<i>ilo, ihi</i>	(global) INTEGER It is assumed that h is already upper triangular in rows and columns 1: $ilo-1$ and $ihi+1:n$. <i>ilo</i> and <i>ihi</i> are normally set by a previous call to p?gebal , and then passed to p?gehrd when the matrix output by p?gebal is reduced to Hessenberg form. Otherwise <i>ilo</i> and <i>ihi</i> should be set to 1 and <i>n</i> respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>h</i>	REAL for pshseqr DOUBLE PRECISION for pdhseqr (global) array, dimension (<i>desch</i> (<i>lld_</i>), <i>LOC_c(n)</i>) The upper Hessenberg matrix H .
<i>desch</i>	(global and local) INTEGER array of dimension <i>dlen_</i> The array descriptor for the distributed matrix h .
<i>z</i>	REAL for pshseqr DOUBLE PRECISION for pdhseqr (global) array If <i>compz</i> = 'V', on entry z must contain the current matrix Z of accumulated transformations from, for example, p?gehrd . If <i>compz</i> = 'I', on entry z need not be set.
<i>descz</i>	(global and local) INTEGER array of dimension <i>dlen_</i> The array descriptor for the distributed matrix z .
<i>work</i>	REAL for pshseqr

DOUBLE PRECISION for pdhseqr
 (local workspace) array, dimension(*lwork*)

lwork (local) INTEGER
 The length of the workspace array *work*.

iwork (local workspace) INTEGER array, dimension (*liwork*)

liwork (local) INTEGER
 The length of the workspace array *iwork*.

OUTPUT Parameters

h If *job* = 'S', *h* is upper quasi-triangular in rows and columns *ilo:ichi*, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $h(i,i) = h(i+1,i+1)$ and $h(i+1,i)*h(i,i+1) < 0$. If *info* = 0 and *job* = 'E', the contents of *h* are unspecified on exit.

wr, wi REAL for pshseqr
 DOUBLE PRECISION for pdhseqr
 (global) array, dimension (*n*)
 The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ichi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and *(i+1)*-th, with *wi(i) > 0* and *wi(i+1) < 0*. If *job* = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*.

z REAL for pshseqr
 DOUBLE PRECISION for pdhseqr
 (global) array
z is updated; transformations are applied only to the submatrix *z(ilo:ichi,ilo:ichi)*.
 If *compz* = 'N', *z* is not referenced.
 If *compz* = 'I' and *info* = 0, *z* contains the orthogonal matrix *Z* of the Schur vectors of *h*.

info INTEGER
 = 0: successful exit
 < 0: if *info* = *-i*, the *i*-th argument had an illegal value (see also below for -7777 and -8888).
 > 0: if *info* = *i*, p?hseqr failed to compute all of the eigenvalues. Elements 1:*ilo*-1 and *i+1:n* of *wr* and *wi* contain those eigenvalues which have been successfully computed. (Failures are rare.)

If $info > 0$ and $job = 'E'$, then on exit, the remaining un converged eigenvalues are the eigen- values of the upper Hessenberg matrix rows and columns i_0 through $info$ of the final, output value of h .

If $info > 0$ and $job = 'S'$, then on exit (*) (initial value of H)* $U = U$ *(final value of H) where U is an orthogonal matrix. The final value of H is upper Hessenberg and quasi-triangular in rows and columns $info+1$ through ihi .

If $info > 0$ and $compz = 'V'$, then on exit (final value of Z) = (initial value of Z)* U where U is the orthogonal matrix in (*) (regardless of the value of job .)

If $info > 0$ and $compz = 'I'$, then on exit (final value of Z) = U where U is the orthogonal matrix in (*) (regardless of the value of job .)

If $info > 0$ and $compz = 'N'$, then z is not accessed.

= -7777: `p?laqr0` failed to converge and `p?laqr1` was called instead.

= -8888: `p?laqr1` failed to converge and `p?laqr0` was called instead.

Singular Value Decomposition

This section describes ScALAPACK routines for computing the singular value decomposition (SVD) of a general m -by- n matrix A (see "Singular Value Decomposition" in LAPACK chapter).

To find the SVD of a general matrix A , this matrix is first reduced to a bidiagonal matrix B by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of B is computed using the LAPACK routine `?bdsqr`.

[Table "Computational Routines for Singular Value Decomposition \(SVD\)"](#) lists ScALAPACK computational routines for performing this decomposition.

Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce A to a bidiagonal matrix	<code>p?gebrd</code>	
Multiply matrix after reduction		<code>p?ormbr/p?unmbr</code>

`p?gebrd`

Reduces a general matrix to bidiagonal form.

