAS routine ?tpsv is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A^*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1.
	Specifies whether the matrix A is upper or lower triangular.
= 'U'	: upper triangular
= 'L'	: lower triangular
<i>trans</i>	CHARACTER*1.
	Specifies the operation applied to A .
= 'N'	: solve $A^*x = s^*b$ (no transpose)
= 'T'	: solve $A^T*x = s^*b$ (transpose)
= 'C'	: solve $A^H*x = s^*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1.
	Specifies whether the matrix A is unit triangular.
= 'N'	: non-unit triangular
= 'U'	: unit triangular
<i>normin</i>	CHARACTER*1.
	Specifies whether $cnorm$ is set.

= 'Y': *cnorm* contains the column norms on entry;
 = 'N': *cnorm* is not set on entry. On exit, the norms will be computed and stored in *cnorm*.

n

INTEGER. The order of the matrix *A*. $n \geq 0$.

ap

REAL for *slatps*
 DOUBLE PRECISION for *dlatps*
 COMPLEX for *clatps*
 DOUBLE COMPLEX for *zlatps*.

Array, DIMENSION ($n(n+1)/2$).

The upper or lower triangular matrix *A*, packed columnwise in a linear array. The *j*-th column of *A* is stored in the array *ap* as follows:

```
if uplo = 'U', ap(i + (j-1) $j/2$ ) = A(i, j) for  $1 \leq i \leq j$ ;  

if uplo = 'L', ap(i + (j-1)( $2n-j$ )/2) = A(i, j) for  $j \leq i \leq n$ .
```

x

REAL for *slatps* DOUBLE PRECISION for *dlatps*
 COMPLEX for *clatps*
 DOUBLE COMPLEX for *zlatps*.

Array, DIMENSION (*n*)

On entry, the right hand side *b* of the triangular system.

cnorm

REAL for *slatps/clatps*
 DOUBLE PRECISION for *dlatps/zlatps*.

Array, DIMENSION (*n*).

If *normin* = 'Y', *cnorm* is an input argument and *cnorm(j)* contains the norm of the off-diagonal part of the *j*-th column of *A*.

If *trans* = 'N', *cnorm(j)* must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm(j)* must be greater than or equal to the 1-norm.

Output Parameters

x

On exit, *x* is overwritten by the solution vector *x*.

scale

REAL for *slatps/clatps*
 DOUBLE PRECISION for *dlatps/zlatps*.

The scaling factor *s* for the triangular system as described above.

If *scale* = 0, the matrix *A* is singular or badly scaled, and the vector *x* is an exact or approximate solution to $A^*x = 0$.

cnorm

If *normin* = 'N', *cnorm* is an output argument and *cnorm(j)* returns the 1-norm of the off-diagonal part of the *j*-th column of *A*.

info

INTEGER.

= 0: successful exit
 < 0: if *info* = -*k*, the *k*-th argument had an illegal value

?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call slatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call dlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call clatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call zlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?latrd reduces *nb* rows and columns of a real symmetric or complex Hermitian matrix *A* to symmetric/Hermitian tridiagonal form by an orthogonal/unitary similarity transformation $Q^T * A * Q$ for real flavors, $Q^H * A * Q$ for complex flavors, and returns the matrices *V* and *W* which are needed to apply the transformation to the unreduced part of *A*.

If *uplo* = 'U', ?latrd reduces the last *nb* rows and columns of a matrix, of which the upper triangle is supplied;

if *uplo* = 'L', ?latrd reduces the first *nb* rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by ?sytrd/?hetrd.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix <i>A</i> is stored: = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix <i>A</i> .
<i>nb</i>	INTEGER. The number of rows and columns to be reduced.
<i>a</i>	REAL for slatrd DOUBLE PRECISION for dlatrd COMPLEX for clatrd DOUBLE COMPLEX for zlatrd.

Array, DIMENSION (lda, n).

On entry, the symmetric/Hermitian matrix A

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda

INTEGER. The leading dimension of the array a . $lda \geq (1, n)$.

ldw

INTEGER.

The leading dimension of the output array w . $ldw \geq \max(1, n)$.

Output Parameters

a

On exit, if $uplo = 'U'$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of a ; the elements above the diagonal with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if $uplo = 'L'$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of a ; the elements below the diagonal with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

e

REAL for `slatrd/clatrd`

DOUBLE PRECISION for `dlatrd/zlatrd`.

If $uplo = 'U'$, $e(n-nb:n-1)$ contains the superdiagonal elements of the last nb columns of the reduced matrix;

if $uplo = 'L'$, $e(1:nb)$ contains the subdiagonal elements of the first nb columns of the reduced matrix.

tau

REAL for `slatrd`

DOUBLE PRECISION for `dlatrd`

COMPLEX for `clatrd`

DOUBLE COMPLEX for `zlatrd`.

Array, DIMENSION (lda, n).

The scalar factors of the elementary reflectors, stored in $tau(n-nb:n-1)$ if $uplo = 'U'$, and in $tau(1:nb)$ if $uplo = 'L'$.

w

REAL for `slatrd`

DOUBLE PRECISION for `dlatrd`

COMPLEX for `clatrd`

DOUBLE COMPLEX for `zlatrd`.

Array, DIMENSION (ldw, n).

The n -by- nb matrix W required to update the unreduced part of A .

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v'$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $a(1: i-1, i)$, and tau in $tau(i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form $H(i) = I - tau * v * v'$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1: i) = 0$ and $v(i+1) = 1$; $v(i+1:n)$ is stored on exit in $a(i+1:n, i)$, and tau in $tau(i)$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2k update of the form:

$$A := A - VW' - WV'.$$

The contents of a on exit are illustrated by the following examples with $n = 5$ and $nb = 2$:

if $uplo = 'U'$:

$$\begin{bmatrix} a & a & a & v_4 & v_4 \\ a & a & v_4 & v_5 & \\ a & 1 & v_5 & & \\ d & 1 & & & \\ d & & & & \end{bmatrix}$$

if $uplo = 'L'$

$$\begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call slatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call dlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call clatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call zlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine solves one of the triangular systems

$$A^*x = s^*b, \text{ or } A^T*x = s^*b, \text{ or } A^H*x = s^*b \text{ (for complex flavors)}$$

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ?trsv is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A^*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A^*x = s^*b$ (no transpose) = 'T': solve $A^T*x = s^*b$ (transpose) = 'C': solve $A^H*x = s^*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$
<i>a</i>	REAL for slatrs DOUBLE PRECISION for dlatrs COMPLEX for clatrs DOUBLE COMPLEX for zlatrs. Array, DIMENSION (<i>lda</i> , <i>n</i>). Contains the triangular matrix A .

If $uplo = 'U'$, the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

If $diag = 'U'$, the diagonal elements of A are also not referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

x REAL for slatrs

DOUBLE PRECISION for dlatrs

COMPLEX for clatrs

DOUBLE COMPLEX for zlatrs .

Array, DIMENSION (n).

On entry, the right hand side b of the triangular system.

$cnorm$ REAL for $\text{slatrs}/\text{clatrs}$

DOUBLE PRECISION for $\text{dlatrs}/\text{zlatrs}$.

Array, DIMENSION (n).

If $normin = 'Y'$, $cnorm$ is an input argument and $cnorm(j)$ contains the norm of the off-diagonal part of the j -th column of A .

If $trans = 'N'$, $cnorm(j)$ must be greater than or equal to the infinity-norm, and if $trans = 'T'$ or ' C' , $cnorm(j)$ must be greater than or equal to the 1-norm.

Output Parameters

x On exit, x is overwritten by the solution vector x .

$scale$ REAL for $\text{slatrs}/\text{clatrs}$

DOUBLE PRECISION for $\text{dlatrs}/\text{zlatrs}$.

Array, DIMENSION (lda, n). The scaling factor s for the triangular system as described above.

If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $A^*x = 0$.

$cnorm$ If $normin = 'N'$, $cnorm$ is an output argument and $cnorm(j)$ returns the 1-norm of the off-diagonal part of the j -th column of A .

$info$ INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument had an illegal value

Application Notes

A rough bound on x is computed; if that is less than overflow, `?trsv` is called, otherwise, specific code is used which checks for possible overflow or divide-by-zero at every operation.

A columnwise scheme is used for solving $Ax = b$. The basic algorithm if A is lower triangular is

```

x[1:n] := b[1:n]
for j = 1, ..., n
  x(j) := x(j) / A(j,j)
  x[j+1:n] := x[j+1:n] - x(j)*a[j+1:n,j]
end

```

Define bounds on the components of x after j iterations of the loop:

```

M(j) = bound on x[1:j]
G(j) = bound on x[j+1:n]
Initially, let M(0) = 0 and G(0) = max{x(i), i=1,...,n}.

```

Then for iteration $j+1$ we have

$$\begin{aligned} M(j+1) &\leq G(j) / |a(j+1, j+1)| \\ G(j+1) &\leq G(j) + M(j+1) * |a[j+2:n, j+1]| \\ &\leq G(j) (1 + cnorm(j+1) / |a(j+1, j+1)|), \end{aligned}$$

where $cnorm(j+1)$ is greater than or equal to the infinity-norm of column $j+1$ of a , not counting the diagonal. Hence

$$G(j) \leq G(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

and

$$|x(j)| \leq (G(0)/|A(j,j)|) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

Since $|x(j)| \leq M(j)$, we use the Level 2 BLAS routine `?trsv` if the reciprocal of the largest $M(j)$, $j=1,\dots,n$, is larger than $\max(\text{underflow}, 1/\text{overflow})$.

The bound on $x(j)$ is also used to determine when a step in the columnwise method can be performed without fear of overflow. If the computed bound is greater than a large constant, x is scaled to prevent overflow, but if the bound overflows, x is set to 0, $x(j)$ to 1, and scale to 0, and a non-trivial solution to $Ax = 0$ is found.

Similarly, a row-wise scheme is used to solve $A^T x = b$ or $A^H x = b$. The basic algorithm for A upper triangular is

```

for j = 1, ..., n
  x(j) := (b(j) - A[1:j-1,j]' x[1:j-1]) / A(j,j)
end

```

We simultaneously compute two bounds

$G(j) = \text{bound on } (b(i) - A[1:i-1, i]' * x[1:i-1]), 1 \leq i \leq j$

$M(j) = \text{bound on } x(i), 1 \leq i \leq j$

The initial values are $G(0) = 0, M(0) = \max\{b(i), i=1,\dots,n\}$, and we add the constraint $G(j) \geq G(j-1)$ and $M(j) \geq M(j-1)$ for $j \geq 1$.

Then the bound on $x(j)$ is

$$M(j) \leq M(j-1) * (1 + cnorm(j)) / |A(j,j)|$$

$$\leq M(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

and we can safely call ?trsv if $1/M(n)$ and $1/G(n)$ are both greater than $\max(\text{underflow}, 1/\text{overflow})$.

?latrz

Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.

Syntax

```
call slatrz( m, n, l, a, lda, tau, work )
call dlatrz( m, n, l, a, lda, tau, work )
call clatrz( m, n, l, a, lda, tau, work )
call zlatrz( m, n, l, a, lda, tau, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?latrz factors the m -by- $(m+l)$ real/complex upper trapezoidal matrix

$$[A1 \ A2] = [A(1:m, 1:m) \ A(1: m, n-l+1:n)]$$

as $(R \ 0) * Z$, by means of orthogonal/unitary transformations. Z is an $(m+l)$ -by- $(m+l)$ orthogonal/unitary matrix and R and $A1$ are m -by- m upper triangular matrices.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
l	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder vectors. $n-m \geq l \geq 0$.
a	REAL for slatrz DOUBLE PRECISION for dlatrz COMPLEX for clatrz

DOUBLE COMPLEX for zlatrz.

Array, DIMENSION (*lda, n*).

On entry, the leading *m*-by-*n* upper trapezoidal part of the array *a* must contain the matrix to be factorized.

lda INTEGER. The leading dimension of the array *a*. *lda* $\geq \max(1, m)$.

work REAL for slatrz

DOUBLE PRECISION for dlatrz

COMPLEX for clatrz

DOUBLE COMPLEX for zlatrz.

Workspace array, DIMENSION (*m*).

Output Parameters

a On exit, the leading *m*-by-*m* upper triangular part of *a* contains the upper triangular matrix *R*, and elements *n-l+1* to *n* of the first *m* rows of *a*, with the array *tau*, represent the orthogonal/unitary matrix *Z* as a product of *m* elementary reflectors.

tau REAL for slatrz

DOUBLE PRECISION for dlatrz

COMPLEX for clatrz

DOUBLE COMPLEX for zlatrz.

Array, DIMENSION (*m*).

The scalar factors of the elementary reflectors.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, *z(k)*, which is used to introduce zeros into the (*m - k + 1*)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where for real flavors

$$T(k) = I - t \alpha u^* u(k)^* T(k)^T, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ z(k) \end{bmatrix}$$

and for complex flavors

$$T(k) = I - \tau u u^H T(k)^H, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an l -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of A_2 .

The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of A_2 , such that the elements of $z(k)$ are in $a(k, l+1), \dots, a(k, n)$.

The elements of r are returned in the upper triangular part of A_1 .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

?laau2

Computes the product $U^* U^T (U^* U^H)$ or $L^T * L (L^H * L)$, where U and L are upper or lower triangular matrices (unblocked algorithm).

Syntax

```
call slauu2( uplo, n, a, lda, info )
call dlauu2( uplo, n, a, lda, info )
call clauu2( uplo, n, a, lda, info )
call zlauu2( uplo, n, a, lda, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?laau2 computes the product $U^* U^T$ or $L^T * L$ for real flavors, and $U^* U^H$ or $L^H * L$ for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If $uplo = 'U'$ or ' u ', then the upper triangle of the result is stored, overwriting the factor U in A .

If $uplo = 'L'$ or ' l ', then the lower triangle of the result is stored, overwriting the factor L in A .

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

$uplo$	CHARACTER*1.
	Specifies whether the triangular factor stored in the array a is upper or lower triangular:
= ' U '	: Upper triangular
= ' L '	: Lower triangular

n INTEGER. The order of the triangular factor U or L . $n \geq 0$.

a REAL for `slauu2`
 DOUBLE PRECISION for `dlauu2`
 COMPLEX for `clauu2`
 DOUBLE COMPLEX for `zlauu2`.
 Array, DIMENSION (*lda, n*). On entry, the triangular factor *U* or *L*.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit,
 if *uplo* = 'U', then the upper triangle of *a* is overwritten with the upper triangle of the product $U^* U^T (U^* U^H)$;
 if *uplo* = 'L', then the lower triangle of *a* is overwritten with the lower triangle of the product $L^T * L (L^H * L)$.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-k$, the *k*-th argument had an illegal value

?lauum

Computes the product $U^* U^T (U^* U^H)$ or $L^T * L (L^H * L)$, where *U* and *L* are upper or lower triangular matrices (blocked algorithm).

Syntax

```
call slauum( uplo, n, a, lda, info )
call dlauum( uplo, n, a, lda, info )
call clauum( uplo, n, a, lda, info )
call zlauum( uplo, n, a, lda, info )
```

C:

```
lapack_int LAPACKE_<?>lauum (int matrix_layout, char uplo, lapack_int n, <datatype> * a, lapack_int lda);
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine `?lauum` computes the product $U^* U^T$ or $L^T * L$ for real flavors, and $U^* U^H$ or $L^H * L$ for complex flavors. Here the triangular factor *U* or *L* is stored in the upper or lower triangular part of the array *a*.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor *U* in *A*.

If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor *L* in *A*.

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1.
	Specifies whether the triangular factor stored in the array <i>a</i> is upper or lower triangular:
= 'U'	: Upper triangular
= 'L'	: Lower triangular
<i>n</i>	INTEGER. The order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$.
<i>a</i>	REAL for <i>slauum</i> DOUBLE PRECISION for <i>dlauum</i> COMPLEX for <i>clauum</i> DOUBLE COMPLEX for <i>zlaum</i> . Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the triangular factor <i>U</i> or <i>L</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', then the upper triangle of <i>a</i> is overwritten with the upper triangle of the product $U^* U^T (U^* U^H)$; if <i>uplo</i> = 'L', then the lower triangle of <i>a</i> is overwritten with the lower triangle of the product $L^T * L (L^H * L)$.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th argument had an illegal value

?orbdb1/?unbdb1

Simultaneously bidiagonalizes the blocks of a tall and skinny matrix with orthonormal columns.

Syntax

- Fortran 95: lapack.f90
- C: mkl.h

Description

The routines ?orbdb1/?unbdb1 simultaneously bidiagonalize the blocks of a tall and skinny matrix X with orthonormal columns:

$$\begin{bmatrix} x_{11} \\ x_{21} \end{bmatrix} = \begin{bmatrix} p_1 & | & p_2 \end{bmatrix} \begin{bmatrix} b_{11} \\ 0 \\ b_{21} \\ 0 \end{bmatrix} q_1^T$$

The size of x_{11} is p by q , and x_{21} is $(m - p)$ by q . q must not be larger than p , $m - p$, or $m - q$.

Tall and Skinny Matrix Routines

$q \leq \min(p, m - p, m - q)$?orbdb1/?unbdb1
$p \leq \min(q, m - p, m - q)$?orbdb2/?unbdb2
$m - p \leq \min(p, q, m - q)$?orbdb3/?unbdb3
$m - q \leq \min(p, q, m - p)$?orbdb4/?unbdb4

The orthogonal/unitary matrices p_1 , p_2 , and q_1 are p -by- p , $(m-p)$ -by- $(m-p)$, $(m-q)$ -by- $(m-q)$, respectively.

p_1 , p_2 , and q_1 are represented as products of elementary reflectors. See the description of ?orcsd2by1/?uncsd2by1 for details on generating p_1 , p_2 , and q_1 using ?orgqr and ?orglq.

The upper-bidiagonal matrices b_{11} and b_{21} of size q by q are represented implicitly by angles $\theta(1), \dots, \theta(q)$ and $\phi(1), \dots, \phi(q-1)$. Every entry in each bidiagonal band is a product of a sine or cosine of θ with a sine or cosine of ϕ . See [Sutton09] or the description of ?orcsd/?uncsd for details.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

m INTEGER. The number of rows in x_{11} plus the number of rows in x_{21} .

p INTEGER. The number of rows in x_{11} . $0 \leq p \leq m$.

q INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq \min(p, m - p, m - q)$.

x11 REAL for sorbdb1

DOUBLE PRECISION for dorbdb1

COMPLEX for cunbdb1

DOUBLE COMPLEX for zunbdb1

Array, DIMENSION (l_{dx11}, q).

On entry, the top block of the orthogonal/unitary matrix to be reduced.

l_{dx11}

INTEGER. The leading dimension of the array X_{11} . $l_{dx11} \geq p$.

x_{21}

REAL for `sorbdb1`

DOUBLE PRECISION for `dorbdb1`

COMPLEX for `cunbdb1`

DOUBLE COMPLEX for `zunbdb1`

Array, DIMENSION (l_{dx21}, q).

On entry, the bottom block of the orthogonal/unitary matrix to be reduced.

l_{dx21}

INTEGER. The leading dimension of the array X_{21} . $l_{dx21} \geq m-p$.

$work$

REAL for `sorbdb1`

DOUBLE PRECISION for `dorbdb1`

COMPLEX for `cunbdb1`

DOUBLE COMPLEX for `zunbdb1`

Workspace array, DIMENSION (l_{work}).

l_{work}

INTEGER. The size of the $work$ array. $l_{work} \geq m-q$

If $l_{work} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to l_{work} is issued by `xerbla`.

Output Parameters

x_{11}

The columns of `tril(x11)` specify reflectors for p_1 and the rows of `triu(x11, 1)` specify reflectors for q_1 , where `tril(A)` denotes the lower triangle of A , and `triu(A)` denotes the upper triangle of A .

x_{21}

On exit, the columns of `tril(x21)` specify the reflectors for p_2

$theta$

REAL for `sorbdb1`

DOUBLE PRECISION for `dorbdb1`

COMPLEX for `cunbdb1`

DOUBLE COMPLEX for `zunbdb1`

Array, DIMENSION (q). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles $theta$ and phi . See the Description section for details.

phi

REAL for `sorbdb1`

DOUBLE PRECISION for `dorbdb1`

COMPLEX for `cunbdb1`

DOUBLE COMPLEX for `zunbdb1`

Array, DIMENSION ($q-1$). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

taup1

REAL for sorbdb1
 DOUBLE PRECISION for dorbdb1
 COMPLEX for cunbdb1
 DOUBLE COMPLEX for zunbdb1
Array, DIMENSION (p).

Scalar factors of the elementary reflectors that define p_1 .

taup2

REAL for sorbdb1
 DOUBLE PRECISION for dorbdb1
 COMPLEX for cunbdb1
 DOUBLE COMPLEX for zunbdb1
Array, DIMENSION ($m-p$).

Scalar factors of the elementary reflectors that define p_2 .

taug1

REAL for sorbdb1
 DOUBLE PRECISION for dorbdb1
 COMPLEX for cunbdb1
 DOUBLE COMPLEX for zunbdb1
Array, DIMENSION (q).

Scalar factors of the elementary reflectors that define q_1 .

info

INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument has an illegal value.

DOUBLE COMPLEX for zunbdb4
Workspace array, DIMENSION (*lwork*).

lwork **INTEGER.** The size of the *work* array. $lwork \geq m-q$

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.

Output Parameters

x11 **On exit:** the columns of `tril(x11)` specify reflectors for p_1 and the rows of `triu(x11,1)` specify reflectors for q_1 .

x21 **On exit,** the columns of `tril(x21)` specify the reflectors for p_2

theta **REAL for sorbdb4**

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (q). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

phi **REAL for sorbdb4**

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($q-1$). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

taup1 **REAL for sorbdb4**

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (p).

Scalar factors of the elementary reflectors that define p_1 .

taup2 **REAL for sorbdb4**

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($m-p$).

Scalar factors of the elementary reflectors that define p_2 .

taug1

REAL for sorbdb4
 DOUBLE PRECISION for dorbdb4
 COMPLEX for cunbdb4
 DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (q).

Scalar factors of the elementary reflectors that define q_1 .

phantom

REAL for sorbdb4
 DOUBLE PRECISION for dorbdb4
 COMPLEX for cunbdb4
 DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (m).

The routine computes an m -by-1 column vector y that is orthogonal to the columns of $[x_{11}; x_{21}]$. $\text{phantom}(1:p)$ and $\text{phantom}(p+1:m)$ contain Householder vectors for $y(1:p)$ and $y(p+1:m)$, respectively.

info

INTEGER.
 = 0: successful exit
 < 0: if $\text{info} = -i$, the i -th argument has an illegal value.

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The ?orbdb5/?unbdb5 routines orthogonalize the column vector

$$x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

with respect to the columns of

$$q = \begin{bmatrix} q_1 \\ q_2 \end{bmatrix}$$

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then some other vector from the orthogonal complement is returned. This vector is chosen in an arbitrary but deterministic way.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>m1</i>	INTEGER	The dimension of <i>x1</i> and the number of rows in <i>q1</i> . $0 \leq m1$.
<i>m2</i>	INTEGER	The dimension of <i>x2</i> and the number of rows in <i>q2</i> . $0 \leq m2$.
<i>n</i>	INTEGER	The number of columns in <i>q1</i> and <i>q2</i> . $0 \leq n$.
<i>x1</i>	REAL for sorbdb5 DOUBLE PRECISION for dordb5 COMPLEX for cundb5 COMPLEX*16 for zundb5 Array of size <i>m1</i> .	The top part of the vector to be orthogonalized.
<i>incx1</i>	INTEGER	Increment for entries of <i>x1</i> .
<i>x2</i>	REAL for sorbdb5 DOUBLE PRECISION for dordb5 COMPLEX for cundb5	

COMPLEX*16 **for** zunbdb5
Array of size $m2$.
The bottom part of the vector to be orthogonalized.

incx2 INTEGER
Increment for entries of $x2$.

q1 REAL **for** sordb5
DOUBLE PRECISION **for** dordb5
COMPLEX **for** cundb5
COMPLEX*16 **for** zunbdb5
Array of size ($ldq1, n$).
The top part of the orthonormal basis matrix.

ldq1 INTEGER
The leading dimension of $q1$. $ldq1 \geq m1$.

q2 REAL **for** sordb5
DOUBLE PRECISION **for** dordb5
COMPLEX **for** cundb5
COMPLEX*16 **for** zunbdb5
Array of size ($ldq2, n$).
The bottom part of the orthonormal basis matrix.

ldq2 INTEGER
The leading dimension of $q2$. $ldq2 \geq m2$.

work REAL **for** sordb5
DOUBLE PRECISION **for** dordb5
COMPLEX **for** cundb5
COMPLEX*16 **for** zunbdb5
Workspace array of size $lwork$.

lwork INTEGER
The size of the array $work$. $lwork \geq n$.

Output Parameters

x1 The top part of the projected vector.
x2 The bottom part of the projected vector.
info INTEGER.
= 0: successful exit

< 0: if $info = -i$, the i -th argument has an illegal value.

?orm2l/?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?orm2l/?unm2l overwrites the general real/complex m -by- n matrix C with

Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T C / Q^H C$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

C^*Q if *side* = 'R' and *trans* = 'N', or

$C^T Q^T / C^* Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by ?geqlf.

Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

side CHARACTER*1.
 = 'L': apply Q or Q^T / Q^H from the left
 = 'R': apply Q or Q^T / Q^H from the right

trans CHARACTER*1.
 = 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m INTEGER. The number of rows of the matrix C . $m \geq 0$.

n INTEGER. The number of columns of the matrix C . $n \geq 0$.

k INTEGER. The number of elementary reflectors whose product defines the matrix Q .
 If *side* = 'L', $m \geq k \geq 0$;
 if *side* = 'R', $n \geq k \geq 0$.

a REAL for sorm21
 DOUBLE PRECISION for dorm21
 COMPLEX for cunm21
 DOUBLE COMPLEX for zunm21.
 Array, DIMENSION (*lda,k*).
 The *i*-th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqlf in the last k columns of its array argument *a*. The array *a* is modified by the routine but restored on exit.

lda INTEGER. The leading dimension of the array *a*.
 If *side* = 'L', *lda* $\geq \max(1, m)$
 if *side* = 'R', *lda* $\geq \max(1, n)$.

tau REAL for sorm21
 DOUBLE PRECISION for dorm21
 COMPLEX for cunm21
 DOUBLE COMPLEX for zunm21.
 Array, DIMENSION (*k*). *tau*(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.

c REAL for sorm21
 DOUBLE PRECISION for dorm21
 COMPLEX for cunm21
 DOUBLE COMPLEX for zunm21.

Array, DIMENSION (ldc, n).
On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array C . $ldc \geq \max(1, m)$.

$work$ REAL for sorm2l
 DOUBLE PRECISION for dorm2l
 COMPLEX for cunm2l
 DOUBLE COMPLEX for zunm2l.

Workspace array, DIMENSION:
 (n) if $side = 'L'$,
 (m) if $side = 'R'$.

Output Parameters

c On exit, c is overwritten by Q^*C or $Q^T*C / Q^{H*}C$, or C^*Q , or C^*Q^T / C^*Q^H .

$info$ INTEGER.
 = 0: successful exit
 < 0: if $info = -i$, the i -th argument had an illegal value

?orm2r/?unm2r

Multiples a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?orm2r/?unm2r overwrites the general real/complex m -by- n matrix C with Q^*C if $side = 'L'$ and $trans = 'N'$, or $Q^T*C / Q^{H*}C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or C^*Q if $side = 'R'$ and $trans = 'N'$, or C^*Q^T / C^*Q^H if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors). Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors $Q = H(1)*H(2)*\dots*H(k)$ as returned by ?geqrf.

Q is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply <i>Q</i> or Q^T / Q^H from the left = 'R': apply <i>Q</i> or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply <i>Q</i> (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> . <i>m</i> ≥ 0 .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> . <i>n</i> ≥ 0 .
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . If <i>side</i> = 'L', <i>m</i> $\geq k \geq 0$; if <i>side</i> = 'R', <i>n</i> $\geq k \geq 0$.
<i>a</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r COMPLEX for cunm2r DOUBLE COMPLEX for zunm2r. Array, DIMENSION (<i>lda,k</i>). The <i>i</i> -th column must contain the vector which defines the elementary reflector $H(i)$, for <i>i</i> = 1, 2, ..., <i>k</i> , as returned by ?geqrf in the first <i>k</i> columns of its array argument <i>a</i> . The array <i>a</i> is modified by the routine but restored on exit.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . If <i>side</i> = 'L', <i>lda</i> $\geq \max(1, m)$; if <i>side</i> = 'R', <i>lda</i> $\geq \max(1, n)$.
<i>tau</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r COMPLEX for cunm2r DOUBLE COMPLEX for zunm2r. Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqrf.
<i>c</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r

COMPLEX for `cunm2r`
 DOUBLE COMPLEX for `zunm2r`.
Array, DIMENSION (ldc, n).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.

work REAL for `sorm2r`
 DOUBLE PRECISION for `dorm2r`
 COMPLEX for `cunm2r`
 DOUBLE COMPLEX for `zunm2r`.
Workspace array, DIMENSION
 (n) if $\text{side} = 'L'$,
 (m) if $\text{side} = 'R'$.

Output Parameters

c On exit, c is overwritten by Q^*C or $Q^T*C / Q^{H*}C$, or C^*Q , or C^*Q^T / C^*Q^H .

info INTEGER.
 = 0: successful exit
 < 0: if $\text{info} = -i$, the i -th argument had an illegal value

?orml2/?unml2

Multiples a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine `?orml2/?unml2` overwrites the general real/complex m -by- n matrix C with

Q^*C if $\text{side} = 'L'$ and $\text{trans} = 'N'$, or
 $Q^T*C / Q^{H*}C$ if $\text{side} = 'L'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors), or
 C^*Q if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or
 C^*Q^T / C^*Q^H if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ for real flavors, or $Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ for complex flavors as returned by `?gelqf`.

Q is of order m if `side` = 'L' and of order n if `side` = 'R'.

Input Parameters

<code>side</code>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<code>trans</code>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<code>m</code>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<code>n</code>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<code>k</code>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If <code>side</code> = 'L', $m \geq k \geq 0$; if <code>side</code> = 'R', $n \geq k \geq 0$.
<code>a</code>	REAL for <code>sorml2</code> DOUBLE PRECISION for <code>dorml2</code> COMPLEX for <code>cunml2</code> DOUBLE COMPLEX for <code>zunml2</code> . Array, DIMENSION (<code>lda, m</code>) if <code>side</code> = 'L', (<code>lda, n</code>) if <code>side</code> = 'R' The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>?gelqf</code> in the first k rows of its array argument <code>a</code> . The array <code>a</code> is modified by the routine but restored on exit.
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> . $lda \geq \max(1, k)$.
<code>tau</code>	REAL for <code>sorml2</code> DOUBLE PRECISION for <code>dorml2</code> COMPLEX for <code>cunml2</code> DOUBLE COMPLEX for <code>zunml2</code> . Array, DIMENSION (k).

$\tau_{au}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `?gelqf`.

c REAL for `sorml2`
 DOUBLE PRECISION for `dorml2`
 COMPLEX for `cunml2`
 DOUBLE COMPLEX for `zunml2`.
 Array, DIMENSION (*ldc*, *n*) On entry, the *m*-by-*n* matrix *C*.
ldc INTEGER. The leading dimension of the array *c*. *ldc* $\geq \max(1, m)$.
work REAL for `sorml2`
 DOUBLE PRECISION for `dorml2`
 COMPLEX for `cunml2`
 DOUBLE COMPLEX for `zunml2`.
 Workspace array, DIMENSION
 (*n*) if *side* = 'L',
 (*m*) if *side* = 'R'

Output Parameters

c On exit, *c* is overwritten by Q^*C or Q^T*C / $Q^{H*}C$, or C^*Q , or C^*Q^T / C^*Q^H .
info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

?ormr2/?unmr2

Multiples a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by `?gerqf` (unblocked algorithm).

Syntax

```
call sormr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dormr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine `?ormr2/?unmr2` overwrites the general real/complex *m*-by-*n* matrix *C* with Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T C / Q^H C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C^* Q$ if $side = 'R'$ and $trans = 'N'$, or

$C^* Q^T / C^* Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1)^* H(2)^* \dots^* H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by `?gerqf`.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$

CHARACTER*1.

= 'L': apply Q or Q^T / Q^H from the left

= 'R': apply Q or Q^T / Q^H from the right

$trans$

CHARACTER*1.

= 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m

INTEGER. The number of rows of the matrix C . $m \geq 0$.

n

INTEGER. The number of columns of the matrix C . $n \geq 0$.

k

INTEGER. The number of elementary reflectors whose product defines the matrix Q .

If $side = 'L'$, $m \geq k \geq 0$;

if $side = 'R'$, $n \geq k \geq 0$.

a

REAL for `sormr2`

DOUBLE PRECISION for `dormr2`

COMPLEX for `cunmr2`

DOUBLE COMPLEX for `zunmr2`.

Array, DIMENSION

(lda, m) if $side = 'L'$,

(lda, n) if $side = 'R'$

The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by `?gerqf` in the last k rows of its array argument a . The array a is modified by the routine but restored on exit.

lda

INTEGER.

The leading dimension of the array a . $lda \geq \max(1, k)$.

tau

REAL for `sormr2`

DOUBLE PRECISION for `dormr2`

COMPLEX for `cunmr2`

DOUBLE COMPLEX for zunmr2.
Array, DIMENSION (k).
tau(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gerqf.

c
REAL for sormr2
DOUBLE PRECISION for dormr2
COMPLEX for cunmr2
DOUBLE COMPLEX for zunmr2.
Array, DIMENSION (ldc, n).
On entry, the m -by- n matrix C .

ldc
INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.

work
REAL for sormr2
DOUBLE PRECISION for dormr2
COMPLEX for cunmr2
DOUBLE COMPLEX for zunmr2.
Workspace array, DIMENSION
(n) if *side* = 'L',
(m) if *side* = 'R'

Output Parameters

c
On exit, c is overwritten by Q^*C or Q^H*C / Q^H*Q , or C^*Q , or C^*Q^T / C^*Q^H .

info
INTEGER.
= 0: successful exit
< 0: if *info* = $-i$, the i -th argument had an illegal value

?ormr3/?unmr3

Multiples a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzrzf (unblocked algorithm).

Syntax

```
call sormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call dormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call cunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call zunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
```

Include Files

C^*Q^T / C^*Q^H if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1)*H(2)*\dots*H(k)$ as returned by ?tzrzf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side

CHARACTER*1.

= 'L': apply Q or Q^T / Q^H from the left

= 'R': apply Q or Q^T / Q^H from the right

trans

CHARACTER*1.

= 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m

INTEGER. The number of rows of the matrix C . $m \geq 0$.

n

INTEGER. The number of columns of the matrix C . $n \geq 0$.

k

INTEGER. The number of elementary reflectors whose product defines the matrix Q .

If $side = 'L'$, $m \geq k \geq 0$;

If $side = 'R'$, $n \geq k \geq 0$.

l

INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors.

If $side = 'L'$, $m \geq l \geq 0$,

If $side = 'R'$, $n \geq l \geq 0$.

a

REAL for sormr3

?pbtf2

*Computes the Cholesky factorization of a symmetric/
Hermitian positive-definite band matrix (unblocked
algorithm).*

Syntax

```
call spbtf2( uplo, n, kd, ab, ldab, info )
call dpbtf2( uplo, n, kd, ab, ldab, info )
call cpbtf2( uplo, n, kd, ab, ldab, info )
call zpbtf2( uplo, n, kd, ab, ldab, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite band matrix A .

The factorization has the form

$A = U^T * U$ for real flavors, $A = U^H * U$ for complex flavors if $uplo = 'U'$, or

$A = L * L^T$ for real flavors, $A = L * L^H$ for complex flavors if $uplo = 'L'$,

where U is an upper triangular matrix, and L is lower triangular. This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1.
	Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix A is stored:
	= 'U': upper triangular
	= 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix A if $uplo = 'U'$, or the number of sub-diagonals if $uplo = 'L'$. $kd \geq 0$.
<i>ab</i>	REAL for spbtf2 DOUBLE PRECISION for dpbtf2 COMPLEX for cpbtf2 DOUBLE COMPLEX for zpbtf2. Array, DIMENSION (<i>ldab</i> , <i>n</i>).

On entry, the upper or lower triangle of the symmetric/ Hermitian band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array ab as follows:

```
if uplo = 'U', ab(kd+1+i-j, j) = A(i, j for  $\max(1, j-kd) \leq i \leq j$ );  
if uplo = 'L', ab(1+i-j, j) = A(i, j for  $j \leq i \leq \min(n, j+kd)$ ).
```

ldab

INTEGER. The leading dimension of the array ab . $ldab \geq kd+1$.

Output Parameters

ab

On exit, If *info* = 0, the triangular factor U or L from the Cholesky factorization $A=U^T \star U$ ($A=U^H \star U$), or $A= L \star L^T$ ($A= L \star L^H$) of the band matrix A , in the same storage format as A .

info

INTEGER.

= 0: successful exit

< 0: if *info* = $-k$, the k -th argument had an illegal value

> 0: if *info* = k , the leading minor of order k is not positive definite, and the factorization could not be completed.

?potf2

Computes the Cholesky factorization of a symmetric/ Hermitian positive-definite matrix (unblocked algorithm).

Syntax

```
call spotf2( uplo, n, a, lda, info )  
call dpotf2( uplo, n, a, lda, info )  
call cpotf2( uplo, n, a, lda, info )  
call zpotf2( uplo, n, a, lda, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?potf2 computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite matrix A . The factorization has the form

$A = U^T \star U$ for real flavors, $A = U^H \star U$ for complex flavors if *uplo* = 'U', or

$A = L \star L^T$ for real flavors, $A = L \star L^H$ for complex flavors if *uplo* = 'L',

where U is an upper triangular matrix, and L is lower triangular.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#)

Input Parameters

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored.

- = 'U': upper triangular
- = 'L': lower triangular

n INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for `sptf2`
 DOUBLE PRECISION or `dpotf2`
 COMPLEX for `cpotf2`
 DOUBLE COMPLEX for `zpotf2`.

Array, DIMENSION (*lda*, *n*).

On entry, the symmetric/Hermitian matrix A .

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix A , and the strictly lower triangular part of *a* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix A , and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*.

lda $\geq \max(1, n)$.

Output Parameters

a On exit, If *info* = 0, the factor U or L from the Cholesky factorization $A = U^T * U$ ($A = U^H * U$), or $A = L * L^T$ ($A = L * L^H$).

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-k$, the *k*-th argument had an illegal value
 > 0: if *info* = *k*, the leading minor of order *k* is not positive definite, and the factorization could not be completed.

?ptts2

Solves a tridiagonal system of the form $A * X = B$ using the $L * D * L^H / L * D * L^H$ factorization computed by ?pttrf.

Syntax

```
call sptts2( n, nrhs, d, e, b, ldb )
call dptts2( n, nrhs, d, e, b, ldb )
call cptts2( iuplo, n, nrhs, d, e, b, ldb )
call zptts2( iuplo, n, nrhs, d, e, b, ldb )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?ptts2 solves a tridiagonal system of the form

$$A^*X = B$$

Real flavors sptts2/dptts2 use the $L^*D^*L^T$ factorization of A computed by [spttrf/dpttrf](#), and complex flavors cptts2/zptts2 use the U^H*D^*U or $L^*D^*L^H$ factorization of A computed by [cpttrf/zpttrf](#).

D is a diagonal matrix specified in the vector d , U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector e , and X and B are n -by- $nrhs$ matrices.

Input Parameters

<i>iuplo</i>	INTEGER. Used with complex flavors only. Specifies the form of the factorization, and whether the vector e is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L . = 1: $A = U^H*D^*U$, e is the superdiagonal of U ; = 0: $A = L^*D^*L^H$, e is the subdiagonal of L
<i>n</i>	INTEGER. The order of the tridiagonal matrix A . $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, that is, the number of columns of the matrix B . $nrhs \geq 0$.
<i>d</i>	REAL for sptts2/cptts2 DOUBLE PRECISION for dptts2/zptts2. Array, DIMENSION (n). The n diagonal elements of the diagonal matrix D from the factorization of A .
<i>e</i>	REAL for sptts2 DOUBLE PRECISION for dptts2 COMPLEX for cptts2 DOUBLE COMPLEX for zptts2. Array, DIMENSION ($n-1$). Contains the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^T$ (for real flavors) or $L^*D^*L^H$ (for complex flavors when <i>iuplo</i> = 0) factorization of A . For complex flavors when <i>iuplo</i> = 1, e contains the $(n-1)$ superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U^H*D^*U$.
<i>B</i>	REAL for sptts2/cptts2 DOUBLE PRECISION for dptts2/zptts2. Array, DIMENSION ($ldb, nrhs$).

On entry, the right hand side vectors B for the system of linear equations.

ldb INTEGER. The leading dimension of the array B . $ldb \geq \max(1, n)$.

Output Parameters

b On exit, the solution vectors, X .

?rscl

Multiples a vector by the reciprocal of a real scalar.

Syntax

```
call srscl( n, sa, sx, incx )
call drscl( n, sa, sx, incx )
call csrsc1( n, sa, sx, incx )
call zdrscl( n, sa, sx, incx )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?rscl multiplies an n -element real/complex vector x by the real scalar $1/a$. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Input Parameters

n INTEGER. The number of components of the vector x .

sa REAL for srscl/csrsc1
DOUBLE PRECISION for drscl/zdrscl.

The scalar a which is used to divide each component of the vector x . sa must be ≥ 0 , or the subroutine will divide by zero.

sx REAL for srscl
DOUBLE PRECISION for drscl
COMPLEX for csrsc1
DOUBLE COMPLEX for zdrscl.
Array, DIMENSION (1+(n-1)* |incx|).

The n -element vector x .

$incx$ INTEGER. The increment between successive values of the vector sx .
If $incx > 0$, $sx(1)=x(1)$, and $sx(1+(i-1)*incx)=x(i)$, $1 < i \leq n$.

Output Parameters

sx On exit, the result x/a .

?syswapr

Applies an elementary permutation on the rows and columns of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyswapr( uplo, n, a, i1, i2 )
call dsyswapr( uplo, n, a, i1, i2 )
call csyswapr( uplo, n, a, i1, i2 )
call zsyswapr( uplo, n, a, i1, i2 )
```

Fortran 95:

```
call syswapr( a, i1, i2[, uplo] )
```

C:

```
lapack_int LAPACKE_<?>syswapr (int matrix_layout, char uplo, lapack_int n, <datatype> * a, lapack_int i1, lapack_int i2);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

The data types are given for the Fortran interface.

uplo CHARACTER*1. Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U \cdot D \cdot U^T$.

If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L \cdot D \cdot L^T$.

n INTEGER. The order of matrix A ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a REAL for ssyswapr

DOUBLE PRECISION for dsyswapr

COMPLEX for csyswapr

DOUBLE COMPLEX for zsyswapr

Array of dimension (lda, n).

The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?sytrf.

$i1$ INTEGER. Index of the first row to swap.

$i2$ INTEGER. Index of the second row to swap.

Output Parameters

a If $info = 0$, the symmetric inverse of the original matrix.

If $info = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.

If $info = 'L'$, the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine syswapr interface are as follows:

a Holds the matrix A of size (n, n).

$i1$ Holds the index for swap.

$i2$ Holds the index for swap.

$uplo$ Indicates how the matrix A has been factored. Must be ' U ' or ' L '.

See Also

?sytrf

?heswapr

Applies an elementary permutation on the rows and columns of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cheswapr( uplo, n, a, i1, i2 )
call zheswapr( uplo, n, a, i1, i2 )
```

Fortran 95:

```
call heswapr( a, i1, i2 [,uplo] )
```

C:

```
lapack_int LAPACKE_<?>heswapr (int matrix_layout, char uplo, lapack_int n, <datatype> * a, lapack_int i1, lapack_int i2);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a Hermitian matrix.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.
	Indicates how the input matrix A has been factored:
	If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor U of the factorization $A = U^*D^*U^H$.
	If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor L of the factorization $A = L^*D^*L^H$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a</i>	COMPLEX for cheswapr DOUBLE COMPLEX for zheswapr Array of dimension (<i>lda</i> , <i>n</i>). The array <i>a</i> contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?hetrf.
<i>i1</i>	INTEGER. Index of the first row to swap.
<i>i2</i>	INTEGER. Index of the second row to swap.

Output Parameters

<i>a</i>	If <i>info</i> = 0, the inverse of the original matrix. If <i>info</i> = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced. If <i>info</i> = 'L', the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.
----------	---

- Fortran: mkl.fi
- Fortran 95: lapack.f90

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U \cdot D \cdot U^T$. If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L \cdot D \cdot L^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a</i>	REAL for ssyswapr1 DOUBLE PRECISION for dsyswapr1 COMPLEX for csyswapr1 DOUBLE COMPLEX for zsyswapr1

Array of dimension (lda, n) .

The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?sytrf .

lda INTEGER. The leading dimension of the array a . $\text{lda} \geq \max(1, n)$.

$i1$ INTEGER. Index of the first row to swap.

$i2$ INTEGER. Index of the second row to swap.

Output Parameters

a If $\text{info} = 0$, the symmetric inverse of the original matrix.

If $\text{info} = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.

If $\text{info} = 'L'$, the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine syswapr1 interface are as follows:

a Holds the matrix A of size (n, n) .

$i1$ Holds the index for swap.

$i2$ Holds the index for swap.

uplo Indicates how the matrix A has been factored. Must be ' U ' or ' L '.

[?sytrf](#)

?sygs2/?hegs2

Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).

Syntax

```
call ssygs2( itype, uplo, n, a, lda, b, ldb, info )
call dsygs2( itype, uplo, n, a, lda, b, ldb, info )
call chegs2( itype, uplo, n, a, lda, b, ldb, info )
call zhegs2( itype, uplo, n, a, lda, b, ldb, info )
```

Include Files

- Fortran: `mkl.fi`

- C: mkl.h

Description

The routine ?sygs2/?hegs2 reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

If *itype* = 1, the problem is

$$A^*x = \lambda * B^*x$$

and *A* is overwritten by $\text{inv}(U^H) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^H)$ for complex flavors and by $\text{inv}(U^T) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^T)$ for real flavors.

If *itype* = 2 or 3, the problem is

$$A^*B^*x = \lambda * x, \text{ or } B^*A^*x = \lambda * x,$$

and *A* is overwritten by $U^*A^*U^H$ or $L^H * A * L$ for complex flavors and by $U^*A^*U^T$ or $L^T * A * L$ for real flavors. Here U^T and L^T are the transpose while U^H and L^H are conjugate transpose of *U* and *L*.

B must be previously factorized by ?potrf as follows:

- $U^H * U$ or $L * L^H$ for complex flavors
- $U^T * U$ or $L^T * L$ for real flavors

Input Parameters

itype

INTEGER.

For complex flavors:

- = 1: compute $\text{inv}(U^H) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^H)$;
- = 2 or 3: compute $U^*A^*U^H$ or $L^H * A * L$.

For real flavors:

- = 1: compute $\text{inv}(U^T) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^T)$;
- = 2 or 3: compute $U^*A^*U^T$ or $L^T * A * L$.

uplo

CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix *A* is stored, and how *B* has been factorized.

- = 'U': upper triangular
- = 'L': lower triangular

n

INTEGER. The order of the matrices *A* and *B*. $n \geq 0$.

a

REAL for ssygs2

DOUBLE PRECISION for dsygs2

COMPLEX for chegs2

DOUBLE COMPLEX for zhegs2.

Array, DIMENSION (*lda*, *n*).

On entry, the symmetric/Hermitian matrix *A*.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda

INTEGER.

The leading dimension of the array a . $lda \geq \max(1, n)$.*b*

REAL for ssygs2

DOUBLE PRECISION for dsygs2

COMPLEX for chegs2

DOUBLE COMPLEX for zhegs2.

Array, DIMENSION (ldb, n).The triangular factor from the Cholesky factorization of B as returned by ?potrf.*ldb*INTEGER. The leading dimension of the array b . $ldb \geq \max(1, n)$.

Output Parameters

*a*On exit, If $info = 0$, the transformed matrix, stored in the same format as A .*info*

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

?sytd2/?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation(unblocked algorithm).