Syntax

Fortran:

```
call psgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)

```

Include Files

- C: mkl_scalapack.h

Description

The p?gebrd routine reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q' \cdot \text{sub}(A) \cdot P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Real pointer into the local memory to an array of dimension ($l1d_a$, $\text{LOCc}(ja+n-1)$). On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .
$work$	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least: $lwork \geq nb * (mpa0 + nqa0 + 1) + nqa0$

where $nb = mb_a = nb_a$,
 $iroffa = \text{mod}(ia-1, nb)$,
 $icoffa = \text{mod}(ja-1, nb)$,
 $iarow = \text{indxg2p}(ia, nb, MYROW, rsrc_a, NPROW)$,
 $iacol = \text{indxg2p}(ja, nb, MYCOL, csrc_a, NPCOL)$,
 $npa0 = \text{numroc}(m + iroffa, nb, MYROW, iarow, NPROW)$,
 $nqa0 = \text{numroc}(n + icoffa, nb, MYCOL, iacol, NPCOL)$.

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, if $m \geq n$, the diagonal and the first superdiagonal of sub(A) are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array τ_{ap} , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array τ_{ap} , represent the orthogonal matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array, size $LOCc(ja + \min(m, n) - 1)$ if $m \geq n$; $LOCr(ia + \min(m, n) - 1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d(i) = a(i, i)$.

d is tied to the distributed matrix A .

e

(local)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array, size $LOCr(ia + \min(m, n) - 1)$ if $m \geq n$; $LOCc(ja + \min(m, n) - 2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B :

If $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$. e is tied to the distributed matrix A .

τ_{aq}, τ_{ap}

(local)

REAL for psgebrd

DOUBLE PRECISION for pdgebrd

COMPLEX for pcgebrd

DOUBLE COMPLEX for pzgebrd.

Arrays, size $LOCc(ja+\min(m,n)-1)$ for τ_{aq} and $LOCr(ia+\min(m,n)-1)$ for τ_{ap} . Contain the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrices Q and P , respectively. τ_{aq} and τ_{ap} are tied to the distributed matrix A . See Application Notes below.

$work(1)$

On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$Q = H(1)*H(2)*\dots*H(n)$, and $P = G(1)*G(2)*\dots*G(n-1)$.

Each $H(i)$ and $G(i)$ has the form:

$H(i) = i - \tau_{aq} * v * v'$ and $G(i) = i - \tau_{ap} * u * u'$

where τ_{aq} and τ_{ap} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{aq} is stored in $\tau_{aq}(ja+i-1)$ and τ_{ap} in $\tau_{ap}(ia+i-1)$.

If $m < n$,

$Q = H(1)*H(2)*\dots*H(m-1)$, and $P = G(1)*G(2)*\dots*G(m)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = i - \tau_{aq} * v * v'$ and $G(i) = i - \tau_{ap} * u * u'$

here τ_{aq} and τ_{ap} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{aq} is stored in $\tau_{aq}(ja+i-1)$ and τ_{ap} in $\tau_{ap}(ia+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?ormbr

Multiples a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

Fortran:

```
call psormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

C:

```
void psormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau ,
float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork ,
MKL_INT *info );

void pdormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau ,
double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

If $\text{vect} = 'Q'$, the p?ormbr routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(c:ic + m - 1, jc:jc + n - 1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q \text{ sub}(C)$	$\text{sub}(C) Q$
<i>trans</i> = 'T':	$Q^T \text{ sub}(C)$	$\text{sub}(C) Q^T$

If *vect* = 'P', the routine overwrites $\text{sub}(C)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$P \text{ sub}(C)$	$\text{sub}(C) P$
<i>trans</i> = 'T':	$P^T \text{ sub}(C)$	$\text{sub}(C) P^T$

Here Q and P^T are the orthogonal distributed matrices determined by [p?gebrd](#) when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q^* B^* P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if *side* = 'L' and $nq = n$ if *side* = 'R'. Thus nq is the order of the orthogonal matrix Q or P^T that is applied.

If *vect* = 'Q', $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If *vect* = 'P', $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If <i>vect</i> = 'Q', then Q or Q^T is applied. If <i>vect</i> = 'P', then P or P^T is applied.
<i>side</i>	(global) CHARACTER. If <i>side</i> = 'L', then Q or Q^T , P or P^T is applied from the left. If <i>side</i> = 'R', then Q or Q^T , P or P^T is applied from the right.
<i>trans</i>	(global) CHARACTER. If <i>trans</i> = 'N', no transpose, Q or P is applied. If <i>trans</i> = 'T', then Q^T or P^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$.
<i>k</i>	(global) INTEGER. If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by p?gebrd ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by p?gebrd . Constraints: $k \geq 0$.