Syntax

```
call ssytd2( uplo, n, a, lda, d, e, tau, info )
call dsytd2( uplo, n, a, lda, d, e, tau, info )
call chetd2( uplo, n, a, lda, d, e, tau, info )
call zhetd2( uplo, n, a, lda, d, e, tau, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?sytd2/?hetd2 reduces a real symmetric/complex Hermitian matrix A to real symmetric tridiagonal form T by an orthogonal/unitary similarity transformation: $Q^T A Q = T$ ($Q^H A Q = T$).

Input Parameters

uplo CHARACTER*1.
 Specifies whether the upper or lower triangular part of the symmetric/
 Hermitian matrix *A* is stored:
 = 'U': upper triangular
 = 'L': lower triangular

n INTEGER. The order of the matrix *A*. $n \geq 0$.

a REAL for ssytd2
 DOUBLE PRECISION for dsytd2
 COMPLEX for chetd2
 DOUBLE COMPLEX for zhetd2.
 Array, DIMENSION (*lda*, *n*).
 On entry, the symmetric/Hermitian matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the
 upper triangular part of the matrix *A*, and the strictly lower triangular part
 of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the
 lower triangular part of the matrix *A*, and the strictly upper triangular part
 of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, if *uplo* = 'U', the diagonal and first superdiagonal of *a* are
 overwritten by the corresponding elements of the tridiagonal matrix *T*, and
 the elements above the first superdiagonal, with the array *tau*, represent
 the orthogonal/unitary matrix *Q* as a product of elementary reflectors;
 if *uplo* = 'L', the diagonal and first subdiagonal of *a* are overwritten by
 the corresponding elements of the tridiagonal matrix *T*, and the elements
 below the first subdiagonal, with the array *tau*, represent the orthogonal/
 unitary matrix *Q* as a product of elementary reflectors.

d REAL for ssytd2/chetd2
 DOUBLE PRECISION for dsytd2/zhetd2.
 Array, DIMENSION (*n*).
 The diagonal elements of the tridiagonal matrix *T*:

$$d(i) = a(i, i).$$

e REAL for ssytd2/chetd2
 DOUBLE PRECISION for dsytd2/zhetd2.
 Array, DIMENSION (*n*-1).
 The off-diagonal elements of the tridiagonal matrix *T*:

$e(i) = a(i,i+1)$ if $uplo = 'U'$,
 $e(i) = a(i+1,i)$ if $uplo = 'L'$.

tau REAL for ssytd2
 DOUBLE PRECISION for dsytd2
 COMPLEX for chetd2
 DOUBLE COMPLEX for zhetd2.
 Array, DIMENSION (n).

The first $n-1$ elements contain scalar factors of the elementary reflectors. *tau(n)* is used as workspace.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument had an illegal value.

?sytf2

Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2( uplo, n, a, lda, ipiv, info )
call dsytf2( uplo, n, a, lda, ipiv, info )
call csytf2( uplo, n, a, lda, ipiv, info )
call zsytf2( uplo, n, a, lda, ipiv, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?sytf2 computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U^T, \text{ or } A = L^* D^* L^T,$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

uplo CHARACTER*1.
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored
 = 'U': upper triangular

= 'L': lower triangular

n INTEGER. The order of the matrix *A*. $n \geq 0$.

a REAL for ssytf2

DOUBLE PRECISION for dsytf2

COMPLEX for csytf2

DOUBLE COMPLEX for zsytf2.

Array, DIMENSION (*lda*, *n*).

On entry, the symmetric matrix *A*.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER.

The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L*.

ipiv INTEGER.

Array, DIMENSION (*n*).

Details of the interchanges and the block structure of *D*

If *ipiv*(*k*) > 0, then rows and columns *k* and *ipiv*(*k*) are interchanged and *D*(*k,k*) is a 1-by-1 diagonal block.

If *uplo* = 'U' and *ipiv*(*k*) = *ipiv*(*k-1*) < 0, then rows and columns *k-1* and -*ipiv*(*k*) are interchanged and *D*(*k-1:k, k-1:k*) is a 2-by-2 diagonal block.

If *uplo* = 'L' and *ipiv*(*k*) = *ipiv*(*k+1*) < 0, then rows and columns *k+1* and -*ipiv*(*k*) were interchanged and *D*(*k:k+1, k:k+1*) is a 2-by-2 diagonal block.

info INTEGER.

= 0: successful exit

< 0: if *info* = -*k*, the *k*-th argument has an illegal value

> 0: if *info* = *k*, *D*(*k,k*) is exactly zero. The factorization are completed, but the block diagonal matrix *D* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?sytf2_rook

Computes the factorization of a real/complex symmetric indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2_rook( uplo, n, a, lda, ipiv, info )
call dsytf2_rook( uplo, n, a, lda, ipiv, info )
call csytf2_rook( uplo, n, a, lda, ipiv, info )
call zsytf2_rook( uplo, n, a, lda, ipiv, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?sytf2_rook computes the factorization of a real/complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

$$A = U^* D^* U^T, \text{ or } A = L^* D^* L^T,$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	REAL for ssytf2_rook DOUBLE PRECISION for dsytf2_rook COMPLEX for csytf2_rook DOUBLE COMPLEX for zsytf2_rook. Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the symmetric matrix A . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of <i>a</i> is not referenced.

If $\text{uplo} = \text{'L'}$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER.

The leading dimension of the array a . $\text{lda} \geq \max(1, n)$.

Output Parameters

a On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .

ipiv INTEGER.

Array, DIMENSION (n).

Details of the interchanges and the block structure of D

If $\text{ipiv}(k) > 0$, then rows and columns k and $\text{ipiv}(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $\text{uplo} = \text{'U'}$ and $\text{ipiv}(k) < 0$ and $\text{ipiv}(k - 1) < 0$, then rows and columns k and $-\text{ipiv}(k)$ were interchanged, rows and columns $k - 1$ and $-\text{ipiv}(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

If $\text{uplo} = \text{'L'}$ and $\text{ipiv}(k) < 0$ and $\text{ipiv}(k + 1) < 0$, then rows and columns k and $-\text{ipiv}(k)$ were interchanged, rows and columns $k + 1$ and $-\text{ipiv}(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

info INTEGER.

= 0: successful exit

< 0: if $\text{info} = -k$, the k -th argument has an illegal value

> 0: if $\text{info} = k$, $D(k,k)$ is exactly zero. The factorization are completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?hetf2

Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call chetf2( uplo, n, a, lda, ipiv, info )
call zhetf2( uplo, n, a, lda, ipiv, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$A = U^* D^* U^H$ or $A = L^* D^* L^H$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U , and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

> 0: if *info* = *k*, $D(k,k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?tgex2

Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.

Syntax

```
call stgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2, work,
lwork, info )
call dtgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2, work,
lwork, info )
call ctgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
call ztgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The real routines stgex2/dtgex2 swap adjacent diagonal blocks (A_{11}, B_{11}) and (A_{22}, B_{22}) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (*A*, *B*) by an orthogonal equivalence transformation. (*A*, *B*) must be in generalized real Schur canonical form (as returned by sgges/dgges), that is, *A* is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. *B* is upper triangular.

The complex routines `ctgex2/ztgex2` swap adjacent diagonal 1-by-1 blocks (A_{11}, B_{11}) and (A_{22}, B_{22}) in an upper triangular matrix pair (A, B) by an unitary equivalence transformation.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

All routines optionally update the matrices Q and Z of generalized Schur vectors:

For real flavors,

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})^T = Q(\text{out}) * A(\text{out}) * Z(\text{out})^T$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})^T = Q(\text{out}) * B(\text{out}) * Z(\text{out})^T.$$

For complex flavors,

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})^H = Q(\text{out}) * A(\text{out}) * Z(\text{out})^H$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})^H = Q(\text{out}) * B(\text{out}) * Z(\text{out})^H.$$

Input Parameters

<code>wantq</code>	LOGICAL. If <code>wantq</code> = .TRUE. : update the left transformation matrix Q ; If <code>wantq</code> = .FALSE. : do not update Q .
<code>wantz</code>	LOGICAL. If <code>wantz</code> = .TRUE. : update the right transformation matrix Z ; If <code>wantz</code> = .FALSE. : do not update Z .
<code>n</code>	INTEGER. The order of the matrices A and B . $n \geq 0$.
<code>a, b</code>	REAL for <code>stgex2</code> DOUBLE PRECISION for <code>dtgex2</code> COMPLEX for <code>ctgex2</code> DOUBLE COMPLEX for <code>ztgex2</code> . Arrays, DIMENSION (<code>lda, n</code>) and (<code>ldb, n</code>), respectively. On entry, the matrices A and B in the pair (A, B).
<code>lda</code>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The leading dimension of the array b . $ldb \geq \max(1, n)$.
<code>q, z</code>	REAL for <code>stgex2</code> DOUBLE PRECISION for <code>dtgex2</code> COMPLEX for <code>ctgex2</code> DOUBLE COMPLEX for <code>ztgex2</code> . Arrays, DIMENSION (<code>ldq, n</code>) and (<code>ldz, n</code>), respectively. On entry, if <code>wantq</code> = .TRUE., q contains the orthogonal/unitary matrix Q , and if <code>wantz</code> = .TRUE., z contains the orthogonal/unitary matrix Z .
<code>ldq</code>	INTEGER. The leading dimension of the array q . $ldq \geq 1$. If <code>wantq</code> = .TRUE., $ldq \geq n$.
<code>ldz</code>	INTEGER. The leading dimension of the array z . $ldz \geq 1$. If <code>wantz</code> = .TRUE., $ldz \geq n$.

<i>j1</i>	INTEGER. The index to the first block (A_{11}, B_{11}). $1 \leq j1 \leq n$.
<i>n1</i>	INTEGER. Used with real flavors only. The order of the first block (A_{11}, B_{11}). $n1 = 0, 1$ or 2 .
<i>n2</i>	INTEGER. Used with real flavors only. The order of the second block (A_{22}, B_{22}). $n2 = 0, 1$ or 2 .
<i>work</i>	REAL for <code>stgex2</code> DOUBLE PRECISION for <code>dtgex2</code> . Workspace array, DIMENSION (<code>max(1, lwork)</code>). Used with real flavors only.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq \max(n * (n2 + n1), 2 * (n2 + n1)^2)$

Output Parameters

<i>a</i>	On exit, the updated matrix A .
<i>B</i>	On exit, the updated matrix B .
<i>Q</i>	On exit, the updated matrix Q . Not referenced if <code>wantq = .FALSE..</code>
<i>Z</i>	On exit, the updated matrix Z . Not referenced if <code>wantz = .FALSE..</code>
<i>info</i>	INTEGER. =0: Successful exit For <code>stgex2/dtgex2</code> : If <code>info = 1</code> , the transformed matrix (A, B) would be too far from generalized Schur form; the blocks are not swapped and (A, B) and (Q, Z) are unchanged. The problem of swapping is too ill-conditioned. If <code>info = -16</code> : <i>lwork</i> is too small. Appropriate value for <i>lwork</i> is returned in <i>work(1)</i> . For <code>ctgex2/ztgex2</code> : If <code>info = 1</code> , the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned.

?tgsy2

Solves the generalized Sylvester equation (unblocked algorithm).

Syntax

```

call ztgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, rdsum, rdscal, iwork, pq, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?tgssy2 solves the generalized Sylvester equation:

$$A^*R - L^*B = scale*C \quad (1)$$

$$D^*R - L^*E = scale*F$$

using Level 1 and 2 BLAS, where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively. For stgssy2/dtgssy2, pairs (A, D) and (B, E) must be in generalized Schur canonical form, that is, A, B are upper quasi triangular and D, E are upper triangular. For ctgssy2/ztgssy2, matrices A, B, D and E are upper triangular (that is, (A, D) and (B, E) in generalized Schur form).

The solution (R, L) overwrites (C, F) .

$0 \leq scale \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation, solving equation (1) corresponds to solve

$$Z^*x = scale*b$$

where Z is defined for real flavors as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B^T, I_n) \\ \text{kron}(I_n, D) & -\text{kron}(E^T, I_n) \end{bmatrix} \quad (2)$$

and for complex flavors as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B^H, I_n) \\ \text{kron}(I_n, D) & -\text{kron}(E^H, I_n) \end{bmatrix} \quad (3)$$

Here I_k is the identity matrix of size k and X^T (X^H) is the transpose (conjugate transpose) of X . $\text{kron}(X, Y)$ denotes the Kronecker product between the matrices X and Y .

For real flavors, if $trans = 'T'$, solve the transposed system

$$Z^T y = scale*b$$

for y , which is equivalent to solving for R and L in

$$A^T R + D^T L = scale*C \quad (4)$$

$$R^T B^T + L^T E^T = scale*(-F)$$

For complex flavors, if $trans = 'C'$, solve the conjugate transposed system

$$Z^H y = scale*b$$

for y , which is equivalent to solving for R and L in

$$A^H * R + D^H * L = \text{scale} * C \quad (5)$$

$$R^* B^H + L^* E^H = \text{scale} * (-F)$$

These cases are used to compute an estimate of $\text{Dif}[(A, D), (B, E)] = \sigma_{\min}(Z)$ using reverse communication with [?lacon](#).

?tgpsy2 also (for $i_{\text{job}} \geq 1$) contributes to the computation in ?tgtsy1 of an upper bound on the separation between two matrix pairs. Then the input (A, D) , (B, E) are sub-pencils of the matrix pair (two matrix pairs) in ?tgtsy1. See [?tgtsy1](#) for details.

Input Parameters

<i>trans</i>	CHARACTER*1. If <i>trans</i> = 'N', solve the generalized Sylvester equation (1); If <i>trans</i> = 'T': solve the transposed system (4). If <i>trans</i> = 'C': solve the conjugate transposed system (5).
<i>ijob</i>	INTEGER. Specifies what kind of functionality is to be performed. If <i>ijob</i> = 0: solve (1) only. If <i>ijob</i> = 1: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (look ahead strategy is used); If <i>ijob</i> = 2: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (?gecon on sub-systems is used). Not referenced if <i>trans</i> = 'T'.
<i>m</i>	INTEGER. On entry, <i>m</i> specifies the order of A and D , and the row dimension of C , F , R and L .
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the order of B and E , and the column dimension of C , F , R and L .
<i>a</i> , <i>b</i>	REAL for stgpsy2 DOUBLE PRECISION for dtgpsy2 COMPLEX for ctgpsy2 DOUBLE COMPLEX for ztgpsy2. Arrays, DIMENSION (<i>lda</i> , <i>m</i>) and (<i>ldb</i> , <i>n</i>), respectively. On entry, <i>a</i> contains an upper (quasi) triangular matrix A , and <i>b</i> contains an upper (quasi) triangular matrix B .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . <i>ldb</i> $\geq \max(1, n)$.
<i>c</i> , <i>f</i>	REAL for stgpsy2 DOUBLE PRECISION for dtgpsy2

COMPLEX for `ctgsy2`

DOUBLE COMPLEX for `ztgsy2`.

Arrays, DIMENSION (ldc, n) and (ldf, n), respectively. On entry, c contains the right-hand-side of the first matrix equation in (1), and f contains the right-hand-side of the second matrix equation in (1).

ldc INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.

d, e REAL for `stgsy2`

DOUBLE PRECISION for `dtgsy2`

COMPLEX for `ctgsy2`

DOUBLE COMPLEX for `ztgsy2`.

Arrays, DIMENSION (lde, n) and (ldf, n), respectively. On entry, d contains an upper triangular matrix D , and e contains an upper triangular matrix E .

lde INTEGER. The leading dimension of the array d . $lde \geq \max(1, n)$.

ldf INTEGER. The leading dimension of the array f . $ldf \geq \max(1, m)$.

$rdsum$ REAL for `stgsy2/ctgsy2`

DOUBLE PRECISION for `dtgsy2/ztgsy2`.

On entry, the sum of squares of computed contributions to the `Dif-` estimate under computation by `?tgsyL`, where the scaling factor $rdscal$ has been factored out.

$rdscal$ REAL for `stgsy2/ctgsy2`

DOUBLE PRECISION for `dtgsy2/ztgsy2`.

On entry, scaling factor used to prevent overflow in $rdsum$.

$iwork$ INTEGER. Used with real flavors only.

Workspace array, DIMENSION ($m+n+2$).

Output Parameters

c On exit, if $ijob = 0$, c is overwritten by the solution R .

f On exit, if $ijob = 0$, f is overwritten by the solution L .

$scale$ REAL for `stgsy2/ctgsy2`

DOUBLE PRECISION for `dtgsy2/ztgsy2`.

On exit, $0 \leq scale \leq 1$. If $0 < scale < 1$, the solutions R and L (C and F on entry) hold the solutions to a slightly perturbed system, but the input matrices A, B, D and E are not changed. If $scale = 0$, R and L hold the solutions to the homogeneous system with $C = F = 0$. Normally $scale = 1$.

<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = 'T', <i>rdsum</i> is not touched.
	Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsvl.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched.
	Note that <i>rdscal</i> only makes sense when ?tgsy2 is called by ?tgsvl.
<i>pq</i>	INTEGER. Used with real flavors only. On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by the routine stgsy2/dtgsy2.
<i>info</i>	INTEGER. On exit, if <i>info</i> is set to = 0: Successful exit < 0: If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument has an illegal value. > 0: The matrix pairs (<i>A</i> , <i>D</i>) and (<i>B</i> , <i>E</i>) have common or very close eigenvalues.

?trti2

Computes the inverse of a triangular matrix
(unblocked algorithm).

Syntax

```
call strtti2( uplo, diag, n, a, lda, info )
call dtrtti2( uplo, diag, n, a, lda, info )
call ctrtti2( uplo, diag, n, a, lda, info )
call ztrtti2( uplo, diag, n, a, lda, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?trti2 computes the inverse of a real/complex upper or lower triangular matrix.

This is the *Level 2 BLAS* version of the algorithm.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
-------------	---

diag CHARACTER*1.
 Specifies whether or not the matrix A is unit triangular.
 = 'N': non-unit triangular
 = 'U': non-unit triangular

n INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for strti2
 DOUBLE PRECISION for dtrti2
 COMPLEX for ctrti2
 DOUBLE COMPLEX for ztrti2.
 Array, DIMENSION (*lda*, *n*).
 On entry, the triangular matrix A .
 If *uplo* = 'U', the leading n -by- n upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading n -by- n lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *a* is not referenced.
 If *diag* = 'U', the diagonal elements of *a* are also not referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, the (triangular) inverse of the original matrix, in the same storage format.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-k$, the k -th argument had an illegal value

clag2z

Converts a complex single precision matrix to a complex double precision matrix.

Syntax

call clag2z(*m*, *n*, *sa*, *ldsa*, *a*, *lda*, *info*)

C:

```
lapack_int LAPACKE_clag2z (int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_float * sa, lapack_int ldsa, lapack_complex_double * a, lapack_int lda);
```

Include Files

- Fortran: mkl.fi

-
- C: mkl.h

Description

This routine converts a complex single precision matrix SA to a complex double precision matrix A .

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix A ($n \geq 0$).
<i>ldsa</i>	INTEGER. The leading dimension of the array sa ; $ldsa \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (lda, n). On entry, contains the m -by- n coefficient matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array a ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION ($ldsa, n$). On exit, contains the m -by- n coefficient matrix SA .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful.

dlag2s

Converts a double precision matrix to a single precision matrix.

Syntax

```
call dlag2s( m, n, a, lda, sa, ldsa, info )
```

C:

```
lapack_int LAPACKE_dlag2s (int matrix_layout, lapack_int m, lapack_int n, const double * a, lapack_int lda, float * sa, lapack_int ldsa);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine converts a double precision matrix SA to a single precision matrix A .

RMAX is the overflow for the single precision arithmetic. dlag2s checks that all the entries of A are between -RMAX and RMAX. If not, the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix A ($n \geq 0$).
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the m -by- n coefficient matrix A .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; <i>lda</i> $\geq \max(1, m)$.
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; <i>ldsa</i> $\geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the m -by- n coefficient matrix SA ; if <i>info</i> > 0, the content of <i>sa</i> is unspecified.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = 1, an entry of the matrix A is greater than the single precision overflow threshold; in this case, the content of <i>sa</i> on exit is unspecified.

slag2d

Converts a single precision matrix to a double precision matrix.

Syntax

```
call slag2d( m, n, sa, ldsa, a, lda, info )
lapack_int LAPACKE_slag2d (int matrix_layout, lapack_int m, lapack_int n, const float * sa, lapack_int ldsa, double * a, lapack_int lda);
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine converts a single precision matrix SA to a double precision matrix A .

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix A ($n \geq 0$).

sa REAL array, DIMENSION (*ldsa*, *n*).
 On entry, contains the *m*-by-*n* coefficient matrix *SA*.

ldsa INTEGER. The leading dimension of the array *sa*; *ldsa* $\geq \max(1, m).$

lda INTEGER. The leading dimension of the array *a*; *lda* $\geq \max(1, m).$

Output Parameters

a DOUBLE PRECISION array, DIMENSION (*lda*, *n*).
 On exit, contains the *m*-by-*n* coefficient matrix *A*.

info INTEGER.
 If *info* = 0, the execution is successful.

zlag2c

Converts a complex double precision matrix to a complex single precision matrix.

Syntax

```
call zlag2c( m, n, a, lda, sa, ldsa, info )
```

C:

```
lapack_int LAPACKE_zlag2c (int matrix_layout, lapack_int m, lapack_int n, const  

                           lapack_complex_double * a, lapack_int lda, lapack_complex_float * sa, lapack_int ldsa);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine converts a double precision complex matrix *SA* to a single precision complex matrix *A*.

RMAX is the overflow for the single precision arithmetic. zlag2c checks that all the entries of *A* are between -RMAX and RMAX. If not, the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Input Parameters

m INTEGER. The number of lines of the matrix *A* (*m* $\geq 0).
n INTEGER. The number of columns in the matrix *A* (*n* ≥ 0).
a DOUBLE COMPLEX array, DIMENSION (*lda*, *n*).
 On entry, contains the *m*-by-*n* coefficient matrix *A*.
lda INTEGER. The leading dimension of the array *a*; *lda* $\geq \max(1, m).
ldsa INTEGER. The leading dimension of the array *sa*; *ldsa* $\geq \max(1, m).$$$

Output Parameters

*sa*COMPLEX array, DIMENSION (*ldsa*, *n*).

On exit, if *info* = 0, contains the *m*-by-*n* coefficient matrix *SA*; if *info* > 0, the content of *sa* is unspecified.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = 1, an entry of the matrix *A* is greater than the single precision overflow threshold; in this case, the content of *sa* on exit is unspecified.

?larfp

Generates a real or complex elementary reflector.

Syntax

FORTRAN 77:

```
call slarfp(n, alpha, x, incx, tau)
call dlarfp(n, alpha, x, incx, tau)
call clarfp(n, alpha, x, incx, tau)
call zlarfp(n, alpha, x, incx, tau)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?larfp routines generate a real or complex elementary reflector *H* of order *n*, such that

```
H * (alpha) = (beta),
( x )   ( 0 )
```

and $H^*H = I$ for real flavors, $\text{conjg}(H)^*H = I$ for complex flavors.

Here

alpha and *beta* are scalars, *beta* is real and non-negative,

x is (*n*-1)-element vector.

H is represented in the form

```
H = I - tau* ( 1 ) * ( 1 v ),
( v )
```

where *tau* is scalar, and *v* is (*n*-1)-element vector .

For real flavors if the elements of *x* are all zero, then *tau* = 0 and *H* is taken to be the unit matrix. Otherwise $1 \leq \text{real}(\tau) \leq 2$.

For complex flavors if the elements of *x* are all zero and *alpha* is real, then *tau* = 0 and *H* is taken to be the unit matrix. Otherwise $1 \leq \text{real}(\tau) \leq 2$, and $\text{abs}(\tau) \leq 1$.

Input Parameters

<i>n</i>	INTEGER. Specifies the order of the elementary reflector.
<i>alpha</i>	REAL for slarf _p DOUBLE PRECISION for dlarf _p COMPLEX for clarf _p DOUBLE COMPLEX for zlarf _p Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for slarf _p DOUBLE PRECISION for dlarf _p COMPLEX for clarf _p DOUBLE COMPLEX for zlarf _p Array, DIMENSION at least (1 + (n - 1)*abs(<i>incx</i>)). It contains the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

Output Parameters

<i>alpha</i>	Overwritten by the value <i>beta</i> .
<i>y</i>	Overwritten by the vector <i>v</i> .
<i>tau</i>	REAL for slarf _p DOUBLE PRECISION for dlarf _p COMPLEX for clarf _p DOUBLE COMPLEX for zlarf _p Contains the scalar <i>tau</i> .

ila?lc

Scans a matrix for its last non-zero column.

Syntax

FORTRAN 77:

```
value = ilaslc(m, n, a, lda)
value = iladlc(m, n, a, lda)
value = ilaclc(m, n, a, lda)
value = ilazlc(m, n, a, lda)
```

Include Files

- Fortran: mkl.fi

-
- C: mkl.h

Description

The ila?lc routines scan a matrix A for its last non-zero column.

Input Parameters

<i>m</i>	INTEGER. Specifies number of rows in the matrix A .
<i>n</i>	INTEGER. Specifies number of columns in the matrix A .
<i>a</i>	REAL for ilaslc DOUBLE PRECISION for iladlc COMPLEX for ilaclc DOUBLE COMPLEX for ilazlc Array, DIMENSION (<i>lda</i> , *). The second dimension of <i>a</i> must be at least $\max(1, n)$. Before entry the leading n -by- n part of the array <i>a</i> must contain the matrix A .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.

Output Parameters

<i>value</i>	INTEGER Number of the last non-zero column.
--------------	--

ila?lr

Scans a matrix for its last non-zero row.

Syntax

FORTRAN 77:

```
value = ilaslr(m, n, a, lda)
value = iladlr(m, n, a, lda)
value = ilaclr(m, n, a, lda)
value = ilazlr(m, n, a, lda)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ila?lr routines scan a matrix A for its last non-zero row.

Input Parameters

<i>m</i>	INTEGER. Specifies number of rows in the matrix <i>A</i> .
<i>n</i>	INTEGER. Specifies number of columns in the matrix <i>A</i> .
<i>a</i>	REAL for <code>ilaslr</code> DOUBLE PRECISION for <code>iladlr</code> COMPLEX for <code>ilaclr</code> DOUBLE COMPLEX for <code>idazlr</code> Array, DIMENSION (<i>lda</i> , *). The second dimension of <i>a</i> must be at least <code>max(1, n)</code> . Before entry the leading <i>n</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least <code>max(1, m)</code> .

Output Parameters

<i>value</i>	INTEGER Number of the last non-zero row.
--------------	---

?gsvj0

Pre-processor for the routine ?gesvj.

Syntax

FORTRAN 77:

```
call sgsvj0(jobv, m, n, a, lda, d, sva, mv, v, ldv, eps, sfmin, tol, nsweep, work, lwork, info)
call dgsvj0(jobv, m, n, a, lda, d, sva, mv, v, ldv, eps, sfmin, tol, nsweep, work, lwork, info)
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

This routine is called from `?gesvj` as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as `?gesvj` does, but it does not check convergence (stopping criterion).

The routine `?gsvj0` enables `?gesvj` to use a simplified version of itself to work on a submatrix of the original matrix.

Input Parameters

<i>jobv</i>	CHARACTER*1. Must be 'V', 'A', or 'N'.
-------------	--

Specifies whether the output from this routine is used to compute the matrix V .

If $jobv = 'V'$, the product of the Jacobi rotations is accumulated by post-multiplying the n -by- n array v .

If $jobv = 'A'$, the product of the Jacobi rotations is accumulated by post-multiplying the mv -by- n array v .

If $jobv = 'N'$, the Jacobi rotations are not accumulated.

m INTEGER. The number of rows of the input matrix A ($m \geq 0$).

n INTEGER. The number of columns of the input matrix B ($m \geq n \geq 0$).

a REAL for sgsvj0

DOUBLE PRECISION for dgsvj0.

Arrays, DIMENSION ($lda, *$). Contains the m -by- n matrix A , such that $A^*\text{diag}(D)$ represents the input matrix. The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

d REAL for sgsvj0

DOUBLE PRECISION for dgsvj0.

Arrays, DIMENSION (n). Contains the diagonal matrix D that accumulates the scaling factors from the fast scaled Jacobi rotations. On entry $A^*\text{diag}(D)$ represents the input matrix.

sva REAL for sgsvj0

DOUBLE PRECISION for dgsvj0.

Arrays, DIMENSION (n). Contains the Euclidean norms of the columns of the matrix $A^*\text{diag}(D)$.

mv INTEGER. The leading dimension of b ; at least $\max(1, p)$.

If $jobv = 'A'$, then mv rows of v are post-multiplied by a sequence of Jacobi rotations.

If $jobv = 'N'$, then mv is not referenced .

v REAL for sgsvj0

DOUBLE PRECISION for dgsvj0.

Array, DIMENSION ($ldv, *$). The second dimension of a must be at least $\max(1, n)$.

If $jobv = 'V'$, then n rows of v are post-multiplied by a sequence of Jacobi rotations.

If $jobv = 'A'$, then mv rows of v are post-multiplied by a sequence of Jacobi rotations.

If $jobv = 'N'$, then v is not referenced.

ldv INTEGER. The leading dimension of the array v ; $ldv \geq 1$

```

 $ldv \geq n$  if  $jobv = 'V'$ ;  

 $ldv \geq mv$  if  $jobv = 'A'$ .  

 $eps$  REAL for sgsvj0  

    DOUBLE PRECISION for dgsvj0.  

    The relative machine precision (epsilon) returned by the routine ?lamch.  

 $sfmin$  REAL for sgsvj0  

    DOUBLE PRECISION for dgsvj0.  

    Value of safe minimum returned by the routine ?lamch.  

 $tol$  REAL for sgsvj0  

    DOUBLE PRECISION for dgsvj0.  

    The threshold for Jacobi rotations. For a pair  $A(:, p), A(:, q)$  of pivot  

    columns, the Jacobi rotation is applied only if  $\text{abs}(\cos(\text{angle}(A(:, p),  

    A(:, q)))) > tol$ .  

 $nsweep$  INTEGER.  

    The number of sweeps of Jacobi rotations to be performed.  

 $work$  REAL for sgsvj0  

    DOUBLE PRECISION for dgsvj0.  

    Workspace array, DIMENSION ( $lwork$ ).  

 $lwork$  INTEGER. The size of the array  $work$ ; at least  $\max(1, m)$ .

```

Output Parameters

a	On exit, $A^*\text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in tol and $nsweep$, respectively
d	On exit, $A^*\text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in tol and $nsweep$, respectively.
sva	On exit, contains the Euclidean norms of the columns of the output matrix $A^*\text{diag}(D)$.
v	If $jobv = 'V'$, then n rows of v are post-multiplied by a sequence of Jacobi rotations. If $jobv = 'A'$, then mv rows of v are post-multiplied by a sequence of Jacobi rotations. If $jobv = 'N'$, then v is not referenced.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

?gsvj1

Pre-processor for the routine ?gesvj, applies Jacobi rotations targeting only particular pivots.

Syntax

FORTRAN 77:

```
call sgsvj1(jobv, m, n, n1, a, lda, d, sva, mv, v, ldv, eps, sfmin, tol, nsweep,
work, lwork, info)
```

```
call dgsvj1(jobv, m, n, n1, a, lda, d, sva, mv, v, ldv, eps, sfmin, tol, nsweep,
work, lwork, info)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

T

This routine is called from ?gesvj as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as ?gesvj does, but it targets only particular pivots and it does not check convergence (stopping criterion).

The routine ?gsvj1 applies few sweeps of Jacobi rotations in the column space of the input m -by- n matrix A . The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding n -by- n Gram matrix $A^* A$. The block-entries (*tiles*) of the (1,2) off-diagonal block are marked by the [x]'s in the following scheme:

	*	*	*	[x]	[x]	[x]	
	*	*	*	[x]	[x]	[x]	
	*	*	*	[x]	[x]	[x]	
	[x]	[x]	[x]	*	*	*	
	[x]	[x]	[x]	*	*	*	
	[x]	[x]	[x]	*	*	*	

row-cycling in the $nblr$ -by- $nblc$ [x] blocks, row-cyclic pivoting inside each [x] block

In terms of the columns of the matrix A , the first $n1$ columns are rotated 'against' the remaining $n-n1$ columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is $n1$ -by- $(n-n1)$ and it is tiled using quadratic tiles. The number of sweeps is specified by $nsweep$, and the orthogonality threshold is set by tol .

Input Parameters

jobv

CHARACTER*1. Must be 'V', 'A', or 'N'.

Specifies whether the output from this routine is used to compute the matrix V .

If $jobv = 'V'$, the product of the Jacobi rotations is accumulated by post-multiplying the n -by- n array v .

If $jobv = 'A'$, the product of the Jacobi rotations is accumulated by post-multiplying the mv -by- n array v .

If $jobv = 'N'$, the Jacobi rotations are not accumulated.

m

INTEGER. The number of rows of the input matrix A ($m \geq 0$).

n INTEGER. The number of columns of the input matrix *B* ($m \geq n \geq 0$).

n1 INTEGER. Specifies the 2-by-2 block partition. The first *n1* columns are rotated 'against' the remaining *n-n1* columns of the matrix *A*.

a REAL for sgsvj1
DOUBLE PRECISION for dgsvj1.
Arrays, DIMENSION (*lda*, *). Contains the m -by- n matrix *A*, such that $A^*\text{diag}(D)$ represents the input matrix. The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, m)$.

d REAL for sgsvj1
DOUBLE PRECISION for dgsvj1.
Arrays, DIMENSION (*n*). Contains the diagonal matrix *D* that accumulates the scaling factors from the fast scaled Jacobi rotations. On entry $A^*\text{diag}(D)$ represents the input matrix.

sva REAL for sgsvj1
DOUBLE PRECISION for dgsvj1.
Arrays, DIMENSION (*n*). Contains the Euclidean norms of the columns of the matrix $A^*\text{diag}(D)$.

mv INTEGER. The leading dimension of *b*; at least $\max(1, p)$.
If *jobv* = 'A', then *mv* rows of *v* are post-multiplied by a sequence of Jacobi rotations.
If *jobv* = 'N', then *mv* is not referenced .

v REAL for sgsvj1
DOUBLE PRECISION for dgsvj1.
Array, DIMENSION (*ldv*, *). The second dimension of *a* must be at least $\max(1, n)$.
If *jobv* = 'V', then *n* rows of *v* are post-multiplied by a sequence of Jacobi rotations.
If *jobv* = 'A', then *mv* rows of *v* are post-multiplied by a sequence of Jacobi rotations.
If *jobv* = 'N', then *v* is not referenced.

ldv INTEGER. The leading dimension of the array *v*; *ldv* ≥ 1
ldv $\geq n$ if *jobv* = 'V';
ldv $\geq mv$ if *jobv* = 'A'.

eps REAL for sgsvj1
DOUBLE PRECISION for dgsvj1.
The relative machine precision (epsilon) returned by the routine [?lamch](#).

<i>sfmin</i>	REAL for sgsvj1 DOUBLE PRECISION for dgsvj1. Value of safe minimum returned by the routine ?lamch.
<i>tol</i>	REAL for sgsvj1 DOUBLE PRECISION for dgsvj1. The threshold for Jacobi rotations. For a pair $A(:, p), A(:, q)$ of pivot columns, the Jacobi rotation is applied only if $\text{abs}(\cos(\text{angle}(A(:, p), A(:, q)))) > tol$.
<i>nsweep</i>	INTEGER. The number of sweeps of Jacobi rotations to be performed.
<i>work</i>	REAL for sgsvj1 DOUBLE PRECISION for dgsvj1. Workspace array, DIMENSION (<i>lwork</i>).
<i>lwork</i>	INTEGER. The size of the array <i>work</i> ; at least $\max(1, m)$.

Output Parameters

<i>a</i>	On exit, $A^*\text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in <i>tol</i> and <i>nsweep</i> , respectively
<i>d</i>	On exit, $A^*\text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in <i>tol</i> and <i>nsweep</i> , respectively.
<i>sva</i>	On exit, contains the Euclidean norms of the columns of the output matrix $A^*\text{diag}(D)$.
<i>v</i>	If <i>jobv</i> = 'V', then <i>n</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations. If <i>jobv</i> = 'A', then <i>mv</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations. If <i>jobv</i> = 'N', then <i>v</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

?sfrk

Performs a symmetric rank-*k* operation for matrix in RFP format.

Syntax

FORTRAN 77:

```
call ssfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
call dsfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
```

C:

```
lapack_int LAPACKE_<?>sfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, <datatype> alpha, const <datatype>* a, lapack_int lda,
<datatype> beta, <datatype>* c );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?sfrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha A^* A + \beta C,$$

or

$$C := \alpha A^T A + \beta C,$$

where:

alpha and *beta* are scalars,

C is an *n*-by-*n* symmetric matrix in [rectangular full packed \(RFP\) format](#),

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>C</i> is stored; if <i>transr</i> = 'T' or 't', the transpose form of RFP <i>C</i> is stored.
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>C</i> := <i>alpha</i> * <i>A</i> * <i>A</i> T + <i>beta</i> * <i>C</i> ; if <i>trans</i> = 'T' or 't', then <i>C</i> := <i>alpha</i> * <i>A</i> T * <i>A</i> + <i>beta</i> * <i>C</i> ;
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i> , and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the matrix <i>A</i> .

The value of k must be at least zero.

<i>alpha</i>	REAL for ssfrk DOUBLE PRECISION for dsfrk Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssfrk DOUBLE PRECISION for dsfrk Array, DIMENSION (<i>lda</i> , <i>ka</i>), where <i>ka</i> is k when <i>trans</i> = 'N' or 'n', and is n otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading n -by- k part of the array <i>a</i> must contain the matrix A , otherwise the leading k -by- n part of the array <i>a</i> must contain the matrix A .
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for ssfrk DOUBLE PRECISION for dsfrk Specifies the scalar <i>beta</i> .
<i>c</i>	REAL for ssfrk DOUBLE PRECISION for dsfrk Array, DIMENSION ($n * (n+1) / 2$). Before entry contains the symmetric matrix <i>C</i> in RFP format.

Output Parameters

<i>c</i>	If <i>trans</i> = 'N' or 'n', then <i>c</i> contains $C := \alpha A^* A + \beta C$; if <i>trans</i> = 'T' or 't', then <i>c</i> contains $C := \alpha A^* A^* + \beta C$;
----------	--

?hfrk

Performs a Hermitian rank- k operation for matrix in RFP format.

Syntax

FORTRAN 77:

```
call chfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
call zhfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
```

C:

```
lapack_int LAPACKE_chfrk( int matrix_layout, char transr, char uplo, char trans,
                           lapack_int n, lapack_int k, float alpha, const lapack_complex_float* a, lapack_int
                           lda, float beta, lapack_complex_float* c );
lapack_int LAPACKE_zhfrk( int matrix_layout, char transr, char uplo, char trans,
                           lapack_int n, lapack_int k, double alpha, const lapack_complex_double* a, lapack_int
                           lda, double beta, lapack_complex_double* c );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?hfrk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha A^H A + \beta C,$$

or

$$C := \alpha A^H A + \beta C,$$

where:

alpha and *beta* are real scalars,

C is an *n*-by-*n* Hermitian matrix in [RFP format](#),

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>C</i> is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP <i>C</i> is stored.
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>C</i> := $\alpha A^H A + \beta C$; if <i>trans</i> = 'C' or 'c', then <i>C</i> := $\alpha A^H A + \beta C$.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i> . The value of <i>k</i> must be at least zero.
<i>alpha</i>	COMPLEX for chfrk DOUBLE COMPLEX for zhfrk Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for chfrk

DOUBLE COMPLEX for zhfrk

Array, DIMENSION (*lda, ka*), where *ka* is *k* when *trans* = 'N' or 'n', and is *n* otherwise. Before entry with *trans* = 'N' or 'n', the leading *n*-by-*k* part of the array *a* must contain the matrix *A*, otherwise the leading *k*-by-*n* part of the array *a* must contain the matrix *A*.

lda INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. When *trans* = 'N' or 'n', then *lda* must be at least $\max(1, n)$, otherwise *lda* must be at least $\max(1, k)$.

beta COMPLEX for chfrk
DOUBLE COMPLEX for zhfrk
Specifies the scalar *beta*.

c COMPLEX for chfrk
DOUBLE COMPLEX for zhfrk
Array, DIMENSION (*n*(n+1)/2*). Before entry contains the Hermitian matrix *C* in in [RFP format](#).

Output Parameters

c If *trans* = 'N' or 'n', then *c* contains $C := \alpha A^H + \beta C$;
if *trans* = 'C' or 'c', then *c* contains $C := \alpha A^H A + \beta C$;

?tfsm

Solves a matrix equation (one operand is a triangular matrix in RFP format).

Syntax

FORTRAN 77:

```
call stfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call dtfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call ctfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call ztfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
```

C:

```
lapack_int LAPACKE_<?>tfsm( int matrix_layout, char transr, char side, char uplo, char trans, char diag, lapack_int m, lapack_int n, <datatype> alpha, const <datatype>* a, <datatype>* b, lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?tfsm routines solve one of the following matrix equations:

*op(A)*X = alpha*B,*

or

$X^* \text{op}(A) = \alpha * B$,

where:

α is a scalar,

X and B are m -by- n matrices,

A is a unit, or non-unit, upper or lower triangular matrix in [rectangular full packed \(RFP\) format](#).

$\text{op}(A)$ can be one of the following:

- $\text{op}(A) = A$ or $\text{op}(A) = A^T$ for real flavors
- $\text{op}(A) = A$ or $\text{op}(A) = A^H$ for complex flavors

The matrix B is overwritten by the solution matrix X .

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. if <i>transr</i> = 'N' or 'n', the normal form of RFP A is stored; if <i>transr</i> = 'T' or 't', the transpose form of RFP A is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP A is stored.
<i>side</i>	CHARACTER*1. Specifies whether $\text{op}(A)$ appears on the left or right of X in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(A)^*X = \alpha * B$; if <i>side</i> = 'R' or 'r', then $X^*\text{op}(A) = \alpha * B$.
<i>uplo</i>	CHARACTER*1. Specifies whether the RFP matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>trans</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>trans</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>trans</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>diag</i>	CHARACTER*1. Specifies whether the RFP matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	INTEGER. Specifies the number of rows of B . The value of <i>m</i> must be at least zero.

<i>n</i>	INTEGER. Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Specifies the scalar <i>alpha</i>.</p> <p>When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.</p>
<i>a</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Array, DIMENSION ($n * (n+1) / 2$). Contains the matrix <i>A</i> in RFP format.</p>
<i>b</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Array, DIMENSION (ldb, n). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the right-hand side matrix <i>B</i>.</p>
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, +m)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
----------	---

?lansf

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix in RFP format.

Syntax

```
val = slansf(norm, transr, uplo, n, a, work)
val = dlansf(norm, transr, uplo, n, a, work)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

T

The function `?lansf` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real symmetric matrix A in the [rectangular full packed \(RFP\) format](#).

Input Parameters

<code>norm</code>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(A_{ij})$, largest absolute value of the matrix A . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<code>transr</code>	CHARACTER*1. Specifies whether the RFP format of matrix A is normal or transposed format. If <code>transr</code> = 'N': RFP format is normal; if <code>transr</code> = 'T': RFP format is transposed.
<code>uplo</code>	CHARACTER*1. Specifies whether the RFP matrix A came from upper or lower triangular matrix. If <code>uplo</code> = 'U': RFP matrix A came from an upper triangular matrix; if <code>uplo</code> = 'L': RFP matrix A came from a lower triangular matrix.
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lansf</code> is set to zero.
<code>a</code>	REAL for <code>slansf</code> DOUBLE PRECISION for <code>dlansf</code> Array, DIMENSION ($n*(n+1)/2$). The upper (if <code>uplo</code> = 'U') or lower (if <code>uplo</code> = 'L') part of the symmetric matrix A stored in RFP format .
<code>work</code>	REAL for <code>slansf</code> . DOUBLE PRECISION for <code>dlansf</code> . Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when <code>norm</code> = 'I' or '1' or 'O'; otherwise, <code>work</code> is not referenced.

Output Parameters

<code>val</code>	REAL for <code>slansf</code> DOUBLE PRECISION for <code>dlansf</code>
------------------	--

Value returned by the function.

?lanhf

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian matrix in RFP format.

Syntax

```
val = clanhf(norm, transr, uplo, n, a, work)
val = zlanhf(norm, transr, uplo, n, a, work)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lanhf returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n complex Hermitian matrix A in the [rectangular full packed \(RFP\) format](#).

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': <i>val</i> = max(abs(A_{ij})), largest absolute value of the matrix A . = '1' or 'O' or 'o': <i>val</i> = norm1(A), 1-norm of the matrix A (maximum column sum), = 'I' or 'i': <i>val</i> = normI(A), infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': <i>val</i> = normF(A), Frobenius norm of the matrix A (square root of sum of squares).
<i>transr</i>	CHARACTER*1. Specifies whether the RFP format of matrix A is normal or conjugate-transposed format. If <i>transr</i> = 'N': RFP format is normal; if <i>transr</i> = 'C': RFP format is conjugate-transposed.
<i>uplo</i>	CHARACTER*1. Specifies whether the RFP matrix A came from upper or lower triangular matrix. If <i>uplo</i> = 'U': RFP matrix A came from an upper triangular matrix; if <i>uplo</i> = 'L': RFP matrix A came from a lower triangular matrix.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.

When $n = 0$, `?lanhf` is set to zero.

a	COMPLEX for <code>clanhf</code> DOUBLE COMPLEX for <code>zlanhf</code> Array, DIMENSION ($n*(n+1)/2$). The upper (if <code>uplo = 'U'</code>) or lower (if <code>uplo = 'L'</code>) part of the Hermitian matrix A stored in RFP format .
$work$	COMPLEX for <code>clanhf</code> . DOUBLE COMPLEX for <code>zlanhf</code> . Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when $norm = 'I'$ or ' 1 ' or ' O '; otherwise, $work$ is not referenced.

Output Parameters

val	COMPLEX for <code>clanhf</code> DOUBLE COMPLEX for <code>zlanhf</code> Value returned by the function.
-------	--

?tfntp

Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).

Syntax

FORTRAN 77:

```
call stfttp( transr, uplo, n, arf, ap, info )
call dtfttp( transr, uplo, n, arf, ap, info )
call ctfttp( transr, uplo, n, arf, ap, info )
call ztfttp( transr, uplo, n, arf, ap, info )
```

C:

```
lapack_int LAPACKE_<?>tfttp( int matrix_layout, char transr, char uplo, lapack_int n,
const <datatype>* arf, <datatype>* ap );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine copies a triangular matrix A from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. = 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for <code>stfttp</code> and <code>dtfttp</code>), = 'C': <i>arf</i> is in the Conjugate-transpose format (for <code>ctfttp</code> and <code>ztfttp</code>).
<i>uplo</i>	CHARACTER*1. Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>arf</i>	REAL for <code>stfttp</code> , DOUBLE PRECISION for <code>dtfttp</code> , COMPLEX for <code>ctfttp</code> , DOUBLE COMPLEX for <code>ztfttp</code> . Array, DIMENSION at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix <i>A</i> stored in the RFP format.

Output Parameters

<i>ap</i>	REAL for <code>stfttp</code> , DOUBLE PRECISION for <code>dtfttp</code> , COMPLEX for <code>ctfttp</code> , DOUBLE COMPLEX for <code>ztfttp</code> . Array, DIMENSION at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix <i>A</i> , packed columnwise in a linear array. The <i>j</i> -th column of <i>A</i> is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$, if <i>uplo</i> = 'L', $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
<i>info</i>	INTEGER. =0: successful exit, < 0: if <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value.

?tftr

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR) .

Syntax

FORTRAN 77:

```
call stfttr( transr, uplo, n, arf, a, lda, info )
call dtfttr( transr, uplo, n, arf, a, lda, info )
call cftttr( transr, uplo, n, arf, a, lda, info )
call zftttr( transr, uplo, n, arf, a, lda, info )
```

C:

```
lapack_int LAPACKE_<?>tfttr( int matrix_layout, char transr, char uplo, lapack_int n,
const <datatype>* arf, <datatype>* a, lapack_int lda );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine copies a triangular matrix A from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. = 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for <code>stfttr</code> and <code>dtfttr</code>), = 'C': <i>arf</i> is in the Conjugate-transpose format (for <code>cftttr</code> and <code>zftttr</code>).
<i>uplo</i>	CHARACTER*1. Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular.
<i>n</i>	INTEGER. The order of the matrices <i>arf</i> and <i>a</i> . $n \geq 0$.
<i>arf</i>	REAL for <code>stfttr</code> , DOUBLE PRECISION for <code>dtfttr</code> , COMPLEX for <code>cftttr</code> , DOUBLE COMPLEX for <code>zftttr</code> . Array, DIMENSION at least $\max(1, n*(n+1)/2)$.
	On entry, the upper or lower triangular matrix A stored in the RFP format.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1,n)$.

Output Parameters

a

```
REAL for stffttr,
DOUBLE PRECISION for dtffttr,
COMPLEX for ctffttr,
DOUBLE COMPLEX for ztffttr.
```

Array, DIMENSION (*lda*, *).

On exit, the triangular matrix *A*. If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *a* is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *a* is not referenced.

info

```
INTEGER.  
=0: successful exit,  
< 0: if info = -i, the i-th parameter had an illegal value.
```

?tpqrt2

Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for *Q*.