<i>a</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja</i> +min(<i>nq</i> , <i>k</i>)-1)) If <i>vect</i> ='Q', and (<i>lld_a</i> , <i>LOCc(ja+nq-1)</i>) If <i>vect</i> = 'P'. <i>nq</i> = <i>m</i> if <i>side</i> = 'L', and <i>nq</i> = <i>n</i> otherwise. The vectors which define the elementary reflectors <i>H(i)</i> and <i>G(i)</i> , whose products determine the matrices <i>Q</i> and <i>P</i> , as returned by p?gebrd. If <i>vect</i> = 'Q', <i>lld_a</i> ≥max(1, <i>LOCr(ia+nq-1)</i>); If <i>vect</i> = 'P', <i>lld_a</i> ≥max(1, <i>LOCr(ia+min(nq, k)-1)</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr. Array, size <i>LOCc(ja+min(nq, k)-1)</i> , if <i>vect</i> = 'Q', and <i>LOCr(ia+min(nq, k)-1)</i> , if <i>vect</i> = 'P'. <i>tau(i)</i> must contain the scalar factor of the elementary reflector <i>H(i)</i> or <i>G(i)</i> , which determines <i>Q</i> or <i>P</i> , as returned by pdgebrd in its array argument <i>tauq</i> or <i>taup</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(jc</i> + <i>n</i> -1)). Contains the local pieces of the distributed matrix sub (<i>C</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descC</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr.

Workspace array of dimension *lwork*.

lwork

(local or global) INTEGER, dimension of *work*, must be at least:

```

If side = 'L'

nq = m;

if ((vect = 'Q' and nq≥k) or (vect is not equal to 'Q' and nq>k)),
iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc;

else

iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc;

end if

else

If side = 'R', nq = n;

if((vect = 'Q' and nq≥k) or (vect is not equal to 'Q' and
nq>k)),
iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc;

else

iaa= ia; jaa= ja+1; mi= m; ni= n-1; icc= ic; jcc= jc+1;

end if

end if

If vect = 'Q',

If side = 'L', lwork≥max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) +
nb_a * nb_a

else if side = 'R',

lwork≥max((nb_a*(nb_a-1))/2, (nqc0 + max(npao +
numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0,
lcmq), mpc0))*nb_a) + nb_a*nb_a

end if

else if vect is not equal to 'Q', if side = 'L',

lwork≥max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +
numroc(numroc(mi+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nqc0))*mb_a) + mb_a*mb_a

else if side = 'R',

lwork≥max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a

end if

end if

where lcm = lcm/NPROW, lcmq = lcm/NPCOL, with lcm =
ilcm(NPROW, NPCOL),

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),

```

```

iacol = indxg2p(jaa, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(mi+icooffa, nb_a, MYCOL, iacol, NPCOL),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icooffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icooffc, nb_c, MYCOL, iccol, NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and optimal size for all
work arrays. Each of these values is returned in the first entry of the
corresponding work array, and no error message is issued by pxerbla.

```

Output Parameters

<i>c</i>	On exit, if <i>vect</i> ='Q', <i>sub(C)</i> is overwritten by $Q^*sub(C)$, or $Q'^*sub(C)$, or $sub(C)*Q'$, or $sub(C)*Q$; if <i>vect</i> ='P', <i>sub(C)</i> is overwritten by $P^*sub(C)$, or $P'^*sub(C)$, or $sub(C)*P$, or $sub(C)*P'$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i* 100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmbr

Multiples a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

Fortran:

```

call pcunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, desc,
work, lwork, info)

call pzunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, desc,
work, lwork, info)

```

C:

```

Description

If $\text{vect} = 'Q'$, the `p?unmbr` routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$\text{side} = 'L'$	$\text{side} = 'R'$
$\text{trans} = 'N':$	$Q^*\text{sub}(C)$	$\text{sub}(C)*Q$
$\text{trans} = 'C':$	$Q^H*\text{sub}(C)$	$\text{sub}(C)*Q^H$

If $\text{vect} = 'P'$, the routine overwrites $\text{sub}(C)$ with

	$\text{side} = 'L'$	$\text{side} = 'R'$
$\text{trans} = 'N':$	$P^*\text{sub}(C)$	$\text{sub}(C)*P$
$\text{trans} = 'C':$	$P^H*\text{sub}(C)$	$\text{sub}(C)*P^H$

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q^*B^*P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $\text{side} = 'L'$ and $nq = n$ if $\text{side} = 'R'$. Thus nq is the order of the unitary matrix Q or P^H that is applied.

If $\text{vect} = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $\text{vect} = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

<code>vect</code>	(global) CHARACTER.
	If $\text{vect} = 'Q'$, then Q or Q^H is applied.
	If $\text{vect} = 'P'$, then P or P^H is applied.
<code>side</code>	(global) CHARACTER.
	If $\text{side} = 'L'$, then Q or Q^H , P or P^H is applied from the left.
	If $\text{side} = 'R'$, then Q or Q^H , P or P^H is applied from the right.

<i>trans</i>	(global) CHARACTER. If <i>trans</i> = 'N', no transpose, <i>Q</i> or <i>P</i> is applied. If <i>trans</i> = 'C', conjugate transpose, Q^H or P^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (<i>C</i>) $n \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (<i>C</i>) $n \geq 0$.
<i>k</i>	(global) INTEGER. If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by p?gebrd; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by p?gebrd. Constraints: $k \geq 0$.
<i>a</i>	(local) COMPLEX for psormbr DOUBLE COMPLEX for pdormbr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , $LOCc(ja + \min(nq, k) - 1)$) if <i>vect</i> ='Q', and (<i>lld_a</i> , $LOCc(ja + nq - 1)$) if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors which define the elementary reflectors <i>H</i> (<i>i</i>) and <i>G</i> (<i>i</i>), whose products determine the matrices <i>Q</i> and <i>P</i> , as returned by p?gebrd. If <i>vect</i> = 'Q', $lld_a \geq \max(1, LOCr(ia + nq - 1))$; If <i>vect</i> = 'P', $lld_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmbr DOUBLE COMPLEX for pzunmbr. Array, size $LOCc(ja + \min(nq, k) - 1)$, if <i>vect</i> = 'Q', and $LOCr(ia + \min(nq, k) - 1)$, if <i>vect</i> = 'P'. <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector <i>H</i> (<i>i</i>) or <i>G</i> (<i>i</i>), which determines <i>Q</i> or <i>P</i> , as returned by p?gebrd in its array argument <i>tauq</i> or <i>taup</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmbr

DOUBLE COMPLEX for pzunmbr
 Pointer into the local memory to an array of dimension (*lld_a*, *LOCc* (*jc* +*n*-1)).
 Contains the local pieces of the distributed matrix sub (*C*).
ic, jc
 (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *C*, respectively.
descC
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *C*.
work
 (local)
 COMPLEX for pcunmbr
 DOUBLE COMPLEX for pzunmbr.
 Workspace array of dimension *lwork*.
lwork
 (local or global) INTEGER, dimension of *work*, must be at least:
If *side* = 'L'
nq = *m*;
if ((*vect* = 'Q' and *nq* ≥ *k*) or (*vect* is not equal to 'Q' and *nq* > *k*)), *iaa*= *ia*; *jaa*= *ja*; *mi*= *m*; *ni*= *n*; *icc*= *ic*; *jcc*= *jc*;

nqc0 = numroc(ni+icooffc, nb_c, MYCOL, iccol, NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the subroutine blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c

On exit, if *vect*='Q', *sub(C)* is overwritten by $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$; if *vect*='P', *sub(C)* is overwritten by $P^* \text{sub}(C)$, or $P'^* \text{sub}(C)$, or $\text{sub}(C) * P$, or $\text{sub}(C) * P'$.

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Generalized Symmetric-Definite Eigen Problems

This section describes ScalAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScalAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

[Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems"](#) lists these routines.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	p?sygst	p?hegst

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

Fortran:

```
call pssygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
call pdsygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

C:

```

Description

The `p?sygst` routine reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$,

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$.

If $ibtype = 2$ or 3 , the problem is

$\text{sub}(A) * \text{sub}(B) * x = \lambda * x$, or $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$,

and $\text{sub}(A)$ is overwritten by $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.

$\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ by p?potrf .

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. If <i>ibtype</i> = 1, compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$; If <i>ibtype</i> = 2 or 3, compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^T * U$. If <i>uplo</i> = 'L', the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L * L^T$.
<i>n</i>	(global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pssygst DOUBLE PRECISION for pdsgst. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for pssygst DOUBLE PRECISION for pdsgst. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by p?potrf .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as $\text{sub}(A)$.
<i>scale</i>	(global) REAL for pssygst DOUBLE PRECISION for pdsygst. Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?hegst

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

Fortran:

```
call pcgdst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
call pzgdst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