Syntax

FORTRAN 77:

```
call stpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call dtpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call ctpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call ztpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
```

Fortran 95:

```
call tpqrt2(a, b, t [, info])
```

```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The input matrix C is an $(n+m)$ -by- n matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \begin{array}{l} \leftarrow n \times n \text{ upper triangular} \\ \leftarrow m \times n \text{ pentagonal} \end{array}$$

where A is an n -by- n upper triangular matrix, and B is an m -by- n pentagonal matrix consisting of an $(m-l)$ -by- n rectangular matrix $B1$ on top of an l -by- n upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \begin{array}{l} \leftarrow (m-l) \times n \text{ rectangular} \\ \leftarrow l \times n \text{ upper trapezoidal} \end{array}$$

The upper trapezoidal matrix $B2$ consists of the first l rows of an n -by- n upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If $l=0$, B is an m -by- n rectangular matrix. If $m=l=n$, B is upper triangular. The matrix W contains the elementary reflectors $H(i)$ in the i th column below the diagonal (of A) in the $(n+m)$ -by- n input matrix C so that W can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \begin{array}{l} \leftarrow n \times n \text{ identity} \\ \leftarrow m \times n \text{ pentagonal} \end{array}$$

Thus, V contains all of the information needed for W , and is returned in array b .

NOTE

V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \begin{array}{l} \leftarrow (m-l) \times n \text{ rectangular} \\ \leftarrow l \times n \text{ upper trapezoidal} \end{array}$$

The columns of V represent the vectors which define the $H(i)$ s.

The $(m+n)$ -by- $(m+n)$ block reflector H is then given by

$H = I - W^* T^* W^T$ for real flavors, and

$H = I - W^* T^* W^H$ for complex flavors

where W^T is the transpose of W , W^H is the conjugate transpose of W , and T is the upper triangular factor of the block reflector.

Input Parameters

m	INTEGER. The total number of rows in the matrix B ($m \geq 0$).
n	INTEGER. The number of columns in B and the order of the triangular matrix A ($n \geq 0$).
l	INTEGER. The number of rows of the upper trapezoidal part of B ($\min(m, n) \geq l \geq 0$).
a, b	REAL for <code>stpqrt2</code> DOUBLE PRECISION for <code>dtpqrt2</code> COMPLEX for <code>ctpqrt2</code> COMPLEX*16 for <code>ztpqrt2</code> . Arrays: a DIMENSION (lda, n) contains the n -by- n upper triangular matrix A . b DIMENSION (ldb, n), the pentagonal m -by- n matrix B . The first ($m-l$) rows contain the rectangular B_1 matrix, and the next l rows contain the upper trapezoidal B_2 matrix.
lda	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
ldb	INTEGER. The leading dimension of b ; at least $\max(1, m)$.
ldt	INTEGER. The leading dimension of t ; at least $\max(1, n)$.

Output Parameters

a	The elements on and above the diagonal of the array contain the upper triangular matrix R .
b	The pentagonal matrix V .
t	REAL for <code>stpqrt2</code> DOUBLE PRECISION for <code>dtpqrt2</code> COMPLEX for <code>ctpqrt2</code> COMPLEX*16 for <code>ztpqrt2</code> . Array, DIMENSION (ldt, n). The upper n -by- n upper triangular factor T of the block reflector.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info < 0$ and $info = -i$, the i th argument had an illegal value.

?tprfb

Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.

Syntax

FORTRAN 77:

```
call stprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)

call dtprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)

call ctprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)

call ztprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)
```

Fortran 95:

```
call tprrfb(t, v, a, b[, direct][, storev][, side][, trans])
```

C:

```
lapack_int LAPACKE_stprfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float * v,
lapack_int ldv, const float * t, lapack_int ldt, float * a, lapack_int lda, float * b,
lapack_int ldb, lapack_int myldwork);

lapack_int LAPACKE_dtprfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double * v,
lapack_int ldv, const double * t, lapack_int ldt, double * a, lapack_int lda, double * b,
lapack_int ldb, lapack_int myldwork);

lapack_int LAPACKE_ctprfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const
lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int
ldt, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int
ldb, lapack_int myldwork);

lapack_int LAPACKE_ztprrfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const
lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * t, lapack_int
ldt, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int
ldb, lapack_int myldwork);
```

Include Files

- Fortran: mkl.fi
- Fortran 95: lapack.f90
- C: mkl.h

Description

The ?tprrfb routine applies a real or complex "triangular-pentagonal" block reflector H , H^T , or H^H from either the left or the right to a real or complex matrix C , which is composed of two blocks A and B .

The block B is m -by- n . If $side = 'R'$, A is m -by- k , and if $side = 'L'$, A is of size k -by- n .

$$\begin{array}{ll}
 \text{direct} = 'F' & \text{direct} = 'B' \\
 \text{side} = 'R' \quad C = \begin{bmatrix} A & B \end{bmatrix} & C = \begin{bmatrix} B & A \end{bmatrix} \\
 \text{side} = 'L' \quad C = \begin{bmatrix} A \\ B \end{bmatrix} & C = \begin{bmatrix} B \\ A \end{bmatrix}
 \end{array}$$

The pentagonal matrix V is composed of a rectangular block $V1$ and a trapezoidal block $V2$. The size of the trapezoidal block is determined by the parameter ℓ , where $0 \leq \ell \leq k$. If $\ell=k$, the $V2$ block of V is triangular; if $\ell=0$, there is no trapezoidal block, thus $V = V1$ is rectangular.

<code>storev='C'</code>	$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 \\ V1 \end{bmatrix}$
	$V2$ is upper trapezoidal (first ℓ rows of k -by- k upper triangular)	$V2$ is lower trapezoidal (last ℓ rows of k -by- k lower triangular matrix)
<code>storev='R'</code>	$V = \begin{bmatrix} V1 & V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 & V1 \end{bmatrix}$
	$V2$ is lower trapezoidal (first ℓ columns of k -by- k lower triangular matrix)	$V2$ is upper trapezoidal (last ℓ columns of k -by- k upper triangular matrix)
<code>storev='C'</code>	V is m -by- k $V2$ is ℓ -by- k	V is n -by- k $V2$ is ℓ -by- k
<code>storev='R'</code>	V is k -by- m $V2$ is k -by- ℓ	V is k -by- n $V2$ is k -by- ℓ

Input Parameters

<code>side</code>	CHARACTER*1. = 'L': apply H , H^T , or H^H from the left, = 'R': apply H , H^T , or H^H from the right.
<code>trans</code>	CHARACTER*1. = 'N': apply H (no transpose), = 'T': apply H^T (transpose), = 'C': apply H^H (conjugate transpose).
<code>direct</code>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors:

= 'F': $H = H(1) H(2) \dots H(k)$ (Forward),
 = 'B': $H = H(k) \dots H(2) H(1)$ (Backward).

storev

CHARACTER*1.

Indicates how the vectors that define the elementary reflectors are stored:

= 'C': Columns,
 = 'R': Rows.

*m*INTEGER. The total number of rows in the matrix B ($m \geq 0$).*n*INTEGER. The number of columns in B ($n \geq 0$).*k*INTEGER. The order of the matrix T , which is the number of elementary reflectors whose product defines the block reflector. ($k \geq 0$)*l*INTEGER. The order of the trapezoidal part of V . ($k \geq l \geq 0$).*v*

REAL for stprfb

DOUBLE PRECISION for dtprfb

COMPLEX for ctprfb

COMPLEX*16 for ztprfb.

DIMENSION (ldv, k) if *storev* = 'C',DIMENSION (ldv, m) if *storev* = 'R' and *side* = 'L',DIMENSION (ldv, n) if *storev* = 'R' and *side* = 'R'.The pentagonal matrix V , which contains the elementary reflectors $H(1)$, $H(2)$, ..., $H(k)$.*ldv*INTEGER. The leading dimension of the array *v*.If *storev* = 'C' and *side* = 'L', at least max(1, *m*).If *storev* = 'C' and *side* = 'R', at least max(1, *n*).If *storev* = 'R', at least *k*.*t*

REAL for stprfb

DOUBLE PRECISION for dtprfb

COMPLEX for ctprfb

COMPLEX*16 for ztprfb.

DIMENSION (ldt, k). The triangular k -by- k matrix T in the representation of the block reflector.*ldt*INTEGER. The leading dimension of the array *t* ($ldt \geq k$).*a*

REAL for stprfb

DOUBLE PRECISION for dtprfb

COMPLEX for ctprfb

COMPLEX*16 for ztprfb.

DIMENSION (*lda*, *n*) if *side* = 'L',
 DIMENSION (*lda*, *k*) if *side* = 'R'.
 The *k*-by-*n* or *m*-by-*k* matrix *A*.

lda INTEGER. The leading dimension of the array *a*.
 If *side* = 'L', at least max(1, *k*).
 If *side* = 'R', at least max(1, *m*).

b REAL for stprfb
 DOUBLE PRECISION for dtprfb
 COMPLEX for ctprfb
 COMPLEX*16 for ztprfb.
 DIMENSION (*ldb*, *n*), the *m*-by-*n* matrix *B*.

ldb INTEGER. The leading dimension of the array *b* (*ldb* $\geq \max(1, m)$).

work REAL for stprfb
 DOUBLE PRECISION for dtprfb
 COMPLEX for ctprfb
 COMPLEX*16 for ztprfb.
 DIMENSION (*ldwork*, *n*) if *side* = 'L',
 DIMENSION (*ldwork*, *k*) if *side* = 'R'.
 Workspace array.

ldwork INTEGER. The leading dimension of the array *work*.
 If *side* = 'L', at least *k*.
 If *side* = 'R', at least *m*.

Output Parameters

a Contains the corresponding block of $H*C$, H^T*C , H^H*C , $C*H$, $C*H^T$, or $C*H^H$.
b Contains the corresponding block of $H*C$, H^T*C , H^H*C , $C*H$, $C*H^T$, or $C*H^H$.

?tpdff

Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

Syntax

FORTRAN 77:

```
call stpttf( transr, uplo, n, ap, arf, info )
call dtpttf( transr, uplo, n, ap, arf, info )
call ctpttf( transr, uplo, n, ap, arf, info )
call ztpttf( transr, uplo, n, ap, arf, info )
```

C:

```
lapack_int LAPACKE_<?>tpttf( int matrix_layout, char transr, char uplo, lapack_int n,  
const <datatype>* ap, <datatype>* arf );
```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine copies a triangular matrix A from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

transr CHARACTER*1.
 = 'N': *arf* must be in the Normal format,
 = 'T': *arf* must be in the Transpose format (for *stpttf* and *dtpttf*),
 = 'C': *arf* must be in the Conjugate-transpose format (for *ctpttf* and
 ztpttf).

uplo CHARACTER*1.
Specifies whether A is upper or lower triangular:
= 'U': A is upper triangular,
= 'L': A is lower triangular.

n INTEGER; The order of the matrix A ; $n \geq 0$.

ap REAL for stpttf,
 DOUBLE PRECISION for dtpttf,
 COMPLEX for ctpttf,
 DOUBLE COMPLEX for ztpttf.
Array, DIMENSION at least $\max(1, n*(n+1)/2)$.

On entry, the upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:

if $uplo = 'U'$, $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,
 if $uplo = 'L'$, $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

Output Parameters

DOUBLE COMPLEX for `ztpttf`.
Array, DIMENSION at least $\max(1, n*(n+1)/2)$.
 On exit, the upper or lower triangular matrix A stored in the RFP format.

info INTEGER.
 =0: successful exit,
 < 0: if *info* = -*i*, the *i*-th parameter had an illegal value.

?tptr

Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR).

Syntax

FORTRAN 77:

```
call stptr( uplo, n, ap, a, lda, info )
call dtptr( uplo, n, ap, a, lda, info )
call cptptr( uplo, n, ap, a, lda, info )
call ztptr( uplo, n, ap, a, lda, info )
```

C:

```
lapack_int LAPACKE_<?>tptr( int matrix_layout, char uplo, lapack_int n,
const <datatype>* ap, <datatype>* a, lapack_int lda );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine copies a triangular matrix A from the standard packed format to the standard full format.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo CHARACTER*1.
 Specifies whether A is upper or lower triangular:
 = 'U': A is upper triangular,
 = 'L': A is lower triangular.

n INTEGER. The order of the matrices *ap* and *a*. $n \geq 0$.

ap REAL for `stptr`,
 DOUBLE PRECISION for `dtptr`,

COMPLEX for `ctpttr`,
 DOUBLE COMPLEX for `ztpttr`.
 Array, DIMENSION at least $\max(1, n*(n+1)/2)$.
 On entry, the upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array `ap` as follows:
 if $uplo = 'U'$, $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,
 if $uplo = 'L'$, $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
`lda` INTEGER. The leading dimension of the array `a`. $lda \geq \max(1,n)$.

Output Parameters

`a` REAL for `stpttr`,
 DOUBLE PRECISION for `dtpttr`,
 COMPLEX for `ctpttr`,
 DOUBLE COMPLEX for `ztpttr`.
 Array, DIMENSION (`lda, *`).
 On exit, the triangular matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of the array `a` contains the upper triangular part of the matrix A , and the strictly lower triangular part of `a` is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of the array `a` contains the lower triangular part of the matrix A , and the strictly upper triangular part of `a` is not referenced.
`info` INTEGER.
 =0: successful exit,
 < 0: if $info = -i$, the i -th parameter had an illegal value.

?trttf

Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).

Syntax

FORTRAN 77:

```
call strttf( transr, uplo, n, a, lda, arf, info )
call dtrttf( transr, uplo, n, a, lda, arf, info )
call ctrttf( transr, uplo, n, a, lda, arf, info )
call ztrttf( transr, uplo, n, a, lda, arf, info )
```

C:

```
lapack_int LAPACKE_<?>trttf( int matrix_layout, char transr, char uplo, lapack_int n,
const <datatype>* a, lapack_int lda, <datatype>* arf );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine copies a triangular matrix A from the standard full format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

<i>transr</i>	CHARACTER*1. = 'N': <i>arf</i> must be in the Normal format, = 'T': <i>arf</i> must be in the Transpose format (for strttf and dtrttf), = 'C': <i>arf</i> must be in the Conjugate-transpose format (for ctrttf and ztrttf).

const <datatype>* a, lapack_int lda, <datatype>* ap );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine copies a triangular matrix A from the standard full format to the standard packed format.

Input Parameters

The data types are given for the Fortran interface. A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See the [C Interface Conventions](#) section for the C interface principal conventions and type definitions.

uplo CHARACTER*1.
 Specifies whether A is upper or lower triangular:
 $= 'U'$: A is upper triangular,
 $= 'L'$: A is lower triangular.

n INTEGER. The order of the matrices a and ap . $n \geq 0$.

a REAL for strttp,
 DOUBLE PRECISION for dtrttp,
 COMPLEX for ctrttp,
 DOUBLE COMPLEX for ztrttp.
 Array, DIMENSION (lda, n).

On entry, the triangular matrix A . If $\text{uplo} = \text{'U'}$, the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If $\text{uplo} = \text{'L'}$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a . $\text{lda} \geq \max(1,n)$.

Output Parameters

ap REAL for strttp ,
 DOUBLE PRECISION for dtrttp ,
 COMPLEX for ctrttp ,
 DOUBLE COMPLEX for ztrttp .
 Array, DIMENSION at least $\max(1, n*(n+1)/2)$.
 On exit, the upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:
 if $\text{uplo} = \text{'U'}$, $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,
 if $\text{uplo} = \text{'L'}$, $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

$info$ INTEGER.
 =0: successful exit,
 < 0: if $info = -i$, the i -th parameter had an illegal value.

?pstf2

Computes the Cholesky factorization with complete pivoting of a real symmetric or complex Hermitian positive semi-definite matrix.

Syntax

```
call spstf2( uplo, n, a, lda, piv, rank, tol, work, info )
call dpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
call cpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
call zpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The real flavors `spstf2` and `dpstf2` compute the Cholesky factorization with complete pivoting of a real symmetric positive semi-definite matrix A . The complex flavors `cpstf2` and `zpstf2` compute the Cholesky factorization with complete pivoting of a complex Hermitian positive semi-definite matrix A . The factorization has the form:

$$P^T * A * P = U^T * U, \text{ if } \text{uplo} = \text{'U'} \text{ for real flavors,}$$

$P^T * A * P = U^H * U$, if $\text{uplo} = \text{'U'}$ for complex flavors,

$P^T * A * P = L * L^T$, if $\text{uplo} = \text{'L'}$ for real flavors,

$P^T * A * P = L * L^H$, if $\text{uplo} = \text{'L'}$ for complex flavors,

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector piv .

This algorithm does not check that A is positive semi-definite. This version of the algorithm calls [level 2 BLAS](#).

Input Parameters

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric or Hermitian matrix A is stored:

= 'U': Upper triangular,

= 'L': Lower triangular.

n

INTEGER. The order of the matrix A . $n \geq 0$.

a

REAL for spstf2 ,
 DOUBLE PRECISION for dpstf2 ,
 COMPLEX for cpstf2 ,
 DOUBLE COMPLEX for zpstf2 .

Array, DIMENSION ($\text{lda}, *$).

On entry, the symmetric matrix A . If $\text{uplo} = \text{'U'}$, the leading n -by- n upper triangular part of the array a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If $\text{uplo} = \text{'L'}$, the leading n -by- n lower triangular part of the array a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

tol

REAL for spstf2 and cpstf2 ,
 DOUBLE PRECISION for dpstf2 and zpstf2 .

A user-defined tolerance.

If $\text{tol} < 0$, $n * \text{ulp} * \max(A(k,k))$ will be used (ulp is the Unit in the Last Place, or Unit of Least Precision). The algorithm terminates at the $(k - 1)$ -st step if the pivot is not greater than tol .

lda

INTEGER. The leading dimension of the matrix A . $\text{lda} \geq \max(1,n)$.

work

REAL for spstf2 and cpstf2 ,
 DOUBLE PRECISION for dpstf2 and zpstf2 .
 Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

piv

INTEGER. Array. DIMENSION at least $\max(1,n)$.

piv is such that the non-zero entries are $P(\text{piv}(k), k) = 1$.

<i>a</i>	On exit, if <i>info</i> = 0, the factor U or L from the Cholesky factorization stored the same way as the matrix <i>A</i> is stored on entry.
<i>rank</i>	INTEGER. The rank of <i>A</i> , determined by the number of steps the algorithm completed.
<i>info</i>	INTEGER. < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th parameter had an illegal value, =0: the algorithm completed successfully, > 0: the matrix <i>A</i> is rank-deficient with the computed rank, returned in <i>rank</i> , or indefinite.

dlat2s

Converts a double-precision triangular matrix to a single-precision triangular matrix.

Syntax

```
call dlat2s( uplo, n, a, lda, sa, ldsa, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine converts a double-precision triangular matrix *A* to a single-precision triangular matrix *SA*. dlat2s checks that all the elements of *A* are between -*RMAX* and *RMAX*, where *RMAX* is the overflow for the single-precision arithmetic. If this condition is not met, the conversion is aborted and a flag is raised. The routine does no parameter checking.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	INTEGER. The number of rows and columns of the matrix <i>A</i> . <i>n</i> ≥ 0.
<i>a</i>	DOUBLE PRECISION. Array, DIMENSION (<i>lda</i> , *). On entry, the <i>n</i> -by- <i>n</i> triangular matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> ≥ <i>max</i> (1, <i>n</i>).
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> . <i>ldsa</i> ≥ <i>max</i> (1, <i>n</i>).

Output Parameters

<i>sa</i>	REAL. Array, DIMENSION (<i>ldsa</i> , *). Only the part of <i>sa</i> determined by <i>uplo</i> is referenced. On exit,
	<ul style="list-style-type: none"> • if <i>info</i> = 0, the <i>n</i>-by-<i>n</i> triangular matrix <i>SA</i>, • if <i>info</i> > 0, the content of the part of <i>sa</i> determined by <i>uplo</i> is unspecified.

<i>info</i>	INTEGER. =0: successful exit, > 0: an element of the matrix <i>A</i> is greater than the single-precision overflow threshold; in this case, the content of the part of <i>sa</i> determined by <i>uplo</i> is unspecified on exit.
-------------	--

zlat2c

Converts a double complex triangular matrix to a complex triangular matrix.

Syntax

```
call zlat2c( uplo, n, a, lda, sa, ldsa, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine is declared in mkl_lapack.fi for FORTRAN 77 interface and in mkl_lapack.h for C interface.

The routine converts a DOUBLE COMPLEX triangular matrix *A* to a COMPLEX triangular matrix *SA*. zlat2c checks that the real and complex parts of all the elements of *A* are between -RMAX and RMAX, where RMAX is the overflow for the single-precision arithmetic. If this condition is not met, the conversion is aborted and a flag is raised. The routine does no parameter checking.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	INTEGER. The number of rows and columns in the matrix <i>A</i> . <i>n</i> ≥ 0.
<i>a</i>	DOUBLE COMPLEX. Array, DIMENSION (<i>lda</i> , *). On entry, the <i>n</i> -by- <i>n</i> triangular matrix <i>A</i> .

lda INTEGER. The leading dimension of the array *a*. $lda \geq max(1,n)$.

ldsa INTEGER. The leading dimension of the array *sa*. $ldsa \geq max(1,n)$.

Output Parameters

sa COMPLEX.

Array, DIMENSION (*ldsa, **).

Only the part of *sa* determined by *uplo* is referenced. On exit,

- if *info* = 0, the *n*-by-*n* triangular matrix *sa*,
- if *info* > 0, the content of the part of *sa* determined by *uplo* is unspecified.

info INTEGER.

=0: successful exit,
 > 0: the real or complex part of an element of the matrix *A* is greater than the single-precision overflow threshold; in this case, the content of the part of *sa* determined by *uplo* is unspecified on exit.

?lacp2

Copies all or part of a real two-dimensional array to a complex array.

Syntax

FORTRAN 77:

```
call clacp2( uplo, m, n, a, lda, b, ldb )
call zlacp2( uplo, m, n, a, lda, b, ldb )
```

C:

```
lapack_int LAPACKE_clacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int n , const float * a , lapack_int lda , lapack_complex_float * b , lapack_int ldb );
lapack_int LAPACKE_zlacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int n , const double * a , lapack_int lda , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine copies all or part of a two-dimensional matrix *A* to another matrix *B*.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>uplo</i>	CHARACTER*1.

Specifies the part of the matrix A to be copied to B .

If $uplo = 'U'$, the upper triangular part of A ;

if $uplo = 'L'$, the lower triangular part of A .

Otherwise, all of the matrix A is copied.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for clacp2

DOUBLE PRECISION for zlacp2

Array $a(1da, n)$, contains the m -by- n matrix A .

If $uplo = 'U'$, only the upper triangle or trapezoid is accessed; if $uplo = 'L'$, only the lower triangle or trapezoid is accessed.

$1da$ INTEGER. The leading dimension of a ; $1da \geq \max(1, m)$.

ldb INTEGER. The leading dimension of the output array b ; $ldb \geq \max(1, m)$.

Output Parameters

b COMPLEX for clacp2

DOUBLE COMPLEX for zlacp2.

Array $b(ldb, m)$, contains the m -by- n matrix B .

On exit, $B = A$ in the locations specified by $uplo$.

?la_gbamv

Performs a matrix-vector operation to calculate error bounds.

Syntax

FORTRAN 77:

```
call sla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)
call dla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)
call cla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)
call zla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_gbamv function performs one of the matrix-vector operations defined as

$y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y)$,

or

$y := \alpha \cdot \text{abs}(A)^T \cdot \text{abs}(x) + \beta \cdot \text{abs}(y),$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- n matrix, with k_l sub-diagonals and k_u super-diagonals.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

<i>trans</i>	INTEGER. Specifies the operation to be performed: If <i>trans</i> = 'BLAS_NO_TRANS', then $y := \alpha \cdot \text{abs}(A) \cdot \text{abs}(x) + \beta \cdot \text{abs}(y)$ If <i>trans</i> = 'BLAS_TRANS', then $y := \alpha \cdot \text{abs}(A^T) \cdot \text{abs}(x) + \beta \cdot \text{abs}(y)$ If <i>trans</i> = 'BLAS_CONJ_TRANS', then $y := \alpha \cdot \text{abs}(A^T) \cdot \text{abs}(x) + \beta \cdot \text{abs}(y)$ The parameter is unchanged on exit.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix A . The value of <i>m</i> must be at least zero. Unchanged on exit.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix A . The value of <i>n</i> must be at least zero. Unchanged on exit.
<i>k_l</i>	INTEGER. Specifies the number of sub-diagonals within the band of A . $k_l \geq 0$.
<i>k_u</i>	INTEGER. Specifies the number of super-diagonals within the band of A . $k_u \geq 0$.
<i>alpha</i>	REAL for <code>sla_gbamv</code> and <code>cla_gbamv</code> DOUBLE PRECISION for <code>dla_gbamv</code> and <code>zla_gbamv</code> Specifies the scalar α . Unchanges on exit.
<i>ab</i>	REAL for <code>sla_gbamv</code> DOUBLE PRECISION for <code>dla_gbamv</code> COMPLEX for <code>cla_gbamv</code> DOUBLE COMPLEX for <code>zla_gbamv</code> <code>Array, DIMENSION (1dab, *)</code> . Before entry, the leading m -by- n part of the array <i>ab</i> must contain the matrix of coefficients. The second dimension of <i>ab</i> must be at least $\max(1, n)$. Unchanged on exit.

<i>ldab</i>	INTEGER. Specifies the leading dimension of <i>ab</i> as declared in the calling (sub)program. The value of <i>ldab</i> must be at least $\max(1, m)$. Unchanged on exit.
<i>x</i>	<p>REAL for <i>sla_gbamv</i></p> <p>DOUBLE PRECISION for <i>dla_gbamv</i></p> <p>COMPLEX for <i>cla_gbamv</i></p> <p>DOUBLE COMPLEX for <i>zla_gbamv</i></p> <p>Array, DIMENSION $(1 + (n - 1) * \text{abs}(incx))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(incx))$ otherwise.</p> <p>Before entry, the incremented array <i>x</i> must contain the vector <i>x</i>.</p>
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>beta</i>	<p>REAL for <i>sla_gbamv</i> and <i>cla_gbamv</i></p> <p>DOUBLE PRECISION for <i>dla_gbamv</i> and <i>zla_gbamv</i></p> <p>Specifies the scalar <i>beta</i>. When <i>beta</i> is zero, you do not need to set <i>y</i> on input.</p>
<i>y</i>	<p>REAL for <i>sla_gbamv</i> and <i>cla_gbamv</i></p> <p>DOUBLE PRECISION for <i>dla_gbamv</i> and <i>zla_gbamv</i></p> <p>Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(incy))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise.</p> <p>Before entry with <i>beta</i> non-zero, the incremented array <i>y</i> must contain the vector <i>y</i>.</p>
<i>incy</i>	<p>INTEGER. Specifies the increment for the elements of <i>y</i>.</p> <p>The value of <i>incy</i> must not be zero. Unchanged on exit.</p>

Output Parameters

<i>y</i>	Updated vector <i>y</i> .
----------	---------------------------

?la_gbrcond

Estimates the Skeel condition number for a general banded matrix.

Syntax

FORTRAN 77:

```
call sla_gbrcond( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, cmode, c, info, work,
iwork )

call dla_gbrcond( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, cmode, c, info, work,
iwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function estimates the Skeel condition number of

$$\text{op}(A) * \text{op}2(C)$$

where

the *cmode* parameter determines *op2* as follows:

<i>cmode</i> Value	op2(C)
1	C
0	I
-1	$\text{inv}(C)$

The Skeel condition number

$$\text{cond}(A) = \text{norminf}(|\text{inv}(A)| |A|)$$

is computed by computing scaling factors R such that

$$\text{diag}(R) * A * \text{op}2(C)$$

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $A*X = B$. If <i>trans</i> = 'T', the system has the form $A^T*X = B$. If <i>trans</i> = 'C', the system has the form $A^H*X = B$.
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>ab</i> , <i>afb</i> , <i>c</i> , <i>work</i>	REAL for <i>sla_gbrcond</i> DOUBLE PRECISION for <i>dla_gbrcond</i> Arrays: <i>ab</i> (<i>ldab</i> ,*) contains the original band matrix A stored in rows from 1 to $kl + ku + 1$. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows:

```

 $ab(ku+1+i-j, j) = A(i, j)$ 
for
 $\max(1, j-ku) \leq i \leq \min(n, j+k1)$ 

 $afb(1:ldafb, *)$  contains details of the LU factorization of the band matrix  $A$ , as
returned by  $?gbtrf$ .  $U$  is stored as an upper triangular band matrix with  $k1+ku$ 
superdiagonals in rows 1 to  $k1+ku+1$ , and the multipliers used during the
factorization are stored in rows  $k1+ku+2$  to  $2*k1+ku+1$ .

 $c$ , DIMENSION  $n$ . The vector  $C$  in the formula  $\text{op}(A) * \text{op2}(C)$ .
 $work$  is a workspace array of DIMENSION  $(5*n)$ .
The second dimension of  $ab$  and  $afb$  must be at least  $\max(1, n)$ .

 $ldab$  INTEGER. The leading dimension of the array  $ab$ .  $ldab \geq k1+ku+1$ .
 $ldafb$  INTEGER. The leading dimension of  $afb$ .  $ldafb \geq 2*k1+ku+1$ .
 $ipiv$  INTEGER.
Array with DIMENSION  $n$ . The pivot indices from the factorization  $A = P*L*U$  as
computed by  $?gbtrf$ . Row  $i$  of the matrix was interchanged with row  $ipiv(i)$ .
 $cmode$  INTEGER. Determines  $\text{op2}(C)$  in the formula  $\text{op}(A) * \text{op2}(C)$  as follows:
If  $cmode = 1$ ,  $\text{op2}(C) = C$ .
If  $cmode = 0$ ,  $\text{op2}(C) = I$ .
If  $cmode = -1$ ,  $\text{op2}(C) = \text{inv}(C)$ .
 $iwork$  INTEGER. Workspace array with DIMENSION  $n$ .
```

Output Parameters

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $i > 0$, the i -th parameter is invalid.

See Also

$?gbtrf$

[?la_gbrcond_c](#)

Computes the infinity norm condition number of
 $\text{op}(A)*\text{inv}(\text{diag}(c))$ for general banded matrices.

Syntax

FORTRAN 77:

```

call cla_gbrcond_c( trans, n, k1, ku, ab, ldab, afb, ldafb, ipiv, c, capply, info,
work, rwork )

call zla_gbrcond_c( trans, n, k1, ku, ab, ldab, afb, ldafb, ipiv, c, capply, info,
work, rwork )

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

```
op(A) * inv(diag(c))
```

where the *c* is a REAL vector for cla_gbrcond_c and a DOUBLE PRECISION vector for zla_gbrcond_c.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$ (No transpose) If <i>trans</i> = 'T', the system has the form $A^T*X = B$ (Transpose) If <i>trans</i> = 'C', the system has the form $A^{H*}X = B$ (Conjugate Transpose = Transpose)
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; <i>n</i> ≥ 0 .
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; <i>kl</i> ≥ 0 .
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; <i>ku</i> ≥ 0 .
<i>ab</i> , <i>afb</i> , <i>work</i>	COMPLEX for cla_gbrcond_c DOUBLE COMPLEX for zla_gbrcond_c Arrays: <i>ab</i> (<i>ldab</i> ,*) contains the original band matrix <i>A</i> stored in rows from 1 to <i>kl</i> + <i>ku</i> + 1. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows: <i>ab</i> (<i>ku</i> +1+ <i>i</i> - <i>j</i> , <i>j</i>) = <i>A</i> (<i>i</i> , <i>j</i>) for <i>max</i> (1, <i>j</i> - <i>ku</i>) $\leq i \leq \min(n, j+k1)$ <i>afb</i> (<i>ldafb</i> ,*) contains details of the LU factorization of the band matrix <i>A</i> , as returned by ?gbtrf. <i>U</i> is stored as an upper triangular band matrix with <i>kl+ku</i> superdiagonals in rows 1 to <i>kl+ku</i> +1, and the multipliers used during the factorization are stored in rows <i>kl+ku</i> +2 to 2*k _{l+ku} +1. <i>work</i> is a workspace array of DIMENSION (5*n). The second dimension of <i>ab</i> and <i>afb</i> must be at least <i>max</i> (1, <i>n</i>). <i>ldab</i> INTEGER. The leading dimension of the array <i>ab</i> . <i>ldab</i> $\geq k1+ku+1$. <i>ldafb</i> INTEGER. The leading dimension of <i>afb</i> . <i>ldafb</i> $\geq 2*kl+ku+1$. <i>ipiv</i> INTEGER.

Array with DIMENSION n . The pivot indices from the factorization $A = P^* L^* U$ as computed by `?gbtrf`. Row i of the matrix was interchanged with row $ipiv(i)$.

$c, rwork$	REAL for <code>cla_gbrcond_c</code> DOUBLE PRECISION for <code>zla_gbrcond_c</code> Array c with DIMENSION n . The vector c in the formula $op(A) * \text{inv}(\text{diag}(c))$. Array $rwork$ with DIMENSION n is a workspace.
$capply$	LOGICAL. If .TRUE., then the function uses the vector c from the formula $op(A) * \text{inv}(\text{diag}(c))$.

Output Parameters

$info$	INTEGER. If $info = 0$, the execution is successful. If $i > 0$, the i -th parameter is invalid.
--------	--

See Also

`?gbtrf`

`?la_gbrcond_x`

Computes the infinity norm condition number of
 $op(A)^*\text{diag}(x)$ for general banded matrices.

Syntax

FORTRAN 77:

```
call cla_gbrcond_x( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, x, info, work,
rwork )

call zla_gbrcond_x( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, x, info, work,
rwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function computes the infinity norm condition number of

$op(A) * \text{diag}(x)$

where the x is a COMPLEX vector for `cla_gbrcond_x` and a DOUBLE COMPLEX vector for `zla_gbrcond_x`.

Input Parameters

$trans$	CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If $trans = 'N'$, the system has the form $A*X = B$ (No transpose)
---------	--

If $\text{trans} = \text{'T'}$, the system has the form $A^T X = B$ (Transpose)

If $\text{trans} = \text{'C'}$, the system has the form $A^H X = B$ (Conjugate Transpose = Transpose)

n INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.

k1 INTEGER. The number of subdiagonals within the band of A ; $k1 \geq 0$.

ku INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.

ab, afb, x, work COMPLEX for `cla_gbrcond_x`

DOUBLE COMPLEX for `zla_gbrcond_x`

Arrays:

ab(1:dab,)* contains the original band matrix A stored in rows from 1 to $k1 + ku + 1$. The j -th column of A is stored in the j -th column of the array *ab* as follows:

ab(ku+1+i-j, j) = A(i, j)

for

$\max(1, j-ku) \leq i \leq \min(n, j+k1)$

afb(1:dafb,)* contains details of the LU factorization of the band matrix A , as returned by `?gbtrf`. U is stored as an upper triangular band matrix with $k1+ku$ superdiagonals in rows 1 to $k1+ku+1$, and the multipliers used during the factorization are stored in rows $k1+ku+2$ to $2*k1+ku+1$.

x, DIMENSION n . The vector *x* in the formula $\text{op}(A) * \text{diag}(x)$.

work is a workspace array of DIMENSION $(2*n)$.

The second dimension of *ab* and *afb* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*. $ldab \geq k1+ku+1$.

ldafb INTEGER. The leading dimension of *afb*. $ldafb \geq 2*k1+ku+1$.

ipiv INTEGER.

Array with DIMENSION n . The pivot indices from the factorization $A = P^* L^* U$ as computed by `?gbtrf`. Row i of the matrix was interchanged with row *ipiv(i)*.

rwork REAL for `cla_gbrcond_x`

DOUBLE PRECISION for `zla_gbrcond_x`

Array *rwork* with DIMENSION n is a workspace.

Output Parameters

info INTEGER.

If $\text{info} = 0$, the execution is successful.

If $i > 0$, the i -th parameter is invalid.

err_bnds_comp, res, ayb, dy, y_tail, rcond, ithresh, rthresh, dz_ub, ignore_cwise,
info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_gbrfsx_extended subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The ?gbrfsx routine calls ?la_gbrfsx_extended to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use ?la_gbrfsx_extended to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

<code>prec_type</code>	INTEGER.
	Specifies the intermediate precision to be used in refinement. The value is defined by ilaprec(p), where p is a CHARACTER and:
If <code>p = 'S'</code> :	Single.
If <code>p = 'D'</code> :	Double.
If <code>p = 'I'</code> :	Indigenous.
If <code>p = 'X', 'E'</code> :	Extra.

<i>trans_type</i>	INTEGER. Specifies the transposition operation on A . The value is defined by <code>ilatrans(t)</code> , where t is a CHARACTER and: If $t = 'N'$: No transpose. If $t = 'T'$: Transpose. If $t = 'C'$: Conjugate Transpose.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<i>k1</i>	INTEGER. The number of subdiagonals within the band of A ; $k1 \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrix B .
<i>ab, afb, b, y</i>	REAL for <code>sla_gbrfsx_extended</code> DOUBLE PRECISION for <code>dla_gbrfsx_extended</code> COMPLEX for <code>cla_gbrfsx_extended</code> DOUBLE COMPLEX for <code>zla_gbrfsx_extended</code> . Arrays: $ab(1dab, *)$, $afb(1dafb, *)$, $b(1db, *)$, $y(1dy, *)$. The array <i>ab</i> contains the original n -by- n matrix A . The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>afb</i> contains the factors L and U from the factorization $A = P^* L^* U$ as computed by <code>?gbtrf</code> . The second dimension of <i>afb</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. The array <i>y</i> on entry contains the solution matrix X as computed by <code>?gbtrs</code> . The second dimension of <i>y</i> must be at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $1dab \geq \max(1, n)$.
<i>ldafb</i>	INTEGER. The leading dimension of the array <i>afb</i> ; $1dafb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices from the factorization $A = P^* L^* U$ as computed by <code>?gbtrf</code> ; row i of the matrix was interchanged with row $ipiv(i)$.
<i>colequ</i>	LOGICAL. If <i>colequ</i> = .TRUE., column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.
<i>c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not accessed.

If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array *b*; *ldb* $\geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; *ldy* $\geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

If *n_norms* ≥ 1 , returns normwise error bounds.

If *n_norms* ≥ 2 , returns componentwise error bounds.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm(i,:)* corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm(:,err)* contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold *sqrt(n) * slamch(ε)* for single precision flavors and *sqrt(n) * dlamch(ε)* for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold *sqrt(n) * slamch(ε)* for single precision flavors and *sqrt(n) * dlamch(ε)* for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z.

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION ($\text{nrhs}, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\varepsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\varepsilon)$ for single precision flavors and

$\sqrt{n} * \text{diamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{diamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s^* (a^* \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^* \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`res, dy, y_tail`

REAL for `sla_gbrfsx_extended`
 DOUBLE PRECISION for `dla_gbrfsx_extended`
 COMPLEX for `cla_gbrfsx_extended`
 DOUBLE COMPLEX for `zla_gbrfsx_extended`.
Workspace arrays of DIMENSION n .
`res` holds the intermediate residual.
`dy` holds the intermediate solution.
`y_tail` holds the trailing bits of the intermediate solution.

`ayb`

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION n .

`rcond`

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If `rcond` is less than the machine precision, in particular, if `rcond = 0`, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

`ithresh`

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

<i>rthresh</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies $\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$ where $\text{norm}(z)$ is the infinity norm of Z . <i>rthresh</i> satisfies $0 < \text{rthresh} \leq 1$.
<i>dz_ub</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Determines when to start considering componentwise convergence. Componentwise <i>dz_ub</i> convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than <i>dz_ub</i> . The default value is 0.25, requiring the first bit to be stable.
<i>ignore_cwise</i>	LOGICAL If .TRUE., the function ignores componentwise convergence. Default value is .FALSE..

Output Parameters

<i>y</i>	REAL for <code>sla_gbrfsx_extended</code> DOUBLE PRECISION for <code>dla_gbrfsx_extended</code> COMPLEX for <code>cla_gbrfsx_extended</code> DOUBLE COMPLEX for <code>zla_gbrfsx_extended</code> . The improved solution matrix Y .
<i>berr_out</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the componentwise relative backward error for right-hand-side j from the formula $\max(i) (\text{abs}(\text{res}(i)) / (\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B)) (i))$ where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z . This is computed by <code>?la_lin_berr</code> .
<i>err_bnds_norm</i> , <i>err_bnds_comp</i>	Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array (<code>1:nrhs, 2</code>). The other elements are kept unchanged.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If $info = -i$, the i -th parameter had an illegal value.

?la_gbrpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a general band matrix.

Syntax

FORTRAN 77:

```
call sla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call dla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call cla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call zla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_gbrpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the equilibrated matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable.

Input Parameters

n	INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
$ncols$	INTEGER. The number of columns of the matrix A ; $ncols \geq 0$.
ab, afb	REAL for <code>sla_gbrpvgrw</code> DOUBLE PRECISION for <code>dla_gbrpvgrw</code> COMPLEX for <code>cla_gbrpvgrw</code> DOUBLE COMPLEX for <code>zla_gbrpvgrw</code> . Arrays: $ab(ldab, *)$, $afb(ldafb, *)$.

ab contains the original band matrix *A* (see [Matrix Storage Schemes](#)) stored in rows from 1 to $k_l + k_u + 1$. The j -th column of *A* is stored in the j -th column of the array *ab* as follows:

$ab(k_l+1+i-j, j) = A(i, j)$

for

$\max(1, j-k_u) \leq i \leq \min(n, j+k_l)$

afb contains details of the LU factorization of the band matrix *A*, as returned by [?gbtrf](#). *U* is stored as an upper triangular band matrix with k_l+k_u superdiagonals in rows 1 to k_l+k_u+1 , and the multipliers used during the factorization are stored in rows k_l+k_u+2 to $2*k_l+k_u+1$.

ldab

INTEGER. The leading dimension of *ab*; $ldab \geq k_l+k_u+1$.

ldafb

INTEGER. The leading dimension of *afb*; $ldafb \geq 2*k_l+k_u+1$.

[?gbtrf](#)

?la_geamv

Computes a matrix-vector product using a general matrix to calculate error bounds.

Syntax

FORTRAN 77:

```
call sla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call dla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call cla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call zla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?la_geamv` routines perform a matrix-vector operation defined as

$y := \alpha * \text{abs}(A) * (x) + \beta * \text{abs}(y),$

or

$y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y),$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

<i>trans</i>	CHARACTER*1. Specifies the operation:
	if <i>trans</i> = BLAS_NO_TRANS , then <i>y</i> := <i>alpha</i> *abs(<i>A</i>)*abs(<i>x</i>) + <i>beta</i> *abs(<i>y</i>)
	if <i>trans</i> = BLAS_TRANS, then <i>y</i> := <i>alpha</i> *abs(<i>A</i> ^T)*abs(<i>x</i>) + <i>beta</i> *abs(<i>y</i>)
	if <i>trans</i> = 'BLAS_CONJ_TRANS, then <i>y</i> := <i>alpha</i> *abs(<i>A</i> ^T)*abs(<i>x</i>) + <i>beta</i> *abs(<i>y</i>).
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>sla_geamv</i> and for <i>cla_geamv</i> DOUBLE PRECISION for <i>dla_geamv</i> and <i>zla_geamv</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for <i>sla_geamv</i> DOUBLE PRECISION for <i>dla_geamv</i> COMPLEX for <i>cla_geamv</i> DOUBLE COMPLEX for <i>zla_geamv</i> Array, DIMENSION (<i>lda</i> , *). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.
<i>x</i>	REAL for <i>sla_geamv</i> DOUBLE PRECISION for <i>dla_geamv</i> COMPLEX for <i>cla_geamv</i> DOUBLE COMPLEX for <i>zla_geamv</i> Array, DIMENSION at least $(1+(n-1)*\text{abs}(incx))$ when <i>trans</i> = 'N' or 'n' and at least $(1+(m - 1)*\text{abs}(incx))$ otherwise. Before entry, the incremented array <i>x</i> must contain the vector <i>X</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must be non-zero.
<i>beta</i>	REAL for <i>sla_geamv</i> and for <i>cla_geamv</i>

DOUBLE PRECISION for `dla_geamv` and `zla_geamv`

Specifies the scalar *beta*. When *beta* is zero, you do not need to set *y* on input.

y

REAL for `sla_geamv` and for `cla_geamv`

DOUBLE PRECISION for `dla_geamv` and `zla_geamv`

Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incy}))$ when *trans* = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with non-zero *beta*, the incremented array *y* must contain the vector *Y*.

incy

INTEGER. Specifies the increment for the elements of *y*.

The value of *incy* must be non-zero.

Output Parameters

y

Updated vector *Y*.

?la_gercond

Estimates the Skeel condition number for a general matrix.

Syntax

FORTRAN 77:

```
call sla_gercond( trans, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
call dla_gercond( trans, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function estimates the Skeel condition number of

$\text{op}(A) * \text{op2}(C)$

where

the *cmode* parameter determines op2 as follows:

cmode Value	op2(C)
1	C
0	I
-1	$\text{inv}(C)$

The Skeel condition number

$\text{cond}(A) = \text{norminf}(|\text{inv}(A)| |A|)$

is computed by computing scaling factors *R* such that

$\text{diag}(R) * A * \text{op2}(C)$

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $A*X = B$ (No transpose). If <i>trans</i> = 'T', the system has the form $A^T*X = B$ (Transpose). If <i>trans</i> = 'C', the system has the form $A^H*X = B$ (Conjugate Transpose = Transpose).
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i> , <i>af</i> , <i>c</i> , <i>work</i>	REAL for <code>sla_gercond</code> DOUBLE PRECISION for <code>dla_gercond</code> Arrays: <i>a</i> (<i>lda</i> ,*) contains the original general <i>n</i> -by- <i>n</i> matrix <i>A</i> . <i>af</i> (<i>ldaf</i> ,*) contains factors <i>L</i> and <i>U</i> from the factorization of the general matrix $A = P*L*U$, as returned by <code>?getrf</code> . <i>c</i> , DIMENSION <i>n</i> . The vector <i>C</i> in the formula $\text{op}(A) * \text{op}2(C)$. <i>work</i> is a workspace array of DIMENSION ($3*n$). The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$. <i>lda</i> INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$. <i>ldaf</i> INTEGER. The leading dimension of <i>af</i> . $ldaf \geq \max(1, n)$. <i>ipiv</i> INTEGER. Array with DIMENSION <i>n</i> . The pivot indices from the factorization $A = P*L*U$ as computed by <code>?getrf</code> . Row <i>i</i> of the matrix was interchanged with row <i>ipiv(i)</i> . <i>cmode</i> INTEGER. Determines $\text{op}2(C)$ in the formula $\text{op}(A) * \text{op}2(C)$ as follows: If <i>cmode</i> = 1, $\text{op}2(C) = C$. If <i>cmode</i> = 0, $\text{op}2(C) = I$. If <i>cmode</i> = -1, $\text{op}2(C) = \text{inv}(C)$. <i>iwork</i> INTEGER. Workspace array with DIMENSION <i>n</i> .

Output Parameters

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>i</i> > 0, the <i>i</i> -th parameter is invalid.
-------------	---

See Also

`?getrf`

?la_gercond_c

Computes the infinity norm condition number of $\text{op}(A)^*\text{inv}(\text{diag}(c))$ for general matrices.

Syntax

FORTRAN 77:

```
call cla_gercond_c( trans, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
call zla_gercond_c( trans, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A)^* \text{inv}(\text{diag}(c))$

where the c is a REAL vector for `cla_gercond_c` and a DOUBLE PRECISION vector for `zla_gercond_c`.

Input Parameters

<code>trans</code>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form $A*X = B$ (No transpose) If <code>trans</code> = 'T', the system has the form $A^T*X = B$ (Transpose) If <code>trans</code> = 'C', the system has the form $A^H*X = B$ (Conjugate Transpose = Transpose)
<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<code>a, af, work</code>	COMPLEX for <code>cla_gercond_c</code> DOUBLE COMPLEX for <code>zla_gercond_c</code> Arrays: $a(lda,*)$ contains the original general n -by- n matrix A . $af(ldaf,*)$ contains the factors L and U from the factorization $A = P^* L^* U$ as returned by <code>?getrf</code> . <code>work</code> is a workspace array of DIMENSION $(2*n)$. The second dimension of <code>a</code> and <code>af</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> . $lda \geq \max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of <code>af</code> . $ldaf \geq \max(1, n)$.
<code>ipiv</code>	INTEGER.

Array with DIMENSION n . The pivot indices from the factorization $A = P^* L^* U$ as computed by `?getrf`. Row i of the matrix was interchanged with row $ipiv(i)$.

$c, rwork$

REAL for `cla_gercond_c`
 DOUBLE PRECISION for `zla_gercond_c`
 Array c with DIMENSION n . The vector c in the formula
 $\text{op}(A) * \text{inv}(\text{diag}(c))$.
 Array $rwork$ with DIMENSION n is a workspace.

$capply$

LOGICAL. If $capply = .TRUE.$, then the function uses the vector c from the formula
 $\text{op}(A) * \text{inv}(\text{diag}(c))$.

Output Parameters

$info$

INTEGER.
 If $info = 0$, the execution is successful.
 If $i > 0$, the i -th parameter is invalid.

See Also

`?getrf`

`?la_gercond_x`

Computes the infinity norm condition number of $\text{op}(A)*\text{diag}(x)$ for general matrices.

Syntax

FORTRAN 77:

```
call cla_gercond_x( trans, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
call zla_gercond_x( trans, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the x is a COMPLEX vector for `cla_gercond_x` and a DOUBLE COMPLEX vector for `zla_gercond_x`.

Input Parameters

$trans$

CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Specifies the form of the system of equations:
 If $trans = 'N'$, the system has the form $A*X = B$ (No transpose)

If $\text{trans} = \text{'T'}$, the system has the form $A^T X = B$ (Transpose)

If $\text{trans} = \text{'C'}$, the system has the form $A^H X = B$ (Conjugate Transpose = Transpose)

n INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.

a, af, x, work COMPLEX for `cla_gercond_x`

DOUBLE COMPLEX for `zla_gercond_x`

Arrays:

a(*lda,**) contains the original general n -by- n matrix A .

af(*ldaf,**) contains the factors L and U from the factorization $A = P^* L^* U$ as returned by `?getrf`.

x, DIMENSION n . The vector *x* in the formula $\text{op}(A) * \text{diag}(x)$.

work is a workspace array of DIMENSION ($2*n$).

The second dimension of *a* and *af* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array *a*. $\text{lda} \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of *af*. $\text{ldaf} \geq \max(1, n)$.

ipiv INTEGER.

Array with DIMENSION n . The pivot indices from the factorization $A = P^* L^* U$ as computed by `?getrf`. Row i of the matrix was interchanged with row *ipiv*(i).

rwork REAL for `cla_gercond_x`

DOUBLE PRECISION for `zla_gercond_x`

Array *rwork* with DIMENSION n is a workspace.

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If $i > 0$, the i -th parameter is invalid.

See Also

`?getrf`

`?la_gerfsx_extended`

Improves the computed solution to a system of linear equations for general matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.