C:

```
void pcgdst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , float *scale , MKL_INT *info );
void pzgdst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , double *scale , MKL_INT *info );

Description

The p?hegst routine reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If *ibtype* = 1, the problem is

$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$,

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$.

If *ibtype* = 2 or 3, the problem is

$\text{sub}(A) * \text{sub}(B) * x = \lambda * x$, or $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$,

and $\text{sub}(A)$ is overwritten by $U^* \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.

$\text{sub}(B)$ must have been previously factorized as $U^H * U$ or $L * L^H$ by [p?potrf](#).

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, compute $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$; If <i>itype</i> = 2 or 3, compute $U^* \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^H * U$. If <i>uplo</i> = 'L', the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L * L^H$.
<i>n</i>	(global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) COMPLEX for pchegst DOUBLE COMPLEX for pzhegst . Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCC(ja</i> + <i>n</i> -1)). On entry, the array contains the local pieces of the <i>n</i> -by- <i>n</i> Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for pchegst DOUBLE COMPLEX for pzhegst . Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCC(jb</i> + <i>n</i> -1)). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by p?potrf .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) REAL for pchegst DOUBLE PRECISION for pzhegst. Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Driver Routines

Table "ScaLAPACK Driver Routines" lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	p?gesv (simple driver) / p?gesvx (expert driver)
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) / p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general <i>m</i> -by- <i>n</i>	p?gels
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev / p?heev (simple driver); p?syevd / p?heevd (simple driver with a divide and conquer algorithm); p?syevx / p?heevx (expert driver); p?syevr / p?heevr (simple driver with MRRR algorithm)
Singular value decomposition	general <i>m</i> -by- <i>n</i>	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

[p?gesv](#)

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

Description

The `p?gesv` routine computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The *LU* decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for psgesv DOUBLE PRECISION for pdgesv COMPLEX for pcgesv DOUBLE COMPLEX for pzgesv. Pointers into the local memory to arrays of local dimension $a(lld_a, LOCc(ja+n-1))$ and $b(lld_b, LOCc(jb+nrhs-1))$, respectively.

On entry, the array a contains the local pieces of the n -by- n distributed matrix sub(A) to be factored.

On entry, the array b contains the right hand side distributed matrix sub(B).

ia, ja (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of sub(A), respectively.

$desc_a$ (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

ib, jb (global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of sub(B), respectively.

$desc_b$ (global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B .

Output Parameters

a Overwritten by the factors L and U from the factorization sub(A) = $P*L*U$; the unit diagonal elements of L are not stored .

b Overwritten by the solution distributed matrix X .

$ipiv$ (local) INTEGER array.

The dimension of $ipiv$ is ($LOCr(m_a) + mb_a$) . This array contains the pivoting information. The (local) row i of the matrix was interchanged with the (global) row $ipiv(i)$.

This array is tied to the distributed matrix A .

$info$ (global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, $U(ia+k-1,ja+k-1)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

p?gesvx

Uses the LU factorization to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

Description

The `p?gesvx` routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $AX = B$, where A denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, B denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and X denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, *af* stands for the subarray *af*(*iaf*:*iaf+n-1*, *jaf*:*jaf+n-1*).

The routine p?gesvx performs the following steps:

1. If *fact* = 'E', real scaling factors *R* and *C* are computed to equilibrate the system:

```
trans = 'N': diag(R) * A * diag(C) * diag(C)^-1 * X = diag(R) * B
trans = 'T': (diag(R) * A * diag(C)) T * diag(R)^-1 * X = diag(C) * B
trans = 'C': (diag(R) * A * diag(C)) H * diag(R)^-1 * X = diag(C) * B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by *diag(R)*A*diag(C)* and *B* by *diag(R)*B* (if *trans*='N') or *diag(C)*B* (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as *A* = *P L U*, where *P* is a permutation matrix, *L* is a unit lower triangular matrix, and *U* is upper triangular.
3. The factored form of *A* is used to estimate the condition number of the matrix *A*. If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for *X* using the factored form of *A*.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix *X* is premultiplied by *diag(C)* (if *trans* = 'N') or *diag(R)* (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

fact

(global) CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If *fact* = 'F' then, on entry, *af* and *ipiv* contain the factored form of *A*. If *equed* is not 'N', the matrix *A* has been equilibrated with scaling factors given by *r* and *c*. Arrays *a*, *af*, and *ipiv* are not modified.

If *fact* = 'N', the matrix *A* is copied to *af* and factored.

If *fact* = 'E', the matrix *A* is equilibrated if necessary, then copied to *af* and factored.

trans

(global) CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If *trans* = 'N', the system has the form *A*X = B* (No transpose);

If *trans* = 'T', the system has the form *A^T*X = B* (Transpose);

If *trans* = 'C', the system has the form *A^H*X = B* (Conjugate transpose);

n

(global) INTEGER. The number of linear equations; the order of the submatrix *A* (*n* \geq 0).

nrhs

(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrices *B* and *X* (*nrhs* \geq 0).

a, *af*, *b*, *work*

(local)

REAL for psgesvx

DOUBLE PRECISION for pdgesvx

COMPLEX for pcgesvx

DOUBLE COMPLEX for pzgesvx.

Pointers into the local memory to arrays of local dimension $a(\text{lld_a}, \text{LOCc}(ja+n-1))$, $af(\text{lld_af}, \text{LOCc}(ja+n-1))$, $b(\text{lld_b}, \text{LOCc}(jb+nrhs-1))$, $\text{work}(\text{lwork})$, respectively.

The array a contains the matrix A . If $\text{fact} = 'F'$ and equed is not ' N ', then A must have been equilibrated by the scaling factors in r and/or c .

The array af is an input argument if $\text{fact} = 'F'$. In this case it contains on entry the factored form of the matrix A , that is, the factors L and U from the factorization $A = P^*L^*U$ as computed by [p?getrf](#). If equed is not ' N ', then af is the factored form of the equilibrated matrix A .

The array b contains on entry the matrix B whose columns are the right-hand sides for the systems of equations.

$\text{work}(*)$ is a workspace array. The dimension of work is (lwork) .

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.

desca

(global and local) INTEGER array, dimension (dlen_a) . The array descriptor for the distributed matrix A .

iaf, jaf

(global) INTEGER. The row and column indices in the global array af indicating the first row and the first column of the subarray $af(iaf:iaf+n-1, jaf:jaf+n-1)$, respectively.

descaf

(global and local) INTEGER array, dimension (dlen_af) . The array descriptor for the distributed matrix AF .

ib, jb

(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of the submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$, respectively.

descb

(global and local) INTEGER array, dimension (dlen_b) . The array descriptor for the distributed matrix B .

ipiv

(local) INTEGER array.

The dimension of ipiv is $(\text{LOCr}(m_\text{a}) + mb_\text{a})$.

The array ipiv is an input argument if $\text{fact} = 'F'$.

On entry, it contains the pivot indices from the factorization $A = P^*L^*U$ as computed by [p?getrf](#); (local) row i of the matrix was interchanged with the (global) row $\text{ipiv}(i)$.

This array must be aligned with $A(ia:ia+n-1, *)$.

equed

(global) CHARACTER*1. Must be ' N ', ' R ', ' C ', or ' B '. equed is an input argument if $\text{fact} = 'F'$. It specifies the form of equilibration that was done:

If $\text{equed} = 'N'$, no equilibration was done (always true if $\text{fact} = 'N'$);

If $\text{equed} = 'R'$, row equilibration was done, that is, A has been premultiplied by $\text{diag}(r)$;
 If $\text{equed} = 'C'$, column equilibration was done, that is, A has been postmultiplied by $\text{diag}(c)$;
 If $\text{equed} = 'B'$, both row and column equilibration was done; A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

r, c

(local) REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.

Arrays, dimension $\text{LOC}_r(m_a)$ and $\text{LOC}_c(n_a)$, respectively.

The array r contains the row scale factors for A , and the array c contains the column scale factors for A . These arrays are input arguments if $\text{fact} = 'F'$ only; otherwise they are output arguments. If $\text{equed} = 'R'$ or $'B'$, A is multiplied on the left by $\text{diag}(r)$; if $\text{equed} = 'N'$ or $'C'$, r is not accessed.

If $\text{fact} = 'F'$ and $\text{equed} = 'R'$ or $'B'$, each element of r must be positive.

If $\text{equed} = 'C'$ or $'B'$, A is multiplied on the right by $\text{diag}(c)$; if $\text{equed} = 'N'$ or $'R'$, c is not accessed.

If $\text{fact} = 'F'$ and $\text{equed} = 'C'$ or $'B'$, each element of c must be positive. Array r is replicated in every process column, and is aligned with the distributed matrix A . Array c is replicated in every process row, and is aligned with the distributed matrix A .

ix, jx

(global) INTEGER. The row and column indices in the global array X indicating the first row and the first column of the submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$, respectively.

desc_x

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix X .

$lwork$

(local or global) INTEGER. The dimension of the array $work$; must be at least $\max(p?gecon(lwork), p?gerfs(lwork)) + \text{LOC}_r(n_a)$.