Syntax

FORTRAN 77:

```

call sla_gerfsx_extended( prec_type, trans_type, n, nrhs, a, lda, af, ldaf, ipiv,
colequ, c, b, ldb, y, ldy, berr_out, n_norms, errs_n, errs_c, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call dla_gerfsx_extended( prec_type, trans_type, n, nrhs, a, lda, af, ldaf, ipiv,
colequ, c, b, ldb, y, ldy, berr_out, n_norms, errs_n, errs_c, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call cla_gerfsx_extended( prec_type, trans_type, n, nrhs, a, lda, af, ldaf, ipiv,
colequ, c, b, ldb, y, ldy, berr_out, n_norms, errs_n, errs_c, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call zla_gerfsx_extended( prec_type, trans_type, n, nrhs, a, lda, af, ldaf, ipiv,
colequ, c, b, ldb, y, ldy, berr_out, n_norms, errs_n, errs_c, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_gerfsx_extended subroutine improves the computed solution to a system of linear equations for general matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The ?gerfsx routine calls ?la_gerfsx_extended to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `errs_n` and `errs_c` for details of the error bounds.

Use ?la_gerfsx_extended to set only the second fields of `errs_n` and `errs_c`.

Input Parameters

<code>prec_type</code>	INTEGER. Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code> , where <code>p</code> is a CHARACTER and: If <code>p = 'S'</code> : Single. If <code>p = 'D'</code> : Double. If <code>p = 'I'</code> : Indigenous. If <code>p = 'X', 'E'</code> : Extra.
<code>trans_type</code>	INTEGER. Specifies the transposition operation on <code>A</code> . The value is defined by <code>ilatrans(t)</code> , where <code>t</code> is a CHARACTER and: If <code>t = 'N'</code> : No transpose. If <code>t = 'T'</code> : Transpose. If <code>t = 'C'</code> : Conjugate Transpose.
<code>n</code>	INTEGER. The number of linear equations; the order of the matrix <code>A</code> ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the matrix <code>B</code> .

a, af, b, y

REAL for `sla_gerfsx_extended`
 DOUBLE PRECISION for `dla_gerfsx_extended`
 COMPLEX for `cla_gerfsx_extended`
 DOUBLE COMPLEX for `zla_gerfsx_extended`.
Arrays: $a(1da,*)$, $af(1daf,*)$, $b(1db,*)$, $y(1dy,*)$.

The array a contains the original matrix n -by- n matrix A . The second dimension of a must be at least $\max(1, n)$.

The array af contains the factors L and U from the factorization $A = P^*L^*U$ as computed by `?getrf`. The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

The array y on entry contains the solution matrix X as computed by `?getrs`. The second dimension of y must be at least $\max(1, nrhs)$.

lda

INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.

ldaf

INTEGER. The leading dimension of the array af ; $ldaf \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices from the factorization $A = P^*L^*U$ as computed by `?getrf`; row i of the matrix was interchanged with row $ipiv(i)$.

colequ

LOGICAL. If $colequ = .TRUE.$, column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

c

REAL for single precision flavors (`sla_gerfsx_extended`,
`cla_gerfsx_extended`)
 DOUBLE PRECISION for double precision flavors (`dla_gerfsx_extended`,
`zla_gerfsx_extended`).
 c contains the column scale factors for A . If $colequ = .FALSE.$, c is not used.

If c is input, each element of c should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

ldy

INTEGER. The leading dimension of the array y ; $ldy \geq \max(1, n)$.

n_norms

INTEGER. Determines which error bounds to return. See `errs_n` and `errs_c` descriptions in *Output Arguments* section below.

If $n_norms \geq 1$, returns normwise error bounds.

If $n_norms \geq 2$, returns componentwise error bounds.

`errs_n`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION ($nrhs, n_err_bnds$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `errs_n(i, :)` corresponds to the i -th right-hand side.

The second index in `errs_n(:, err)` contains the following three fields:

`err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

`err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`errs_c`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side *i*, on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params(3) = 0.0*), then *errs_c* is not accessed. If *n_err_bnds < 3*, then at most the first *(:,n_err_bnds)* entries are returned.

The first index in *errs_c(i,:)* corresponds to the *i*-th right-hand side.

The second index in *errs_c(:,err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.
<i>err=2</i>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<i>err=3</i>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix <i>Z</i> . Let $z = s * (a * \text{diag}(x))$, where <i>x</i> is the solution for the current right-hand side and <i>s</i> scales each row of <i>a * diag(x)</i> by a power of the radix so all absolute row sums of <i>z</i> are approximately 1. Use this subroutine to set only the second field above.

<i>res, dy, y_tail</i>	REAL for <code>sla_gerfsx_extended</code> DOUBLE PRECISION for <code>dla_gerfsx_extended</code> COMPLEX for <code>cla_gerfsx_extended</code> DOUBLE COMPLEX for <code>zla_gerfsx_extended</code> . Workspace arrays of DIMENSION <i>n</i> . <i>res</i> holds the intermediate residual. <i>dy</i> holds the intermediate solution. <i>y_tail</i> holds the trailing bits of the intermediate solution.
<i>ayb</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Workspace array, DIMENSION <i>n</i> .
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>ithresh</i>	INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>errs_n</i> and <i>errs_c</i> may no longer be trustworthy.
<i>rthresh</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies $\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$ where $\text{norm}(z)$ is the infinity norm of <i>Z</i> . <i>rthresh</i> satisfies $0 < \text{rthresh} \leq 1$. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.
<i>dz_ub</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Determines when to start considering componentwise convergence. Componentwise <i>dz_ub</i> convergence is only considered after each component of the solution <i>y</i> is stable, that is, the relative change in each component is less than <i>dz_ub</i> . The default value is 0.25, requiring the first bit to be stable.

ignore_cwise LOGICAL
If .TRUE., the function ignores componentwise convergence. Default value is .FALSE.

Output Parameters

<i>y</i>	REAL for <code>sla_gerfsx_extended</code> DOUBLE PRECISION for <code>dla_gerfsx_extended</code> COMPLEX for <code>cla_gerfsx_extended</code> DOUBLE COMPLEX for <code>zla_gerfsx_extended</code> .
<i>berr_out</i>	The improved solution matrix <i>Y</i> .
<i>errs_n, errs_c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least <code>max(1, nrhs)</code> . Contains the componentwise relative backward error for right-hand-side <i>j</i> from the formula $\max(i) \left(\frac{\ res(i)\ }{\ op(A)\ \ y\ + \ B\ } \right)$ where <code>abs(z)</code> is the componentwise absolute value of the matrix or vector <i>Z</i> . This is computed by <code>?la_lin_berr</code> .
<i>info</i>	Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array <code>(1:nrhs, 2)</code> . The other elements are kept unchanged.
	INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = <i>-i</i> , the <i>i</i> -th parameter had an illegal value.

?la heamv

Computes a matrix-vector product using a Hermitian indefinite matrix to calculate error bounds.

Syntax

FORTRAN 77:

```
call cla_heamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)  
call zla_heamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_heamv routines perform a matrix-vector operation defined as

$$y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y),$$

where:

α and β are scalars,

x and y are vectors,

A is an n -by- n Hermitian matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array A is to be referenced: If <i>uplo</i> = 'BLAS_UPPER', only the upper triangular part of A is to be referenced, If <i>uplo</i> = 'BLAS_LOWER', only the lower triangular part of A is to be referenced.
<i>n</i>	INTEGER. Specifies the number of rows and columns of the matrix A . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>cla_heamv</code> DOUBLE PRECISION for <code>zla_heamv</code> Specifies the scalar α .
<i>a</i>	COMPLEX for <code>cla_heamv</code> DOUBLE COMPLEX for <code>zla_heamv</code> Array, DIMENSION (<i>lda</i> , *). Before entry, the leading m -by- n part of the array <i>a</i> must contain the matrix of coefficients. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	COMPLEX for <code>cla_heamv</code> DOUBLE COMPLEX for <code>zla_heamv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>X</i> .

<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must be non-zero.
<i>beta</i>	REAL for <code>cla_heamv</code> DOUBLE PRECISION for <code>zla_heamv</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is zero, you do not need to set <i>y</i> on input.
<i>y</i>	REAL for <code>cla_heamv</code> DOUBLE PRECISION for <code>zla_heamv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry with non-zero <i>beta</i> , the incremented array <i>y</i> must contain the vector <i>Y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must be non-zero.

Output Parameters

<i>y</i>	Updated vector <i>Y</i> .
----------	---------------------------

?la_hercond_c

Computes the infinity norm condition number of $\text{op}(A)^* \text{inv}(\text{diag}(c))$ for Hermitian indefinite matrices.

Syntax

FORTRAN 77:

```
call cla_hercond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
call zla_hercond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function computes the infinity norm condition number of

$\text{op}(A)^* \text{inv}(\text{diag}(c))$

where the *c* is a REAL vector for `cla_hercond_c` and a DOUBLE PRECISION vector for `zla_hercond_c`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
-------------	--

<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code> Array, DIMENSION (<i>lda</i> , *). On entry, the n -by- n matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $\text{lda} \geq \max(1, n)$.
<i>af</i>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code> Array, DIMENSION (<i>ldaf</i> , *). The block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by <code>?hetrf</code> . The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of the array <i>af</i> . $\text{ldaf} \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array with DIMENSION <i>n</i> . Details of the interchanges and the block structure of <i>D</i> as determined by <code>?hetrf</code> .
<i>c</i>	REAL for <code>cla_hercond_c</code> DOUBLE PRECISION for <code>zla_hercond_c</code> Array <i>c</i> with DIMENSION <i>n</i> . The vector <i>c</i> in the formula $\text{op}(A) * \text{inv}(\text{diag}(c))$.
<i>capply</i>	LOGICAL. If .TRUE., then the function uses the vector <i>c</i> from the formula $\text{op}(A) * \text{inv}(\text{diag}(c))$.
<i>work</i>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code> Array DIMENSION $2*n$. Workspace.
<i>rwork</i>	REAL for <code>cla_hercond_c</code> DOUBLE PRECISION for <code>zla_hercond_c</code> Array DIMENSION <i>n</i> . Workspace.

Output Parameters

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If $i > 0$, the <i>i</i> -th parameter is invalid.
-------------	---

`?hetrf`

?la_hercond_x

Computes the infinity norm condition number of
 $\text{op}(A) * \text{diag}(x)$ for Hermitian indefinite matrices.

Syntax

FORTRAN 77:

```
call cla_hercond_x( uplo, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
call zla_hercond_x( uplo, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the x is a COMPLEX vector for `cla_hercond_x` and a DOUBLE COMPLEX vector for `zla_hercond_x`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <code>uplo</code> = 'U', the upper triangle of A is stored, If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A; $n \geq 0$.
<code>a</code>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code> Array, DIMENSION (<code>lda, *</code>). On entry, the n -by- n matrix A. The second dimension of <code>a</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> . $\text{lda} \geq \max(1, n)$.
<code>af</code>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code> Array, DIMENSION (<code>ldaf, *</code>). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?hetrf</code> . The second dimension of <code>af</code> must be at least $\max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of the array <code>af</code> . $\text{ldaf} \geq \max(1, n)$.
<code>ipiv</code>	INTEGER. Array with DIMENSION n . Details of the interchanges and the block structure of D as determined by <code>?hetrf</code> .

<i>x</i>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code>
	Array <i>x</i> with DIMENSION <i>n</i> . The vector <i>x</i> in the formula $\text{op}(A) * \text{inv}(\text{diag}(x))$.
<i>work</i>	COMPLEX for <code>cla_hercond_c</code> DOUBLE COMPLEX for <code>zla_hercond_c</code>
	Array DIMENSION $2*n$. Workspace.
<i>rwork</i>	REAL for <code>cla_hercond_c</code> DOUBLE PRECISION for <code>zla_hercond_c</code>
	Array DIMENSION <i>n</i> . Workspace.

Output Parameters

info INTEGER.
If *info* = 0, the execution is successful.
If *i* > 0, the *i*-th parameter is invalid.

?la_herfsx_extended

Improves the computed solution to a system of linear equations for Hermitian indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.

Syntax

FORTRAN 77:

```
call cla_herfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, ipiv, colequ, c,
b, ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )
call zla_herfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, ipiv, colequ, c,
b, ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?la_herfsx_extended` subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?herfsx` routine calls `?la_herfsx_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use `?la_herfsx_extended` to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

`prec_type`

INTEGER.

Specifies the intermediate precision to be used in refinement. The value is defined by `ilaprec(p)`, where `p` is a CHARACTER and:

If `p = 'S'`: Single.

If `p = 'D'`: Double.

If `p = 'I'`: Indigenous.

If `p = 'X', 'E'`: Extra.

`uplo`

CHARACTER*1. Must be '`U`' or '`L`'.

Specifies the triangle of `A` to store:

If `uplo = 'U'`, the upper triangle of `A` is stored,

If `uplo = 'L'`, the lower triangle of `A` is stored.

`n`

INTEGER. The number of linear equations; the order of the matrix `A`; $n \geq 0$.

`nrhs`

INTEGER. The number of right-hand sides; the number of columns of the matrix `B`.

`a, af, b, y`

COMPLEX for `cla_herfsx_extended`

DOUBLE COMPLEX for `zla_herfsx_extended`.

Arrays: `a(1da,*), af(1daf,*), b(1db,*), y(1dy,*)`.

The array `a` contains the original n -by- n matrix `A`. The second dimension of `a` must be at least `max(1,n)`.

The array `af` contains the block diagonal matrix `D` and the multipliers used to obtain the factor `U` or `L` as computed by `?hetrf`. The second dimension of `af` must be at least `max(1,n)`.

The array `b` contains the right-hand-side of the matrix `B`. The second dimension of `b` must be at least `max(1,nrhs)`.

The array `y` on entry contains the solution matrix `X` as computed by `?hetrs`. The second dimension of `y` must be at least `max(1,nrhs)`.

`lda`

INTEGER. The leading dimension of the array `a`; `lda` $\geq \max(1,n)$.

`ldaf`

INTEGER. The leading dimension of the array `af`; `ldaf` $\geq \max(1,n)$.

`ipiv`

INTEGER.

Array, DIMENSION `n`. Details of the interchanges and the block structure of `D` as determined by `?hetrf`.

colequ LOGICAL. If *colequ* = .TRUE., column equilibration was done to *A* before calling this routine. This is needed to compute the solution and error bounds correctly.

c REAL for *cla_herfsx_extended*
 DOUBLE PRECISION for *zla_herfsx_extended*.
c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not used.
 If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array *b*; *ldb* $\geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; *ldy* $\geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.
 If *n_norms* ≥ 1 , returns normwise error bounds.
 If *n_norms* ≥ 2 , returns componentwise error bounds.

err_bnds_norm REAL for *cla_herfsx_extended*
 DOUBLE PRECISION for *zla_herfsx_extended*.
 Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.
 Normwise relative error in the *i*-th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.
 The first index in *err_bnds_norm(i, :)* corresponds to the *i*-th right-hand side.
 The second index in *err_bnds_norm(:, err)* contains the following three fields:

<i>err=1</i>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold <i>sqrt(n) * slamch(ε)</i> for <i>cla_herfsx_extended</i> and <i>sqrt(n) * dlamch(ε)</i> for <i>zla_herfsx_extended</i> .
--------------	---

`err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `cla_herfsx_extended` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zla_herfsx_extended`. This error bound should only be trusted if the previous boolean is true.

`err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `cla_herfsx_extended` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zla_herfsx_extended` to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for `cla_herfsx_extended`
DOUBLE PRECISION for `zla_herfsx_extended`.
Array, DIMENSION ($nrhs, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>cla_herfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>zla_herfsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>cla_herfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>zla_herfsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>cla_herfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>zla_herfsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z . Let $z = s^* (a^* \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^* \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.
<code>res, dy, y_tail</code>	COMPLEX for <code>cla_herfsx_extended</code> DOUBLE COMPLEX for <code>zla_herfsx_extended</code> . Workspace arrays of DIMENSION n . <code>res</code> holds the intermediate residual. <code>dy</code> holds the intermediate solution. <code>y_tail</code> holds the trailing bits of the intermediate solution.
<code>ayb</code>	REAL for <code>cla_herfsx_extended</code> DOUBLE PRECISION for <code>zla_herfsx_extended</code> . Workspace array, DIMENSION n .
<code>rcond</code>	REAL for <code>cla_herfsx_extended</code> DOUBLE PRECISION for <code>zla_herfsx_extended</code> .

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

rthresh

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < rthresh * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Determines when to start considering componentwise convergence.

Componentwise *dz_ub* convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If .TRUE., the function ignores componentwise convergence. Default value is .FALSE..

Output Parameters

y

COMPLEX for `cla_herfsx_extended`

DOUBLE COMPLEX for `zla_herfsx_extended`.

The improved solution matrix Y .

berr_out

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Array, DIMENSION $nrhs$. *berr_out*(j) contains the componentwise relative backward error for right-hand-side j from the formula

$$\max(i) (\text{abs}(\text{res}(i)) / (\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B))(i))$$

where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z . This is computed by `?la_lin_berr`.

`err_bnds_norm`,
`err_bnds_comp`

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array (`1:nrhs, 2`). The other elements are kept unchanged.

`info`

INTEGER. If $info = 0$, the execution is successful. The solution to every right-hand side is guaranteed.
If $info = -i$, the i -th parameter had an illegal value.

?la_herpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a Hermitian indefinite matrix.

Syntax

FORTRAN 77:

```
call cla_herpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call zla_herpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?la_herpvgrw` routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element norm* is used. If this is much less than 1, the stability of the *LU* factorization of the equilibrated matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable.

Input Parameters

`uplo`

CHARACTER*1. Must be '`U`' or '`L`'.
Specifies the triangle of A to store:
If $uplo = 'U'$, the upper triangle of A is stored,
If $uplo = 'L'$, the lower triangle of A is stored.

`n`

INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.

<i>info</i>	INTEGER. The value of INFO returned from ?hetrf, that is, the pivot in column <i>info</i> is exactly 0.
<i>a, af</i>	COMPLEX for cla_herpgrw DOUBLE COMPLEX for zla_herpgrw. Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *). <i>a</i> contains the n -by- n matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>af</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?hetrf. The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of array <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of array <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION n . Details of the interchanges and the block structure of <i>D</i> as determined by ?hetrf.
<i>work</i>	REAL for cla_herpgrw DOUBLE PRECISION for zla_herpgrw. Array, DIMENSION $2*n$. Workspace.

See Also

?hetrf

?la_lin_berr

Computes component-wise relative backward error.

Syntax

FORTRAN 77:

```
call sla_lin_berr(n, nz, nrhs, res, ayb, berr)
call dla_lin_berr(n, nz, nrhs, res, ayb, berr)
call cla_lin_berr(n, nz, nrhs, res, ayb, berr)
call zla_lin_berr(n, nz, nrhs, res, ayb, berr)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_lin_berr computes a component-wise relative backward error from the formula:

$$\max(i) (\text{abs}(R(i)) / (\text{abs}(\text{op}(A_s)) * \text{abs}(Y) + \text{abs}(B_s))) (i)$$

where $\text{abs}(Z)$ is the component-wise value of the matrix or vector *Z*.

Input Parameters

<i>n</i>	INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.
<i>nz</i>	INTEGER. The parameter for guarding against spuriously zero residuals. $(nz+1) * \text{slamch}(\text{'Safe minimum'})$ is added to $R(i)$ in the numerator of the relative backward error formula. The default value is n .
<i>nrhs</i>	INTEGER. Number of right-hand sides, the number of columns in the matrices AYB , RES , and $BERR$; $nrhs \geq 0$.
<i>res, ayb</i>	REAL for <code>sla_lin_berr</code> , <code>cla_lin_berr</code> DOUBLE PRECISION for <code>dla_lin_berr</code> , <code>zla_lin_berr</code> Arrays, DIMENSION ($n, nrhs$). <i>res</i> is the residual matrix, that is, the matrix R in the relative backward error formula. <i>ayb</i> is the denominator of that formula, that is, the matrix $\text{abs}(op(A_s)) * \text{abs}(Y) + \text{abs}(B_s)$. The matrices A , Y , and B are from iterative refinement. See description of <code>?la_gerfsx_extended</code> .

Output Parameters

<i>berr</i>	REAL for <code>sla_lin_berr</code> DOUBLE PRECISION for <code>dla_lin_berr</code> COMPLEX for <code>cla_lin_berr</code> DOUBLE COMPLEX for <code>zla_lin_berr</code> The component-wise relative backward error.

?la_porcond

Estimates the Skeel condition number for a symmetric positive-definite matrix.

Syntax

FORTRAN 77:

```
call sla_porcond( uplo, n, a, lda, af, ldaf, cmode, c, info, work, iwork )
call dla_porcond( uplo, n, a, lda, af, ldaf, cmode, c, info, work, iwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function estimates the Skeel condition number of

`op(A) * op2(C)`

where

the `cmode` parameter determines `op2` as follows:

<code>cmode Value</code>	<code>op2(C)</code>
1	C
0	I
-1	$\text{inv}(C)$

The Skeel condition number

`cond(A) = norminf(|inv(A)| |A|)`

is computed by computing scaling factors R such that

`diag(R)*A*op2(C)`

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. Specifies the triangle of A to store: If <code>uplo</code> = ' <code>U</code> ', the upper triangle of A is stored, If <code>uplo</code> = ' <code>L</code> ', the lower triangle of A is stored.
<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<code>a, af, c, work</code>	REAL for <code>sla_porcond</code> DOUBLE PRECISION for <code>dla_porcond</code> Arrays: <code>a (lda,*)</code> contains the n -by- n matrix A . <code>af (ldaf,*)</code> contains the triangular factor <code>L</code> or <code>U</code> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, as computed by <code>?potrf</code> . <code>c, DIMENSION n</code> . The vector C in the formula <code>op(A) * op2(C)</code> . <code>work</code> is a workspace array of DIMENSION $(3*n)$. The second dimension of <code>a</code> and <code>af</code> must be at least <code>max(1, n)</code> .
<code>lda</code>	INTEGER. The leading dimension of the array <code>ab</code> . $lda \geq \max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of <code>af</code> . $ldaf \geq \max(1, n)$.
<code>cmode</code>	INTEGER. Determines <code>op2(C)</code> in the formula <code>op(A) * op2(C)</code> as follows: If <code>cmode</code> = 1, <code>op2(C) = C</code> . If <code>cmode</code> = 0, <code>op2(C) = I</code> .

If $cmode = -1$, $\text{op2}(C) = \text{inv}(C)$.
 $iwork$ INTEGER. Workspace array with DIMENSION n .

Output Parameters

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $i > 0$, the i -th parameter is invalid.

See Also

?potrf

?la_porcond_c

Computes the infinity norm condition number of
 $\text{op}(A)^*\text{inv}(\text{diag}(c))$ for Hermitian positive-definite
matrices.

Syntax

FORTRAN 77:

```
call cla_porcond_c( uplo, n, a, lda, af, ldaf, c, capply, info, work, rwork )
call zla_porcond_c( uplo, n, a, lda, af, ldaf, c, capply, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{inv}(\text{diag}(c))$

where the c is a REAL vector for `cla_porcond_c` and a DOUBLE PRECISION vector for `zla_porcond_c`.

Input Parameters

$uplo$ CHARACTER*1. Must be 'U' or 'L'.
Specifies the triangle of A to store:
If $uplo = 'U'$, the upper triangle of A is stored,
If $uplo = 'L'$, the lower triangle of A is stored.

n INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.

a COMPLEX for `cla_porcond_c`
DOUBLE COMPLEX for `zla_porcond_c`
Array, DIMENSION ($lda, *$). On entry, the n -by- n matrix A . The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

af COMPLEX for `cla_porcond_c`
 DOUBLE COMPLEX for `zla_porcond_c`
 Array, DIMENSION (*ldaf*, *). The triangular factor L or U from the Cholesky factorization
 $A = U^H * U$ or $A = L * L^H$,
 as computed by `?potrf`.
 The second dimension of *af* must be at least $\max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*. $ldaf \geq \max(1, n)$.

c REAL for `cla_porcond_c`
 DOUBLE PRECISION for `zla_porcond_c`
 Array *c* with DIMENSION *n*. The vector *c* in the formula
 $op(A) * \text{inv}(\text{diag}(c))$.

capply LOGICAL. If .TRUE., then the function uses the vector *c* from the formula
 $op(A) * \text{inv}(\text{diag}(c))$.

work COMPLEX for `cla_porcond_c`
 DOUBLE COMPLEX for `zla_porcond_c`
 Array DIMENSION $2*n$. Workspace.

rwork REAL for `cla_porcond_c`
 DOUBLE PRECISION for `zla_porcond_c`
 Array DIMENSION *n*. Workspace.

Output Parameters

info INTEGER.
 If *info* = 0, the execution is successful.
 If *i* > 0, the *i*-th parameter is invalid.

See Also

`?potrf`

`?la_porcond_x`

Computes the infinity norm condition number of
 $op(A)*\text{diag}(x)$ for Hermitian positive-definite matrices.

Syntax

FORTRAN 77:

```
call cla_porcond_x( uplo, n, a, lda, af, ldaf, x, info, work, rwork )
call zla_porcond_x( uplo, n, a, lda, af, ldaf, x, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the x is a COMPLEX vector for `cla_porcond_x` and a DOUBLE COMPLEX vector for `zla_porcond_x`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <code>uplo</code> = 'U', the upper triangle of A is stored, If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<code>a</code>	COMPLEX for <code>cla_porcond_c</code> DOUBLE COMPLEX for <code>zla_porcond_c</code> Array, DIMENSION (<code>lda, *</code>). On entry, the n -by- n matrix A . The second dimension of <code>a</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> . $\text{lda} \geq \max(1, n)$.
<code>af</code>	COMPLEX for <code>cla_porcond_c</code> DOUBLE COMPLEX for <code>zla_porcond_c</code> Array, DIMENSION (<code>ldaf, *</code>). The triangular factor L or U from the Cholesky factorization $A = U^H * U$ or $A = L * L^H$, as computed by <code>?potrf</code> . The second dimension of <code>af</code> must be at least $\max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of the array <code>af</code> . $\text{ldaf} \geq \max(1, n)$.
<code>x</code>	COMPLEX for <code>cla_porcond_c</code> DOUBLE COMPLEX for <code>zla_porcond_c</code> Array <code>x</code> with DIMENSION n . The vector x in the formula $\text{op}(A) * \text{inv}(\text{diag}(x))$.
<code>work</code>	COMPLEX for <code>cla_porcond_c</code> DOUBLE COMPLEX for <code>zla_porcond_c</code> Array DIMENSION $2*n$. Workspace.
<code>rwork</code>	REAL for <code>cla_porcond_c</code>

DOUBLE PRECISION for zla_porcond_c
Array DIMENSION n . Workspace.

Output Parameters

info INTEGER.
If $info = 0$, the execution is successful.
If $i > 0$, the i -th parameter is invalid.

?la_porfsx_extended

Improves the computed solution to a system of linear equations for symmetric or Hermitian positive-definite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.

Syntax

FORTRAN 77:

```
call sla_porfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, colequ, c, b,
                           ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
                           rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call dla_porfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, colequ, c, b,
                           ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
                           rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call cla_porfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, colequ, c, b,
                           ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
                           rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call zla_porfsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, colequ, c, b,
                           ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
                           rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_porfsx_extended subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The ?herfsx routine calls ?la_porfsx_extended to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

Use ?la_porfsx_extended to set only the second fields of *err_bnds_norm* and *err_bnds_comp*.

Input Parameters

<i>prec_type</i>	INTEGER. Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code> , where <i>p</i> is a CHARACTER and: If <i>p</i> = 'S': Single. If <i>p</i> = 'D': Double. If <i>p</i> = 'I': Indigenous. If <i>p</i> = 'X', 'E': Extra.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix <i>A</i> ; <i>n</i> ≥ 0.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i> .
<i>a</i> , <i>af</i> , <i>b</i> , <i>y</i>	REAL for <code>sla_porfsx_extended</code> DOUBLE PRECISION for <code>dla_porfsx_extended</code> COMPLEX for <code>cla_porfsx_extended</code> DOUBLE COMPLEX for <code>zla_porfsx_extended</code> . Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *), <i>b</i> (<i>ldb</i> , *), <i>y</i> (<i>ldy</i> , *). The array <i>a</i> contains the original <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least <code>max(1, n)</code> . The array <i>af</i> contains the triangular factor <i>L</i> or <i>U</i> from the Cholesky factorization as computed by <code>?potrf</code> : $A = U^T * U$ or $A = L * L^T$ for real flavors, $A = U^H * U$ or $A = L * L^H$ for complex flavors. The second dimension of <i>af</i> must be at least <code>max(1, n)</code> . The array <i>b</i> contains the right-hand-side of the matrix <i>B</i> . The second dimension of <i>b</i> must be at least <code>max(1, nrhs)</code> . The array <i>y</i> on entry contains the solution matrix <i>X</i> as computed by <code>?potrs</code> . The second dimension of <i>y</i> must be at least <code>max(1, nrhs)</code> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; <i>lda</i> ≥ <code>max(1, n)</code> .
<i>ldaf</i>	INTEGER. The leading dimension of the array <i>af</i> ; <i>ldaf</i> ≥ <code>max(1, n)</code> .
<i>colequ</i>	LOGICAL. If <i>colequ</i> = .TRUE., column equilibration was done to <i>A</i> before calling this routine. This is needed to compute the solution and error bounds correctly.
<i>c</i>	REAL for <code>sla_porfsx_extended</code> and <code>cla_porfsx_extended</code>

DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

`c` contains the column scale factors for `A`. If `colequ = .FALSE.`, `c` is not used.

If `c` is input, each element of `c` should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

`ldb`

INTEGER. The leading dimension of the array `b`; $ldb \geq \max(1, n)$.

`ldy`

INTEGER. The leading dimension of the array `y`; $ldy \geq \max(1, n)$.

`n_norms`

INTEGER. Determines which error bounds to return. See `err_bnds_norm` and `err_bnds_comp` descriptions in *Output Arguments* section below.

If $n_norms \geq 1$, returns normwise error bounds.

If $n_norms \geq 2$, returns componentwise error bounds.

`err_bnds_norm`

REAL for `sla_porfsx_extended` and `cla_porfsx_extended`
 DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Array, DIMENSION (`nrhs, n_err_bnds`). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.

Normwise relative error in the i -th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i,:)` corresponds to the i -th right-hand side.

The second index in `err_bnds_norm(:,err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\varepsilon)$ for `sla_porfsx_extended/cla_porfsx_extended` and $\text{sqrt}(n) * \text{dlamch}(\varepsilon)$ for `dla_porfsx_extended/zla_porfsx_extended`.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is

greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$
 for
 $\text{sla_porfsx_extended}/\text{cla_porfsx_extended}$
and $\sqrt{n} * \text{dlamch}(\epsilon)$ for
 $\text{dla_porfsx_extended}/\text{zla_porfsx_extended}$. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number.
 Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for
 $\text{sla_porfsx_extended}/\text{cla_porfsx_extended}$
and $\sqrt{n} * \text{dlamch}(\epsilon)$ for
 $\text{dla_porfsx_extended}/\text{zla_porfsx_extended}$ to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for $\text{sla_porfsx_extended}$ and $\text{cla_porfsx_extended}$
 DOUBLE PRECISION for $\text{dla_porfsx_extended}$ and $\text{zla_porfsx_extended}$.

Array, DIMENSION ($\text{nrhs}, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}}_{ji} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bbound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z . Let $z = s^* (a^* \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a^* \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.

```
res, dy, y_tail
REAL for sla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended
COMPLEX for cla_porfsx_extended
DOUBLE COMPLEX for zla_porfsx_extended.

Workspace arrays of DIMENSION n.
res holds the intermediate residual.
dy holds the intermediate solution.
y_tail holds the trailing bits of the intermediate solution.
```

`ayb` REAL for `sla_porfsx_extended` and `cla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Workspace array, DIMENSION n .

rcond REAL for `sla_porfsx_extended` and `cla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

rthresh REAL for `sla_porfsx_extended` and `cla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < rthresh * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub REAL for `sla_porfsx_extended` and `cla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Determines when to start considering componentwise convergence. Componentwise *dz_ub* convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise LOGICAL

If .TRUE., the function ignores componentwise convergence. Default value is .FALSE..

Output Parameters

y REAL for `sla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended`
 COMPLEX for `cla_porfsx_extended`
 DOUBLE COMPLEX for `zla_porfsx_extended`.

The improved solution matrix Y .

`berr_out`

REAL for `sla_porfsx_extended` and `cla_porfsx_extended`
 DOUBLE PRECISION for `dla_porfsx_extended` and
`zla_porfsx_extended`.

Array, DIMENSION $nrhs$. `berr_out(j)` contains the componentwise relative backward error for right-hand-side j from the formula

$$\max(i) \left(\frac{\text{abs}(\text{res}(i))}{\left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right)(i)} \right)$$

where `abs(z)` is the componentwise absolute value of the matrix or vector Z . This is computed by `?la_lin_berr`.

`err_bnds_norm`,
`err_bnds_comp`

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array ($1:nrhs, 2$). The other elements are kept unchanged.

`info`

INTEGER. If $info = 0$, the execution is successful. The solution to every right-hand side is guaranteed.
 If $info = -i$, the i -th parameter had an illegal value.

?la_porpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a symmetric or Hermitian positive-definite matrix.

Syntax

FORTRAN 77:

```
call sla_porpvgrw( uplo, ncols, a, lda, af, ldaf, work )
call dla_porpvgrw( uplo, ncols, a, lda, af, ldaf, work )
call cla_porpvgrw( uplo, ncols, a, lda, af, ldaf, work )
call zla_porpvgrw( uplo, ncols, a, lda, af, ldaf, work )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?la_porpvgrw` routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element norm* is used. If this is much less than 1, the stability of the *LU* factorization of the equilibrated matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Specifies the triangle of A to store: If <code>uplo</code> = ' <code>U</code> ', the upper triangle of A is stored, If <code>uplo</code> = ' <code>L</code> ', the lower triangle of A is stored.
<code>ncols</code>	INTEGER. The number of columns of the matrix A ; $ncols \geq 0$.
<code>a</code> , <code>af</code>	REAL for <code>sla_porpvgrw</code> DOUBLE PRECISION for <code>dla_porpvgrw</code> COMPLEX for <code>cla_porpvgrw</code> DOUBLE COMPLEX for <code>zla_porpvgrw</code> . Arrays: $a(1:lda, *)$, $af(1:ldaf, *)$. The array <code>a</code> contains the input n -by- n matrix A . The second dimension of <code>a</code> must be at least $\max(1, n)$. The array <code>af</code> contains the triangular factor <code>L</code> or <code>U</code> from the Cholesky factorization as computed by <code>?potrf</code> : $A = U^T * U$ or $A = L * L^T$ for real flavors, $A = U^H * U$ or $A = L * L^H$ for complex flavors. The second dimension of <code>af</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of <code>a</code> ; $lda \geq \max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of <code>af</code> ; $ldaf \geq \max(1, n)$.
<code>work</code>	REAL for <code>sla_porpvgrw</code> and <code>cla_porpvgrw</code> DOUBLE PRECISION for <code>dla_porpvgrw</code> and <code>zla_porpvgrw</code> . Workspace array, dimension $2*n$.

See Also

`?potrf`

`?laqhe`

Scales a Hermitian matrix.

Syntax

```
call claqhe( uplo, n, a, lda, s, scond, amax, equed )
call zlaqhe( uplo, n, a, lda, s, scond, amax, equed )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine equilibrates a Hermitian matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether to store the upper or lower part of the Hermitian matrix A . If <i>uplo</i> = 'U', the upper triangular part of A ; if <i>uplo</i> = 'L', the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	COMPLEX for claqhe DOUBLE COMPLEX for zlaghe Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the Hermitian matrix A . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of matrix A and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of matrix A and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(n, 1)$.
<i>s</i>	REAL for claqhe DOUBLE PRECISION for zlaghe Array, DIMENSION (<i>n</i>). The scale factors for A .
<i>scond</i>	REAL for claqhe DOUBLE PRECISION for zlaghe Ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for claqhe DOUBLE PRECISION for zlaghe Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	If <i>equed</i> = 'Y', <i>a</i> contains the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$.
----------	--

equed CHARACTER*1.

Specifies whether or not equilibration was done.

If `eqed = 'N'`: No equilibration.

If `equed = 'Y'`: Equilibration was done, that is, A has been replaced by $\text{diag}(s)^*A^*\text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*. The parameter *thresh* is a threshold value used to decide if scaling should be done based on the ratio of the scaling factors. If $scond < thresh$, scaling is done.

The `large` and `small` parameters are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If `amax > large` or `amax < small`, scaling is done.

?laghp

Scales a Hermitian matrix stored in packed form.

Syntax

```
call claqhp( uplo, n, ap, s, scond, amax, equed )
call zlaqhp( uplo, n, ap, s, scond, amax, equed )
```

Include Files

- Fortran: mkl.fi
 - C: mkl.h

Description

The routine equilibrates a Hermitian matrix A using the scaling factors in the vector s .

Input Parameters

uplo CHARACTER*1.

Specifies whether to store the upper or lower part of the Hermitian matrix A .

If $\text{uplo} = \text{'U'}$, the upper triangular part of A ;

if $uplo = 'L'$, the lower triangular part of A .

$$n \geq 0.$$

ap COMPLEX for claghp

DOUBLE COMPLEX for zlaqhp

Array, DIMENSION ($n*(n+1)/2$). The Hermitian matrix A.

- If $uplo = 'U'$, the upper triangular part of the Hermitian matrix A is stored in the packed array ap as follows:

$$ap(i + (\lceil j-1 \rceil) * \lceil j/2 \rceil) = A(i, j) \text{ for } 1 \leq i \leq j.$$

- If $uplo = 'L'$, the lower triangular part of Hermitian matrix A is stored in the packed array ap as follows:

$$ap(i + (j-1)*(2n-j)/2) = A(i, j) \text{ for } j \leq i \leq n.$$

*s*REAL for `claqhp`DOUBLE PRECISION for `zlaqhp`Array, DIMENSION (*n*). The scale factors for A .*scond*REAL for `claqhp`DOUBLE PRECISION for `zlaqhp`Ratio of the smallest $s(i)$ to the largest $s(i)$.*amax*REAL for `claqhp`DOUBLE PRECISION for `zlaqhp`

Absolute value of largest matrix entry.

Output Parameters

*a*If $equed = 'Y'$, *a* contains the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$ in the same storage format as on input.*equed*

CHARACTER*1.

Specifies whether or not equilibration was done.

If $equed = 'N'$: No equilibration.If $equed = 'Y'$: Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*. The parameter *thresh* is a threshold value used to decide if scaling should be done based on the ratio of the scaling factors. If $scond < \text{thresh}$, scaling is done.

The *large* and *small* parameters are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > \text{large}$ or $amax < \text{small}$, scaling is done.

?larcm

Multiples a square real matrix by a complex matrix.

Syntax

```
call clarcm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

```
call zlarcm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine performs a simple matrix-matrix multiplication of the form

$$C = A^*B,$$

where A is m -by- m and real, B is m -by- n and complex, C is m -by- n and complex.

Input Parameters

m	INTEGER. The number of rows and columns of the matrix A and of the number of rows of the matrix C ($m \geq 0$).
n	INTEGER. The number of columns of the matrix B and the number of columns of the matrix C ($n \geq 0$).
a	REAL for clarcm DOUBLE PRECISION for zlarcm Array, DIMENSION (lda, m). Contains the m -by- m matrix A .
lda	INTEGER. The leading dimension of the array a , $lda \geq \max(1, m)$.
b	COMPLEX for clarcm DOUBLE COMPLEX for zlarcm Array, DIMENSION (ldb, n). Contains the m -by- n matrix B .
ldb	INTEGER. The leading dimension of the array b , $ldb \geq \max(1, n)$.
ldc	INTEGER. The leading dimension of the output array c , $ldc \geq \max(1, m)$.
$rwork$	REAL for clarcm DOUBLE PRECISION for zlarcm Workspace array, DIMENSION ($2*m*n$).

Output Parameters

c	COMPLEX for clarcm DOUBLE COMPLEX for zlarcm Array, DIMENSION (ldc, n). Contains the m -by- n matrix C .
-----	--

?la_gerpvgew

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a general matrix.

Syntax

FORTRAN 77:

```
call sla_gerpvgew( n, ncols, a, lda, af, ldaf )
call dla_gerpvgew( n, ncols, a, lda, af, ldaf )
```

```
call cla_gerpvgrw( n, ncols, a, lda, af, ldaf )
call zla_gerpvgrw( n, ncols, a, lda, af, ldaf )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_gerpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the equilibrated matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<i>n</i>	INTEGER. The number of linear equations, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>ncols</i>	INTEGER. The number of columns of the matrix <i>A</i> ; $ncols \geq 0$.
<i>a</i> , <i>af</i>	REAL for sla_gerpvgrw DOUBLE PRECISION for dla_gerpvgrw COMPLEX for cla_gerpvgrw DOUBLE COMPLEX for zla_gerpvgrw. Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *).
	The array <i>a</i> contains the input <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>af</i> contains the factors L and U from the factorization triangular factor L or U from the Cholesky factorization $A = P^*L^*U$ as computed by ?getrf. The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.

?getrf

?larscl2

Performs reciprocal diagonal scaling on a vector.

Syntax

FORTRAN 77:

```
call slarscl2(m, n, d, x, ldx)
call dlarscl2(m, n, d, x, ldx)
call clarscl2(m, n, d, x, ldx)
call zlarscl2(m, n, d, x, ldx)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?larscl2 routines perform reciprocal diagonal scaling on a vector

$$x := D^{-1} \cdot x,$$

where:

x is a vector, and

D is a diagonal matrix.

Input Parameters

m	INTEGER. Specifies the number of rows of the matrix D and the number of elements of the vector x . The value of m must be at least zero.
n	INTEGER. The number of columns of D and x . The value of n must be at least zero.
d	REAL for slarscl2 and clarscl2. DOUBLE PRECISION for dlarscl2 and zlarscl2. Array, DIMENSION m . Diagonal matrix D stored as a vector of length m .
x	REAL for slarscl2. DOUBLE PRECISION for dlarscl2. COMPLEX for clarscl2. DOUBLE COMPLEX for zlarscl2. Array, DIMENSION ($l dx, n$). The vector x to scale by D .
$l dx$	INTEGER. The leading dimension of the vector x . The value of $l dx$ must be at least zero.

Output Parameters

x	Scaled vector x .
-----	---------------------

?lascl2

Performs diagonal scaling on a vector.

Syntax

FORTRAN 77:

```
call slascl2(m, n, d, x, ldx)
call dlascl2(m, n, d, x, ldx)
call clascl2(m, n, d, x, ldx)
call zlascl2(m, n, d, x, ldx)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?lascl2 routines perform diagonal scaling on a vector

$x := D \cdot x$,

where:

x is a vector, and

D is a diagonal matrix.

Input Parameters

m	INTEGER. Specifies the number of rows of the matrix D and the number of elements of the vector x . The value of m must be at least zero.
n	INTEGER. The number of columns of D and x . The value of n must be at least zero.
d	REAL for slascl2 and clascl2. DOUBLE PRECISION for dlascl2 and zlascl2. Array, DIMENSION m . Diagonal matrix D stored as a vector of length m .
x	REAL for slascl2. DOUBLE PRECISION for dlascl2. COMPLEX for clascl2. DOUBLE COMPLEX for zlascl2. Array, DIMENSION ($l dx, n$). The vector x to scale by D .
$l dx$	INTEGER. The leading dimension of the vector x . The value of $l dx$ must be at least zero.

Output Parameters

x	Scaled vector x .
-----	---------------------

?la_syamv

Computes a matrix-vector product using a symmetric indefinite matrix to calculate error bounds.

Syntax

FORTRAN 77:

```
call sla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call dla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call cla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

```
call zla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_syamv routines perform a matrix-vector operation defined as

$$y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y),$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *n*-by-*n* Hermitian matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the array *A* is to be referenced:

If *uplo* = 'BLAS_UPPER', only the upper triangular part of *A* is to be referenced,

If *uplo* = 'BLAS_LOWER', only the lower triangular part of *A* is to be referenced.

n

INTEGER. Specifies the number of rows and columns of the matrix *A*. The value of *n* must be at least zero.

alpha

REAL for *sla_syamv* and *cla_syamv*

DOUBLE PRECISION for *dla_syamv* and *zla_syamv*.

Specifies the scalar *alpha*.

a

REAL for *sla_syamv*

DOUBLE PRECISION for *dla_syamv*

COMPLEX for *cla_syamv*

DOUBLE COMPLEX for *zla_syamv*.

Array, DIMENSION (*lda*, *). Before entry, the leading *m*-by-*n* part of the array *a* must contain the matrix of coefficients. The second dimension of *a* must be at least $\max(1, n)$.

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, n)$.

x

REAL for *sla_syamv*

DOUBLE PRECISION for `dla_syamv`
 COMPLEX for `cla_syamv`

DOUBLE COMPLEX for `zla_syamv`.

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the vector X .

incx INTEGER. Specifies the increment for the elements of x .

The value of *incx* must be non-zero.

beta REAL for `sla_syamv` and `cla_syamv`

DOUBLE PRECISION for `dla_syamv` and `zla_syamv`

Specifies the scalar *beta*. When *beta* is zero, you do not need to set y on input.

y REAL for `sla_syamv` and `cla_syamv`

DOUBLE PRECISION for `dla_syamv` and `zla_syamv`

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry with non-zero *beta*, the incremented array y must contain the vector Y .

incy INTEGER. Specifies the increment for the elements of y .

The value of *incy* must be non-zero.

Output Parameters

y Updated vector Y .

?la_syrcond

Estimates the Skeel condition number for a symmetric indefinite matrix.

Syntax

FORTRAN 77:

```
call sla_syrcond( uplo, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
call dla_syrcond( uplo, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function estimates the Skeel condition number of

$\text{op}(A) * \text{op}2(C)$

where

the *cmode* parameter determines $\text{op}2$ as follows:

<i>cmode</i> Value	<i>op2(C)</i>
1	C
0	I
-1	$\text{inv}(C)$

The Skeel condition number

`cond(A) = norminf(|inv(A)| |A|)`

is computed by computing scaling factors R such that

`diag(R) * A * op2(C)`

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <i>uplo</i> = 'U', the upper triangle of A is stored, If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<i>a, af, c, work</i>	REAL for <code>sla_syrcond</code> DOUBLE PRECISION for <code>dla_syrcond</code> Arrays: <i>ab</i> (<i>lda,*</i>) contains the n -by- n matrix A . <i>af</i> (<i>ldaf,*</i>) contains the The block diagonal matrix D and the multipliers used to obtain the factor L or U as computed by <code>?sytrf</code> . The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$. <i>c</i> , DIMENSION n . The vector C in the formula $\text{op}(A) * \text{op2}(C)$. <i>work</i> is a workspace array of DIMENSION $(3*n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>ab</i> . $\text{lda} \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> . $\text{ldaf} \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array with DIMENSION n . Details of the interchanges and the block structure of D as determined by <code>?sytrf</code> .
<i>cmode</i>	INTEGER. Determines <i>op2(C)</i> in the formula $\text{op}(A) * \text{op2}(C)$ as follows: If <i>cmode</i> = 1, $\text{op2}(C) = C$. If <i>cmode</i> = 0, $\text{op2}(C) = I$. If <i>cmode</i> = -1, $\text{op2}(C) = \text{inv}(C)$.

iwork INTEGER. Workspace array with DIMENSION n .

Output Parameters

info INTEGER.

If $info = 0$, the execution is successful.

If $i > 0$, the i -th parameter is invalid.

See Also

[?sytrf](#)

?la_syrcond_c

Computes the infinity norm condition number of $\text{op}(A) * \text{inv}(\text{diag}(c))$ for symmetric indefinite matrices.

Syntax

FORTRAN 77:

```
call cla_syrcond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
call zla_syrcond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{inv}(\text{diag}(c))$

where the c is a REAL vector for `cla_syrcond_c` and a DOUBLE PRECISION vector for `zla_syrcond_c`.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.

Specifies the triangle of A to store:

If $uplo = 'U'$, the upper triangle of A is stored,

If $uplo = 'L'$, the lower triangle of A is stored.

n INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.

a COMPLEX for `cla_syrcond_c`

DOUBLE COMPLEX for `zla_syrcond_c`

Array, DIMENSION ($lda, *$). On entry, the n -by- n matrix A . The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

af COMPLEX for `cla_syrcond_c`

DOUBLE COMPLEX for zla_syrcond_c
 Array, DIMENSION (*ldaf*, *). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?sytrf. The second dimension of *af* must be at least $\max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*. $ldaf \geq \max(1, n)$.

ipiv INTEGER.
 Array with DIMENSION *n*. Details of the interchanges and the block structure of D as determined by ?sytrf.

c
 REAL for cla_syrcond_c
 DOUBLE PRECISION for zla_syrcond_c
 Array *c* with DIMENSION *n*. The vector *c* in the formula
 $op(A) * \text{inv}(\text{diag}(c))$.

capply LOGICAL. If .TRUE., then the function uses the vector *c* from the formula
 $op(A) * \text{inv}(\text{diag}(c))$.

work COMPLEX for cla_syrcond_c
 DOUBLE COMPLEX for zla_syrcond_c
 Array DIMENSION $2*n$. Workspace.

rwork REAL for cla_syrcond_c
 DOUBLE PRECISION for zla_syrcond_c
 Array DIMENSION *n*. Workspace.

Output Parameters

info INTEGER.
 If *info* = 0, the execution is successful.
 If *i* > 0, the *i*-th parameter is invalid.

See Also

?sytrf

?la_syrcond_x

Computes the infinity norm condition number of $op(A)*\text{diag}(x)$ for symmetric indefinite matrices.

Syntax

FORTRAN 77:

```
call cla_syrcond_x( uplo, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
call zla_syrcond_x( uplo, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the x is a COMPLEX vector for `cla_syrcond_x` and a DOUBLE COMPLEX vector for `zla_syrcond_x`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <code>uplo</code> = 'U', the upper triangle of A is stored, If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A; $n \geq 0$.
<code>a</code>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array, DIMENSION (<code>lda, *</code>). On entry, the n -by- n matrix A. The second dimension of <code>a</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> . $\text{lda} \geq \max(1, n)$.
<code>af</code>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array, DIMENSION (<code>ldaf, *</code>). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?sytrf</code> . The second dimension of <code>af</code> must be at least $\max(1, n)$.
<code>ldaf</code>	INTEGER. The leading dimension of the array <code>af</code> . $\text{ldaf} \geq \max(1, n)$.
<code>ipiv</code>	INTEGER. Array with DIMENSION n . Details of the interchanges and the block structure of D as determined by <code>?sytrf</code> .
<code>x</code>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array <code>x</code> with DIMENSION n . The vector x in the formula $\text{op}(A) * \text{inv}(\text{diag}(x))$.
<code>work</code>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array DIMENSION $2*n$. Workspace.

rwork REAL for `cla_syrcond_c`
 DOUBLE PRECISION for `zla_syrcond_c`
 Array DIMENSION *n*. Workspace.

Output Parameters

info INTEGER.
 If *info* = 0, the execution is successful.
 If *i* > 0, the *i*-th parameter is invalid.

See Also

[?sytrf](#)

?la_syrfxsx_extended

Improves the computed solution to a system of linear equations for symmetric indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.

Syntax

FORTRAN 77:

```
call sla_syrfxsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, ipiv, colequ, c,
b, ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,

call cla_syrfxsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, ipiv, colequ, c,
b, ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )

call zla_syrfxsx_extended( prec_type, uplo, n, nrhs, a, lda, af, ldaf, ipiv, colequ, c,
b, ldb, y, ldy, berr_out, n_norms, err_bnds_norm, err_bnds_comp, res, ayb, dy, y_tail,
rcond, ithresh, rthresh, dz_ub, ignore_cwise, info )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The `?la_syrfxsx_extended` subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?syrfxsx` routine calls `?la_syrfxsx_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use `?la_syrfxsx_extended` to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

<i>prec_type</i>	INTEGER. Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code> , where <i>p</i> is a CHARACTER and: If <i>p</i> = 'S': Single. If <i>p</i> = 'D': Double. If <i>p</i> = 'I': Indigenous. If <i>p</i> = 'X', 'E': Extra.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The number of linear equations; the order of the matrix <i>A</i> ; <i>n</i> ≥ 0.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i> .
<i>a</i> , <i>af</i> , <i>b</i> , <i>y</i>	REAL for <code>sla_syrfsx_extended</code> DOUBLE PRECISION for <code>dla_syrfsx_extended</code> COMPLEX for <code>cla_syrfsx_extended</code> DOUBLE COMPLEX for <code>zla_syrfsx_extended</code> . Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *), <i>b</i> (<i>ldb</i> , *), <i>y</i> (<i>ldy</i> , *). The array <i>a</i> contains the original <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least <code>max(1, n)</code> . The array <i>af</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by <code>?sytrf</code> . The second dimension of <i>af</i> must be at least <code>max(1, n)</code> . The array <i>b</i> contains the right-hand-side of the matrix <i>B</i> . The second dimension of <i>b</i> must be at least <code>max(1, nrhs)</code> . The array <i>y</i> on entry contains the solution matrix <i>X</i> as computed by <code>?sytrs</code> . The second dimension of <i>y</i> must be at least <code>max(1, nrhs)</code> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; <i>lda</i> ≥ <code>max(1, n)</code> .
<i>ldaf</i>	INTEGER. The leading dimension of the array <i>af</i> ; <i>ldaf</i> ≥ <code>max(1, n)</code> .
<i>ipiv</i>	INTEGER. Array with DIMENSION <i>n</i> . Details of the interchanges and the block structure of <i>D</i> as determined by <code>?sytrf</code> .
<i>colequ</i>	LOGICAL. If <i>colequ</i> = .TRUE., column equilibration was done to <i>A</i> before calling this routine. This is needed to compute the solution and error bounds correctly.

c

REAL for `sla_syrfxsx_extended` and `cla_syrfxsx_extended`
 DOUBLE PRECISION for `dla_syrfxsx_extended` and
`zla_syrfxsx_extended`.

c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not used.

If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

INTEGER. The leading dimension of the array *b*; *ldb* $\geq \max(1, n)$.

ldy

INTEGER. The leading dimension of the array *y*; *ldy* $\geq \max(1, n)$.

n_norms

INTEGER. Determines which error bounds to return. See `err_bnds_norm` and `err_bnds_comp` descriptions in *Output Arguments* section below.

If *n_norms* ≥ 1 , returns normwise error bounds.

If *n_norms* ≥ 2 , returns componentwise error bounds.

err_bnds_norm

REAL for `sla_syrfxsx_extended` and `cla_syrfxsx_extended`
 DOUBLE PRECISION for `dla_syrfxsx_extended` and
`zla_syrfxsx_extended`.

Array, DIMENSION (*nrhs, n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.

Normwise relative error in the *i*-th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i,:)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold <code>sqrt(n)*slamch('E')</code> for <code>sla_syrfxsx_extended/cla_syrfxsx_extended</code> and <code>sqrt(n)*dlamch('E')</code> for <code>dla_syrfxsx_extended/zla_syrfxsx_extended</code>
.	

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for
`sla_syrfsx_extended/cla_syrfsx_extended` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for
`dla_syrfsx_extended/zla_syrfsx_extended`. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for
`sla_syrfsx_extended/cla_syrfsx_extended` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for
`dla_syrfsx_extended/zla_syrfsx_extended` to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp` REAL for `sla_syrfsx_extended` and `cla_syrfsx_extended`

DOUBLE PRECISION for `dla_syrfsx_extended` and `zla_syrfsx_extended`.

Array, DIMENSION ($nrhs, n_{\text{err_bnds}}$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_{\text{err_bnds}} < 3$, then at most the first $(:, n_{\text{err_bnds}})$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for <code>sla_syrfssx_extended/cla_syrfssx_extended</code> and $\sqrt(n) * \text{dlamch}(\epsilon)$ for <code>dla_syrfssx_extended/zla_syrfssx_extended</code> .
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for <code>sla_syrfssx_extended/cla_syrfssx_extended</code> and $\sqrt(n) * \text{dlamch}(\epsilon)$ for <code>dla_syrfssx_extended/zla_syrfssx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt(n) * \text{slamch}(\epsilon)$ for <code>sla_syrfssx_extended/cla_syrfssx_extended</code> and $\sqrt(n) * \text{dlamch}(\epsilon)$ for <code>dla_syrfssx_extended/zla_syrfssx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \infty) * \text{norm}(z, \infty))$ for some appropriately scaled matrix Z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.

```
res, dy, y_tail
REAL for sla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended
COMPLEX for cla_syrfssx_extended
DOUBLE COMPLEX for zla_syrfssx_extended.

Workspace arrays of DIMENSION n.

res holds the intermediate residual.
dy holds the intermediate solution.
y_tail holds the trailing bits of the intermediate solution.
```

<i>ayb</i>	REAL for <code>sla_syrfsx_extended</code> and <code>cla_syrfsx_extended</code> DOUBLE PRECISION for <code>dla_syrfsx_extended</code> and <code>zla_syrfsx_extended</code> . Workspace array, DIMENSION <i>n</i> .
<i>rcond</i>	REAL for <code>sla_syrfsx_extended</code> and <code>cla_syrfsx_extended</code> DOUBLE PRECISION for <code>dla_syrfsx_extended</code> and <code>zla_syrfsx_extended</code> . Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>ithresh</i>	INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in <code>err_bnds_norm</code> and <code>err_bnds_comp</code> may no longer be trustworthy.
<i>rthresh</i>	REAL for <code>sla_syrfsx_extended</code> and <code>cla_syrfsx_extended</code> DOUBLE PRECISION for <code>dla_syrfsx_extended</code> and <code>zla_syrfsx_extended</code> . Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies $\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$ where $\text{norm}(z)$ is the infinity norm of <i>Z</i> . <i>rthresh</i> satisfies $0 < \text{rthresh} \leq 1$. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.
<i>dz_ub</i>	REAL for <code>sla_syrfsx_extended</code> and <code>cla_syrfsx_extended</code> DOUBLE PRECISION for <code>dla_syrfsx_extended</code> and <code>zla_syrfsx_extended</code> . Determines when to start considering componentwise convergence. Componentwise <i>dz_ub</i> convergence is only considered after each component of the solution <i>y</i> is stable, that is, the relative change in each component is less than <i>dz_ub</i> . The default value is 0.25, requiring the first bit to be stable.
<i>ignore_cwise</i>	LOGICAL If .TRUE., the function ignores componentwise convergence. Default value is .FALSE..

Output Parameters

<i>y</i>	REAL for <code>sla_syrfxsx_extended</code> DOUBLE PRECISION for <code>dla_syrfxsx_extended</code> COMPLEX for <code>cla_syrfxsx_extended</code> DOUBLE COMPLEX for <code>zla_syrfxsx_extended</code> . The improved solution matrix <i>Y</i> .
<i>berr_out</i>	REAL for <code>sla_syrfxsx_extended</code> and <code>cla_syrfxsx_extended</code> DOUBLE PRECISION for <code>dla_syrfxsx_extended</code> and <code>zla_syrfxsx_extended</code> . Array, DIMENSION <i>nrhs</i> . <i>berr_out(j)</i> contains the componentwise relative backward error for right-hand-side <i>j</i> from the formula $\max(i) (\text{abs}(\text{res}(i)) / (\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B))(i))$ where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector <i>Z</i> . This is computed by <code>?la_lin_berr</code> .
<i>err_bnds_norm</i> , <i>err_bnds_comp</i>	Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array (1: <i>nrhs</i> , 2). The other elements are kept unchanged.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

[?la_syrpvgrw](#)

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a symmetric indefinite matrix.

Syntax

FORTRAN 77:

```
call sla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call dla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call cla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call zla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_syrpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the equilibrated matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <i>uplo</i> = 'U', the upper triangle of A is stored, If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.
<i>info</i>	INTEGER. The value of INFO returned from ?sytrf, that is, the pivot in column <i>info</i> is exactly 0.
<i>a</i> , <i>af</i>	REAL for sla_syrpvgrw DOUBLE PRECISION for dla_syrpvgrw COMPLEX for cla_syrpvgrw DOUBLE COMPLEX for zla_syrpvgrw. Arrays: <i>a</i> (<i>lda</i> , *), <i>af</i> (<i>ldaf</i> , *). The array <i>a</i> contains the input n -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>af</i> contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?sytrf. The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $\text{lda} \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> ; $\text{ldaf} \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION n . Details of the interchanges and the block structure of D as determined by ?sytrf.
<i>work</i>	REAL for sla_syrpvgrw and cla_syrpvgrw DOUBLE PRECISION for dla_syrpvgrw and zla_syrpvgrw. Workspace array, dimension $2*n$.

See Also

?sytrf

?la_wwaddw

Adds a vector into a doubled-single vector.

Syntax**FORTRAN 77:**

```
call sla_wwaddw( n, x, y, w )
call dla_wwaddw( n, x, y, w )
call cla_wwaddw( n, x, y, w )
call zla_wwaddw( n, x, y, w )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The ?la_wwaddw routine adds a vector W into a doubled-single vector (X, Y) . This works for all existing IBM hex and binary floating-point arithmetics, but not for decimal.

Input Parameters

<i>n</i>	INTEGER. The length of vectors X , Y , and W .
<i>x, y, w</i>	REAL for <code>sla_wwaddw</code> DOUBLE PRECISION for <code>dla_wwaddw</code> COMPLEX for <code>cla_wwaddw</code> DOUBLE COMPLEX for <code>zla_wwaddw</code> . Arrays DIMENSION <i>n</i> . <i>x</i> and <i>y</i> contain the first and second parts of the doubled-single accumulation vector, respectively. <i>w</i> contains the vector W to be added.

Output Parameters

<i>x, y</i>	Contain the first and second parts of the doubled-single accumulation vector, respectively, after adding the vector W .

Utility Functions and Routines

This section describes LAPACK utility functions and routines. Summary information about these routines is given in the following table:

LAPACK Utility Routines

Routine Name	Data Types	Description
ilaver		Returns the version of the Lapack library.

Routine Name	Data Types	Description
<code>ilaenv</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>iparmq</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>ieeeck</code>		Checks if the infinity and NaN arithmetic is safe. Called by <code>ilaenv</code> .
<code>?labad</code>	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<code>?lamch</code>	s, d	Determines machine parameters for floating-point arithmetic.
<code>?lamc1</code>	s, d	Called from <code>?lamc2</code> . Determines machine parameters given by <i>beta</i> , <i>t</i> , <i>rnd</i> , <i>ieee1</i> .
<code>?lamc2</code>	s, d	Used by <code>?lamch</code> . Determines machine parameters specified in its arguments list.
<code>?lamc3</code>	s, d	Called from <code>?lamc1</code> - <code>?lamc5</code> . Intended to force <i>a</i> and <i>b</i> to be stored prior to doing the addition of <i>a</i> and <i>b</i> .
<code>?lamc4</code>	s, d	This is a service routine for <code>?lamc2</code> .
<code>?lamc5</code>	s, d	Called from <code>?lamc2</code> . Attempts to compute the largest machine floating-point number, without overflow.
<code>chla_transtype</code>		Translates a BLAST-specified integer constant to the character string specifying a transposition operation.
<code>iladiag</code>		Translates a character string specifying whether a matrix has a unit diagonal or not to the relevant BLAST-specified integer constant.
<code>ilaprec</code>		Translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.
<code>ilatrans</code>		Translates a character string specifying a transposition operation to the BLAST-specified integer constant.
<code>ilauplo</code>		Translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.
<code>xerbla_array</code>		Assists other languages in calling the <code>xerbla</code> function.

See Also

`Isame` Tests two characters for equality regardless of the case.

`Isamen` Tests two character strings for equality regardless of the case.

`second/dsecnd` Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

`xerbla` Error handling function called by BLAS, LAPACK, VML, and VSL functions.

ilaver

Returns the version of the LAPACK library.

Syntax

```
call ilaver( vers_major, vers_minor, vers_patch )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This routine returns the version of the LAPACK library.

Output Parameters

<code>vers_major</code>	INTEGER. Returns the major version of the LAPACK library.
<code>vers_minor</code>	INTEGER. Returns the minor version from the major version of the LAPACK library.
<code>vers_patch</code>	INTEGER. Returns the patch version from the minor version of the LAPACK library.

ilaenv

Environmental enquiry function that returns values for tuning algorithmic performance.

Syntax

```
value = ilaenv( ispec, name, opts, n1, n2, n3, n4 )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The enquiry function `ilaenv` is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See `ispec` below for a description of the parameters.

This version provides a set of parameters that should give good, but not optimal, performance on many of the currently available computers.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

ispec

INTEGER.

Specifies the parameter to be returned as the value of `ilaenv`:

- = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance.
- = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.
- = 3: the crossover point (in a block routine, for n less than this value, an unblocked routine should be used)
- = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (deprecated)
- = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k -by- m , where k is given by `ilaenv(2, ...)` and m by `ilaenv(5, ...)`
- = 6: the crossover point for the SVD (when reducing an m -by- n matrix to bidiagonal form, if $\max(m, n)/\min(m, n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.)
- = 7: the number of processors
- = 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems (deprecated).
- = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?gelsd` and `?gesdd`)
- =10: ieee NaN arithmetic can be trusted not to trap
- =11: infinity arithmetic can be trusted not to trap
- $12 \leq ispec \leq 16$: `?hseqr` or one of its subroutines, see `iparmq` for detailed explanation.

name

CHARACTER* (*). The name of the calling subroutine, in either upper case or lower case.

opts

CHARACTER* (*). The character options to the subroutine *name*, concatenated into a single character string. For example, *uplo* = 'U', *trans* = 'T', and *diag* = 'N' for a triangular routine would be specified as *opts* = 'UTN'.

n1, n2, n3, n4

INTEGER. Problem dimensions for the subroutine *name*; these may not all be required.

Output Parameters

value

INTEGER.

If *value* ≥ 0 : the value of the parameter specified by *ispec*;

If *value* = $-k < 0$: the k -th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. `opts` is a concatenation of all of the character options to subroutine `name`, in the same order that they appear in the argument list for `name`, even if they are not used in determining the value of the parameter specified by `ispec`.
2. The problem dimensions n_1, n_2, n_3, n_4 are specified in the order that they appear in the argument list for `name`. n_1 is used first, n_2 second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal blocksize for `strtri` as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
if( nb.le.1 ) nb = max( 1, n )
```

Below is an example of `ilaenv` usage in C language:

```
#include <stdio.h>
#include "mkl.h"

int main(void)
{
    int size = 1000;
    int ispec = 1;
    int dummy = -1;

    int blockSize1 = ilaenv(&ispec, "dsytrd", "U", &size, &dummy, &dummy);
    int blockSize2 = ilaenv(&ispec, "dormtr", "LUN", &size, &size, &dummy, &dummy);

    printf("DSYTRD blocksize = %d\n",
blockSize1);
    printf("DORMTR blocksize = %d\n", blockSize2);

    return 0;
}
```

See Also

[?hseqr](#)
[iparmq](#)

iparmq

Environmental enquiry function which returns values for tuning algorithmic performance.

Syntax

`value = iparmq(ispec, name, opts, n, ilo, ihi, lwork)`

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function sets problem and machine dependent parameters useful for `?hseqr` and its subroutines. It is called whenever `ilaenv` is called with $12 \leq ispec \leq 16$.

Input Parameters

<i>ispec</i>	INTEGER. Specifies the parameter to be returned as the value of <code>iparmq</code> : = 12: (<i>inmin</i>) Matrices of order <i>nmin</i> or less are sent directly to <code>?lahqr</code> , the implicit double shift QR algorithm. <i>nmin</i> must be at least 11. = 13: (<i>inwin</i>) Size of the deflation window. This is best set greater than or equal to the number of simultaneous shifts <i>ns</i> . Larger matrices benefit from larger deflation windows. = 14: (<i>inibl</i>) Determines when to stop nibbling and invest in an (expensive) multi-shift QR sweep. If the aggressive early deflation subroutine finds <i>ld</i> converged eigenvalues from an order <i>nw</i> deflation window and $ld > (nw * nibble) / 100$, then the next QR sweep is skipped and early deflation is applied immediately to the remaining active diagonal block. Setting <code>iparmq(ispec=14)=0</code> causes <code>TTQRE</code> to skip a multi-shift QR sweep whenever early deflation finds a converged eigenvalue. Setting <code>iparmq(ispec=14)</code> greater than or equal to 100 prevents <code>TTQRE</code> from skipping a multi-shift QR sweep. = 15: (<i>nshfts</i>) The number of simultaneous shifts in a multi-shift QR iteration. = 16: (<i>iacc22</i>) <code>iparmq</code> is set to 0, 1 or 2 with the following meanings. 0: During the multi-shift QR sweep, <code>?laqr5</code> does not accumulate reflections and does not use matrix-matrix multiply to update the far-from-diagonal matrix entries. 1: During the multi-shift QR sweep, <code>?laqr5</code> and/or <code>?laqr3</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. 2: During the multi-shift QR sweep, <code>?laqr5</code> accumulates reflections and takes advantage of 2-by-2 block structure during matrix-matrix multiplies. (If <code>?trrm</code> is slower than <code>?gemm</code> , then <code>iparmq(ispec=16)=1</code> may be more efficient than <code>iparmq(ispec=16)=2</code> despite the greater level of arithmetic work implied by the latter choice.)
<i>name</i>	CHARACTER* (*). The name of the calling subroutine.
<i>opts</i>	CHARACTER* (*). This is a concatenation of the string arguments to <code>TTQRE</code> .
<i>n</i>	INTEGER. <i>n</i> is the order of the Hessenberg matrix <i>H</i> .
<i>ilo, ihi</i>	INTEGER. It is assumed that <i>H</i> is already upper triangular in rows and columns 1: <i>ilo-1</i> and <i>ihi+1:n</i> .
<i>lwork</i>	INTEGER.

The amount of workspace available.

Output Parameters

<i>value</i>	INTEGER. If <i>value</i> ≥ 0 : the value of the parameter specified by <i>iparmq</i> ; If <i>value</i> = $-k < 0$: the <i>k</i> -th argument had an illegal value.
--------------	--

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, *n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal blocksize for `strtri` as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
if( nb.le.1 ) nb = max( 1, n )
```

ieeeck

Checks if the infinity and NaN arithmetic is safe.

Called by `ilaenv`.

Syntax

```
ival = ieeeck( ispec, zero, one )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The function `ieeeck` is called from `ilaenv` to verify that infinity and possibly NaN arithmetic is safe, that is, will not trap.

Input Parameters

<i>ispec</i>	INTEGER. Specifies whether to test just for infinity arithmetic or both for infinity and NaN arithmetic: If <i>ispec</i> = 0: Verify infinity arithmetic only. If <i>ispec</i> = 1: Verify infinity and NaN arithmetic.
<i>zero</i>	REAL. Must contain the value 0.0 This is passed to prevent the compiler from optimizing away this code.

<i>one</i>	REAL. Must contain the value 1.0 This is passed to prevent the compiler from optimizing away this code.
------------	--

Output Parameters

<i>ival</i>	INTEGER. If <i>ival</i> = 0: Arithmetic failed to produce the correct answers. If <i>ival</i> = 1: Arithmetic produced the correct answers.
-------------	---

?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call slabad( small, large )
call dlabad( small, large )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine takes as input the values computed by `slamch/dlamch` for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `?lamch`. This subroutine is needed because `?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Input Parameters

<i>small</i>	REAL for slabad DOUBLE PRECISION for dlabad. The underflow threshold as computed by <code>?lamch</code> .
<i>large</i>	REAL for slabad DOUBLE PRECISION for dlabad. The overflow threshold as computed by <code>?lamch</code> .

Output Parameters

<i>small</i>	On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = slamch( cmach )
```

```
val = dlamch( cmach )
```

C:

```
<datatype> LAPACKE_<?>lamch (char cmach);
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The function ?lamch determines single precision and double precision machine parameters.

Input Parameters

<i>cmach</i>	CHARACTER*1. Specifies the value to be returned by ?lamch: = 'E' or 'e', <i>val</i> = <i>eps</i> = 'S' or 's', <i>val</i> = <i>smin</i> = 'B' or 'b', <i>val</i> = <i>base</i> = 'P' or 'p', <i>val</i> = <i>eps</i> * <i>base</i> = 'n' or 'n', <i>val</i> = <i>t</i> = 'R' or 'r', <i>val</i> = <i>rnd</i> = 'M' or 'm', <i>val</i> = <i>emin</i> = 'U' or 'u', <i>val</i> = <i>rmin</i> = 'L' or 'l', <i>val</i> = <i>emax</i> = 'O' or 'o', <i>val</i> = <i>rmax</i> where <i>eps</i> = relative machine precision; <i>smin</i> = safe minimum, such that $1/smin$ does not overflow; <i>base</i> = base of the machine; <i>prec</i> = <i>eps</i> * <i>base</i> ; <i>t</i> = number of (<i>base</i>) digits in the mantissa; <i>rnd</i> = 1.0 when rounding occurs in addition, 0.0 otherwise; <i>emin</i> = minimum exponent before (gradual) underflow; <i>rmin</i> = <i>underflow_threshold</i> - <i>base</i> ^(<i>emin</i>-1) ; <i>emax</i> = largest exponent before overflow; <i>rmax</i> = <i>overflow_threshold</i> - (<i>base</i> ^{<i>emax</i>})*(1- <i>eps</i>).
--------------	---

NOTE

You can use a character string for *cmach* instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, 'Precision' is interpreted as 'p'.

Output Parameters

<i>val</i>	REAL for <code>slamch</code>
	DOUBLE PRECISION for <code>dlamch</code>
	Value returned by the function.

?lamc1

Called from ?lamc2. Determines machine parameters given by beta, t, rnd, ieee1.

Syntax

```
call slamc1( beta, t, rnd, ieee1 )
call dlamc1( beta, t, rnd, ieee1 )
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

The routine `?lamc1` determines machine parameters given by *beta, t, rnd, ieee1*.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>ieee1</i>	LOGICAL. Specifies whether rounding appears to be done in the <i>ieee</i> 'round to nearest' style.

?lamc2

Used by ?lamch. Determines machine parameters specified in its arguments list.

Syntax

```
call slamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
call dlamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lamc2 determines machine parameters specified in its arguments list.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>eps</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest positive number such that $f1(1.0 - \text{eps}) < 1.0$, where <i>f1</i> denotes the computed value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow occurs.
<i>rmin</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest normalized number for the machine, given by $\text{base}^{\text{emin}-1}$, where <i>base</i> is the floating point value of <i>beta</i> .
<i>emax</i>	INTEGER. The maximum exponent before overflow occurs.
<i>rmax</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The largest positive number for the machine, given by $\text{base}^{\text{emax}(1 - \text{eps})}$, where <i>base</i> is the floating point value of <i>beta</i> .

?lamc3

Called from ?lamc1-?lamc5. Intended to force *a* and *b* to be stored prior to doing the addition of *a* and *b*.

Syntax

```
val = slamc3( a, b )
val = dlamc3( a, b )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine is intended to force A and B to be stored prior to doing the addition of A and B , for use in situations where optimizers might hold one of these in a register.

Input Parameters

a, b	REAL for slamc3 DOUBLE PRECISION for dlamc3
	The values a and b .

Output Parameters

val	REAL for slamc3 DOUBLE PRECISION for dlamc3
	The result of adding values a and b .

?lamc4

This is a service routine for ?lamc2.

Syntax

```
call slamc4( emin, start, base )
call dlamc4( emin, start, base )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

This is a service routine for ?lamc2.

Input Parameters

$start$	REAL for slamc4 DOUBLE PRECISION for dlamc4
	The starting point for determining $emin$.
$base$	INTEGER. The base of the machine.

Output Parameters

emin INTEGER. The minimum exponent before (gradual) underflow, computed by setting $a = start$ and dividing by $base$ until the previous a can not be recovered.

?lamc5

Called from ?lamc2. Attempts to compute the largest machine floating-point number, without overflow.

Syntax

```
call slamc5( beta, p, emin, ieee, emax, rmax)
call dlamc5( beta, p, emin, ieee, emax, rmax)
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine ?lamc5 attempts to compute $rmax$, the largest machine floating-point number, without overflow. It assumes that $emax + \text{abs}(emin)$ sum approximately to a power of 2. It will fail on machines where this assumption does not hold, for example, the Cyber 205 ($emin = -28625$, $emax = 28718$). It will also fail if the value supplied for $emin$ is too large (that is, too close to zero), probably with overflow.

Input Parameters

<i>beta</i>	INTEGER. The base of floating-point arithmetic.
<i>p</i>	INTEGER. The number of base <i>beta</i> digits in the mantissa of a floating-point value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow.
<i>ieee</i>	LOGICAL. A logical flag specifying whether or not the arithmetic system is thought to comply with the IEEE standard.

Output Parameters

<i>emax</i>	INTEGER. The largest exponent before overflow.
<i>rmax</i>	REAL for slamc5 DOUBLE PRECISION for dlamc5 The largest machine floating-point number.

chla_transtype

Translates a BLAST-specified integer constant to the character string specifying a transposition operation.

Syntax

```
val = chla_transtype( trans )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `chla_transtype` function translates a BLAST-specified integer constant to the character string specifying a transposition operation.

The function returns a `CHARACTER*1`. If the input is not an integer indicating a transposition operator, then `val` is '`x`'. Otherwise, the function returns the constant value corresponding to `trans`.

Input Parameters

<code>trans</code>	INTEGER. Specifies the form of the system of equations: If <code>trans</code> = <code>BLAS_NO_TRANS</code> = 111: No transpose. If <code>trans</code> = <code>BLAS_TRANS</code> = 112: Transpose. If <code>trans</code> = <code>BLAS_CONJ_TRANS</code> = 113: Conjugate Transpose.
--------------------	--

Output Parameters

<code>val</code>	<code>CHARACTER*1</code> Character that specifies a transposition operation.
------------------	---

iladiag

Translates a character string specifying whether a matrix has a unit diagonal to the relevant BLAST-specified integer constant.

Syntax

```
val = iladiag( diag )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `iladiag` function translates a character string specifying whether a matrix has a unit diagonal or not to the relevant BLAST-specified integer constant.

The function returns an `INTEGER`. If `val` < 0, the input is not a character indicating a unit or non-unit diagonal. Otherwise, the function returns the constant value corresponding to `diag`.

Input Parameters

<code>diag</code>	<code>CHARACTER*1</code> .
-------------------	----------------------------

Specifies the form of the system of equations:

If $diag = 'N'$: A is non-unit triangular.

If $diag = 'U'$: A is unit triangular.

Output Parameters

`val` INTEGER

Value returned by the function.

ilaprec

Translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.

Syntax

`val = ilaprec(prec)`

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `ilaprec` function translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.

The function returns an INTEGER. If $val < 0$, the input is not a character indicating a supported intermediate precision. Otherwise, the function returns the constant value corresponding to `prec`.

Input Parameters

`prec` CHARACTER*1.

Specifies the form of the system of equations:

If $prec = 'S'$: Single.

If $prec = 'D'$: Double.

If $prec = 'I'$: Indigenous.

If $prec = 'X', 'E'$: Extra.

Output Parameters

`val` INTEGER

Value returned by the function.

ilatrans

Translates a character string specifying a transposition operation to the BLAST-specified integer constant.

Syntax

```
val = ilatrans( trans )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `ilatrans` function translates a character string specifying a transposition operation to the BLAST-specified integer constant.

The function returns a `INTEGER`. If `val < 0`, the input is not a character indicating a transposition operator. Otherwise, the function returns the constant value corresponding to `trans`.

Input Parameters

<code>trans</code>	<code>CHARACTER*1.</code>
Specifies the form of the system of equations:	
If <code>trans = 'N'</code> :	No transpose.
If <code>trans = 'T'</code> :	Transpose.
If <code>trans = 'C'</code> :	Conjugate Transpose.

Output Parameters

<code>val</code>	<code>INTEGER</code>
Character that specifies a transposition operation.	

ilauplo

Translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.

Syntax

```
val = ilauplo( uplo )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `ilauplo` function translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.

The function returns an `INTEGER`. If `val < 0`, the input is not a character indicating an upper- or lower-triangular matrix. Otherwise, the function returns the constant value corresponding to `uplo`.

Input Parameters

<code>diag</code>	<code>CHARACTER.</code>
-------------------	-------------------------

Specifies the form of the system of equations:

If $\text{diag} = \text{'U'}$: A is upper triangular.

If $\text{diag} = \text{'L'}$: A is lower triangular.

Output Parameters

val INTEGER

Value returned by the function.

xerbla_array

Assists other languages in calling the xerbla function.

Syntax

```
call xerbla_array( srname_array, srname_len, info )
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The routine assists other languages in calling the error handling `xerbla` function. Rather than taking a Fortran string argument as the function name, `xerbla_array` takes an array of single characters along with the array length. The routine then copies up to 32 characters of that array into a Fortran string and passes that to `xerbla`. If called with a non-positive `srname_len`, the routine will call `xerbla` with a string of all blank characters.

If some macro or other device makes `xerbla_array` available to C99 by a name `lapack_xerbla` and with a common Fortran calling convention, a C99 program could invoke `xerbla` via:

```
{
    int flen = strlen(__func__);
    lapack_xerbla(__func__, &flen, &info);
}
```

Providing `xerbla_array` is not necessary for intercepting LAPACK errors. `xerbla_array` calls `xerbla`.

Output Parameters

srname_array CHARACTER(1).

Array, dimension (*srname_len*). The name of the routine that called `xerbla_array`.

srname_len INTEGER.

The length of the name in `srname_array`.

info INTEGER.

Position of the invalid parameter in the parameter list of the calling routine.

Test Functions and Routines

This section describes LAPACK test functions and routines. Summary information about these routines is given in the following table:

LAPACK Test Routines

Routine Name	Data Types	Description
?lagge	s, d, c, z	Generates a general m -by- n matrix .
?laghe	c, z	Generates a complex Hermitian matrix .
?lagsy	s, d, c, z	Generates a symmetric matrix by pre- and post- multiplying a real diagonal matrix with a random unitary matrix .
?latms	s, d, c, z	Generates a general m -by- n matrix with specific singular values.

?lagge

Generates a general m -by- n matrix .

Syntax

C:

```
lapack_int LAPACKE_<?>lagge (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, const <datatype> * d, <datatype> * a, lapack_int lda, lapack_int * iseed);
```

Include Files

- C: mkl.h

Description

The routine generates a general m -by- n matrix A , by pre- and post- multiplying a real diagonal matrix D with random matrices U and V :

$$A := U^* D^* V,$$

where U and V are orthogonal for real flavors and unitary for complex flavors. The lower and upper bandwidths may then be reduced to kl and ku by additional orthogonal transformations.

Input Parameters

The data types are given for the Fortran interface.

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).
<i>kl</i>	INTEGER. The number of nonzero subdiagonals within the band of A ($0 \leq kl \leq m-1$).
<i>ku</i>	INTEGER. The number of nonzero superdiagonals within the band of A ($0 \leq ku \leq n-1$).
<i>d</i>	REAL for slagge, clagge

DOUBLE PRECISION for dlagge, zlagge.

The array d with the dimension of ($\min(m, n)$) contains the diagonal elements of the diagonal matrix D .

lda INTEGER. The leading dimension of the array a ($lda \geq m$).

$iseed$ INTEGER.

The array $iseed$ with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and $iseed(4)$ must be odd.

Output Parameters

a REAL for slagge

DOUBLE PRECISION for dlagge

COMPLEX for clagge

DOUBLE COMPLEX for zlagge.

The array a with dimensions of (lda, n) contains the generated m -by- n matrix D .

$iseed$ The array $iseed$ contains the updated seed on exit.

?laghe

Generates a complex Hermitian matrix .

Syntax

C:

```
lapack_int LAPACKE_<?>laghe (int matrix_layout, lapack_int n, lapack_int k, const
<datatype> * d, <datatype> * a, lapack_int lda, lapack_int * iseed);
```

Include Files

- C: mkl.h

Description

The routine generates a complex Hermitian matrix A , by pre- and post- multiplying a complex diagonal matrix D with random unitary matrix:

$$A := U^* D^* U^T$$

The semi-bandwidth may then be reduced to k by additional unitary transformations.

Input Parameters

The data types are given for the Fortran interface.

n INTEGER. The order of the matrix A ($n \geq 0$).

k INTEGER. The number of nonzero subdiagonals within the band of A ($0 \leq k \leq n-1$).

<i>d</i>	COMPLEX for claghe DOUBLE COMPLEX for zlaghe.
	The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix <i>D</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> (<i>lda</i> $\geq n$).
<i>iseed</i>	INTEGER. The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> (4) must be odd.

Output Parameters

<i>a</i>	COMPLEX for claghe DOUBLE COMPLEX for zlaghe.
	The array <i>a</i> with dimensions of (<i>lda</i> , <i>n</i>) contains the generated <i>n</i> -by- <i>n</i> Hermitian matrix <i>D</i> .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

?lagsy

Generates a symmetric matrix by pre- and post-multiplying a real diagonal matrix with a random unitary matrix .

Syntax

C:

```
lapack_int LAPACKE_<?>lagsy (int matrix_layout, lapack_int n, lapack_int k, const
<datatype> * d, <datatype> * a, lapack_int lda, lapack_int * iseed);
```

Include Files

- C: mkl.h

Description

SLAGSY generates a symmetric matrix *A* by pre- and post- multiplying a real diagonal matrix *D* with a random matrix *U*:

$$A := U^* D^* U^T,$$

where *U* is orthogonal for real flavors and unitary for complex flavors. The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

Input Parameters

The data types are given for the Fortran interface.

<i>n</i>	INTEGER. The order of the matrix <i>A</i> (<i>n</i> ≥ 0).
----------	--

<i>k</i>	INTEGER. The number of nonzero subdiagonals within the band of A ($0 \leq k \leq n-1$).
<i>d</i>	REAL for slagsy, clagsy DOUBLE PRECISION for dlagsy, zlagsy. The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix D .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> (<i>lda</i> $\geq n$).
<i>iseed</i>	INTEGER. The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> (4) must be odd.

Output Parameters

<i>a</i>	REAL for slagsy DOUBLE PRECISION for dlagsy COMPLEX for clagsy DOUBLE COMPLEX for zlagsy. The array <i>a</i> with dimensions of (<i>lda</i> , <i>n</i>) contains the generated symmetric <i>n</i> -by- <i>n</i> matrix D .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

?latms

Generates a general *m*-by-*n* matrix with specific singular values.

Syntax

Fortran:

```
call slatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
call dlatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
call clatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
call zlatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
```

C:

```
lapack_int LAPACKE_slatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, float * a, lapack_int lda);
```

```
lapack_int LAPACKE_dlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, double * a, lapack_int lda);

lapack_int LAPACKE_clatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_double * a, lapack_int lda);
```

Include Files

- C: mkl.h

Description

The ?latms routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to d , where d is input or computed according to $mode$, $cond$, $dmax$, and sym as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:

Method A

1. Generate a dense m -by- n matrix by multiplying d on the left and the right by random unitary matrices, then:
2. Reduce the bandwidth according to kl and ku , using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to m and n) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and lda is at least m (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than $(1/2)*n$ for symmetric or Hermitian or less than $.3*n+m$ for nonsymmetric), or lda is less than m and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the $pack$ parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

Input Parameters

The data types are given for the Fortran interface.

m

INTEGER. The number of rows of the matrix A ($m \geq 0$).

n

INTEGER. The number of columns of the matrix A ($n \geq 0$). If the matrix is not symmetric ($sym \neq 'N'$) n must equal m .

<i>dist</i>	CHARACTER*1. Specifies the type of distribution to be used to generate the random singular values or eigenvalues:
	<ul style="list-style-type: none"> • 'U': uniform distribution (0, 1) • 'S': symmetric uniform distribution (-1, 1) • 'N': normal distribution (0, 1)
<i>iseed</i>	INTEGER. Array with size 4.
	Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and <i>iseed</i> (4) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to ?latms to continue the same random number sequence.
<i>sym</i>	CHARACTER*1.
	If <i>sym</i> ='S' or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by <i>d</i> , <i>cond</i> , <i>mode</i> , and <i>dmax</i> ; they can be positive, negative, or zero.
	If <i>sym</i> ='P', the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by <i>d</i> , <i>cond</i> , <i>mode</i> , and <i>dmax</i> .
	If <i>sym</i> ='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by <i>d</i> , <i>cond</i> , <i>mode</i> , and <i>dmax</i> .
<i>d</i>	REAL for slatms and clatms DOUBLE PRECISION for dlatms and zlatms Array, size (MIN(<i>m</i> , <i>n</i>))
	This array is used to specify the singular values or eigenvalues of A (see the description of <i>sym</i>). If <i>mode</i> =0, then <i>d</i> is assumed to contain the eigenvalues or singular values, otherwise elements of <i>d</i> are computed according to <i>mode</i> , <i>cond</i> , and <i>dmax</i> .
<i>mode</i>	INTEGER. Describes how the singular/eigenvalues are specified.
	<ul style="list-style-type: none"> • <i>mode</i> = 0: use <i>d</i> as input • <i>mode</i> = 1: set <i>d</i>(1) = 1 and <i>d</i>(2:<i>n</i>) = 1.0/<i>cond</i> • <i>mode</i> = 2: set <i>d</i>(1:<i>n</i>-1) = 1 and <i>d</i>(<i>n</i>) = 1.0/<i>cond</i> • <i>mode</i> = 3: set <i>d</i>(<i>i</i>) = <i>cond</i>^{-(<i>i</i>-1)/(<i>n</i>-1)} • <i>mode</i> = 4: set <i>d</i>(<i>i</i>) = 1 - (<i>i</i>-1)/(<i>n</i>-1)*(1-1/<i>cond</i>) • <i>mode</i> = 5: set elements of <i>d</i> to random numbers in the range (1/<i>cond</i>, 1) such that their logarithms are uniformly distributed. • <i>mode</i> = 6: set elements of <i>d</i> to random numbers from same distribution as the rest of the matrix.
	<i>mode</i> < 0 has the same meaning as ABS(<i>mode</i>), except that the order of the elements of <i>d</i> is reversed. Thus, if <i>mode</i> is positive, <i>d</i> has entries ranging from 1 to 1/ <i>cond</i> , if negative, from 1/ <i>cond</i> to 1.
	If <i>sym</i> ='S' or 'H', and <i>mode</i> is not 0, 6, nor -6, then the elements of <i>d</i> are also given a random sign (multiplied by +1 or -1).

cond REAL for `slatms` and `clatms`
 DOUBLE PRECISION for `dlatms` and `zlatms`
 Used in setting *d* as described for the *mode* parameter. If used, *cond* ≥ 1 .

dmax REAL for `slatms` and `clatms`
 DOUBLE PRECISION for `dlatms` and `zlatms`
 If *mode* is not -6, 0 nor 6, the contents of *d*, as computed according to *mode* and *cond*, are scaled by *dmax* / $\max(\text{abs}(d(i)))$; thus, the maximum absolute eigenvalue or singular value (the norm) is $\text{abs}(dmax)$.

NOTE

dmax need not be positive: if *dmax* is negative (or zero), *d* will be scaled by a negative number (or zero).

kl INTEGER. Specifies the lower bandwidth of the matrix. For example, *kl*=0 implies upper triangular, *kl*=1 implies upper Hessenberg, and *kl* being at least *m* - 1 means that the matrix has full lower bandwidth. *kl* must equal *ku* if the matrix is symmetric or Hermitian.

ku INTEGER. Specifies the upper bandwidth of the matrix. For example, *ku*=0 implies lower triangular, *ku*=1 implies lower Hessenberg, and *ku* being at least *n* - 1 means that the matrix has full upper bandwidth. *kl* must equal *ku* if the matrix is symmetric or Hermitian.

pack CHARACTER*1. Specifies packing of matrix:

- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
- 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
- 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
- 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store *A* in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

	'Z'	'B'	'Q'	'C'	'R'
GB: general band			x		
PB: symmetric positive definite band		x	x		
SB: symmetric band	x		x		
HB: Hermitian band		x	x		
TB: triangular band	x		x		
PP: symmetric positive definite packed				x	x

If two calls to `?latms` differ only in the *pack* parameter, they generate mathematically equivalent matrices.

1da

INTEGER. *lda* specifies the first dimension of *a* as declared in the calling program.

If `pack='N', 'U', 'L', 'C', or 'R'`, then `lda` must be at least m .

If `pack='B'` or `'Q'`, then `lda` must be at least $\text{MIN}(k_1, m - 1)$ (which is equal to $\text{MIN}(k_u, n - 1)$).

If $\text{pack} = \text{'Z}'$, lda must be large enough to hold the packed array: $\text{MIN}(ku, n - 1) + \text{MIN}(kl, m - 1) + 1$.

Output Parameters

*i*seed

The array *iseed* contains the updated seed.

d

The array d contains the updated seed.

NOTE

The array d is not modified if $mode = 0$.

a

REAL for slatms

DOUBLE PRECISION for dlatms

COMPLEX for clatms

DOUBLE COMPLEX for zlatms

Array of size lda by n .

The array a contains the

a is first generated in full (unpacked) form, and then

by *pack*. Thus, the first *m* elements of the first *n* columns are always modified. If *pack* specifies a packed or banded storage scheme, all *lda*

elements of the first n columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

work

```
REAL for slatms
DOUBLE PRECISION for dlatms
COMPLEX for clatms
DOUBLE COMPLEX for zlatms
Array of size (3*MAX( $n, m$ ))
```

Workspace.

info

INTEGER. Error code. *info* is set to one of the following values:

- 0: normal return
- -1: m negative or unequal to n and $\text{sym}='S'$, ' H ', or ' P '
- -2: n negative
- -3: dist illegal string
- -5: sym illegal string
- -7: mode not in range -6 to 6
- -8: cond less than 1.0, and mode not -6, 0 nor 6
- -10: k_1 negative
- -11: k_u negative, or $\text{sym} \neq 'N'$ and k_u not equal to k_1
- -12: pack illegal string, or $\text{pack}='U'$ or ' L ', and $\text{sym}='N'$; or $\text{pack}='C'$ or ' Q ' and $\text{sym}='N'$ and k_1 is not zero; or $\text{pack}='R'$ or ' B ' and $\text{sym}='N'$ and k_u is not zero; or $\text{pack}='U', 'L', 'C', 'R', 'B'$, or ' Q ', and m is not n .
- 14: l_da is less than m , or $\text{pack}='Z'$ and l_da is less than $\text{MIN}(k_u, n - 1) + \text{MIN}(k_1, m - 1) + 1$.
- 2: Cannot scale to d_{\max} (maximum singular value is 0)
- 3: Error return from [lagge](#), [?laghe](#), or [lagsy](#)

ScaLAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complexm, and double complex precision. See the `mkl_scalapack.h` header file for C declarations of ScaLAPACK routines.

NOTE

ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Sections in this chapter include descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also gives the opportunity to use BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix (array) and its corresponding process and memory location is contained in the array called the *array descriptor* associated with each global matrix.

Let A be a two-dimensional block cyclicly distributed matrix with the array descriptor array $desca$. The meaning of each array descriptor element depends on the type of the matrix A . The tables [Array descriptor for dense matrices](#) and [Array descriptor for narrow-band and tridiagonal matrices](#) describe the meaning of each element for the different types of matrices.

Array descriptor for dense matrices ($dlen=9$)

Element Name	Stored in	Description	Element Index Number
$dtype_a$	$desca(dtype_)$	Descriptor type (=1 for dense matrices).	1
$ctxt_a$	$desca(ctxt_)$	BLACS context handle for the process grid.	2
m_a	$desca(m_)$	Number of rows in the global matrix A .	3
n_a	$desca(n_)$	Number of columns in the global matrix A .	4
mb_a	$desca(mb_)$	Row blocking factor.	5
nb_a	$desca(nb_)$	Column blocking factor.	6
$rsrc_a$	$desca(rsrc_)$	Process row over which the first row of the global matrix A is distributed.	7
$csrc_a$	$desca(csrc_)$	Process column over which the first column of the global matrix A is distributed.	8
lId_a	$desca(lId_)$	Leading dimension of the local matrix A .	9

Array descriptor for narrow-band and tridiagonal matrices ($dlen=7$)

Element Name	Stored in	Description	Element Index Number
$dtype_a$	$desca(dtype_)$	Descriptor type	1
		<ul style="list-style-type: none"> • $dtype_a=501$: 1-by-P grid, • $dtype_a=502$: P-by-1 grid. 	
$ctxt_a$	$desca(ctxt_)$	BLACS context handle indicating the BLACS process grid over which the global matrix A is distributed. The context itself is global, but the handle (the integer value) can vary.	2
n_a	$desca(n_)$	The size of the matrix dimension being distributed.	3
nb_a	$desca(nb_)$	The blocking factor used to distribute the distributed dimension of the matrix A .	4
src_a	$desca(src_)$	The process row or column over which the first row or column of the matrix A is distributed.	5
lId_a	$desca(lId_)$	The leading dimension of the local matrix storing the local blocks of the distributed matrix A . The minimum value of lId_a depends on $dtype_a$. <ul style="list-style-type: none"> • $dtype_a=501$: $lId_a \geq \max(\text{size of undistributed dimension}, 1)$, • $dtype_a=502$: $lId_a \geq \max(nb_a, 1)$. 	6
Not applicable		Reserved for future use.	7

Similar notations are used for different matrices. For example: lId_b is the leading dimension of the local matrix storing the local blocks of the distributed matrix B and $dtype_z$ is the type of the global matrix Z .

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix $\text{sub}(A)$ of the global matrix A defined by the following 6 values (for dense matrices):

m	The number of rows of $\text{sub}(A)$
n	The number of columns of $\text{sub}(A)$

<i>a</i>	A pointer to the local matrix containing the entire global matrix A
<i>ia</i>	The row index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>ja</i>	The column index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>desca</i>	The array descriptor for the global matrix <i>A</i>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Notice revision #20110804

Routine Naming Conventions

For each routine introduced in this chapter, you can use the ScalAPACK name. The naming convention for ScalAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScalAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

ScalAPACK names have the structure *p?yyzzz* or *p?yyzz*, which is described below.

The initial letter *p* is a distinctive prefix of ScalAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

<i>s</i>	real, single precision
<i>d</i>	real, double precision
<i>c</i>	complex, single precision
<i>z</i>	complex, double precision

The second and third letters *yy* indicate the matrix type as:

<i>ge</i>	general
<i>gb</i>	general band
<i>gg</i>	a pair of general matrices (for a generalized problem)
<i>dt</i>	general tridiagonal (diagonally dominant-like)
<i>db</i>	general band (diagonally dominant-like)
<i>po</i>	symmetric or Hermitian positive-definite
<i>pb</i>	symmetric or Hermitian positive-definite band
<i>pt</i>	symmetric or Hermitian positive-definite tridiagonal
<i>sy</i>	symmetric

st	symmetric tridiagonal (real)
he	Hermitian
or	orthogonal
tr	triangular (or quasi-triangular)
tz	trapezoidal
un	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

sv	a <i>simple</i> driver for solving a linear system
svx	an <i>expert</i> driver for solving a linear system
ls	a driver for solving a linear least squares problem
ev	a simple driver for solving a symmetric eigenvalue problem
evd	a simple driver for solving an eigenvalue problem using a divide and conquer algorithm
evx	an expert driver for solving a symmetric eigenvalue problem
svd	a driver for computing a singular value decomposition
gvx	an expert driver for solving a generalized symmetric definite eigenvalue problem

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Linear Equations

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded

- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table "Computational Routines for Systems of Linear Equations"](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding *driver routine* that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf`(*LU* factorization) and then `p?getrs`(computing the solution).

Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

[Table "Computational Routines for Systems of Linear Equations"](#) lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	<code>p?getrf</code>	<code>p?geequ</code>	<code>p?getrs</code>	<code>p?gecon</code>	<code>p?gerfs</code>	<code>p?getri</code>
general band (partial pivoting)	<code>p?gbtrf</code>		<code>p?gbtrs</code>			
general band (no pivoting)	<code>p?dbtrf</code>		<code>p?dbtrs</code>			
general tridiagonal (no pivoting)	<code>p?dttrf</code>		<code>p?dttrs</code>			
symmetric/Hermitian positive-definite	<code>p?potrf</code>	<code>p?poequ</code>	<code>p?potrs</code>	<code>p?pocon</code>	<code>p?porfs</code>	<code>p?potri</code>
symmetric/Hermitian positive-definite, band	<code>p?pbtrf</code>		<code>p?pbtrs</code>			
symmetric/Hermitian positive-definite, tridiagonal	<code>p?pttrf</code>		<code>p?pttrs</code>			
triangular			<code>p?trtrs</code>	<code>p?trcon</code>	<code>p?trrfs</code>	<code>p?trtri</code>

In this table ? stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex).

Routines for Matrix Factorization

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

`p?getrf`

Computes the LU factorization of a general m-by-n distributed matrix.

Syntax

Fortran:

```
call psgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pdgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pcgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pzgetrf(m, n, a, ia, ja, desca, ipiv, info)
```

C:

```
void psgetrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_INT *info );
void pdgetrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pcgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pzgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?getrf routine forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = P \cdot L \cdot U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The routine uses partial pivoting, with row interchanges.

Input Parameters

m (global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; $n \geq 0$.

n (global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; $n \geq 0$.

a (local)

```
REAL for psgetrf
DOUBLE PRECISION for pdgetrf
COMPLEX for pcgetrf
DOUBLE COMPLEX for pzgetrf.
```

Pointer into the local memory to an array of local dimension (*lld_a*, *LOCc(ja+n-1)*).

Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	Overwritten by local pieces of the factors <i>L</i> and <i>U</i> from the factorization $A = P*L*U$. The unit diagonal elements of <i>L</i> are not stored.
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is (<i>LOCr(m_a) + mb_a</i>). This array contains the pivoting information: local row <i>i</i> was interchanged with global row <i>ipiv(i)</i> . This array is tied to the distributed matrix <i>A</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> = <i>i</i> , u_{ii} is 0. The factorization has been completed, but the factor <i>U</i> is exactly singular. Division by zero will occur if you use the factor <i>U</i> for solving a system of linear equations.

p?gbtrf

Computes the LU factorization of a general *n*-by-*n* banded distributed matrix.