$iwork$

(local, pgesvx/pdgesvx only) INTEGER. Workspace array. The dimension of $iwork$ is ($lwork$).

$liwork$

(local, pgesvx/pdgesvx only) INTEGER. The dimension of the array $iwork$, must be at least $\text{LOC}_r(n_a)$.

$rwork$

(local) REAL for pgesvx

DOUBLE PRECISION for pzgesvx.

Workspace array, used in complex flavors only.

The dimension of $rwork$ is ($lwork$).

$lrwork$

(local or global, pgesvx/pzgesvx only) INTEGER. The dimension of the array $rwork$; must be at least $2 * \text{LOC}_c(n_a)$.

Output Parameters

x

(local)

REAL for psgesvx

DOUBLE PRECISION for pdgesvx

COMPLEX for pcgesvx

DOUBLE COMPLEX for pzgesvx.

Pointer into the local memory to an array of local dimension

 $x(\text{lld_}x, LOCC(jx+nrhs-1))$.If $\text{info} = 0$, the array x contains the solution matrix X to the *original* system of equations. Note that A and B are modified on exit if $\text{equed} \neq 'N'$, and the solution to the *equilibrated* system is: $\text{diag}(C)^{-1}X$, if $\text{trans} = 'N'$ and $\text{equed} = 'C'$ or $'B'$; and $\text{diag}(R)^{-1}X$, if $\text{trans} = 'T'$ or $'C'$ and $\text{equed} = 'R'$ or $'B'$.

a

Array a is not modified on exit if $\text{fact} = 'F'$ or $'N'$, or if $\text{fact} = 'E'$ and $\text{equed} = 'N'$.If $\text{equed} \neq 'N'$, A is scaled on exit as follows: $\text{equed} = 'R'$: $A = \text{diag}(R) * A$ $\text{equed} = 'C'$: $A = A * \text{diag}(c)$ $\text{equed} = 'B'$: $A = \text{diag}(R) * A * \text{diag}(c)$

af

If $\text{fact} = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = P*L*U$ of the original matrix A (if $\text{fact} = 'N'$) or of the equilibrated matrix A (if $\text{fact} = 'E'$). See the description of a for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(R)^{-1}B$ if $\text{trans} = 'N'$ and $\text{equed} = 'R'$ or $'B'$;overwritten by $\text{diag}(c)^{-1}B$ if $\text{trans} = 'T'$ and $\text{equed} = 'C'$ or $'B'$; not changed if $\text{equed} = 'N'$.

r, c

These arrays are output arguments if $\text{fact} \neq 'F'$.See the description of r, c in *Input Arguments* section.

rcond

(global) REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

ferr, berr

(local) REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays, size $LOCC(n_b)$ each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays *ferr* and *berr* are both replicated in every process row, and are aligned with the matrices *B* and *X*.

ipiv

If *fact* = 'N' or 'E', then *ipiv* is an output argument and on exit contains the pivot indices from the factorization $A = P \cdot L \cdot U$ of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E').

equed

If *fact* ≠ 'F', then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

work(1)

If *info*=0, on exit *work(1)* returns the minimum value of *lwork* required for optimum performance.

iwork(1)

If *info*=0, on exit *iwork(1)* returns the minimum value of *liwork* required for optimum performance.

rwork(1)

If *info*=0, on exit *rwork(1)* returns the minimum value of *lrwork* required for optimum performance.

info

INTEGER. If *info*=0, the execution is successful.

info < 0: if the *i*th argument is an array and the *j*th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*. If *info* = *i*, and *i* ≤ *n*, then *U(i,i)* is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution and error bounds could not be computed. If *info* = *i*, and *i* = *n* + 1, then *U* is nonsingular, but *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

p?gbsv

Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.

Syntax

Fortran:

```
call psgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pdgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pcgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)

```

Include Files

- C: mkl_scalapack.h

Description

The p?gbsv routine computes the solution to a real or complex system of linear equations