Syntax

Fortran:

```
call psgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pdgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pcgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pzgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
```

C:

```
void psgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , float *af , MKL_INT *laf , float *work , MKL_INT
*lwork , MKL_INT *info );
void pdgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *af , MKL_INT *laf , double *work , MKL_INT
*lwork , MKL_INT *info );
void pcgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *af , MKL_INT *laf ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?gbtrf` routine computes the *LU* factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK routine `?gbtrf`. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P \cdot L \cdot U \cdot Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>a</i>	(local) REAL for <code>psgbtrf</code> DOUBLE PRECISION for <code>pdgbtrf</code> COMPLEX for <code>pcgbtrf</code> DOUBLE COMPLEX for <code>pzgbtrf</code> . Pointer into the local memory to an array of local dimension (<i>lld_a</i> , $LOC_C(ja+n-1)$) where $lld_a \geq 2*bwl + 2*bwu + 1$. Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix A . If $desca(dtype_) = 501$, then $dlen_ \geq 7$;

else if $\text{desca}(\text{dtype}_\perp) = 1$, then $\text{dlen}_\perp \geq 9$.

laf

(local) INTEGER. The dimension of the array af .

Must be $\text{laf} \geq (\text{NB}+\text{bwu}) * (\text{bwl}+\text{bwu}) + 6 * (\text{bwl}+\text{bwu}) * (\text{bwl}+2 * \text{bwu})$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $\text{af}(1)$.

work

(local) Same type as a . Workspace array of dimension lwork .

lwork

(local or global) INTEGER. The size of the work array ($\text{lwork} \geq 1$). If lwork is too small, the minimal acceptable size will be returned in $\text{work}(1)$ and an error code is returned.

Output Parameters

a

On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

ipiv

(local) INTEGER array.

The dimension of ipiv must be $\geq \text{desca}(\text{NB})$.

Contains pivot indices for local factorizations. Note that you *should not alter* the contents of this array between factorization and solve.

af

(local)

REAL for psgbtrf

DOUBLE PRECISION for pdgbtrf

COMPLEX for pcgbtrf

DOUBLE COMPLEX for pzgbtrf .

Array, dimension (laf).

Auxiliary Fillin space. Fillin is created during the factorization routine p?gbtrf and this is stored in af .

Note that if a linear system is to be solved using p?gbtrs after the factorization routine, af must not be altered after the factorization.

$\text{work}(1)$

On exit, $\text{work}(1)$ contains the minimum value of lwork required for optimum performance.

info

(global) INTEGER.

If $\text{info}=0$, the execution is successful.

$\text{info} < 0$:

If the i th argument is an array and the j th entry had an illegal value, then $\text{info} = -(i*100+j)$; if the i th argument is a scalar and had an illegal value, then $\text{info} = -i$.

$\text{info} > 0$:

If $\text{info} = k \leq \text{NPROCS}$, the submatrix stored on processor info and factored locally was not nonsingular, and the factorization was not completed. If $\text{info} = k > \text{NPROCS}$, the submatrix stored on processor info-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbtrf

Computes the LU factorization of a n-by-n diagonally dominant-like banded distributed matrix.

Syntax

Fortran:

```
call psdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pddbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pcdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pzdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
```

C:

```
void psdbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );
void pddbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );
void pcdbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT
*ja , MKL_INT *desca , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzdbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?dbtrf` routine computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Input Parameters

n	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).

<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of <i>A</i> $(0 \leq bwu \leq n-1)$.
<i>a</i>	(local) REAL for psdbtrf DOUBLE PRECISION for pdhbtrf COMPLEX for pcdbtrf DOUBLE COMPLEX for pzdbtrf. Pointer into the local memory to an array of local dimension $(lld_a, LOCc(ja+n-1))$. Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 501, then <i>dlen_</i> ≥ 7 ; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9 .
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> $\geq NB*(bwl+bwu)+6*(\max(bwl,bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af(1)</i> .
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be <i>lwork</i> $\geq (\max(bwl,bwu))^2$. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work(1)</i> and an error code is returned.

Output Parameters

<i>a</i>	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>af</i>	(local) REAL for psdbtrf DOUBLE PRECISION for pdhbtrf COMPLEX for pcdbtrf DOUBLE COMPLEX for pzdbtrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine <i>p?dbtrf</i> and this is stored in <i>af</i> .

Note that if a linear system is to be solved using `p?dbtrs` after the factorization routine, `af` must not be altered after the factorization.

`work(1)`

On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.

If `info=0`, the execution is successful.

`info < 0`:

If the `i`-th argument is an array and the `j`-th entry had an illegal value, then `info = -(i*100+j)`; if the `i`-th argument is a scalar and had an illegal value, then `info = -i`. `info > 0`:

If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not diagonally dominant-like, and the factorization was not completed. If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dttrf

Computes the LU factorization of a diagonally dominant-like tridiagonal distributed matrix.

Syntax

Fortran:

```
call psdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pddttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pcdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pzdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
```

C:

```
void psdttrf (MKL_INT *n , float *dl , float *d , float *du , MKL_INT *ja , MKL_INT
*idesca , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );
void pddttrf (MKL_INT *n , double *dl , double *d , double *du , MKL_INT *ja , MKL_INT
*idesca , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );
void pcdttrf (MKL_INT *n , MKL_Complex8 *dl , MKL_Complex8 *d , MKL_Complex8 *du ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
void pzdttrf (MKL_INT *n , MKL_Complex16 *dl , MKL_Complex16 *d , MKL_Complex16 *du ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16
*work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?dttrf` routine computes the LU factorization of an n -by- n real/complex diagonally dominant-like tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting for stability.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P \cdot L \cdot U \cdot P^T,$$

where P is a permutation matrix, and L and U are banded lower and upper triangular matrices, respectively.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
dl, d, du	(local) REAL for pspttrf DOUBLE PRECISON for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Pointers to the local arrays of dimension $(desca(nb_))$ each. On entry, the array dl contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, $dl(1)$ is not referenced, and dl must be aligned with d . On entry, the array d contains the local part of the global vector storing the diagonal elements of the matrix. On entry, the array du contains the local part of the global vector storing the super-diagonal elements of the matrix. $du(n)$ is not referenced, and du must be aligned with d .
ja	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A . If $desca(dtype_)$ = 501, then $dlen_ \geq 7$; else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.
laf	(local) INTEGER. The dimension of the array af . Must be $laf \geq 2*(NB+2)$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af(1)$.
$work$	(local) Same type as d . Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER. The size of the $work$ array, must be at least $lwork \geq 8*NPCOL$.

Output Parameters

dl, d, du	On exit, overwritten by the information containing the factors of the matrix.
af	(local)

REAL for psdttrf
 DOUBLE PRECISION for pdattrf
 COMPLEX for pcdttrf
 DOUBLE COMPLEX for pzdttrf.
 Array, dimension (*laf*).

Auxiliary Fillin space. Fillin is created during the factorization routine p?dttrf and this is stored in *af*.

Note that if a linear system is to be solved using [p?dttrs](#) after the factorization routine, *af* must not be altered.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.

If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*) ; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not diagonally dominant-like, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

Fortran:

```
call pspotrf(uplo, n, a, ia, ja, desca, info)
call pdpotrf(uplo, n, a, ia, ja, desca, info)
call pcpotrf(uplo, n, a, ia, ja, desca, info)
call pzpotrf(uplo, n, a, ia, ja, desca, info)
```

C:

```
void pspotrf (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdpotrf (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
void pcpotrf (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

```
void pzpotrf (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?potrf` routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $\text{sub}(A)$.

The factorization has the form

$\text{sub}(A) = U^H * U$ if $\text{uplo} = 'U'$, or

$\text{sub}(A) = L * L^H$ if $\text{uplo} = 'L'$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. Must be ' <code>U</code> ' or ' <code>L</code> '. If <code>uplo</code> = ' <code>U</code> ', the array <code>a</code> stores the upper triangular part of the matrix <code>sub(A)</code> that is factored as $U^H * U$. If <code>uplo</code> = ' <code>L</code> ', the array <code>a</code> stores the lower triangular part of the matrix <code>sub(A)</code> that is factored as $L * L^H$.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pspotrf</code> DOUBLE PRECISON for <code>pdpotrf</code> COMPLEX for <code>pcpotrf</code> DOUBLE COMPLEX for <code>pzpotrf</code> . Pointer into the local memory to an array of dimension $(\text{lld}_a, \text{LOCc}(ja + n - 1))$. On entry, this array contains the local pieces of the n -by- n symmetric/ Hermitian distributed matrix $\text{sub}(A)$ to be factored. Depending on <code>uplo</code> , the array <code>a</code> contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see <code>uplo</code>).
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix A .

Output Parameters

a The upper or lower triangular part of *a* is overwritten by the Cholesky factor *U* or *L*, as specified by *uplo*.

info (global) INTEGER.
 If *info*=0, the execution is successful;
info < 0: if the *i*-th argument is an array, and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 If *info* = *k* > 0, the leading minor of order *k*, *A*(*ia*:*ia+k-1*, *ja*:*ja+k-1*), is not positive-definite, and the factorization could not be completed.

p?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite banded distributed matrix.

Syntax

Fortran:

```
call pspbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pdpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pcpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pzpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
```

C:

```
void pspbtrf (char *uplo , MKL_INT *n , MKL_INT *bw , float *a , MKL_INT *ja , MKL_INT
*desca , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );
void pdpbtrf (char *uplo , MKL_INT *n , MKL_INT *bw , double *a , MKL_INT *ja ,
MKL_INT *desca , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );
void pcpbtrf (char *uplo , MKL_INT *n , MKL_INT *bw , MKL_Complex8 *a , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzpbtrf (char *uplo , MKL_INT *n , MKL_INT *bw , MKL_Complex16 *a , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?pbtrf routine computes the Cholesky factorization of an *n*-by-*n* real symmetric or complex Hermitian positive-definite banded distributed matrix *A*(1:*n*, *ja*:*ja+n-1*).

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P * U^H * U * P^T$, if $\text{uplo} = \text{'U'}$, or

$A(1:n, ja:ja+n-1) = P * L * L^H * P^T$, if $\text{uplo} = \text{'L'}$,

where P is a permutation matrix and U and L are banded upper and lower triangular matrices, respectively.

Input Parameters

uplo

(global) CHARACTER*1. Must be '*U*' or '*L*'.

If *uplo* = '*U*', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

If *uplo* = '*L*', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

n

(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$.

($n \geq 0$).

bw

(global) INTEGER.

The number of superdiagonals of the distributed matrix if *uplo* = '*U*', or the number of subdiagonals if *uplo* = '*L*' ($bw \geq 0$).

a

(local)

REAL for pspbtrf

DOUBLE PRECISON for pdpbtrf

COMPLEX for pcpbtrf

DOUBLE COMPLEX for pzpbtrf.

Pointer into the local memory to an array of dimension

(*lld_a*, *LOCc(ja+n-1)*).

On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored.

ja

(global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

If *desca(dtype_)* = 501, then *dlen_* ≥ 7 ;

else if *desca(dtype_)* = 1, then *dlen_* ≥ 9 .

laf

(local) INTEGER. The dimension of the array *af*.

Must be *laf* $\geq (\text{NB} + 2 * bw) * bw$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af(1)*.

work

(local) Same type as *a*. Workspace array of dimension *lwork*.

lwork

(local or global) INTEGER. The size of the *work* array, must be *lwork* $\geq bw^2$.

Output Parameters

a On exit, if *info*=0, contains the permuted triangular factor *U* or *L* from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$, as specified by *uplo*.

af (local)
 REAL for pspbtrf
 DOUBLE PRECISON for pdpbtrf
 COMPLEX for pcpbtrf
 DOUBLE COMPLEX for pzpbtrf.

Array, dimension (*laf*). Auxiliary Fillin space. Fillin is created during the factorization routine *p?pbtrf* and this is stored in *af*. Note that if a linear system is to be solved using *p?pbtrs* after the factorization routine, *af* must not be altered.

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 If *info*=0, the execution is successful.
info < 0:
 If the *i*th argument is an array and the *j*th entry had an illegal value, then *info* = -(*i**100+*j*) ; if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*.
info>0:
 If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
 If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?pttrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite tridiagonal distributed matrix.

Syntax

Fortran:

```
call pspttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pdpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pcpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pzpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
```

C:

```

void pspttrf (MKL_INT *n , float *d , float *e , MKL_INT *ja , MKL_INT *desca , float
*af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pdpttrf (MKL_INT *n , double *d , double *e , MKL_INT *ja , MKL_INT *desca ,
double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );

void pcpttrf (MKL_INT *n , float *d , MKL_Complex8 *e , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzpttrf (MKL_INT *n , double *d , MKL_Complex16 *e , MKL_INT *ja , MKL_INT
*desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork ,
MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?pttrf routine computes the Cholesky factorization of an n -by- n real symmetric or complex hermitian positive-definite tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P \cdot L \cdot D \cdot L^H \cdot P^T, \text{ or}$$

$$A(1:n, ja:ja+n-1) = P \cdot U^H \cdot D \cdot U \cdot P^T,$$

where P is a permutation matrix, and U and L are tridiagonal upper and lower triangular matrices, respectively.

Input Parameters

n (global) INTEGER. The order of the distributed submatrix $A(1:n,$
 $ja:ja+n-1)$
 $(n \geq 0)$.

d, e (local)
REAL for pspttrf
DOUBLE PRECISON for pdpttrf
COMPLEX for pcpttrf
DOUBLE COMPLEX for pzpttrf.
Pointers into the local memory to arrays of dimension (*desca(nb_)*) each.
On entry, the array *d* contains the local part of the global vector storing the main diagonal of the distributed matrix *A*.
On entry, the array *e* contains the local part of the global vector storing the upper diagonal of the distributed matrix *A*.

ja (global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 501, then <i>dlen_</i> ≥ 7 ; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9 .
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> $\geq \text{NB}+2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>d</i> and <i>e</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least <i>lwork</i> $\geq 8 * \text{NPCOL}$.

Output Parameters

<i>d, e</i>	On exit, overwritten by the details of the factorization.
<i>af</i>	(local) REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?pttrf and this is stored in <i>af</i> . Note that if a linear system is to be solved using p?pttrs after the factorization routine, <i>af</i> must not be altered.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. <i>info</i> > 0: If <i>info</i> = <i>k</i> $\leq \text{NPROCS}$, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> $> \text{NPROCS}$, the submatrix stored on processor <i>info-NPROCS</i> representing interactions with other processors was not nonsingular, and the factorization was not completed.

Routines for Solving Systems of Linear Equations

This section describes the ScalAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.

Syntax

Fortran:

```
call psgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

C:

```
void psgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb ,

Description

The p?getrs routine solves a system of distributed linear equations with a general n -by- n distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by p?getrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),
 $\text{sub}(A)^T * X = \text{sub}(B)$ (transpose),
 $\text{sub}(A)^H * X = \text{sub}(B)$ (conjugate transpose),
where $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$.

Before calling this routine, you must call p?getrf to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)^*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $\text{sub}(A)^H*X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(global) REAL for psgetrs DOUBLE PRECISION for pdgetrs COMPLEX for pcgetrs DOUBLE COMPLEX for pzgetrs. Pointers into the local memory to arrays of local dimension $a(lld_a, LOCr(ja+n-1))$ and $b(lld_b, LOCr(jb+nrhs-1))$, respectively. On entry, the array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P^*L^*U$; the unit diagonal elements of <i>L</i> are not stored. On entry, the array <i>b</i> contains the right hand sides $\text{sub}(B)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is $(LOCr(m_a) + mb_a)$. This array contains the pivoting information: local row <i>i</i> of the matrix was interchanged with the global row <i>ipiv(i)</i> . This array is tied to the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	On exit, overwritten by the solution distributed matrix <i>X</i> .
----------	--

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then
 $info = -(i*100+j)$; if the *i*-th argument is a scalar and had an illegal
 value, then *info* = *i*.

p?gbtrs

Solves a system of distributed linear equations with a general band matrix, using the LU factorization computed by p?gbtrf.

Syntax

Fortran:

```
call psgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)

call pdgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)

call pcgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)

call pzgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)
```

C:

Description

The p?gbtrs routine solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the LU factorization computed by p?gbtrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T X = \text{sub}(B)$ (transpose),
 $\text{sub}(A)^H X = \text{sub}(B)$ (conjugate transpose),
where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this routine, you must call [p?gbtrf](#) to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)^* X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $\text{sub}(A)^T X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $\text{sub}(A)^H X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(global) REAL for psgbtrs DOUBLE PRECISION for pdgbtrs COMPLEX for pcgbtrs DOUBLE COMPLEX for pzgbtrs. Pointers into the local memory to arrays of local dimension $a(1ld_a, LOC_c(ja+n-1))$ and $b(1ld_b, LOC_c(nrhs))$, respectively. The array <i>a</i> contains details of the LU factorization of the distributed band matrix <i>A</i> . On entry, the array <i>b</i> contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 501, then <i>dlen_</i> ≥ 7 ; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9 .

<i>ib</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 502 , then <i>dlen_</i> \geq 7; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> \geq 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> \geq NB*(<i>bwl</i> + <i>bwu</i>)+6* <i>(bwl</i> + <i>bwu</i>)*(<i>bwl</i> +2* <i>bwu</i>). If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least <i>lwork</i> \geq <i>nrhs</i> * (NB+2 * <i>bwl</i> +4 * <i>bwu</i>).

Output Parameters

<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> must be \geq <i>desca</i> (NB) . Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.
<i>b</i>	On exit, overwritten by the local pieces of the solution distributed matrix <i>X</i> .
<i>af</i>	(local) REAL for psgbtrs DOUBLE PRECISION for pdgbtrs COMPLEX for pcgbtrs DOUBLE COMPLEX for pzgbtrs. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?gbtrf and this is stored in <i>af</i> . Note that if a linear system is to be solved using p?gbtrs after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>) ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?dbtrs

Solves a system of linear equations with a diagonally dominant-like banded distributed matrix using the factorization computed by p?dbtrf.

Syntax

FORTRAN 77:

```
call psdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pddbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,

Description

The p?dbtrs routine solves for X one of the systems of equations:

```
sub(A)*X = sub(B),
(sub(A))T*X = sub(B), or
(sub(A))H*X = sub(B),
```

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by p?dbtrf.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
--------------	--

Indicates the form of the equations:

If $\text{trans} = \text{'N'}$, then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .

If $\text{trans} = \text{'T'}$, then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .

If $\text{trans} = \text{'C'}$, then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X .

n (global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

bwl (global) INTEGER. The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).

bwu (global) INTEGER. The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$).

nrhs (global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).

a, b (local)

REAL for psdbtrs

DOUBLE PRECISON for pddbtrs

COMPLEX for pcdptrs

DOUBLE COMPLEX for pzdbtrs.

Pointers into the local memory to arrays of local dimension $a(\text{lld}_a, \text{LOCc}(ja+n-1))$ and $b(\text{lld}_b, \text{LOCc}(nrhs))$, respectively.

On entry, the array *a* contains details of the LU factorization of the band matrix A , as computed by p?dbtrf.

On entry, the array *b* contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$.

ja (global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix A .

If $\text{desca}(\text{dtype}_-) = 501$, then $\text{dlen}_- \geq 7$;

else if $\text{desca}(\text{dtype}_-) = 1$, then $\text{dlen}_- \geq 9$.

ib (global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix B .

If $\text{descb}(\text{dtype}_-) = 502$, then $\text{dlen}_- \geq 7$;

else if $\text{descb}(\text{dtype}_-) = 1$, then $\text{dlen}_- \geq 9$.

af, work (local)

REAL for psdbtrs
 DOUBLE PRECISION for pdabtrs
 COMPLEX for pcdbtrs
 DOUBLE COMPLEX for pzdbtrs.

Arrays of dimension (*laf*) and (*lwork*), respectively. The array *af* contains auxiliary Fillin space. Fillin is created during the factorization routine p?dbtrf and this is stored in *af*.

The array *work* is a workspace array.

laf

(local) INTEGER. The dimension of the array *af*.

Must be $laf \geq NB * (bw1 + bwu) + 6 * (\max(bw1, bwu))^2$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

desca

(local or global) INTEGER. The size of the array *work*, must be at least

$lwork \geq (\max(bw1, bwu))^2$.

Output Parameters

b

On exit, this array contains the local pieces of the solution distributed matrix *X*.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

INTEGER. If *info*=0, the execution is successful. *info* < 0:

if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?dttrs

Solves a system of linear equations with a diagonally dominant-like tridiagonal distributed matrix using the factorization computed by p?dttrf.

Syntax

Fortran:

```
call psdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pcdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pzdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

C:

```

void psdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl , float *d ,
              float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
              MKL_INT *descb , float *af , MKL_INT *laf , float *work ,
              MKL_INT *lwork , MKL_INT *info );

void pddttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl , double *d ,
               double *du , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
               MKL_INT *descb , double *af , MKL_INT *laf , double *work ,
               MKL_INT *lwork , MKL_INT *info );

void pcdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *dl ,
               MKL_Complex8 *d , MKL_Complex8 *du , MKL_INT *ja , MKL_INT *desca ,
               MKL_Complex8 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af ,
               MKL_INT *laf , MKL_Complex8 *work , MKL_INT *lwork ,
               MKL_INT *info );

void pzdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *dl ,
               MKL_Complex16 *d , MKL_Complex16 *du , MKL_INT *ja , MKL_INT *desca ,
               MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af ,
               MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork ,
               MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?dttrs routine solves for X one of the systems of equations:

```

sub(A)*X = sub(B),
(sub(A))^T*X = sub(B), or
(sub(A))^H*X = sub(B),

```

where $\text{sub}(A) = (1:n, ja:ja+n-1)$; is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by p?dttrf.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
	Indicates the form of the equations:
	If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X .
	If <i>trans</i> = 'T', then $(\text{sub}(A))^T*X = \text{sub}(B)$ is solved for X .
	If <i>trans</i> = 'C', then $(\text{sub}(A))^H*X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>dl, d, du</i>	(local)
	REAL for psdttrs
	DOUBLE PRECISION for pddttrs
	COMPLEX for pcdttrs
	DOUBLE COMPLEX for pzdttrs.
	Pointers to the local arrays of dimension (<i>desca(nb_)</i>) each.

On entry, these arrays contain details of the factorization. Globally, $d(1)$ and $du(n)$ are not referenced; dl and du must be aligned with d .

ja (global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

desca (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A . If $desca(dtype_)$ = 501 or 502, then $dlen_ \geq 7$;
else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.

b (local) Same type as d .
 Pointer into the local memory to an array of local dimension
 $b(lld_b, LOCc(nrhs))$.
 On entry, the array b contains the local pieces of the n -by- $nrhs$ right hand side distributed matrix sub(B).

ib (global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).

descb (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B .
If $descb(dtype_)$ = 502, then $dlen_ \geq 7$;
else if $descb(dtype_)$ = 1, then $dlen_ \geq 9$.

af, work (local) REAL for psdttrs
 DOUBLE PRECISION for pddttrs
 COMPLEX for pcdttrs
 DOUBLE COMPLEX for pzdttrs.

Arrays of dimension (*laf*) and (*lwork*), respectively.

The array *af* contains auxiliary Fillin space. Fillin is created during the factorization routine $p?dttrf$ and this is stored in *af*. If a linear system is to be solved using $p?dttrs$ after the factorization routine, *af* must not be altered.

The array *work* is a workspace array.

laf (local) INTEGER. The dimension of the array *af*.
 Must be $laf \geq NB * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2 * bwu)$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

lwork (local or global) INTEGER. The size of the array *work*, must be at least
 $lwork \geq 10 * NPCOL + 4 * nrhs$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix X .
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of $\lceil \text{work} \rceil$ required for optimum performance.
<i>info</i>	INTEGER. If $\text{info}=0$, the execution is successful. $\text{info} < 0$: if the i -th argument is an array and the j -th entry had an illegal value, then $\text{info} = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?potrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian distributed positive-definite matrix.

Syntax

Fortran:

```
call pspotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

C:

```
void pspotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *info );
void pdpotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb , MKL_INT *info );

Description

The p?potrs routine solves for X a system of distributed linear equations in the form:

$\text{sub}(A) * X = \text{sub}(B)$,

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

This routine uses Cholesky factorization

`sub(A) = UH*U, or sub(A) = L*LH`

computed by `p?potrf`.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be 'U' or 'L'. If <code>uplo</code> = 'U', upper triangle of <code>sub(A)</code> is stored; If <code>uplo</code> = 'L', lower triangle of <code>sub(A)</code> is stored.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix <code>sub(B)</code> ($nrhs \geq 0$).
<code>a, b</code>	(local) REAL for <code>pspotrs</code> DOUBLE PRECISION for <code>pdpotrs</code> COMPLEX for <code>pcpotrs</code> DOUBLE COMPLEX for <code>pzpotrs</code> . Pointers into the local memory to arrays of local dimension <code>a(lld_a, LOCc(ja+n-1))</code> and <code>b(lld_b, LOCc(jb+nrhs-1))</code> , respectively. The array <code>a</code> contains the factors <code>L</code> or <code>U</code> from the Cholesky factorization <code>sub(A) = L*L^H</code> or <code>sub(A) = U^H*U</code> , as computed by <code>p?potrf</code> . On entry, the array <code>b</code> contains the local pieces of the right hand sides <code>sub(B)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>A</code> .
<code>ib, jb</code>	(global) INTEGER. The row and column indices in the global array <code>B</code> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively.
<code>descb</code>	(local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>B</code> .

Output Parameters

<code>b</code>	Overwritten by the local pieces of the solution matrix <code>X</code> .
<code>info</code>	INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : if the i -th argument is an array and the j -th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian positive-definite band matrix.

Syntax

Fortran:

```
call pspbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pdpbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pcpbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pzpbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

C:

Description

The p?pbtrs routine solves for X a system of distributed linear equations in the form:

$\text{sub}(A) * X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses Cholesky factorization

$\text{sub}(A) = P * U^H * U * P^T$, or $\text{sub}(A) = P * L * L^H * P^T$

computed by p?pbtrf.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, upper triangle of $\text{sub}(A)$ is stored;
 If $uplo = 'L'$, lower triangle of $\text{sub}(A)$ is stored.

n (global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

bw (global) INTEGER. The number of superdiagonals of the distributed matrix if $uplo = 'U'$, or the number of subdiagonals if $uplo = 'L'$ ($bw \geq 0$).

nrhs (global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).

a, b (local)

REAL for pspbtrs
 DOUBLE PRECISION for pdpbtrs
 COMPLEX for pcpbtrs
 DOUBLE COMPLEX for pzpbtrs.

Pointers into the local memory to arrays of local dimension $a(lld_a, LOCc(ja+n-1))$ and $b(lld_b, LOCc(nrhs-1))$, respectively.

The array *a* contains the permuted triangular factor *U* or *L* from the Cholesky factorization $\text{sub}(A) = P^* U^{H*} U^* P^T$, or $\text{sub}(A) = P^* L^* L^{H*} P^T$ of the band matrix *A*, as returned by [p?pbtrf](#).

On entry, the array *b* contains the local pieces of the *n*-by-*nrhs* right hand side distributed matrix $\text{sub}(B)$.

ja (global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

If $\text{desca}(\text{dtype}_) = 501$, then $dlen_ \geq 7$;
 else if $\text{desca}(\text{dtype}_) = 1$, then $dlen_ \geq 9$.

ib (global) INTEGER. The row index in the global array *B* indicating the first row of the submatrix $\text{sub}(B)$.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

If $\text{descb}(\text{dtype}_) = 502$, then $dlen_ \geq 7$;
 else if $\text{descb}(\text{dtype}_) = 1$, then $dlen_ \geq 9$.

af, work (local) Arrays, same type as *a*.

The array *af* is of dimension (*laf*). It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?dbtrf](#) and this is stored in *af*.

The array *work* is a workspace array of dimension *lwork*.

laf (local) INTEGER. The dimension of the array *af*.

Must be $\text{laf} \geq nrhs * bw$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af(1)$.

$lwork$ (local or global) INTEGER. The size of the array $work$, must be at least $lwork \geq bw^2$.

Output Parameters

b On exit, if $info=0$, this array contains the local pieces of the n -by- $nrhs$ solution distributed matrix X .

$work(1)$ On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$ INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal distributed matrix using the factorization computed by p?pttrf.

Syntax

Fortran:

```
call pspttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pdpttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

C:

```
void pspttrs (MKL_INT *n , MKL_INT *nrhs , float *d , float *e , MKL_INT *ja , MKL_INT
*desca , float *b , MKL_INT *ib , MKL_INT *descb , float *af , MKL_INT *laf , float
*work , MKL_INT *lwork , MKL_INT *info );
void pdpttrs (MKL_INT *n , MKL_INT *nrhs , double *d , double *e , MKL_INT *ja ,
MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb , double *af , MKL_INT
*laf , double *work , MKL_INT *lwork , MKL_INT *info );
void pcpttrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *d , MKL_Complex8 *e ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *descb ,
MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzpttrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb ,
MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Description

The `p?pttrs` routine solves for X a system of distributed linear equations in the form:

`sub(A) * X = sub(B)`,

where `sub(A) = A(1:n, ja:ja+n-1)` is an n -by- n real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and `sub(B)` denotes the distributed matrix `B(ib:ib+n-1, 1:nrhs)`.

This routine uses the factorization

`sub(A) = P * L * D * LH * PT`, or `sub(A) = P * UH * D * U * PT`

computed by `p?pttrf`.

Input Parameters

<code>uplo</code>	(global, used in complex flavors only) CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. If <code>uplo</code> = ' <code>U</code> ', upper triangle of <code>sub(A)</code> is stored; If <code>uplo</code> = ' <code>L</code> ', lower triangle of <code>sub(A)</code> is stored.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix <code>sub(B)</code> ($nrhs \geq 0$).
<code>d, e</code>	(local) REAL for <code>pspttrs</code> DOUBLE PRECISION for <code>pdpttrs</code> COMPLEX for <code>pcpttrs</code> DOUBLE COMPLEX for <code>pzpttrs</code> . Pointers into the local memory to arrays of dimension (<code>desca(nb_)</code>) each. These arrays contain details of the factorization as returned by <code>p?pttrf</code>
<code>ja</code>	(global) INTEGER. The index in the global array <code>A</code> that points to the start of the matrix to be operated on (which may be either all of <code>A</code> or a submatrix of <code>A</code>).
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>A</code> . If <code>desca(dtype_) = 501</code> or <code>502</code> , then <code>dlen_ ≥ 7</code> ; else if <code>desca(dtype_) = 1</code> , then <code>dlen_ ≥ 9</code> .
<code>b</code>	(local) Same type as <code>d, e</code> . Pointer into the local memory to an array of local dimension <code>b(lld_b, LOCc(nrhs))</code> .

On entry, the array b contains the local pieces of the n -by- $nrhs$ right hand side distributed matrix sub(B).

ib	(global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
$descb$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B . If $descb(dtype_)$ = 502, then $dlen_ \geq 7$; else if $descb(dtype_)$ = 1, then $dlen_ \geq 9$.
$af, work$	(local) REAL for pspttrs DOUBLE PRECISION for pdpttrs COMPLEX for pcpttrs DOUBLE COMPLEX for pzpttrs. Arrays of dimension (laf) and ($lwork$), respectively. The array af contains auxiliary Fillin space. Fillin is created during the factorization routine p?pttrf and this is stored in af . The array $work$ is a workspace array.
laf	(local) INTEGER. The dimension of the array af . Must be $laf \geq NB+2$. If laf is not large enough, an error code is returned and the minimum acceptable size will be returned in $af(1)$.
$lwork$	(local or global) INTEGER. The size of the array $work$, must be at least $lwork \geq (10+2*\min(100,nrhs))*NPCOL+4*nrhs$.

Output Parameters

b	On exit, this array contains the local pieces of the solution distributed matrix X .
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	INTEGER. If $info=0$, the execution is successful. $info < 0$: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?trtrs

Solves a system of linear equations with a triangular distributed matrix.

Syntax

Fortran:

```
call pstrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdtrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pctrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pztrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

C:

```
void pstrtrs (char *uplo , char *trans , char *diag , MKL_INT *n , MKL_INT *nrhs ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pdtrtrs (char *uplo , char *trans , char *diag , MKL_INT *n , MKL_INT *nrhs ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pctrtrs (char *uplo , char *trans , char *diag , MKL_INT *n , MKL_INT *nrhs ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pztrtrs (char *uplo , char *trans , char *diag , MKL_INT *n , MKL_INT *nrhs ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?trtrs routine solves for X one of the following systems of linear equations:

```
sub(A)*X = sub(B),
(sub(A))T*X = sub(B), or
(sub(A))H*X = sub(B),
```

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Indicates whether $\text{sub}(A)$ is upper or lower triangular:

If *uplo* = 'U', then $\text{sub}(A)$ is upper triangular.

If *uplo* = 'L', then $\text{sub}(A)$ is lower triangular.

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If *trans* = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X .

If *trans* = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X .

If $\text{trans} = \text{'C'}$, then $\text{sub}(A)^H X = \text{sub}(B)$ is solved for X .

diag

(global) CHARACTER*1. Must be ' N ' or ' U '.

If $\text{diag} = \text{'N'}$, then $\text{sub}(A)$ is not a unit triangular matrix.

If $\text{diag} = \text{'U'}$, then $\text{sub}(A)$ is unit triangular.

n

(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

nrhs

(global) INTEGER. The number of right-hand sides; i.e., the number of columns of the distributed matrix $\text{sub}(B)$ ($\text{nrhs} \geq 0$).

a, b

(local)

REAL for pstrtrs

DOUBLE PRECISION for pdtrtrs

COMPLEX for pcptrtrs

DOUBLE COMPLEX for pzptrtrs.

Pointers into the local memory to arrays of local dimension

$a(\text{lld}_a, \text{LOCc}(ja+n-1))$ and $b(\text{lld}_b, \text{LOCc}(jb+nrhs-1))$, respectively.

The array a contains the local pieces of the distributed triangular matrix $\text{sub}(A)$.

If $\text{uplo} = \text{'U'}$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $\text{uplo} = \text{'L'}$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

If $\text{diag} = \text{'U'}$, the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1.

On entry, the array b contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desc_a

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

ib, jb

(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.

desc_b

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B .

Output Parameters

b

On exit, if $\text{info}=0$, $\text{sub}(B)$ is overwritten by the solution matrix X .

info INTEGER. If *info*=0, the execution is successful.

info < 0:

if the *i*th argument is an array and the *j*th entry had an illegal value, then
info = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal
value, then *info* = -*i*;

info > 0:

if *info* = *i*, the *i*-th diagonal element of sub(*A*) is zero, indicating that the
submatrix is singular and the solutions *X* have not been computed.

Routines for Estimating the Condition Number

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

Fortran:

```
call psgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pdgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pcgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)

call pzgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)
```

C:

```
void psgecon (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );

void pdgecon (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , double *work , MKL_INT *lwork ,
MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );

void pcgecon (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );

void pzgecon (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?gecon` routine estimates the reciprocal of the condition number of a general distributed real/complex matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ in either the 1-norm or infinity-norm, using the *LU* factorization computed by `p?getrf`.

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

... : ! : ! : ! : ! : ! : ! : ! : ! : ! : ! : ! : ! : ! : !

Input Parameters

norm

(global) CHARACTER*1. Must be '1' or 'O' or 'I'.

Specifies whether the 1-norm condition number or the infinity-norm condition number is required.

If *norm* = '1' or 'O', then the 1-norm is used;

If *norm* = 'I', then the infinity-norm is used.

n

(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

a

(local)

REAL for psgecon

DOUBLE PRECISION for pdgecon

COMPLEX for pcgecon

DOUBLE COMPLEX for pzgecon.

Pointer into the local memory to an array of dimension $a(\text{lld}_a, \text{LOCc}(\text{ja} + n - 1))$.

The array *a* contains the local pieces of the factors *L* and *U* from the factorization $\text{sub}(A) = P*L*U$; the unit diagonal elements of *L* are not stored.

ia, ja

(global) INTEGER. The row and column indices in the global array *A* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

anorm

(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors.

If *norm* = '1' or 'O', the 1-norm of the original distributed matrix $\text{sub}(A)$;

If *norm* = 'I', the infinity-norm of the original distributed matrix $\text{sub}(A)$.

<i>work</i>	(local) REAL for psgecon DOUBLE PRECISION for pdgecon COMPLEX for pcgecon DOUBLE COMPLEX for pzgecon.
	The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a)) + 2 * LOCc(n + \text{mod}(ja-1, nb_a)) + \max(2, \max(nb_a * \max(1, \text{ceil}(NPROW-1, NPCOL)), LOCc(n + \text{mod}(ja-1, nb_a)) + nb_a * \max(1, \text{ceil}(NPCOL-1, NPROW)))) .$
	<i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a)) + \max(2, \max(nb_a * \text{ceil}(NPROW-1, NPCOL), LOCc(n + \text{mod}(ja-1, nb_a)) + nb_a * \text{ceil}(NPCOL-1, NPROW))) .$
	<i>LOCr</i> and <i>LOCc</i> values can be computed using the ScaLAPACK tool function <i>numroc</i> ; <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> .
<i>iwork</i>	(local) INTEGER. Workspace array, size (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia-1, mb_a)) .$
<i>rwork</i>	(local) REAL for pcgecon DOUBLE PRECISION for pzgecon Workspace array, size (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq \max(1, 2 * LOCc(n + \text{mod}(ja-1, nb_a))) .$

Output Parameters

<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The reciprocal of the condition number of the distributed matrix <i>sub(A)</i> . See Description.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.

<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful.
	<i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>) ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?pocon

Estimates the reciprocal of the condition number (in the 1 - norm) of a symmetric / Hermitian positive-definite distributed matrix.

Syntax

Fortran:

```
call pspocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pdpocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pcpocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)

call pzpocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)
```

C:

```
void pspocon (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );

void pdpocon (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , double *work , MKL_INT *lwork ,
MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );

void pcpocon (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );

void pzpocon (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,

Description

The p?pocon routine estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, using the Cholesky factorization $\text{sub}(A) = U^H \cdot U$ or $\text{sub}(A) = L \cdot L^H$ computed by p?potrf.

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

www.ijerph.org | ISSN: 1660-4601 | DOI: 10.3390/ijerph17030894

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the factor stored in sub(<i>A</i>) is upper or lower triangular. If <i>uplo</i> = 'U', sub(<i>A</i>) stores the upper triangular factor <i>U</i> of the Cholesky factorization sub (<i>A</i>) = $U^H * U$. If <i>uplo</i> = 'L', sub(<i>A</i>) stores the lower triangular factor <i>L</i> of the Cholesky factorization sub (<i>A</i>) = $L * L^H$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	(local) REAL for pspocon DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon. Pointer into the local memory to an array of dimension <i>a</i> (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). The array <i>a</i> contains the local pieces of the factors <i>L</i> or <i>U</i> from the Cholesky factorization sub (<i>A</i>) = $U^H * U$, or sub (<i>A</i>) = $L * L^H$, as computed by p?potrf.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors. The 1-norm of the symmetric/Hermitian distributed matrix sub(<i>A</i>).
<i>work</i>	(local) REAL for pspocon DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.

<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> .
	<i>For real flavors:</i>
	<i>lwork</i> must be at least
	$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a)) + 2 * LOCc(n + \text{mod}(ja-1, nb_a)) + \max(2, \max(nb_a * \text{ceil}(NPROW-1, NPCOL), LOCc(n + \text{mod}(ja-1, nb_a)) + nb_a * \text{ceil}(NPCOL-1, NPROW))).$
	<i>For complex flavors:</i>
	<i>lwork</i> must be at least
	$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a)) + \max(2, \max(nb_a * \max(1, \text{ceil}(NPROW-1, NPCOL)), LOCc(n + \text{mod}(ja-1, nb_a)) + nb_a * \max(1, \text{ceil}(NPCOL-1, NPROW)))).$
<i>iwork</i>	(local) INTEGER. Workspace array, size (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia-1, mb_a))$.
<i>rwork</i>	(local) REAL for pcpocon DOUBLE PRECISION for pzpocon Workspace array, size (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq 2 * LOCc(n + \text{mod}(ja-1, nb_a))$.

Output Parameters

<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The reciprocal of the condition number of the distributed matrix $\text{sub}(A)$.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork(1)</i>	On exit, <i>iwork(1)</i> contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork(1)</i>	On exit, <i>rwork(1)</i> contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = $-(i * 100 + j)$; if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

p?trcon

Estimates the reciprocal of the condition number of a triangular distributed matrix in either 1-norm or infinity-norm.

Syntax

Fortran:

```
call pstrcon(
  norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, iwork, liwork, info)
call pdtrcon(
  norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, iwork, liwork, info)
call pcptrcon(
  norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, rwork, lrwork, info)
call pzptrcon(
  norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, rwork, lrwork, info)
```

C:

```
void pstrcon (char *norm , char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT
  *ia , MKL_INT *ja , MKL_INT *desca , float *rcond , float *work , MKL_INT *lwork ,
  MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
void pdtrcon (char *norm , char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT
  *ia , MKL_INT *ja , MKL_INT *desca , double *rcond , double *work , MKL_INT *lwork ,
  MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
void pcptrcon (char *norm , char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a ,
  MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *rcond , MKL_Complex8 *work ,
  MKL_INT *lwork , float *rwork , MKL_INT *lrwork , MKL_INT *info );
void pzptrcon (char *norm , char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a ,

```

Include Files

- C: mkl_scalapack.h

Description

The p?trcon routine estimates the reciprocal of the condition number of a triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, in either the 1-norm or the infinity-norm.

The norm of $\text{sub}(A)$ is computed and an estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, then the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

Input Parameters

<i>norm</i>	(global) CHARACTER*1. Must be '1' or 'O' or 'I'.
	Specifies whether the 1-norm condition number or the infinity-norm condition number is required.

If $norm = '1'$ or ' ∞ ', then the 1-norm is used;
 If $norm = 'I'$, then the infinity-norm is used.

uplo
 (global) CHARACTER*1. Must be ' U ' or ' L '.
 If $uplo = 'U'$, $\text{sub}(A)$ is upper triangular. If $uplo = 'L'$, $\text{sub}(A)$ is lower triangular.

diag
 (global) CHARACTER*1. Must be ' N ' or ' U '.
 If $diag = 'N'$, $\text{sub}(A)$ is non-unit triangular. If $diag = 'U'$, $\text{sub}(A)$ is unit triangular.

n
 (global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$, ($n \geq 0$).

a
 (local)
 REAL for pstrcon
 DOUBLE PRECISION for pdtrcon
 COMPLEX for pcstrcon
 DOUBLE COMPLEX for pztrcon.
 Pointer into the local memory to an array of dimension
 $a(1:ld_a, 1:LOCc(ja+n-1))$.
 The array *a* contains the local pieces of the triangular distributed matrix $\text{sub}(A)$.
 If $uplo = 'U'$, the leading n -by- n upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced.
 If $uplo = 'L'$, the leading n -by- n lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced.
 If $diag = 'U'$, the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1.

ia, ja
 (global) INTEGER. The row and column indices in the global array *A* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

work
 (local)
 REAL for pstrcon
 DOUBLE PRECISION for pdtrcon
 COMPLEX for pcstrcon
 DOUBLE COMPLEX for pztrcon.
 The array *work* of dimension (*lwork*) is a workspace array.

lwork
 (local or global) INTEGER. The dimension of the array *work*.

For real flavors:

lwork must be at least

$$\begin{aligned} lwork \geq 2 * LOCr(n+mod(ia-1, mb_a)) + LOCc(n+mod(ja-1, nb_a)) + \\ \max(2, \max(nb_a * \max(1, \text{ceil}(NPROW-1, NPCOL)), \\ LOCc(n+mod(ja-1, nb_a)) + nb_a * \max(1, \text{ceil}(NPCOL-1, NPROW)))) . \end{aligned}$$

For complex flavors:

lwork must be at least

$$\begin{aligned} lwork \geq 2 * LOCr(n+mod(ia-1, mb_a)) + \max(2, \max(nb_a * \text{ceil}(\\ NPROW-1, NPCOL), \\ LOCc(n+mod(ja-1, nb_a)) + nb_a * \text{ceil}(NPCOL-1, NPROW)))) . \end{aligned}$$

iwork

(local) INTEGER. Workspace array, size (*lwork*). Used in real flavors only.

liwork

(local or global) INTEGER. The dimension of the array *iwork*; used in real flavors only. Must be at least

$$liwork \geq LOCr(n+mod(ia-1, mb_a)) .$$

rwork

(local) REAL for pcpoco

DOUBLE PRECISION for pzpocon

Workspace array, size (*lrwork*). Used in complex flavors only.

lrwork

(local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least

$$lrwork \geq LOCc(n+mod(ja-1, nb_a)) .$$

Output Parameters

rcond

(global) REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The reciprocal of the condition number of the distributed matrix sub(*A*).

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1)

On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1)

On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info

(global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*) ; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Refining the Solution and Estimating Its Error

This section describes the ScalAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

Fortran:

```
call psgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pdgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pcgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)

call pzgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
```

C:

```
void psgerfs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *af , MKL_INT *iaf , MKL_INT *jaf , MKL_INT
*descaf , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *ferr , float *berr ,

Description

The `p?gerfs` routine improves the computed solution to one of the systems of linear equations

`sub(A) *sub(X) = sub(B)`,

`sub(A)T*sub(X) = sub(B)`, or

`sub(A)H*sub(X) = sub(B)` and provides error bounds and backward error estimates for the solution.

Here `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`, `sub(B) = B(ib:ib+n-1, jb:jb+nrhs-1)`, and `sub(X) = X(ix:ix+n-1, jx:jx+nrhs-1)`.

Input Parameters

<code>trans</code>	(global) CHARACTER*1. Must be ' <code>N</code> ' or ' <code>T</code> ' or ' <code>C</code> '.
	Specifies the form of the system of equations:
	If <code>trans = 'N'</code> , the system has the form <code>sub(A) *sub(X) = sub(B)</code> (No transpose);
	If <code>trans = 'T'</code> , the system has the form <code>sub(A)^T*sub(X) = sub(B)</code> (Transpose);
	If <code>trans = 'C'</code> , the system has the form <code>sub(A)^H*sub(X) = sub(B)</code> (Conjugate transpose).
<code>n</code>	(global) INTEGER. The order of the distributed submatrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices <code>sub(B)</code> and <code>sub(X)</code> ($nrhs \geq 0$).
<code>a, af, b, x</code>	(local) REAL for <code>psgerfs</code> DOUBLE PRECISION for <code>pdgerfs</code> COMPLEX for <code>pcgerfs</code> DOUBLE COMPLEX for <code>pzgerfs</code> . Pointers into the local memory to arrays of local dimension <code>a(lld_a, LOCc(ja+n-1)), af(lld_af, LOCc(jaf+n-1)), b(lld_b, LOCc(jb+nrhs-1))</code> , and <code>x(lld_x, LOCc(jx+nrhs-1))</code> , respectively. The array <code>a</code> contains the local pieces of the distributed matrix <code>sub(A)</code> . The array <code>af</code> contains the local pieces of the distributed factors of the matrix <code>sub(A) = P*L*U</code> as computed by <code>p?getrf</code> . The array <code>b</code> contains the local pieces of the distributed matrix of right hand sides <code>sub(B)</code> . On entry, the array <code>x</code> contains the local pieces of the distributed solution matrix <code>sub(X)</code> .

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>AF</i> indicating the first row and the first column of the submatrix $\text{sub}(AF)$, respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>ipiv</i>	(local) INTEGER. Array, dimension $\text{LOCr}(m_af + mb_af)$. This array contains pivoting information as computed by p?getrf . If $ipiv(i)=j$, then the local row <i>i</i> was swapped with the global row <i>j</i> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <i>psgerfs</i> DOUBLE PRECISION for <i>pdgerfs</i> COMPLEX for <i>pcgerfs</i> DOUBLE COMPLEX for <i>pzgerfs</i> . The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * \text{LOCr}(n + \text{mod}(ia-1, mb_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * \text{LOCr}(n + \text{mod}(ia-1, mb_a))$

<i>iwork</i>	(local) INTEGER. Workspace array, size (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOC_r(n + \text{mod}(ib-1, mb_b))$.
<i>rwork</i>	(local) REAL for pcgerfs DOUBLE PRECISION for pzgerfs Workspace array, size (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOC_r(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOC_c(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of $\text{sub}(X)$. If XTRUE is the true solution corresponding to $\text{sub}(X)$, <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in $\text{sub}(X)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>X</i> . The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix <i>X</i> .
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork(1)</i>	On exit, <i>iwork(1)</i> contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork(1)</i>	On exit, <i>rwork(1)</i> contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?porfs

Improves the computed solution to a system of linear equations with symmetric/Hermitian positive definite distributed matrix and provides error bounds and backward error estimates for the solution.

Syntax

Fortran:

```
call psporfs(uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descraf, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pdporfs(uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descraf, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pcporfs(uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descraf, b, ib, jb, descb,

Description

The p?porfs routine improves the computed solution to the system of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$,

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

```
sub(B) = B(ib:ib+n-1, jb:jb+nrhs-1),
sub(X) = X(ix:ix+n-1, jx:jx+nrhs-1)
```

are right-hand side and solution submatrices, respectively. This routine also provides error bounds and backward error estimates for the solution.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(<i>A</i>) is stored. If <i>uplo</i> = 'U', sub(<i>A</i>) is upper triangular. If <i>uplo</i> = 'L', sub(<i>A</i>) is lower triangular.
<i>n</i>	(global) INTEGER. The order of the distributed matrix sub(<i>A</i>) (<i>n</i> ≥0).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices sub(<i>B</i>) and sub(<i>X</i>) (<i>nrhs</i> ≥0).
<i>a</i> , <i>af</i> , <i>b</i> , <i>x</i>	(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. Pointers into the local memory to arrays of local dimension <i>a</i> (lld_a,LOCc(ja+n-1)), <i>af</i> (lld_af,LOCc(ja+n-1)), <i>b</i> (lld_b,LOCc(jb+nrhs-1)), and <i>x</i> (lld_x,LOCc(jx+nrhs-1)), respectively. The array <i>a</i> contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric/Hermitian distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. The array <i>af</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization sub(<i>A</i>) = <i>L</i> * <i>L</i> ^H or sub(<i>A</i>) = <i>U</i> ^H * <i>U</i> , as computed by p?potrf. On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides sub(<i>B</i>). On entry, the array <i>x</i> contains the local pieces of the solution vectors sub(<i>X</i>). <i>ia</i> , <i>ja</i> (global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively. <i>desca</i> (global and local) INTEGER array, dimension (dlen_). The array descriptor for the distributed matrix <i>A</i> .

<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>AF</i> indicating the first row and the first column of the submatrix sub(<i>AF</i>), respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix sub(<i>X</i>), respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$
<i>iwork</i>	(local) INTEGER. Workspace array, size (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b)).$
<i>rwork</i>	(local) REAL for pcporfs DOUBLE PRECISION for pzporfs Workspace array, size (<i>lrwork</i>). Used in complex flavors only.

lrwork (local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

x On exit, contains the improved solution vectors.

ferr, berr REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, dimension $LOCc(jb+nrhs-1)$ each.

The array *ferr* contains the estimated forward error bound for each solution vector of $\text{sub}(X)$.

If X_{TRUE} is the true solution corresponding to $\text{sub}(X)$, *ferr* is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - X_{TRUE})$ divided by the magnitude of the largest element in $\text{sub}(X)$. The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix X .

The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix X .

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

iwork(1) On exit, *iwork(1)* contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1) On exit, *rwork(1)* contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*) ; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?trrfs

Provides error bounds and backward error estimates for the solution to a system of linear equations with a distributed triangular coefficient matrix.

Syntax

Fortran:

```
call pstrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, x, ix,
jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

```

Include Files

- C: mkl_scalapack.h

Description

The p?trrfs routine provides error bounds and backward error estimates for the solution to one of the systems of linear equations

```

sub(A)*sub(X) = sub(B),
sub(A)T*sub(X) = sub(B), or
sub(A)H*sub(X) = sub(B),
where sub(A) = A(ia:ia+n-1, ja:ja+n-1) is a triangular matrix,
sub(B) = B(ib:ib+n-1, jb:jb+nrhs-1), and
sub(X) = X(ix:ix+n-1, jx:jx+nrhs-1).

```

The solution matrix X must be computed by p?trtrs or some other means before entering this routine. The routine p?trrfs does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

If $uplo = 'U'$, $\text{sub}(A)$ is upper triangular. If $uplo = 'L'$, $\text{sub}(A)$ is lower triangular.

trans

(global) CHARACTER*1. Must be 'N' or 'T' or 'C'.

Specifies the form of the system of equations:

If $trans = 'N'$, the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose);

If $trans = 'T'$, the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose);

If $trans = 'C'$, the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).

diag

CHARACTER*1. Must be 'N' or 'U'.

If $diag = 'N'$, then $\text{sub}(A)$ is non-unit triangular.

If $diag = 'U'$, then $\text{sub}(A)$ is unit triangular.

n

(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

nrhs

(global) INTEGER. The number of right-hand sides, that is, the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).

a, b, x

(local)

REAL for pstrrfs

DOUBLE PRECISION for pdtrrfs

COMPLEX for pcrrrfs

DOUBLE COMPLEX for pztrrfs.

Pointers into the local memory to arrays of local dimension

$a(\text{lld}_a, LOCC(ja+n-1))$, $b(\text{lld}_b, LOCC(jb+nrhs-1))$, and

$x(\text{lld}_x, LOCC(jx+nrhs-1))$, respectively.

The array a contains the local pieces of the original triangular distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

If $diag = 'U'$, the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1.

On entry, the array b contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$.

On entry, the array x contains the local pieces of the solution vectors $\text{sub}(X)$.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix sub(<i>X</i>), respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) REAL for pstrrfs DOUBLE PRECISION for pdtrrfs COMPLEX for pctrrfs DOUBLE COMPLEX for pztrrfs. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$
	<i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$
<i>iwork</i>	(local) INTEGER. Workspace array, size (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b)).$
<i>rwork</i>	(local) REAL for pctrrfs DOUBLE PRECISION for pztrrfs Workspace array, size (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors.
-------------------	------------------------------------

DOUBLE PRECISION for double precision flavors.

Arrays, dimension $\text{LOCc}(jb+nrhs-1)$ each.

The array $ferr$ contains the estimated forward error bound for each solution vector of $\text{sub}(X)$.

If $XTRUE$ is the true solution corresponding to $\text{sub}(X)$, $ferr$ is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in $\text{sub}(X)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix X .

The array $berr$ contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix X .

$work(1)$

On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$iwork(1)$

On exit, $iwork(1)$ contains the minimum value of $liwork$ required for optimum performance (for real flavors).

$rwork(1)$

On exit, $rwork(1)$ contains the minimum value of $lrwork$ required for optimum performance (for complex flavors).

$info$

(global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Routines for Matrix Inversion

This section describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

Fortran:

```
call psgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pdgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pcgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pzgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

C:

```

void psgetri (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pdgetri (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , double *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pcgetri (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );

void pzgetri (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?getri routine computes the inverse of a general distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by p?getrf. This method inverts U and then computes the inverse of $\text{sub}(A)$ by solving the system

```
inv(sub(A)) * L = inv(U)
```

```
for inv(sub(A)).
```

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgetri DOUBLE PRECISION for pdgetri COMPLEX for pcgetri DOUBLE COMPLEX for pzgetri. Pointer into the local memory to an array of local dimension $a(lld_a, LOCo(ja+n-1))$. On entry, the array <i>a</i> contains the local pieces of the L and U obtained by the factorization $\text{sub}(A) = P^* L^* U$ computed by p?getrf.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgetri DOUBLE PRECISION for pdgetri

COMPLEX for pcgetri

DOUBLE COMPLEX for pzgetri.

The array *work* of dimension (*lwork*) is a workspace array.

lwork

(local) INTEGER. The dimension of the array *work*. *lwork* must be at least

$lwork \geq LOCr(n + \text{mod}(ia-1, mb_a)) * nb_a$.

The array *work* is used to keep at most an entire column block of sub(*A*).

iwork

(local) INTEGER. Workspace array used for physically transposing the pivots, size (*liwork*).

liwork

(local or global) INTEGER. The dimension of the array *iwork*.

The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
```

```
    liwork = LOCc(n_a + mod(ja-1, nb_a)) + nb_a
```

```
else
```

```
    liwork = LOCc(n_a + mod(ja-1, nb_a)) +
```

```
    max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)), nb_a)
```

```
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

ipiv

(local) INTEGER.

Array, dimension ($LOCr(m_a) + mb_a$).

This array contains the pivoting information.

If $ipiv(i)=j$, then the local row *i* was swapped with the global row *j*.

This array is tied to the distributed matrix *A*.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1)

On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance.

info

(global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then $info = -(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

info > 0:

If *info* = *i*, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax**Fortran:**

```
call pspotri(uplo, n, a, ia, ja, desca, info)
call pdpotri(uplo, n, a, ia, ja, desca, info)
call pcpotri(uplo, n, a, ia, ja, desca, info)
call pzpotri(uplo, n, a, ia, ja, desca, info)
```

C:

```
void pspotri (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info );
void pdpotri (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
void pcpotri (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
void pzpotri (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?potri` routine computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $\text{sub}(A) = U^H \cdot U$ or $\text{sub}(A) = L \cdot L^H$ computed by `p?potrf`.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored.
	If <code>uplo</code> = ' <code>U</code> ', upper triangle of $\text{sub}(A)$ is stored. If <code>uplo</code> = ' <code>L</code> ', lower triangle of $\text{sub}(A)$ is stored.
<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pspotri</code> DOUBLE PRECISION for <code>pdpotri</code> COMPLEX for <code>pcpotri</code> DOUBLE COMPLEX for <code>pzpotri</code> .

Pointer into the local memory to an array of local dimension $a(1\text{ld_}a, LOCc(ja+n-1))$.

On entry, the array a contains the local pieces of the triangular factor U or L from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by p?potrf.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

Output Parameters

a

On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of $\text{sub}(A)$.

$info$

(global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = i$, the (i, i) element of the factor U or L is zero, and the inverse could not be computed.

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

Fortran:

```
call pstrtri(uplo, diag, n, a, ia, ja, desca, info)
call pdtrtri(uplo, diag, n, a, ia, ja, desca, info)
call pctrtri(uplo, diag, n, a, ia, ja, desca, info)
call pztrtri(uplo, diag, n, a, ia, ja, desca, info)
```

C:

```
void pstrtri (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
void pdtrtri (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
void pctrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pztrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?trtri` routine computes the inverse of a real or complex upper or lower triangular distributed matrix
 $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular. If <code>uplo</code> = ' <code>U</code> ', $\text{sub}(A)$ is upper triangular. If <code>uplo</code> = ' <code>L</code> ', $\text{sub}(A)$ is lower triangular.
<code>diag</code>	CHARACTER*1. Must be ' <code>N</code> ' or ' <code>U</code> '. Specifies whether or not the distributed matrix $\text{sub}(A)$ is unit triangular. If <code>diag</code> = ' <code>N</code> ', then $\text{sub}(A)$ is non-unit triangular. If <code>diag</code> = ' <code>U</code> ', then $\text{sub}(A)$ is unit triangular.
<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pstrtri</code> DOUBLE PRECISION for <code>pdtrtri</code> COMPLEX for <code>pctrtri</code> DOUBLE COMPLEX for <code>pztrtri</code> . Pointer into the local memory to an array of local dimension $a(1\text{ld}_a, LOCc(ja+n-1))$. The array <code>a</code> contains the local pieces of the triangular distributed matrix $\text{sub}(A)$. If <code>uplo</code> = ' <code>U</code> ', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix to be inverted, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <code>uplo</code> = ' <code>L</code> ', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix A .

Output Parameters

a On exit, overwritten by the (triangular) inverse of the original matrix.

info (global) INTEGER. If *info*=0, the execution is successful.

info < 0:
If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:
If *info* = *k*, *A*(*ia*+*k*-1, *ja*+*k*-1) is exactly zero. The triangular matrix sub(*A*) is singular and its inverse can not be computed.

Routines for Matrix Equilibration

ScalAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

Fortran:

```
call psgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pdgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pcgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pzgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

C:

```
void psgeequ (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , MKL_INT
*info );
void pdgeequ (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
void pcgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
MKL_INT *info );
void pzgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?geequ` routine computes row and column scalings intended to equilibrate an m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

$r(i)$ and $c(j)$ are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $\text{sub}(A)$ but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

The auxiliary function `p?laqge` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>psgeequ</code> DOUBLE PRECISION for <code>pdgeequ</code> COMPLEX for <code>pcgeequ</code> DOUBLE COMPLEX for <code>pzgeequ</code> . Pointer into the local memory to an array of local dimension $a(1\text{ld}_a, LOCc(ja+n-1))$. The array a contains the local pieces of the m -by- n distributed matrix whose equilibration factors are to be computed.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

Output Parameters

r, c	(local) REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCr(m_a)$ and $LOCr(n_a)$, respectively. If $info = 0$, or $info > ia+m-1$, the array r ($ia:ia+m-1$) contains the row scale factors for $\text{sub}(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A .
--------	---

If $info = 0$, the array $c(ja:ja+n-1)$ contains the column scale factors for $\text{sub}(A)$. c is aligned with the distributed matrix A , and replicated down every process row. c is tied to the distributed matrix A .

$\text{rowcnd}, \text{colcnd}$

(global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

If $info = 0$ or $info > ia+m-1$, rowcnd contains the ratio of the smallest $r(i)$ to the largest $r(i)$ ($ia \leq i \leq ia+m-1$). If $\text{rowcnd} \geq 0.1$ and amax is neither too large nor too small, it is not worth scaling by $r(ia:ia+m-1)$.

If $info = 0$, colcnd contains the ratio of the smallest $c(j)$ to the largest $c(j)$ ($ja \leq j \leq ja+n-1$).

If $\text{colcnd} \geq 0.1$, it is not worth scaling by $c(ja:ja+n-1)$.

amax

(global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest matrix element. If amax is very close to overflow or very close to underflow, the matrix should be scaled.

info

(global) INTEGER. If $\text{info}=0$, the execution is successful.

$\text{info} < 0$:

If the i th argument is an array and the j th entry had an illegal value, then $\text{info} = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

$\text{info} > 0$:

If $\text{info} = i$ and

$i \leq m$, the i th row of the distributed matrix

$\text{sub}(A)$ is exactly zero;

$i > m$, the $(i-m)$ th column of the distributed

matrix $\text{sub}(A)$ is exactly zero.

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

Fortran:

```
call pspoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pdpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pcpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pzpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
```

C:

```

void pspoequ (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
void pdpoequ (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
void pcpoequ (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
void pzpoequ (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *sr , double *sc , double *scond , double *amax , MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The `p?poequ` routine computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ and reduce its condition number (with respect to the two-norm). The output arrays `sr` and `sc` return the row and column scale factors

.....

These factors are chosen so that the scaled distributed matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has ones on the diagonal.

This choice of `sr` and `sc` puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pspoequ</code> DOUBLE PRECISION for <code>pdpoequ</code> COMPLEX for <code>pcpoequ</code> DOUBLE COMPLEX for <code>pzpoequ</code> . Pointer into the local memory to an array of local dimension $a(1:l_d_a, LOCc(ja+n-1))$.
	The array <code>a</code> contains the n -by- n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

Output Parameters

sr, sc

(local)

REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Arrays, dimension *LOCr(m_a)* and *LOCc(n_a)*, respectively.

If *info* = 0, the array *sr(ia:ia+n-1)* contains the row scale factors for sub(*A*). *sr* is aligned with the distributed matrix *A*, and replicated across every process column. *sr* is tied to the distributed matrix *A*.

If *info* = 0, the array *sc(ja:ja+n-1)* contains the column scale factors for sub(*A*). *sc* is aligned with the distributed matrix *A*, and replicated down every process row. *sc* is tied to the distributed matrix *A*.

scond

(global)

REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

If *info* = 0, *scond* contains the ratio of the smallest *sr(i)* (or *sc(j)*) to the largest *sr(i)* (or *sc(j)*), with

ia≤*i*≤*ia+n-1* and *ja*≤*j*≤*ja+n-1*.

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *sr* (or *sc*).

amax

(global)

REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

info

(global) INTEGER.

If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*) ; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *k*, the *k*-th diagonal entry of sub(*A*) is nonpositive.

Orthogonal Factorizations

This section describes the ScalAPACK routines for the *QR* (*RQ*) and *LQ* (*QL*) factorization of matrices. Routines for the *RZ* factorization as well as for generalized *QR* and *RQ* factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table "Computational Routines for Orthogonal Factorizations" lists ScalAPACK routines that perform orthogonal factorization of matrices.

Computational Routines for Orthogonal Factorizations

p?geqrf

Computes the QR factorization of a general *m*-by-*n* matrix.

Syntax

Fortran:

```
call psgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgeqrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeqrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?geqrf routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = Q \cdot R$$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). REAL for psgeqrf DOUBLE PRECISION for pdgeqrf. COMPLEX for pcgeqrf. DOUBLE COMPLEX for pzgeqrf Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb_a * (mp0 + nq0 + nb_a)$, where

```

iroff = mod(ia-1, mb_a), icooff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc(n+icooff, nb_a, MYCOL, iacol, NPCOL), and numroc,
indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL
can be determined by calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	The elements on and above the diagonal of sub(<i>A</i>) contain the min(<i>m,n</i>)-by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if <i>m</i> ≥ <i>n</i>); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Array, size <i>LOCc</i> (ja+min(<i>m,n</i>)-1). Contains the scalar factor <i>tau</i> of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0, the execution is successful. < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i* 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where *k* = min(*m,n*).

Each *H(i)* has the form

$$H(i) = I - tau * v * v'$$

where τ_{ii} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ_{ii} in $\tau_{ii}(ja+i-1)$.

p?geqpf

Computes the QR factorization of a general m-by-n matrix with pivoting.

Syntax

Fortran:

```
call psgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pdgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pcgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pzgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
```

C:

```
void psgeqpf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja ,
              MKL_INT *desca , MKL_INT *ipiv , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeqpf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
              MKL_INT *desca , MKL_INT *ipiv , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
              MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
              *lwork , float *rwork , MKL_INT *lrwork , MKL_INT *info );
void pzgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
              MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
              *lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?geqpf routine forms the QR factorization with column pivoting of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$\text{sub}(A) * P = Q * R$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf.

Pointer into the local memory to an array of local dimension ($l1d_a$, $LOCc(ja+n-1)$).

Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.

ia, ja
(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.

desca
(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix *A*.

work
(local).

REAL for *psgeqpf*
DOUBLE PRECISION for *pdgeqpf*.
COMPLEX for *pcgeqpf*.
DOUBLE COMPLEX for *pzgeqpf*

Workspace array of dimension *lwork*.

lwork
(local or global) INTEGER, dimension of *work*, must be at least

For real flavors:

$$lwork \geq \max(3, mp0 + nq0) + LOCc(ja+n-1) + nq0.$$

For complex flavors:

$$lwork \geq \max(3, mp0 + nq0) .$$

Here

```
iroff = mod(ia-1, mb_a), icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL),
LOCc(ja+n-1) = numroc(ja+n-1, nb_a, MYCOL, csrc_a, NPCOL),
and numroc, indxg2p are ScaLAPACK tool functions.
```

You can determine MYROW, MYCOL, NPROW and NPCOL by calling the blacs_gridinfo subroutine.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a
The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m, n)$ -by- n upper trapezoidal matrix *R* (*R* is upper triangular if $m \geq n$); the elements below the diagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

<i>ipiv</i>	(local) INTEGER. Array, size $LOCc(ja+n-1)$. $ipiv(i) = k$, the local i -th column of $\text{sub}(A)*P$ was the global k -th column of $\text{sub}(A)$. <i>ipiv</i> is tied to the distributed matrix A .
<i>tau</i>	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf. Array, size $LOCc(ja+\min(m, n)-1)$. Contains the scalar factor <i>tau</i> of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*\dots*H(k)$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H = I - tau*v*v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$.

The matrix P is represented in *ipiv* as follows: if $ipiv(j)=i$ then the j -th column of P is the i -th canonical unit vector.

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

Fortran:

```
call psorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?orgqr` routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?geqrf`.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
<code>k</code>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<code>a</code>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Pointer into the local memory to an array of local dimension $(\text{lld}_a, \text{LOCc}(ja+n-1))$. The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja + k - 1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<code>desca</code>	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .
<code>tau</code>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Array, size $\text{LOCc}(ja+k-1)$. Contains the scalar factor τ_j of elementary reflectors $H(j)$ as returned by <code>p?geqrf</code> . τ_j is tied to the distributed matrix A .
<code>work</code>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code>

Workspace array of dimension of *lwork*.

lwork

(local or global) INTEGER, dimension of *work*.

Must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where

$iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW})$,

$iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL})$,

$mpa0 = \text{numroc}(m+iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW})$,

$nqa0 = \text{numroc}(n+icoffa, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$;

indxg2p and *numroc* are ScalAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

Contains the local pieces of the *m*-by-*n* distributed matrix Q.

work(1)

On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

Fortran:

```
call pcungqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pzungqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void pcungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q .
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ormqr

Multiples a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

Fortran:

```

call psormqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pdormqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

```

C:

```

void psormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );

```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?ormqr` routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<code>trans = 'T':</code>	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?geqrf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

<code>side</code>	(global) CHARACTER
	<code>= 'L':</code> Q or Q^T is applied from the left.
	<code>= 'R':</code> Q or Q^T is applied from the right.
<code>trans</code>	(global) CHARACTER
	<code>= 'N'</code> , no transpose, Q is applied.
	<code>= 'T'</code> , transpose, Q^T is applied.
<code>m</code>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<code>k</code>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <code>side = 'L'</code> , $m \geq k \geq 0$ If <code>side = 'R'</code> , $n \geq k \geq 0$.
<code>a</code>	(local) REAL for <code>psormqr</code> DOUBLE PRECISION for <code>pdormqr</code> . Pointer into the local memory to an array of dimension (<code>lld_a</code> , <code>LOCc(ja+k-1)</code>). The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <code>side = 'L'</code> , $lld_a \geq \max(1, LOCr(ia+m-1))$ If <code>side = 'R'</code> , $lld_a \geq \max(1, LOCr(ia+n-1))$
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Array, size $LOC_C(ja+k-1)$. Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by p?geqrf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Pointer into the local memory to an array of local dimension (<i>lld_c</i> , $LOC_C(jc+n-1)$). Contains the local pieces of the distributed matrix <i>sub(C)</i> to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: <i>if side = 'L',</i> <i>lwork ≥ max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a</i> <i>else if side = 'R',</i> <i>lwork ≥ max((nb_a * (nb_a - 1)) / 2, (nqc0 + max(npa0 + numroc(numroc(n + ioffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a</i> <i>end if</i> <i>where</i> <i>lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),</i> <i>iroffa = mod(ia-1, mb_a),</i> <i>icoffa = mod(ja-1, nb_a),</i> <i>iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),</i> <i>npoa0 = numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),</i> <i>iroffc = mod(ic-1, mb_c),</i>

```

    icooffc = mod(jc-1, nb_c),
    icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
    iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
    mpc0= numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
    nqc0= numroc(n+icooffc, nb_c, MYCOL, iccol, NPCOL),
    ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
    NPROW and NPCOL can be determined by calling the subroutine
    blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pixerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C)$, or $\text{sub}(C) * Q^T$, or $\text{sub}(C) * Q$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i* 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmqr

Multiples a complex matrix by the unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

Fortran:

```

call pcunmqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pzunmqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

```

C:

```

void pcunmqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzunmqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

This routine overwrites the general complex m -by- n distributed matrix sub $(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$
<i>trans</i> = 'T':	$Q^H \text{sub}(C)$
	$\text{sub}(C)^* Q$
	$\text{sub}(C)^* Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by [p?geqrf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^H is applied from the left.
= 'R':	Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'C',	conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr . Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+k-1)</i>). The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja + k - 1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', <i>lld_a</i> $\geq \max(1, LOCr(ia+m-1))$ If <i>side</i> = 'R', <i>lld_a</i> $\geq \max(1, LOCr(ia+n-1))$

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunmqr</code> DOUBLE COMPLEX for <code>pzunmqr</code> Array, size $LOC_C(ja+k-1)$. Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by <code>p?geqrf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for <code>pcunmqr</code> DOUBLE COMPLEX for <code>pzunmqr</code> . Pointer into the local memory to an array of local dimension (<i>lld_c</i> , $LOC_C(jc+n-1)$). Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for <code>pcunmqr</code> DOUBLE COMPLEX for <code>pzunmqr</code> . Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$ else if <i>side</i> = 'R', $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + numroc(numroc(n+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$ end if where $lcmq = lcm/NPCOL \text{ with } lcm = \text{ilcm}(NPROW, NPCOL),$ $iroffa = \text{mod}(ia-1, mb_a),$

```

        icooffa = mod(ja-1, nb_a),
        iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
        npa0 = numroc(n+iroffa, mb_a, MYROW, iarow, NPROW),
        iroffc = mod(ic-1, mb_c),
        icooffc = mod(jc-1, nb_c),
        icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
        iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
        mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
        nqc0 = numroc(n+icooffc, nb_c, MYCOL, iccol, NPCOL),
        ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
        NPROW and NPCOL can be determined by calling the subroutine
        blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q^H$, or $\text{sub}(C) * Q$.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i * 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = -i.

p?gelqf

Computes the LQ factorization of a general rectangular matrix.

Syntax

Fortran:

```

call psgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)

```

C:

```

void psgelqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

```

```

void pdgelqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

*info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?gelqf routine computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ia:ia+n-1) = L*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ia:ia+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Workspace array of dimension <i>lwork</i> .

lwork (local or global) INTEGER, dimension of *work*, must be at least $lwork \geq mb_a^* (mp0 + nq0 + mb_a)$, where

$$\begin{aligned} iroff &= \text{mod}(ia-1, mb_a), \\ icoff &= \text{mod}(ja-1, nb_a), \\ iarow &= \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}), \\ iacol &= \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}), \\ mp0 &= \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}), \\ nq0 &= \text{numroc}(n+icooff, nb_a, \text{MYCOL}, iacol, \text{NPCOL}) \end{aligned}$$

`indxg2p` and `numroc` are ScalAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a The elements on and below the diagonal of $\text{sub}(A)$ contain the m by $\min(m, n)$ lower trapezoidal matrix L (L is lower trapezoidal if $m \leq n$); the elements above the diagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau (local)
 REAL for `psgelqf`
 DOUBLE PRECISION for `pdgelqf`
 COMPLEX for `pcgelqf`
 DOUBLE COMPLEX for `pzgelqf`
 Array, size $LOCr(ia+\min(m, n)-1)$.
 Contains the scalar factors of elementary reflectors. *tau* is tied to the distributed matrix *A*.

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i * 100 + j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and τ in $\tau(ia+i-1)$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

Fortran:

```
call psorglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?orglq routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?gelqf.

Input Parameters

m (global) INTEGER. The number of rows in the submatrix sub(Q); ($m \geq 0$).

n (global) INTEGER. The number of columns in the submatrix sub(Q) ($n \geq m \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).

a (local)

REAL for psorglq

DOUBLE PRECISION for pdorglq

Pointer into the local memory to an array of local dimension (lld_a , $LOCc(ja+n-1)$). On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a^* (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$ $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW}),$ $nqa0 = \text{numroc}(n+icoffa, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> to be factored.
<i>tau</i>	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Array, size <i>LOCr</i> (<i>ia+k</i> - 1). Contains the scalar factors <i>tau</i> of elementary reflectors <i>H(i)</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unqlq

Generates the unitary matrix Q of the LQ factorization formed by [p?gelqf](#).

Syntax**Fortran:**

```
call pcunglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzunglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void pcunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

Description

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = (H(k))^H \dots * (H(2))^H * (H(1))^H \text{ as returned by } \text{p?gelqf}.$$

Input Parameters

m (global) INTEGER. The number of rows in the submatrix sub(Q) ($m \geq 0$).

n (global) INTEGER. The number of columns in the submatrix sub(Q) ($n \geq m \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).

a (local)

COMPLEX for pcunglq
DOUBLE COMPLEX for pzunglq

Pointer into the local memory to an array of local dimension (*lld_a*, *LOCc(ja+n-1)*). On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gelqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Array, size $LOCr(ia+k-1)$. Contains the scalar factors <i>tau</i> of elementary reflectors $H(i)$. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$ $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW}),$ $nqa0 = \text{numroc}(n+icoffa, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>MYROW</i> , <i>MYCOL</i> , <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

Output Parameters

<i>a</i>	Contains the local pieces of the m -by- n distributed matrix <i>Q</i> to be factored.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ormlq

Multiples a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

Fortran:

```
call psormlq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work, lwork,
info)
```

```
call pdormlq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work, lwork,
info)
```

C:

```
void psormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *desc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *desc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?ormlq routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by p?gelqf. Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^T is applied from the left.
= 'R':	Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'T',	transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(<i>C</i>) ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>), if <i>side</i> = 'L' and (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>), if <i>side</i> = 'R'. The <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its distributed matrix argument <i>A</i> (<i>ia</i> : <i>ia+k-1</i> , <i>ja</i> :*). <i>A</i> (<i>ia</i> : <i>ia+k-1</i> , <i>ja</i> :*) is modified by the routine but restored on exit.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq Array, size <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau</i> (<i>i</i>) of elementary reflectors <i>H</i> (<i>i</i>) as returned by p?gelqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq Pointer into the local memory to an array of local dimension (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic</i> , <i>jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormlq

DOUBLE PRECISION for pdormlq.

Workspace array of dimension of *lwork*.

lwork

(local or global) INTEGER, dimension of the array *work*; must be at least:

If *side* = 'L',

```
lwork ≥ max((mb_a * (mb_a-1))/2, (mpc0+max mqa0) +
numroc(numroc(m + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nqc0)) * mb_a + mb_a * mb_a
```

else if *side* = 'R',

```
lwork ≥ max((mb_a * (mb_a-1))/2, (mpc0+nqc0) * mb_a + mb_a * mb_a
```

end if

where

lcm = *lcm*/NPROW with *lcm* = ilcm (NPROW, NPCOL),

iroffa = mod(*ia*-1, *mb_a*),

icoffa = mod(*ja*-1, *nb_a*),

iacol = indxg2p(*ja*, *nb_a*, MYCOL, csrc_a, NPCOL),

mqa0 = numroc(*m+icoffa*, *nb_a*, MYCOL, *iacol*, NPCOL),

iroffc = mod(*ic*-1, *mb_c*),

icoffc = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, MYROW, rsrc_c, NPROW),

iccol = indxg2p(*jc*, *nb_c*, MYCOL, csrc_c, NPCOL),

mpc0 = numroc(*m+iroffc*, *mb_c*, MYROW, *icrow*, NPROW),

nqc0 = numroc(*n+icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c

Overwritten by the product *Q**sub(*C*), or *Q'* *sub (*C*), or sub(*C*)**Q'*, or sub(*C*)**Q*

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?unmlq

Multiples a general matrix by the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax

Fortran:

```
call pcunmlq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmlq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void pcunmlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C \ (ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q^* \text{sub}(C)$	$\text{sub}(C)^* Q$
$trans = 'T':$	$Q^H \text{sub}(C)$	$\text{sub}(C)^* Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by p?gelqf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER
$= 'L':$	Q or Q^H is applied from the left.
$= 'R':$	Q or Q^H is applied from the right.
$trans$	(global) CHARACTER
$= 'N'$,	no transpose, Q is applied.

$= 'C'$, conjugate transpose, Q^H is applied.

m (global) INTEGER. The number of rows in the distributed matrix sub(*C*) ($m \geq 0$).

n (global) INTEGER. The number of columns in the distributed matrix sub(*C*) ($n \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix *Q*. Constraints:

If *side* = 'L', $m \geq k \geq 0$

If *side* = 'R', $n \geq k \geq 0$.

a (local)

COMPLEX for pcunm_{lq}

DOUBLE COMPLEX for pzunm_{lq}.

Pointer into the local memory to an array of dimension (*lld_a*, *LOCc(ja+m-1)*), if *side* = 'L', and (*lld_a*, *LOCc(ja+n-1)*), if *side* = 'R', where *lld_a* $\geq \max(1, LOC_r(ia+k-1))$. The *i*-th column must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the *k* rows of its distributed matrix argument *A(ia:ia+k-1, ja:*)*. *A(ia:ia+k-1, ja:*)* is modified by the routine but restored on exit.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

tau (local)

COMPLEX for pcunm_{lq}

DOUBLE COMPLEX for pzunm_{lq}

Array, size *LOCc(ia+k-1)*.

Contains the scalar factor *tau* (*i*) of elementary reflectors $H(i)$ as returned by p?gelqf. *tau* is tied to the distributed matrix *A*.

c (local)

COMPLEX for pcunm_{lq}

DOUBLE COMPLEX for pzunm_{lq}.

Pointer into the local memory to an array of local dimension (*lld_c*, *LOCc(jc+n-1)*).

Contains the local pieces of the distributed matrix sub(*C*) to be factored.

ic, jc (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.

work (local)

COMPLEX for `pcunmlq`
DOUBLE COMPLEX for `pzunmlq`.

Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of the array *work*; must be at least:
If *side* = 'L',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + max mqa0) + numroc(numroc(m + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0) * mb_a + mb_a * mb_a$$
else if *side* = 'R',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a$$
end if
where
lcm = *lcm*/NPROW with *lcm* = ilcm (NPROW, NPCOL),
iroffa = mod(*ia*-1, *mb_a*),
icoffa = mod(*ja*-1, *nb_a*),
iacol = indxg2p(*ja*, *nb_a*, MYCOL, *csrc_a*, NPCOL),
mqa0 = numroc(m + *icoffa*, *nb_a*, MYCOL, *iacol*, NPCOL),
iroffc = mod(*ic*-1, *mb_c*),
icoffc = mod(*jc*-1, *nb_c*),
icrow = indxg2p(*ic*, *mb_c*, MYROW, *rsrc_c*, NPROW),
iccol = indxg2p(*jc*, *nb_c*, MYCOL, *csrc_c*, NPCOL),
mpc0 = numroc(m + *iroffc*, *mb_c*, MYROW, *icrow*, NPROW),
nqc0 = numroc(n + *icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),
ilcm, `indxg2p` and `numroc` are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c Overwritten by the product *Q**sub(*C*), or *Q'**sub (*C*), or sub(*C*)**Q'*, or sub(*C*)**Q*

<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	<p>(global) INTEGER.</p> <p>= 0: the execution is successful.</p> <p>< 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = - (<i>i</i>* 100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p>

p?geqlf

Computes the QL factorization of a general matrix.

Syntax

Fortran:

```
call psgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgeqlf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeqlf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgeqlf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzgeqlf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?geqlf routine forms the *QL* factorization of a real/complex distributed *m*-by-*n* matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q \cdot L$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; (<i>m</i> \geq 0).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ (<i>n</i> \geq 0).
<i>a</i>	<p>(local)</p> <p>REAL for psgeqlf</p>

DOUBLE PRECISION for pdgeqlf

COMPLEX for pcgeqlf

DOUBLE COMPLEX for pzgeqlf

Pointer into the local memory to an array of local dimension ($l1d_a$, $LOCc(ja+n-1)$). Contains the local pieces of the distributed matrix sub(A) to be factored.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ia:ia+n-1)$, respectively.

$desca$

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

$work$

(local)

REAL for psgeqlf

DOUBLE PRECISION for pdgeqlf

COMPLEX for pcgeqlf

DOUBLE COMPLEX for pzgeqlf

Workspace array of dimension $lwork$.

$lwork$

(local or global) INTEGER, dimension of $work$, must be at least $lwork \geq nb_a * (mp0 + nq0 + nb_a)$, where

$iroff = \text{mod}(ia-1, mb_a),$

$icoff = \text{mod}(ja-1, nb_a),$

$iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$

$iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}),$

$mp0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}),$

$nq0 = \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$

`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

a

On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ

(local)

REAL for psgeqlf
 DOUBLE PRECISION for pdgeqlf
 COMPLEX for pcgeqlf
 DOUBLE COMPLEX for pzgeqlf
 Array, size $\text{LOCc}(ja+n-1)$.

Contains the scalar factors of elementary reflectors. τ_u is tied to the distributed matrix A .

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja)$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau_u v v'$$

where τ_u is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ_u in $\tau_u(ja+n-k+i-1)$.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

Fortran:

```
call psorgql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?orgql` routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by `p?geqlf`.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$, ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$, ($m \geq n \geq 0$).
<code>k</code>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<code>a</code>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Pointer into the local memory to an array of local dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, the j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its distributed matrix argument $A(ia:*, ja+n-k:ja+n-1)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix A .
<code>tau</code>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Array, size <code>LOCc(ja+n-1)</code> . Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. τ is tied to the distributed matrix A .
<code>work</code>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Workspace array of dimension <code>lwork</code> .
<code>lwork</code>	(local or global) INTEGER, dimension of <code>work</code> , must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$

```

        icooffa = mod(ja-1, nb_a),
        iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
        iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
        mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
        nqa0 = numroc(n+icooffa, nb_a, MYCOL, iacol, NPCOL)

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = -(i*100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?ungql

Generates the unitary matrix Q of the QL factorization formed by `p?geqlf`.

Syntax

Fortran:

```
call pcungql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void pcunmql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *desc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
void pzunmql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *desc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: `mkl_scalapack.h`

Description

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first n columns of a product of k elementary reflectors of order m

$Q = (H(k))^H \dots * (H(2))^H * (H(1))^H$ as returned by [p?geqlf](#).

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Pointer into the local memory to an array of local dimension ($l1d_a$, $LOCc(ja+n-1)$). On entry, the j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(ia:*, ja+n-k: ja+n-1)$.
ia , ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .
tau	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Array, size $LOCr(ia+n-1)$. Contains the scalar factors τ_j of elementary reflectors $H(j)$. τ_j is tied to the distributed matrix A .
$work$	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$

```

mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> to be factored.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i * 100 + j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ormql

Multiples a general matrix by the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

Fortran:

```
call psormql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```

void psormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?ormql routine overwrites the general real *m*-by-*n* distributed matrix $\text{sub}(C) = C \ (ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	<i>sub(C)*Q</i>
<i>trans</i> = 'T':	<i>sub(C)*Q^T</i>

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?geqlf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
	= 'L': Q or Q^T is applied from the left.
	= 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER
	= 'N', no transpose, Q is applied.
	= 'T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <i>sub(C)</i> , ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <i>sub(C)</i> , ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psormql DOUBLE PRECISION for pdormql . Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+k-1)</i>). The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?gelqf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1).A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', <i>lld_a</i> $\geq \max(1, LOCr(ia+m-1))$, If <i>side</i> = 'R', <i>lld_a</i> $\geq \max(1, LOCr(ia+n-1))$.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local)

```

REAL for psormql
DOUBLE PRECISION for pdormql.

Array, size  $LOC_C(ja+n-1)$ .
Contains the scalar factor  $\tau_u(j)$  of elementary reflectors  $H(j)$  as returned
by p?geqlf.  $\tau_u$  is tied to the distributed matrix  $A$ .
```

c

(local)

```

REAL for psormql
DOUBLE PRECISION for pdormql.

Pointer into the local memory to an array of local dimension ( $lloc_c$ ,
 $LOC_C(jc+n-1)$ ) .
Contains the local pieces of the distributed matrix sub( $C$ ) to be factored.
```

ic, jc

(global) INTEGER. The row and column indices in the global array c
indicating the first row and the first column of the submatrix C ,
respectively.

descC

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor
for the distributed matrix C .

work

(local)

```

REAL for psormql
DOUBLE PRECISION for pdormql.

Workspace array of dimension  $lwork$ .
```

lwork

(local or global) INTEGER, dimension of *work*, must be at least:

```

If side = 'L',
    lwork  $\geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$ 
else if side = 'R',
    lwork  $\geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max npa0) +
    \text{numroc}(\text{numroc}(n + \text{icooffc}, nb_a, 0, 0, \text{NPCOL}), nb_a, 0, 0,
    lcmq), mpc0) * nb_a + nb_a * nb_a$ 
end if
where
lcm = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icooffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icooffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
```

$mpc0 = \text{numroc}(m+iroffc, mb_c, \text{MYROW}, icrow, \text{NPROW}),$
 $nqc0 = \text{numroc}(n+icoffc, nb_c, \text{MYCOL}, iccol, \text{NPCOL}),$
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

c	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^*\text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmql

Multiples a general matrix by the unitary matrix Q of the QL factorization formed by p?geqlf.

Syntax

Fortran:

```
call pcunmql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pzunmql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void pcunmql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzunmql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C \ (ic:ic+m-1, jc:jc+n-1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$	$\text{sub}(C)^* Q$
<i>trans</i> = 'C':	$Q^H \text{sub}(C)$	$\text{sub}(C)^* Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?geqlf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^H is applied from the left.
= 'R':	Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'C',	conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmql DOUBLE COMPLEX for pzunmql . Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+k-1)</i>). The <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1).A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', <i>lld_a</i> $\geq \max(1, LOCr(ia+m-1))$, If <i>side</i> = 'R', <i>lld_a</i> $\geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunmql</code> DOUBLE COMPLEX for <code>pzunmql</code> Array, size $LOC_C(ia+n-1)$. Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by <code>p?geqlf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for <code>pcunmql</code> DOUBLE COMPLEX for <code>pzunmql</code> . Pointer into the local memory to an array of local dimension ($l1d_c$, $LOC_C(jc+n-1)$). Contains the local pieces of the distributed matrix <i>sub(C)</i> to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for <code>pcunmql</code> DOUBLE COMPLEX for <code>pzunmql</code> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: <code>If side = 'L',</code> <code>lwork ≥ max((nb_a * (nb_a-1))/2, (nqc0+mpc0)*nb_a + nb_a*nb_a)</code> <code>else if side = 'R',</code> <code>lwork ≥ max((nb_a * (nb_a-1))/2, (nqc0+max npa0) +</code> <code>numroc(numroc(n+icooffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0,</code> <code>lcmq), mpc0)*nb_a) + nb_a*nb_a</code> <code>end if</code> <code>where</code> <code>lcmq = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),</code> <code>iroffa = mod(ia-1, mb_a),</code> <code>icooffa = mod(ja-1, nb_a),</code> <code>iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),</code> <code>npa0 = numroc (n + iroffa, mb_a, MYROW, iarow, NPROW),</code> <code>iroffc = mod(ic-1, mb_c),</code>

```

icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+icoffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the subroutine
blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{ sub}(C)$, or $Q' \text{ sub } (C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i* 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?gerqf

Computes the RQ factorization of a general rectangular matrix.

Syntax

Fortran:

```

call psgerqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerqf(m, n, a, ia, ja, desca, tau, work, lwork, info)

```

C:

```

void psgerqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgerqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

```

```
void pzgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?gerqf routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = R \cdot Q$$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; $(m \geq 0)$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; $(n \geq 0)$.
<i>a</i>	(local) REAL for psgeqr DOUBLE PRECISION for pdgeqr COMPLEX for pcgeqr DOUBLE COMPLEX for pzgeqr. Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). REAL for psgeqr DOUBLE PRECISION for pdgeqr. COMPLEX for pcgeqr. DOUBLE COMPLEX for pzgeqr Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iwoff = \text{mod}(ia-1, mb_a),$ $icoff = \text{mod}(ja-1, nb_a),$

```

        iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
        iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
        mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
        nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL) and numroc,
indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL
can be determined by calling the subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a	On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
τ	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf . Array, size $LOCr(ia+m-1)$. Contains the scalar factor τ of elementary reflectors. τ is tied to the distributed matrix A .
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau u v^T$$

where τ_{ii} is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ_{ii} in $\tau_{ii}(ia+m-k+i-1)$.

p?orgqr

Generates the orthogonal matrix Q of the RQ factorization formed by p?gerqf.

Syntax

Fortran:

```
call psorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?orgqr routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last m rows of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?gerqf.

Input Parameters

m (global) INTEGER. The number of rows in the submatrix sub(Q), ($m \geq 0$).

n (global) INTEGER. The number of columns in the submatrix sub(Q), ($n \geq m \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).

a (local)

REAL for psorgqr

DOUBLE PRECISION for pdorgqr

Pointer into the local memory to an array of local dimension (lld_a , $LOCc(ja+n-1)$). The i -th column must contain the vector which defines the elementary reflector $H(i)$, $ja \leq j \leq ja+k-1$, as returned by p?gerqf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorgqr
 DOUBLE PRECISION for pdorgqr
 Array, size $LOCc(ja+k-1)$.
 Contains the scalar factor *tau* (*i*) of elementary reflectors $H(i)$ as returned by p?gerqf. *tau* is tied to the distributed matrix *A*.

work (local)
 REAL for psorgqr
 DOUBLE PRECISION for pdorgqr
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where
 $iroffa = \text{mod}(ia-1, mb_a),$
 $icoffa = \text{mod}(ja-1, nb_a),$
 $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$
 $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$
 $mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW),$
 $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$
indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a Contains the local pieces of the *m*-by-*n* distributed matrix Q.

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?ungrq

Generates the unitary matrix Q of the RQ factorization formed by [p?gerqf](#).

Syntax**Fortran:**

```
call pcungrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void pcungrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzungrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This routine generates the m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by [p?gerqf](#).

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix sub(Q); ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix sub(Q) ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrqc Pointer into the local memory to an array of dimension (lld_a, LOCc(ja + n - 1)). The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia + m - k \leq i \leq ia + m - 1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia + m - k : ia + m - 1, ja : *)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension (dlen_). The array descriptor for the distributed matrix A .

<i>tau</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Array, size $LOC_r(ia+m-1)$. Contains the scalar factor <i>tau</i> (<i>i</i>) of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where <i>iroffa</i> = mod(<i>ia</i> -1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>ja</i> -1, <i>nb_a</i>), <i>iarow</i> = indxg2p(<i>ia</i> , <i>mb_a</i> , MYROW, rsrc_a, NPROW), <i>iacol</i> = indxg2p(<i>ja</i> , <i>nb_a</i> , MYCOL, csrc_a, NPCOL), <i>mpa0</i> = numroc(<i>m+iroffa</i> , <i>mb_a</i> , MYROW, <i>iarow</i> , NPROW), <i>nqa0</i> = numroc(<i>n+icoffa</i> , <i>nb_a</i> , MYCOL, <i>iacol</i> , NPCOL) indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ormrq

Multiples a general matrix by the orthogonal matrix *Q* of the RQ factorization formed by p?gerqf.

Syntax

Fortran:

```
call psormrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void psormrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?ormrq` routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$
$trans = 'T':$	$Q^T * \text{sub}(C)$
	$\text{sub}(C) * Q$
	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) \ H(2) \dots \ H(k)$$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^T is applied from the left.
= 'R':	Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'T',	transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.

<i>a</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>) if <i>side</i> = 'L', and (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) if <i>side</i> = 'R'. The <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*) . A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Array, size <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau</i> (<i>i</i>) of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq Pointer into the local memory to an array of local dimension (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L',

```

lwork ≥ max((mb_a * (mb_a-1))/2, (mpc0 + max(mqa0 +
numroc(numroc(n+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nqc0)) * mb_a) + mb_a * mb_a

else if side = 'R',
lwork ≥ max((mb_a * (mb_a-1))/2, (mpc0 + nqc0) * mb_a) +
mb_a * mb_a

end if

where

lcm = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icooffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(n+icooffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icooffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icooffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the subroutine
blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^*\text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i * 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmrq

Multiples a general matrix by the unitary matrix Q of the RQ factorization formed by p?gerqf.

Syntax

Fortran:

```
call pcunmrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void pcunmrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzunmrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This routine overwrites the general complex m -by- n distributed matrix sub (C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$	$\text{sub}(C)*Q$
<i>trans</i> = 'C':	$Q^H * \text{sub}(C)$	$\text{sub}(C)*Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$

as returned by [p?gerqf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER ='L': Q or Q^H is applied from the left. ='R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER ='N', no transpose, Q is applied. ='C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$, ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$, ($n \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

If $\text{side} = \text{'L'}$, $m \geq k \geq 0$

If $\text{side} = \text{'R'}$, $n \geq k \geq 0$.

a (local)

COMPLEX for `pcunmrq`

DOUBLE COMPLEX for `pzunmrq`.

Pointer into the local memory to an array of dimension (lld_a , $\text{LOCc}(ja + m - 1)$) if $\text{side} = \text{'L'}$, and (lld_a , $\text{LOCc}(ja + n - 1)$) if $\text{side} = \text{'R'}$. The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia + k - 1$, as returned by `p?gerqf` in the k rows of its distributed matrix argument $A(ia:ia + k - 1, ja^*) \cdot A(ia:ia + k - 1, ja^*)$ is modified by the routine but restored on exit.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

descA (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix *A*.

tau (local)

COMPLEX for `pcunmrq`

DOUBLE COMPLEX for `pzunmrq`

Array, size $\text{LOCc}(ja + k - 1)$.

Contains the scalar factor *tau* (i) of elementary reflectors $H(i)$ as returned by `p?gerqf`. *tau* is tied to the distributed matrix *A*.

c (local)

COMPLEX for `pcunmrq`

DOUBLE COMPLEX for `pzunmrq`.

Pointer into the local memory to an array of local dimension (lld_c , $\text{LOCc}(jc + n - 1)$).

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

ic, jc (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix *C*.

work (local)

COMPLEX for `pcunmrq`

DOUBLE COMPLEX for `pzunmrq`.

Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:

```

If side = 'L',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 +
max(mqa0+numroc(numroc(n+iroffc, mb_a, 0, 0, NPROW), mb_a,
0, 0, lcmp), nqc0)*mb_a) + mb_a*mb_a

else if side = 'R',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) +
mb_a*mb_a

end if

where

lcm = lcm/NPROW with lcm = ilcm(NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.
```

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$ or $Q'^*\text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?tzrzf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax**Fortran:**

```
call pstzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdtzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)

Description

The `p?tzrzf` routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = (R \ 0) * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$; ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pstzrzf</code> DOUBLE PRECISION for <code>pdtzrzf</code> . COMPLEX for <code>pctzrzf</code> . DOUBLE COMPLEX for <code>pztzrzf</code> .

Pointer into the local memory to an array of dimension (lld_a , $LOCc(ja + n - 1)$). Contains the local pieces of the m -by- n distributed matrix sub (A) to be factored.

ia, ja
(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca
(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

work
(local)
REAL for `pstzrzf`
DOUBLE PRECISION for `pdtzrzf`.
COMPLEX for `pctzrzf`.
DOUBLE COMPLEX for `pztzrzf`.

Workspace array of dimension $lwork$.

lwork
(local or global) INTEGER, dimension of $work$, must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where
 $iroff = \text{mod}(ia-1, mb_a)$,
 $icoff = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW})$,
 $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL})$,
 $mp0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW})$,
 $nq0 = \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$
`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.
If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a
On exit, the leading m -by- m upper triangular part of sub(A) contains the upper triangular matrix R , and elements $m+1$ to n of the first m rows of sub (A), with the array τ , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.

work(1)
On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

tau
(local)
REAL for `pstzrzf`
DOUBLE PRECISION for `pdtzrzf`.
COMPLEX for `pctzrzf`.

DOUBLE COMPLEX for pztzrzf.

Array, size $\text{LOC}_r(ia+m-1)$.

Contains the scalar factor of elementary reflectors. τ is tied to the distributed matrix A .

info (global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$\begin{pmatrix} \dots & \dots & \dots \\ \dots & \dots & \dots \\ \dots & \dots & \dots \end{pmatrix} = \begin{pmatrix} 1 & & \\ & \ddots & \\ & & 1 \end{pmatrix} \begin{pmatrix} \dots & \dots & \dots \\ \dots & \dots & \dots \\ \dots & \dots & \dots \end{pmatrix}$$

where

$$T(k) = I - \tau u(k) u(k)^T,$$

$$\begin{pmatrix} \dots & \dots & \dots \\ \dots & \dots & \dots \\ \dots & \dots & \dots \end{pmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$. Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

p?ormrz

Multiples a general matrix by the orthogonal matrix from a reduction to upper triangular form formed by p?tzrzf.

Syntax

Fortran:

```
call psormrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work, lwork, info)
```

```
call pdormrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work, lwork, info)
```

C:

Description

This routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$
<i>trans</i> = 'T':	$Q^T \text{sub}(C)$
	$\text{sub}(C)^* Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by [p?tzrzf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^T is applied from the left.
= 'R':	Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'T',	transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>l</i>	(global) The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$

If $\text{side} = \text{'R'}$, $n \geq l \geq 0$.

a (local)

REAL for psormrz

DOUBLE PRECISION for pdormrz.

Pointer into the local memory to an array of dimension (lld_a , $\text{LOCc}(ja+m-1)$) if $\text{side} = \text{'L'}$, and (lld_a , $\text{LOCc}(ja+n-1)$) if $\text{side} = \text{'R'}$, where $\text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1))$.

The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?tzrzf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*) \cdot A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

descA

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psormrz

DOUBLE PRECISION for pdormrz

Array, size $\text{LOCc}(ia+k-1)$.

Contains the scalar factor *tau* (i) of elementary reflectors $H(i)$ as returned by p?tzrzf. *tau* is tied to the distributed matrix *A*.

c

(local)

REAL for psormrz

DOUBLE PRECISION for pdormrz

Pointer into the local memory to an array of local dimension (lld_c , $\text{LOCc}(jc+n-1)$).

Contains the local pieces of the distributed matrix sub(*C*) to be factored.

ic, jc

(global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psormrz

DOUBLE PRECISION for pdormrz.

Workspace array of dimension of *lwork*.

lwork

(local or global) INTEGER, dimension of *work*, must be at least:

```

If side = 'L',
lwork  $\geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 +
numroc(numroc(n+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
1cmp), nqc0)) * mb_a) + mb\_a * mb\_a

else if side = 'R',
lwork  $\geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a) +
mb\_a * mb\_a

end if

where

lcm = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the subroutine
blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and optimal size for all
work arrays. Each of these values is returned in the first entry of the
corresponding work array, and no error message is issued by pxerbla.$$ 
```

Output Parameters

<i>c</i>	Overwritten by the product <i>Q</i> *sub(<i>C</i>), or <i>Q</i> '*sub (<i>C</i>), or sub(<i>C</i>)* <i>Q</i> ', or sub(<i>C</i>)* <i>Q</i>
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmrz

Multiples a general matrix by the unitary transformation matrix from a reduction to upper triangular form determined by p?tzrzf.

Syntax**Fortran:**

```
call pcunmrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void pcunmrz (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *tau , MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzunmrz (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$
<i>trans</i> = 'C':	$\text{sub}(C)^* Q$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$

as returned by pctzrzf/pztzrzf. Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^H is applied from the left.
= 'R':	Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'C',	conjugate transpose, Q^H is applied.

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(<i>C</i>), ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(<i>C</i>), ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>l</i>	(global) INTEGER. The columns of the distributed submatrix sub(<i>A</i>) containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ If <i>side</i> = 'R', $n \geq l \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>) if <i>side</i> = 'L', and (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) if <i>side</i> = 'R', where <i>lld_a</i> $\geq \max(1, LOCr(ja+k-1))$. The <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument <i>A</i> (<i>ia</i> : <i>ia+k-1</i> , <i>ja</i> *). <i>A</i> (<i>ia</i> : <i>ia+k-1</i> , <i>ja</i> *) is modified by the routine but restored on exit.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz Array, size <i>LOCc(ia+k-1)</i> . Contains the scalar factor <i>tau</i> (<i>i</i>) of elementary reflectors $H(i)$ as returned by p?gerqf . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of local dimension (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.

ic, jc (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.

work (local)
 COMPLEX for `pcunmrz`
 DOUBLE COMPLEX for `pzunmrz`.
 Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:
If *side* = 'L',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, 1cmp), nqc0)) * mb_a) + mb_a * mb_a$$
else if *side* = 'R',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$$
end if
where

$$\begin{aligned} 1cm &= lcm/NPROW \text{ with } lcm = \text{ilcm}(NPROW, NPCOL), \\ iroffa &= \text{mod}(ia-1, mb_a), \\ icooffa &= \text{mod}(ja-1, nb_a), \\ iacol &= \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL), \\ mqa0 &= \text{numroc}(m + icooffa, nb_a, MYCOL, iacol, NPCOL), \\ iroffc &= \text{mod}(ic-1, mb_c), \\ icooffc &= \text{mod}(jc-1, nb_c), \\ icrow &= \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW), \\ iccol &= \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL), \\ mpc0 &= \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW), \\ nqc0 &= \text{numroc}(n + icooffc, nb_c, MYCOL, iccol, NPCOL), \end{aligned}$$
 ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ggqrft

Computes the generalized QR factorization.

Syntax

Description

The p?ggqrft routine forms the generalized QR factorization of an *n*-by-*m* matrix

`sub(A) = A(ia:ia+n-1, ja:ja+m-1)`

and an n -by- p matrix

`sub(B) = B(ib:ib+n-1, jb:jb+p-1):`

as

`sub(A) = Q*R, sub(B) = Q*T*Z,`

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

If $n \geq m$

$$R = \begin{pmatrix} R_{11} \\ 0 \end{pmatrix} \begin{matrix} m \\ n-m \\ m \end{matrix}$$

or if $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \end{pmatrix} \begin{matrix} n \\ n-m \\ n \end{matrix}$$

where R_{11} is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ p-n & n \end{pmatrix} n, \text{ if } n \leq p,$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n-p \\ p \end{pmatrix}, \text{ if } n > p,$$

where T_{12} or T_{21} is an upper triangular matrix.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GQR factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the QR factorization of $\text{inv}(\text{sub}(B))^* \text{sub}(A)$:

`inv(sub(B))*sub(A) = Z^H*(inv(T)*R)`

Input Parameters

`n` (global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).

`m` (global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).

`p` INTEGER. The number of columns in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).

`a` (local)

REAL for psggqrf
 DOUBLE PRECISION for pdggqrf
 COMPLEX for pcggqrf
 DOUBLE COMPLEX for pzggqrf.

Pointer into the local memory to an array of dimension (lld_a , $LOCc(ja+m-1)$). Contains the local pieces of the n -by- m matrix sub(A) to be factored.

ia, ja
 (global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca
 (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

b
 (local)
 REAL for psggqrf
 DOUBLE PRECISION for pdggqrf
 COMPLEX for pcggqrf
 DOUBLE COMPLEX for pzggqrf.

Pointer into the local memory to an array of dimension (lld_b , $LOCc(jb+p-1)$). Contains the local pieces of the n -by- p matrix sub(B) to be factored.

ib, jb
 (global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

descb
 (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B .

work
 (local)
 REAL for psggqrf
 DOUBLE PRECISION for pdggqrf
 COMPLEX for pcggqrf
 DOUBLE COMPLEX for pzggqrf.
 Workspace array of dimension $lwork$.

lwork
 (local or global) INTEGER. Dimension of *work*, must be at least

$$lwork \geq \max(nb_a * (npa0 + mqa0 + nb_a), \max((nb_a * (nb_a - 1)) / 2, (pqb0 + npb0) * nb_a) + nb_a * nb_a, mb_b * (npb0 + pqb0 + mb_b)),$$
 where

$$\begin{aligned}iroffa &= \text{mod}(ia-1, mb_A), \\icoffa &= \text{mod}(ja-1, nb_a), \\iarow &= \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),\end{aligned}$$

```

iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
nra0 = numroc (n+iroffa, mb_a, MYROW, iarow, NPROW),
mqa0 = numroc (m+icooffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc (n+iroffa, mb_b, MYROW, Ibrow, NPROW),
pqb0 = numroc (m+icoffb, nb_b, MYCOL, ibcol, NPCOL)
and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and optimal size for all
work arrays. Each of these values is returned in the first entry of the
corresponding work array, and no error message is issued by pxerbla.

```

Output Parameters

a

On exit, the elements on and above the diagonal of sub (*A*) contain the $\min(n, m)$ -by- m upper trapezoidal matrix *R* (*R* is upper triangular if $n \geq m$); the elements below the diagonal, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of $\min(n,m)$ elementary reflectors. (See Application Notes below).

taua, *taub*

(local)

REAL for psggqr
 DOUBLE PRECISION for pdggqr
 COMPLEX for pcggqr
 DOUBLE COMPLEX for pzggqr.

Arrays, size $LOCc(ja+\min(n,m)-1)$ for *taua* and $LOCr(ib+n-1)$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *taua* is tied to the distributed matrix *A*. (See Application Notes below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See Application Notes below).

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = i - \tau_{aua} v v'$$

where τ_{aua} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ_{aua} in $\tau_{aua}(ja+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(ib) * H(ib+1) * \dots * H(ib+k-1), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = i - \tau_{aub} v v'$$

where τ_{aub} is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and τ_{aub} in $\tau_{aub}(ib+n-k-i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormrq/p?unmqr](#).

p?ggrqf

Computes the generalized RQ factorization.

Include Files

- C: mkl scalapack.h

Description

The `p?gqrqf` routine forms the generalized RQ factorization of an m -by- n matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ and a p -by- n matrix $\text{sub}(B) = (ib:ib+p-1, ja:ja+n-1)$:

$$\text{sub}(A) = R^*Q, \quad \text{sub}(B) = Z^*T^*Q,$$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = m \begin{pmatrix} 0 & R_{12} \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} \\ R_{12} \\ \vdots \\ R_m \end{pmatrix}^m - n \quad , \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} \\ 0 \end{pmatrix} \begin{matrix} n \\ p-n \end{matrix}, \text{ if } p \geq n$$

or

10.1007/s00339-017-0363-1

where T^{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GRQ factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the RQ factorization of $\text{sub}(A)^*\text{inv}(\text{sub}(B))$:

$$\text{sub}(A) * \text{inv}(\text{sub}(B)) = (R * \text{inv}(T)) * Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrices sub (<i>A</i>) ($m \geq 0$).
<i>p</i>	INTEGER. The number of rows in the distributed matrix sub(<i>B</i>) ($p \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrices sub(<i>A</i>) and sub(<i>B</i>) ($n \geq 0$).
<i>a</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja</i> + <i>n</i> -1)). Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix sub(<i>A</i>) to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desc_a</i>	(global and local) INTEGER array, dimension (<i>dlen_a</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb</i> + <i>n</i> -1)). Contains the local pieces of the <i>p</i> -by- <i>n</i> matrix sub(<i>B</i>) to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>desc_b</i>	(global and local) INTEGER array, dimension (<i>dlen_b</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf.

Workspace array of dimension of *lwork*.

lwork

(local or global) INTEGER.

Dimension of *work*, must be at least $lwork \geq \max(mb_a * (mpa0 + nqa0 + mb_a), \max((mb_a * (mb_a - 1)) / 2, (ppb0 + nqb0) * mb_a) + mb_a * mb_a, nb_b * (ppb0 + nqb0 + nb_b))$, where

```

iroffa = mod(ia-1, mb_A),
icooffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc (m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc (m+icooffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
ppb0 = numroc (p+iroffb, mb_b, MYROW, ibrow, NPROW),
nqb0 = numroc (n+icoffb, nb_b, MYCOL, ibcol, NPCOL)
and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors (see *Application Notes* below).

taua, *taub*

(local)

REAL for psggqr
DOUBLE PRECISION for pdggqr
COMPLEX for pcggqr
DOUBLE COMPLEX for pzggqr.

Arrays, size $LOCr(ia+m-1)$ for *taua* and $LOCc(jb+\min(p, n)-1)$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . *taua* is tied to the distributed matrix *A*. (See *Application Notes* below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See *Application Notes* below).

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ia)*H(ia+1)*\dots*H(ia+k-1),$$

where $k = \min(m, n)$.

Each *H*(*i*) has the form

$$H(i) = i - taua * v * v'$$

where *tau*_a is a real/complex scalar, and *v* is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in *A*(*ia+m-k+i-1*, *ja:j+n-k+i-2*), and *tau*_a in *tau*_a(*ia+m-k-1*). To form *Q* explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use *Q* to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix *Z* is represented as a product of elementary reflectors

$$Z = H(jb)*H(jb+1)*\dots*H(jb+k-1), \text{ where } k = \min(p, n).$$

Each *H*(*i*) has the form

$$H(i) = i - taub * v * v'$$

where *taub* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in *B*(*ib+i:ib+p-1*, *jb+i-1*), and *taub* in *taub*(*jb+i-1*). To form *Z* explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use *Z* to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

Symmetric Eigenproblems

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form *T* and then find the eigenvalues and eigenvectors of the tridiagonal matrix *T*. ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenproblems"](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the *QTQ* algorithm, or bisection followed by inverse iteration).

Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/ Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $A = QTQ^H$	p?sytrd/p?hetrd		
Multiply matrix after reduction		p?ormtr/p?unmtr	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a QTQ method			steqr2*
Find selected eigenvalues of a tridiagonal matrix T via bisection			p?stebz
Find selected eigenvectors of a tridiagonal matrix T by inverse iteration			p?stein

* This routine is described as part of auxiliary ScaLAPACK routines.

p?sytrd

Reduces a symmetric matrix to real symmetric
tridiagonal form by an orthogonal similarity
transformation.

Syntax

Fortran:

```
call pssytrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

C:

```
void pssytrd (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tau , float *work , MKL_INT *lwork , MKL_INT
*info );
void pdsytrd (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tau , double *work , MKL_INT *lwork ,
MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?sytrd` routine reduces a real symmetric matrix `sub(A)` to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q' * \text{sub}(A) * Q = T,$$

where `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`.

Input Parameters

<code>uplo</code>	(global) CHARACTER.
	Specifies whether the upper or lower triangular part of the symmetric matrix <code>sub(A)</code> is stored:
If <code>uplo = 'U'</code> ,	upper triangular
If <code>uplo = 'L'</code> ,	lower triangular

n (global) INTEGER. The order of the distributed matrix sub(*A*) ($n \geq 0$).

a (local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Pointer into the local memory to an array of dimension (*lld_a*, *LOCc(ja* +*n*-1)). On entry, this array contains the local pieces of the symmetric distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See *Application Notes* below.

ia, *ja* (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

work (local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:

lwork $\geq \max(\text{NB} * (np + 1), 3 * \text{NB}),$

where NB = *mb_a* = *nb_a*,

np = numroc(*n*, NB, MYROW, *iarow*, NPROW),

iarow = indxg2p(*ia*, NB, MYROW, *rsrc_a*, NPROW).

indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, if *uplo* = 'U', the diagonal and first superdiagonal of sub(*A*) are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal matrix *Q* as a product of elementary reflectors; if *uplo* = 'L', the diagonal and first subdiagonal of sub(*A*) are overwritten by the

corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array τ , represent the orthogonal matrix Q as a product of elementary reflectors. See *Application Notes* below.

d

(local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Arrays, size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T :

$$d(i) = A(i,i).$$

d is tied to the distributed matrix *A*.

e

(local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Arrays, size $LOCc(ja+n-1)$ if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$$e(i) = A(i,i+1) \text{ if } uplo = 'U',$$

$$e(i) = A(i+1,i) \text{ if } uplo = 'L'.$$

e is tied to the distributed matrix *A*.

tau

(local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Arrays, size $LOCc(ja+n-1)$. This array contains the scalar factors *tau* of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100 + *j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = i - \tau * v * v',$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$Q = H(1) \ H(2) \dots \ H(n-1)$.

Each $H(i)$ has the form

$H(i) = i - tau * v * v'$,

where tau is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and tau in $\tau_{\text{au}}(ja+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $\text{uplo} = 'U'$:

$$\begin{array}{cccccc} \dots & \dots & \dots & \dots & \dots & \dots \\ | & & & & & | \\ \dots & \dots & \dots & \dots & \dots & \dots \end{array}$$

If $\text{uplo} = 'L'$:

$$\begin{array}{cccccc} \dots & \dots & \dots & \dots & \dots & \dots \\ | & & & & & | \\ \dots & \dots & \dots & \dots & \dots & \dots \end{array}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?ormtr

Multiples a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?syrtd.

Syntax

Fortran:

```
call psormtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descC, work, lwork, info)
```

```
call pdormtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descC, work, lwork, info)
```

C:

```
void psormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descC , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descC , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if *side* = 'L' and $nq = n$ if *side* = 'R'.

Q is defined as the product of nq elementary reflectors, as returned by p?sytrd.

If *uplo* = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

If *uplo* = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER
= 'L':	Q or Q^T is applied from the left.
= 'R':	Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER
= 'N',	no transpose, Q is applied.
= 'T',	transpose, Q^T is applied.
<i>uplo</i>	(global) CHARACTER.
= 'U':	Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd;
= 'L':	Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psormtr DOUBLE PRECISION for pdormtr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>) if <i>side</i> ='L', or (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by p?sytrd. If <i>side</i> ='L', <i>lld_a</i> $\geq \max(1, LOCr(ia+m-1))$;

If $\text{side} = 'R'$, $\text{lld}_a \geq \max(1, \text{LOCr}(ia+n-1))$.

ia, ja
(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca
(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

tau
(local)
REAL for psormtr
DOUBLE PRECISION for pdormtr.
Array, size of *ltau* where
if $\text{side} = 'L'$ and $\text{uplo} = 'U'$, $\text{ltau} = \text{LOCc}(m_a)$,
if $\text{side} = 'L'$ and $\text{uplo} = 'L'$, $\text{ltau} = \text{LOCc}(ja+m-2)$,
if $\text{side} = 'R'$ and $\text{uplo} = 'U'$, $\text{ltau} = \text{LOCc}(n_a)$,
if $\text{side} = 'R'$ and $\text{uplo} = 'L'$, $\text{ltau} = \text{LOCc}(ja+n-2)$.
tau(i) must contain the scalar factor of the elementary reflector *H(i)*, as returned by p?sytrd. *tau* is tied to the distributed matrix *A*.

c
(local) REAL for psormtr
DOUBLE PRECISION for pdormtr.
Pointer into the local memory to an array of dimension (*lld_a*, *LOCc(ja+n-1)*). Contains the local pieces of the distributed matrix sub (*C*).

ic, jc
(global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC
(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.

work
(local)
REAL for psormtr
DOUBLE PRECISION for pdormtr.
Workspace array of dimension *lwork*.

lwork
(local or global) INTEGER, dimension of *work*, must be at least:
if $\text{uplo} = 'U'$,
 $\text{iaa} = ia; \text{jaa} = ja+1, \text{icc} = ic; \text{jcc} = jc;$
else $\text{uplo} = 'L'$,
 $\text{iaa} = ia+1, \text{jaa} = ja;$
If $\text{side} = 'L'$,
 $\text{icc} = ic+1; \text{jcc} = jc;$
else $\text{icc} = ic; \text{jcc} = jc+1;$

```

    end if
    end if
    If side = 'L',
      mi= m-1; ni= n
      lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) +
      nb_a*nb_a
    else
      If side = 'R',
        mi= m; mi = n-1;
        lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
        max(npa0+numroc(numroc(ni+icooffc, nb_a, 0, 0, NPCOL), nb_a,
        0, 0, lcmq), mpc0))*nb_a)+ nb_a*nb_a
      end if
      where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
            iroffa = mod(iaa-1, mb_a),
            icoffa = mod(jaa-1, nb_a),
            iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
            npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
            iroffc = mod(jcc-1, mb_c),
            icooffc = mod(jcc-1, nb_c),
            icrow = indxg2p(jcc, mb_c, MYROW, rsrc_c, NPROW),
            iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
            mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
            nqc0 = numroc(ni+icooffc, nb_c, MYCOL, iccol, NPCOL),
            ilcm, indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL,
            NPROW and NPCOL can be determined by calling the subroutine
            blacs_gridinfo. If lwork = -1, then lwork is global input and a
            workspace query is assumed; the routine only calculates the minimum and
            optimal size for all work arrays. Each of these values is returned in the first
            entry of the corresponding work array, and no error message is issued by
            pxerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

Fortran:

```
call pchetrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

C:

```
void pchetrd (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
void pzhetrd (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?hetrd routine reduces a complex Hermitian matrix $\text{sub}(A)$ to Hermitian tridiagonal form T by a unitary similarity transformation:

$$Q' \text{sub}(A) Q = T$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER.
	Specifies whether the upper or lower triangular part of the Hermitian matrix $\text{sub}(A)$ is stored:
	If <i>uplo</i> = 'U', upper triangular
	If <i>uplo</i> = 'L', lower triangular
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) COMPLEX for pchetrd DOUBLE COMPLEX for pzhetrd. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see *Application Notes* below).

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

work

(local)

COMPLEX for *pchetr**d*

DOUBLE COMPLEX for *pzhetr**d*.

Workspace array of dimension *lwork*.

lwork

(local or global) INTEGER, dimension of *work*, must be at least:

lwork $\geq \max(NB * (np + 1), 3 * NB)$

where $NB = mb_a = nb_a$,

$np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$,

$iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$.

indxg2p and *numroc* are ScalAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pixerbla*.

Output Parameters

a

On exit,

If $uplo = 'U'$, the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements above the first superdiagonal, with the array *tau*, represent the unitary matrix *Q* as a product of elementary reflectors; if $uplo = 'L'$, the diagonal and first subdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements below the first subdiagonal, with the array *tau*, represent the unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

d

(local)

REAL for *pchetr**d*

DOUBLE PRECISION for *pzhetr**d*.

Arrays, size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix *T*:

$d(i) = A(i,i).$
 d is tied to the distributed matrix A .

e (local)
REAL for pchetrd
DOUBLE PRECISION for pzhetrd.
Arrays, size $LOCc(ja+n-1)$ if $uplo = 'U'$; $LOCc(ja+n-2)$ - otherwise.
The off-diagonal elements of the tridiagonal matrix T :
 $e(i) = A(i,i+1)$ if $uplo = 'U'$,
 $e(i) = A(i+1,i)$ if $uplo = 'L'$.
 e is tied to the distributed matrix A .

tau (local) COMPLEX for pchetrd
DOUBLE COMPLEX for pzhetrd.
Arrays, size $LOCc(ja+n-1)$. This array contains the scalar factors tau of the elementary reflectors. tau is tied to the distributed matrix A .

$work(1)$ On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$ (global) INTEGER.
= 0: the execution is successful.
< 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each $H(i)$ has the form

$$H(i) = i - tau * v * v^T,$$

where tau is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and tau in $tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = i - tau * v * v^T,$$

where tau is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and tau in $tau(ja+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If `uplo = 'L'`:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?unmtr

Multiples a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.

Syntax

Fortran:

```
call pcunmtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
call pzunmtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

C:

```
void pcunmtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
void pzunmtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

`side = 'L'`

`side = 'R'`

<i>trans</i> = 'N':	$Q^* \text{sub}(C)$	$\text{sub}(C)^* Q$
<i>trans</i> = 'C':	$Q^H \text{sub}(C)$	$\text{sub}(C)^* Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $\text{side} = 'L'$ and $nq = n$ if $\text{side} = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by [p?hetrd](#).

If $\text{uplo} = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $\text{uplo} = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<i>uplo</i>	(global) CHARACTER. = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd ; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pcunmtr DOUBLE PRECISION for pzunmtr . Pointer into the local memory to an array of dimension $(\text{lld}_a, \text{LOCc}(ja+m-1))$ if $\text{side} = 'L'$, or $(\text{lld}_a, \text{LOCc}(ja+n-1))$ if $\text{side} = 'R'$. Contains the vectors which define the elementary reflectors, as returned by p?hetrd . If $\text{side} = 'L'$, $\text{lld}_a \geq \max(1, \text{LOCr}(ia+m-1))$; If $\text{side} = 'R'$, $\text{lld}_a \geq \max(1, \text{LOCr}(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .

tau

(local)

COMPLEX for pcunmtr

DOUBLE COMPLEX for pzunmtr.

Array, size of *ltau* where

```
If side = 'L' and uplo = 'U', ltau = LOCC(m_a),
if side = 'L' and uplo = 'L', ltau = LOCC(ja+m-2),
if side = 'R' and uplo = 'U', ltau = LOCC(n_a),
if side = 'R' and uplo = 'L', ltau = LOCC(ja+n-2).
```

tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by p?hetrd. *tau* is tied to the distributed matrix *A*.

c

(local) COMPLEX for pcunmtr

DOUBLE COMPLEX for pzunmtr.

Pointer into the local memory to an array of dimension (*lld_a*, LOCC(ja +
n-1)). Contains the local pieces of the distributed matrix sub (*C*).

ic, jc

(global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.

work

(local)

COMPLEX for pcunmtr

DOUBLE COMPLEX for pzunmtr.

Workspace array of dimension *lwork*.*lwork*(local or global) INTEGER, dimension of *work*, must be at least:

```
If uplo = 'U',
iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
iaa= ia+1, jaa= ja;
If side = 'L',
icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
mi= m-1; ni= n
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) +
nb_a*nb_a
```

```

else
  If side = 'R',
    mi= m; mi = n-1;
    lwork  $\geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 +$ 
     $\max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb\_a, 0, 0, \text{NPCOL}), nb\_a,$ 
     $0, 0, lcmq), mpc0) * nb\_a) + nb\_a * nb\_a$ 
  end if
  where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
  iroffa = mod(iaa-1, mb_a),
  icooffa = mod(jaa-1, nb_a),
  iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
  npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
  iroffc = mod(icc-1, mb_c),
  icooffc = mod(jcc-1, nb_c),
  icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
  iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
  mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
  nqc0 = numroc(ni+icooffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the subroutine
blacs_gridinfo. If lwork = -1, then lwork is global input and a
workspace query is assumed; the routine only calculates the minimum and
optimal size for all work arrays. Each of these values is returned in the first
entry of the corresponding work array, and no error message is issued by
pxerbla.

```

Output Parameters

c

Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$.

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
then *info* = - *i*

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

Fortran:

```
call psstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
iblock, isplit, work, iwork, liwork, info)
```

```
call pdstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,

MKL_INT *m , MKL_INT *nsplit , double *w , MKL_INT *iblock , MKL_INT *isplit , double
*work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?stebz routine computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval [vl vu], or the eigenvalues indexed *il* through *iu*. A static partitioning of work is done at the beginning of p?stebz which results in all processes finding an (almost) equal number of eigenvalues.

Input Parameters

<i>ictxt</i>	(global) INTEGER. The BLACS context handle.
<i>range</i>	(global) CHARACTER. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval [vl, vu]. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>order</i>	(global) CHARACTER. Must be 'B' or 'E'. If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<i>n</i>	(global) INTEGER. The order of the tridiagonal matrix <i>T</i> (<i>n</i> ≥0).
<i>vl</i> , <i>vu</i>	(global) REAL for psstebz DOUBLE PRECISION for pdstebz. If <i>range</i> = 'V', the routine computes the lower and the upper bounds for the eigenvalues on the interval [1, vu]. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.

il, iu

(global)

INTEGER. Constraint: $1 \leq il \leq iu \leq n$.

If $range = 'I'$, the index of the smallest eigenvalue is returned for il and of the largest eigenvalue for iu (assuming that the eigenvalues are in ascending order) must be returned. il must be at least 1. iu must be at least il and no greater than n .

If $range = 'A'$ or ' V ', il and iu are not referenced.

abstol

(global)

REAL for `psstebz`DOUBLE PRECISION for `pdstebz`.

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width $abstol$. If $abstol \leq 0$, then the tolerance is taken as $ulp \cdot \|T\|_1$, where ulp is the machine precision, and $\|T\|_1$ means the 1-norm of T .

Eigenvalues will be computed most accurately when $abstol$ is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), $abstol$ should be set to $2 * p?lamch('S')$.

d

(global)

REAL for `psstebz`DOUBLE PRECISION for `pdstebz`.Array, size (n).

Contains n diagonal elements of the tridiagonal matrix T . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

e

(global)

REAL for `psstebz`DOUBLE PRECISION for `pdstebz`.Array, size ($n - 1$).

Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix T . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

work

(local)

REAL for `psstebz`DOUBLE PRECISION for `pdstebz`.Array, size $\max(5n, 7)$. This is a workspace array.*lwork*(local) INTEGER. The size of the *work* array must be $\geq \max(5n, 7)$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork(local) INTEGER. Array, size $\max(4n, 14)$. This is a workspace array.*liwork*(local) INTEGER. the size of the *iwork* array must $\geq \max(4n, 14, \text{NPROCS})$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

m(global) INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$ *nsplit*(global) INTEGER. The number of diagonal blocks detected in T .
 $1 \leq nsplit \leq n$ *w*

(global)

REAL for `psstebz`DOUBLE PRECISION for `pdstebz`.Array, size (n). On exit, the first m elements of *w* contain the eigenvalues on all processes.*iblock*

(global) INTEGER.

Array, size (n). At each row/column j where $e(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit $iblock(i)$ specifies which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs to.

NOTE

In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

isplit

(global) INTEGER.

Array, size (n).Contains the splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, etc., and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$. (Only the first $nsplit$ elements are used, but since the $nsplit$ values are not known, n words must be reserved for *isplit*.)*info*

(global) INTEGER.

If $info = 0$, the execution is successful.

If $\text{info} < 0$, if $\text{info} = -i$, the i -th argument has an illegal value.

If $\text{info} > 0$, some or all of the eigenvalues fail to converge or not computed.

If $\text{info} = 1$, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

If $\text{info} = 2$, mismatch between the number of eigenvalues output and the number desired.

If $\text{info} = 3$: $\text{range} = 'i'$, and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating point arithmetic. Increase the *fudge* parameter, recompile, and try again.

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

Fortran:

```
call psstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pdstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pcstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pzstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?stein` routine computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK routine) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

`p = NPROW*NPCOL` is the total number of processes.

Input Parameters

<code>n</code>	(global) INTEGER. The order of the matrix T ($n \geq 0$).
<code>m</code>	(global) INTEGER. The number of eigenvectors to be returned.
<code>d, e, w</code>	<p>(global)</p> <p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors.</p> <p>Arrays: <code>d(*)</code> contains the diagonal elements of T.</p> <p><code>size (n)</code>.</p> <p><code>e(*)</code> contains the off-diagonal elements of T.</p> <p><code>size (n-1)</code>.</p> <p><code>w(*)</code> contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array <code>w</code> from <code>p?stebz</code> with <code>order = 'B'</code> is expected. The array should be replicated in all processes.)</p> <p><code>size(m)</code></p>
<code>iblock</code>	<p>(global) INTEGER.</p> <p>Array, <code>size (n)</code>. The submatrix indices associated with the corresponding eigenvalues in <code>w--1</code> for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array <code>iblock</code> from <code>p?stebz</code> is expected here).</p>
<code>isplit</code>	<p>(global) INTEGER.</p> <p>Array, <code>size (n)</code>. The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <code>isplit(1)</code>, the second of rows/columns <code>isplit(1)+1</code> through <code>isplit(2)</code>, etc., and the <code>nsplit</code>-th consists of rows/columns <code>isplit(nsplits-1)+1</code> through <code>isplit(nsplits)=n</code>. (The output array <code>isplit</code> from <code>p?stebz</code> is expected here.)</p>

<i>orfac</i>	(global) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.
	<i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within $\text{orfac} * \mathbf{T} $ of each other are to be orthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if <i>orfac</i> is equal to zero. A default value of 1000 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local). REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, size (<i>lwork</i>).
<i>lwork</i>	(local) INTEGER. <i>lwork</i> controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00))/n)$. Eigenvectors corresponding to eigenvalue clusters of size <i>nvec</i> - $\text{ceil}(m/p)$ + 1 are guaranteed to be orthogonal (the orthogonality is similar to that obtained from ?stein2).

NOTE

lwork must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p)*n$ and should have the same input value on all processes.

	It is the minimum value of <i>lwork</i> input on different processes that is significant.
	If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.
<i>iwork</i>	(local) INTEGER. Workspace array, size $(3n+p+1)$.
<i>liwork</i>	(local) INTEGER. The size of the array <i>iwork</i> . It must be greater than $(3*n + p + 1)$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

`z`

(local)
REAL for `psstein`
DOUBLE PRECISION for `pdstein`
COMPLEX for `pcstein`
DOUBLE COMPLEX for `pzstein`.

Array, size (`descz(dlen_)`, $n/\text{NPCOL} + \text{NB}$). `z` contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [?stein2](#)). On output, `z` is distributed across the p processes in block cyclic format.

`work(1)`

On exit, `work(1)` gives a lower bound on the workspace ($lwork$) that guarantees the user desired orthogonalization (see `orfac`). Note that this may overestimate the minimum workspace needed.

`iwork`

On exit, `iwork(1)` contains the amount of integer workspace required. On exit, the `iwork(2)` through `iwork(p+2)` indicate the eigenvectors computed by each process. Process i computes eigenvectors indexed $iwork(i+2)+1$ through `iwork(i+3)`.

`ifail`

(global) **INTEGER**. Array, size (m). On normal exit, all elements of `ifail` are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in [?stein](#)), then `info > 0` is returned. If $\text{mod}(info, m+1) > 0$, then for $i=1$ to $\text{mod}(info, m+1)$, the eigenvector corresponding to the eigenvalue $w(ifail(i))$ failed to converge (w refers to the array of eigenvalues on output).

`iclustr`

(global) **INTEGER**. Array, size ($2*p$)

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see `lwork`, `orfac` and `info`). Eigenvectors corresponding to clusters of eigenvalues indexed `iclustr(2*I-1)` to `iclustr(2*I)`, $i = 1$ to $\text{info}/(m+1)$, could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. `iclustr` is a zero terminated array ---(`iclustr(2*k).ne. 0.and.iclustr(2*k+1).eq.0`) if and only if k is the number of clusters.

`gap`

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The info/m output values in this array correspond to the $\text{info}/(m+1)$ clusters indicated by the array iclustr . As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(O(n) * \text{macheps}) / \text{gap}(i)$.

info

(global) INTEGER.

If $\text{info} = 0$, the execution is successful.If $\text{info} < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$,If the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.If $\text{info} < 0$: if $\text{info} = -i$, the i -th argument had an illegal value.If $\text{info} > 0$: if $\text{mod}(\text{info}, m+1) = i$, then i eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array ifail . If $\text{info}/(m+1) = i$, then eigenvectors corresponding to i clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array iclustr .

Nonsymmetric Eigenvalue Problems

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

[Table "Computational Routines for Solving Nonsymmetric Eigenproblems"](#) lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	p?gehrd		
Multiply the matrix after reduction		p?ormhr / p?unmhr	
Find eigenvalues and Schur factorization			p?lahqr , p?hseqr

[p?gehrd](#)

Reduces a general matrix to upper Hessenberg form.

Syntax

Fortran:

```
call psgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```

void psgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT
*info );

void pdgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , double *a , MKL_INT *ia ,

MKL_INT *lwork , MKL_INT *info );

```

Include Files

- C: mkl_scalapack.h

Description

The p?gehrd routine reduces a real/complex general distributed matrix sub (A) to upper Hessenberg form H by an orthogonal or unitary similarity transformation

$$Q^T \text{sub}(A) Q = H,$$

where $\text{sub}(A) = A(i_a+n-1:i_a+n-1, j_a+n-1:j_a+n-1)$.

Input Parameters

n (global) INTEGER. The order of the distributed matrix sub(A) ($n \geq 0$).

ilo, *ihi* (global) INTEGER.

It is assumed that sub(A) is already upper triangular in rows $i_a:i_a+ilo-2$ and $i_a+ihi:i_a+n-1$ and columns $j_a:j_a+ilo-2$ and $j_a+ihi:j_a+n-1$. (See Application Notes below).

If $n > 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.

a (local) REAL for psgehrd

DOUBLE PRECISION for pdgehrd

COMPLEX for pcgehrd

DOUBLE COMPLEX for pzgehrd.

Pointer into the local memory to an array of dimension (*lld_a*, *LOCc(ja+n-1)*). On entry, this array contains the local pieces of the n -by- n general distributed matrix sub(A) to be reduced.

ia, *ja*

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix A .

work

(local)

REAL for psgehrd
 DOUBLE PRECISION for pdgehrd
 COMPLEX for pcgehrd
 DOUBLE COMPLEX for pzgehrd.
 Workspace array of dimension *lwork*.

lwork

(local or global) INTEGER, dimension of the array *work*. *lwork* is local input and must be at least

```
lwork ≥ NB * NB + NB * max(ihip+1, ihlp+inlq)  

where NB = mb_a = nb_a,  

iroffa = mod(ia-1, NB),  

icoffa = mod(ja-1, NB),  

ioff = mod(ia+ilo-2, NB), iarow = indxg2p(ia, NB, MYROW,  

rsrc_a, NPROW), ihip = numroc(ihi+iroffa, NB, MYROW, iarow,  

NPROW),  

ilrow = indxg2p(ia+ilo-1, NB, MYROW, rsrc_a, NPROW),  

ihlp = numroc(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPROW),  

ilcol = indxg2p(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL),  

inlq = numroc(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL),  

indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL, NPROW  

and NPCOL can be determined by calling the subroutine blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, the upper triangle and the first subdiagonal of sub(*A*) are overwritten with the upper Hessenberg matrix *H*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau

(local). REAL for psgehrd
 DOUBLE PRECISION for pdgehrd
 COMPLEX for pcgehrd
 DOUBLE COMPLEX for pzgehrd.
 Array, size at least max(*ja*+*n*-2).

The scalar factors of the elementary reflectors (see *Application Notes* below). Elements *ja*:*ja*+*ilo*-2 and *ja*+*ihi*:*ja*+*n*-2 of *tau* are set to zero. *tau* is tied to the distributed matrix *A*.

<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(iло+1)*\dots*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = i - tau * v * v'$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $a(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and tau in $\tau(a(ja+ilo+i-2))$. The contents of $a(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, H denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?ormhr

Multiples a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

Fortran:

```
call psormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

C:

```
void psormhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau ,
float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork ,
MKL_INT *info );
```

```
void pdormhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau ,
double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?ormhr` routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q^* \text{sub}(C)$	$\text{sub}(C)*Q$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$	$\text{sub}(C)*Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $\text{side} = 'L'$ and $nq = n$ if $\text{side} = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by `p?gehrd`.

$Q = H(i_{lo}) H(i_{lo+1}) \dots H(i_{hi-1})$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

ilo, ihi

(global) INTEGER.

ilo and *ihi* must have the same values as in the previous call of p?gehrd. *Q* is equal to the unit matrix except for the distributed submatrix $Q(ia + ilo : ia + ihi - 1, ia + ilo : ja + ihi - 1)$.

If *side* = 'L', $1 \leq ilo \leq ihi \leq \max(1, m)$;

If *side* = 'R', $1 \leq ilo \leq ihi \leq \max(1, n)$;

ilo and *ihi* are relative indexes.

a

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Pointer into the local memory to an array of dimension (*lld_a*, *LOCc(ja + m - 1)*) if *side* = 'L', and (*lld_a*, *LOCc(ja + n - 1)*) if *side* = 'R'.

Contains the vectors which define the elementary reflectors, as returned by p?gehrd.

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Array, size *LOCc(ja + m - 2)*, if *side* = 'L', and *LOCc(ja + n - 2)* if *side* = 'R'.

This array contains the scalar factors *tau(j)* of the elementary reflectors *H(j)* as returned by p?gehrd. *tau* is tied to the distributed matrix *A*.

c

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Pointer into the local memory to an array of dimension (*lld_c*, *LOCc(jc + n - 1)*).

Contains the local pieces of the distributed matrix sub(*C*).

ic, jc

(global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.

descC

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Workspace array with dimension *lwork*.

lwork (local or global) INTEGER.

The dimension of the array *work*.

lwork must be at least $iaa = ia + ilo; jaa = ja + ilo - 1$;

If *side* = 'L',

$$mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc; lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$$

else if *side* = 'R',

$$mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo; lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npao + \text{numroc}(\text{numroc}(ni + ioffc, nb_a, 0, 0, \text{NPCOL}), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$$

end if

where $lcmq = lcm/\text{NPCOL}$ with $lcm = \text{ilcm}(\text{NPROW}, \text{NPCOL})$,

$$\text{iroffa} = \text{mod}(iaa - 1, mb_a),$$

$$\text{icoffa} = \text{mod}(jaa - 1, nb_a),$$

$$\text{iarow} = \text{idxg2p}(iaa, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$$

$$\text{npao} = \text{numroc}(ni + \text{iroffa}, mb_a, \text{MYROW}, \text{iarow}, \text{NPROW}),$$

$$\text{iroffc} = \text{mod}(icc - 1, mb_c), \text{icoffc} = \text{mod}(jcc - 1, nb_c),$$

$$\text{icrow} = \text{idxg2p}(icc, mb_c, \text{MYROW}, rsrc_c, \text{NPROW}),$$

$$\text{iccol} = \text{idxg2p}(jcc, nb_c, \text{MYCOL}, csrc_c, \text{NPCOL}),$$

$$\text{mpc0} = \text{numroc}(mi + \text{iroffc}, mb_c, \text{MYROW}, \text{icrow}, \text{NPROW}),$$

$$\text{nqc0} = \text{numroc}(ni + \text{icoffc}, nb_c, \text{MYCOL}, \text{iccol}, \text{NPCOL}),$$

ilcm, *idxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pixerbla*.

Output Parameters

c sub(*C*) is overwritten by $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$.

work(1) On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.

= 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?unmhr

Multiples a general matrix by the unitary transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

Fortran:

```
call pcunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
call pzunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

C:

```
void pcunmhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *tau , MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzunmhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex16 *tau , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Description

This routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$\text{side} = 'L'$	$\text{side} = 'R'$
$\text{trans} = 'N':$	$Q^* \text{sub}(C)$	$\text{sub}(C)*Q$
$\text{trans} = 'H':$	$Q^H * \text{sub}(C)$	$\text{sub}(C)*Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $\text{side} = 'L'$ and $nq = n$ if $\text{side} = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1)$.

Input Parameters

side	(global) CHARACTER
$= 'L':$	Q or Q^H is applied from the left.
$= 'R':$	Q or Q^H is applied from the right.
trans	(global) CHARACTER

= 'N', no transpose, Q is applied.

= 'C', conjugate transpose, Q^H is applied.

m
(global) INTEGER. The number of rows in the distributed submatrix sub (C)
($m \geq 0$).

n
(global) INTEGER. The number of columns in the distributed submatrix sub
(C) ($n \geq 0$).

ilo, ihi
(global) INTEGER

These must be the same parameters *ilo* and *ihi*, respectively, as supplied to p?gehrd. Q is equal to the unit matrix except in the distributed submatrix Q ($ia+ilo:ia+ihi-1, ia+ilo:ja+ihi-1$).

If *side* = 'L', then $1 \leq ilo \leq ihi \leq \max(1, m)$.

If *side* = 'R', then $1 \leq ilo \leq ihi \leq \max(1, n)$

ilo and *ihi* are relative indexes.

a
(local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Pointer into the local memory to an array of dimension (*lld_a*, LOC $c(ja+m-1)$) if *side* = 'L', and (*lld_a*, LOC $c(ja+n-1)$) if *side* = 'R'.

Contains the vectors which define the elementary reflectors, as returned by p?gehrd.

ia, ja
(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca
(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

tau
(local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Array, size LOC $c(ja+m-2)$, if *side* = 'L', and LOC $c(ja+n-2)$ if *side* = 'R'.

This array contains the scalar factors $\tau(j)$ of the elementary reflectors $H(j)$ as returned by p?gehrd. *tau* is tied to the distributed matrix *A*.

c
(local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Pointer into the local memory to an array of dimension (*lld_c*, LOC $c(jc+n-1)$).

Contains the local pieces of the distributed matrix sub(*C*).

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for <i>pcunmhr</i> DOUBLE COMPLEX for <i>pzunmhr</i> . Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	(local or global) The dimension of the array <i>work</i> . <i>lwork</i> must be at least <i>iaa</i> = <i>ia</i> + <i>ilo</i> ; <i>jaa</i> = <i>ja</i> + <i>ilo</i> -1; If <i>side</i> = 'L', <i>mi</i> = <i>ihi</i> - <i>ilo</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> + <i>ilo</i> ; <i>jcc</i> = <i>jc</i> ; <i>lwork</i> $\geq \max((nb_a * (nb_a-1))/2, (nqc0+mpc0)*nb_a) + nb_a * nb_aelse if side = 'R',mi = m; ni = ihi-ilo; icc = ic; jcc = jc + ilo; lwork \geq\max((nb_a * (nb_a-1))/2, (nqc0 + \max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) *nb_a) + nb_a * nb_aend ifwhere lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),iroffa = mod(iaa-1, mb_a),icoffa = mod(jaa-1, nb_a),iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),iroffc = mod(icc-1, mb_c),icoffc = mod(jcc-1, nb_c),icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),ilcm, indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL,NPROW and NPCOL can be determined by calling the subroutineblacs_gridinfo.If lwork = -1, then lwork is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.$

Output Parameters

<i>c</i>	<i>C</i> is overwritten by $Q^* \text{sub}(C)$ or $Q'^*\text{sub}(C)$ or $\text{sub}(C)*Q'$ or $\text{sub}(C)*Q$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

Fortran:

```
call pslahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info)
call pdlahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info)
```

C:

```
void pslahqr (MKL_INT *wantt , MKL_INT *wantz , MKL_INT *n , MKL_INT *ilo , MKL_INT
*ihi , float *a , MKL_INT *desca , float *wr , float *wi , MKL_INT *iloz , MKL_INT
*ihiz , float *z , MKL_INT *descz , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *ilwork , MKL_INT *info );
void pdlahqr (MKL_INT *wantt , MKL_INT *wantz , MKL_INT *n , MKL_INT *ilo , MKL_INT
*ihi , double *a , MKL_INT *desca , double *wr , double *wi , MKL_INT *iloz , MKL_INT
*ihiz , double *z , MKL_INT *descz , double *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *ilwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

Input Parameters

<i>wantt</i>	(global) LOGICAL If <i>wantt</i> = .TRUE., the full Schur form <i>T</i> is required; If <i>wantt</i> = .FALSE., only eigenvalues are required.
<i>wantz</i>	(global) LOGICAL. If <i>wantz</i> = .TRUE., the matrix of Schur vectors <i>z</i> is required;

If `wantz` = .FALSE., Schur vectors are not required.

`n` (global) INTEGER. The order of the Hessenberg matrix A (and z if `wantz`). ($n \geq 0$).

`ilo, ihi` (global) INTEGER.

It is assumed that A is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $A(ilo, ilo-1) = 0$ (unless $ilo = 1$). `p?lahqr` works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of A if `wantt` is .TRUE.. $1 \leq ilo \leq \max(1, ihi); ihi \leq n$.

`a` (global)

REAL for `pslahqr`

DOUBLE PRECISION for `pdlahqr`

Array, DIMENSION (`descA(1ld_)`, *). On entry, the upper Hessenberg matrix A .

`descA` (global and local) INTEGER array, dimension (`dlen_`). The array descriptor for the distributed matrix A .

`iloz, ihiz` (global) INTEGER. Specify the rows of z to which transformations must be applied if `wantz` is .TRUE.. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.

`z` (global) REAL for `pslahqr`

DOUBLE PRECISION for `pdlahqr`

Array. If `wantz` is .TRUE., on entry z must contain the current matrix Z of transformations accumulated by `pdhseqr`. If `wantz` is .FALSE., z is not referenced.

`descZ` (global and local) INTEGER array, dimension (`dlen_`). The array descriptor for the distributed matrix Z .

`work` (local)

REAL for `pslahqr`

DOUBLE PRECISION for `pdlahqr`

Workspace array with dimension `lwork`.

`lwork` (local) INTEGER. The dimension of `work`. `lwork` is assumed big enough so that $lwork \geq 3*n + \max(2*\max(descZ(1ld_), descA(1ld_)) + 2*LOCq(n), 7*\text{ceil}(n/hbl)/\text{lcm}(NPROW, NPCOL))$.

If `lwork` = -1, then `work(1)` gets set to the above number and the code returns immediately.

`iwork`

(global and local) INTEGER array of size `ilwork`.

`ilwork`

(local) INTEGER This holds some of the $iblk$ integer arrays.

Output Parameters

<i>a</i>	On exit, if <i>wantt</i> is .TRUE., <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ih</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> is .FALSE., the contents of <i>A</i> are unspecified on exit.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>wr, wi</i>	(global replicated output) REAL for pslahqr DOUBLE PRECISION for pdlahqr Arrays, DIMENSION(<i>n</i>) each. The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ih</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)-th, with <i>wi(i)>0</i> and <i>wi(i+1)<0</i> . If <i>wantt</i> is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>A</i> . <i>A</i> may be returned with larger diagonal blocks until the next release.
<i>z</i>	On exit <i>z</i> has been updated; transformations are applied only to the submatrix <i>z(iloz:ihiz, ilo:ih)</i> .
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: parameter number <i>-info</i> incorrect or inconsistent > 0: p?lahqr failed to compute all the eigenvalues <i>ilo</i> to <i>ih</i> in a total of $30 * (ih - ilo + 1)$ iterations; if <i>info = i</i> , elements <i>i+1:ih</i> of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed.

p?hseqr

Computes eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

Fortran:

```
call pshseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
call pdhseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

p?hseqr computes the eigenvalues of an upper Hessenberg matrix *H* and, optionally, the matrices *T* and *Z* from the Schur decomposition $H = Z^*T^*Z^T$, where *T* is an upper quasi-triangular matrix (the Schur form), and *Z* is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q^*H^*Q^T = (QZ)^*T^*(QZ)^T$.

Input Parameters

<i>job</i>	(global) CHARACTER*1 = 'E': compute eigenvalues only; = 'S': compute eigenvalues and the Schur form T .
<i>compz</i>	(global) CHARACTER*1 = 'N': no Schur vectors are computed; = 'I': z is initialized to the unit matrix and the matrix Z of Schur vectors of h is returned; = 'V': z must contain an orthogonal matrix Q on entry, and the product Q^*Z is returned.
<i>n</i>	(global) INTEGER The order of the Hessenberg matrix h . $n \geq 0$.