$\text{sub}(A) * X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- rhs distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U * Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>rhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($rhs \geq 0$).
<i>a, b</i>	(local) REAL for psgbsv DOUBLE PRECISON for pdgbsv COMPLEX for pcgbsv DOUBLE COMPLEX for pzgbsv. Pointers into the local memory to arrays of local dimension $a(\text{lld}_a, \text{LOCc}(ja+n-1))$ and $b(\text{lld}_b, \text{LOCc}(rhs))$, respectively. On entry, the array <i>a</i> contains the local pieces of the global array <i>A</i> . On entry, the array <i>b</i> contains the right hand side distributed matrix $\text{sub}(B)$.
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 501, then <i>dlen_</i> ≥ 7 ; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9 .
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb(dtype_)</i> = 502, then <i>dlen_</i> ≥ 7 ; else if <i>descb(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9 .
<i>work</i>	(local) REAL for psgbsv DOUBLE PRECISON for pdgbsv COMPLEX for pcgbsv DOUBLE COMPLEX for pzgbsv. Workspace array of dimension (<i>lwork</i>).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least $\begin{aligned} lwork \geq & (NB+bwu) * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2 * bwu) + \\ & + \max(nrhs * (NB+2 * bwl+4 * bwu), 1). \end{aligned}$

Output Parameters

<i>a</i>	On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.
<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> must be at least <i>desca(NB)</i> . This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. <i>info</i> > 0:

If $info = k \leq \text{NPROCS}$, the submatrix stored on processor $info$ and factored locally was not nonsingular, and the factorization was not completed. If $info = k > \text{NPROCS}$, the submatrix stored on processor $info-\text{NPROCS}$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbsv

Solves a general band system of linear equations.

Syntax

Description

The p?dbsv routine solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl , bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Input Parameters

n (global) INTEGER. The order of the distributed submatrix A , ($n \geq 0$).

bwl (global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.

<i>bwu</i>	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$).
<i>a</i>	(local). REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv. Pointer into the local memory to an array with leading dimension $lld_a \geq (bwl+bwu+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7 ; If 2d type (<i>dtype_a</i> =1), <i>dlen</i> ≥ 9 . The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv. Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7 ; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9 . The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for psdbsv DOUBLE PRECISION for pddbsv

COMPLEX for `pcdbsv`

DOUBLE COMPLEX for `pzdbsv`.

Temporary workspace. This space may be overwritten in between calls to routines. `work` must be the size given in `lwork`.

`lwork`

(local or global) INTEGER. Size of user-input workspace `work`. If `lwork` is too small, the minimal acceptable size will be returned in `work(1)` and an error code is returned.

$$\begin{aligned} lwork \geq nb(bwl+bwu) + & 6\max(bwl, bwu) * \max(bwl, bwu) \\ & + \max(\max(bwl, bwu) nrhs), \quad \max(bwl, bwu) * \max(bwl, bwu) \end{aligned}$$

Output Parameters

`a`

On exit, this array contains information containing details of the factorization.

Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

`b`

On exit, this contains the local piece of the solutions distributed matrix X .

`work`

On exit, `work(1)` contains the minimal `lwork`.

`info`

(local) INTEGER. If `info`=0, the execution is successful.

< 0: If the i -th argument is an array and the j -entry had an illegal value, then `info` = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

> 0: If `info` = k < NPROCS, the submatrix stored on processor `info` and factored locally was not positive definite, and the factorization was not completed.

If `info` = k > NPROCS, the submatrix stored on processor `info`-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?dtsv

Solves a general tridiagonal system of linear equations.

Syntax

Fortran:

```
call psdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pddtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pcdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pzdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
```

C:

```
void psdtsv (MKL_INT *n , MKL_INT *nrhs , float *dl , float *d , float *du , MKL_INT

Description

The routine solves a system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$,

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into $L U$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$).
<i>dl</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $d/(1)$ is not referenced, and dl must be aligned with d . Must be of size $> desca(nb_)$.
<i>d</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d .

<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7 ; If 2d type (<i>dtype_a</i> =1), <i>dlen</i> ≥ 9 . The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdtsv DOUBLE PRECISON for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer into the local memory to an array of local lead dimension <i>lld_b</i> > <i>nb</i> . On entry, this array contains the local pieces of the right hand sides <i>B</i> (<i>ib</i> : <i>ib+n-1</i> , 1: <i>nrhs</i>).
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7 ; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9 . The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for psdtsv DOUBLE PRECISON for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned. <i>lwork</i> $>$ (12*NPCOL+3* <i>nb</i>) +max((10+2*min(100, <i>nrhs</i>))*NPCOL+4* <i>nrhs</i> , 8*NPCOL)

Output Parameters

<i>dl</i>	On exit, this array contains information containing the * factors of the matrix.
-----------	--

<i>d</i>	On exit, this array contains information containing the * factors of the matrix. Must be of size > <i>desca(nb_)</i> .
<i>du</i>	On exit, this array contains information containing the * factors of the matrix. Must be of size > <i>desca(nb_)</i> .
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i>	On exit, <i>work(1)</i> contains the minimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: If <i>info</i> = <i>k</i> < NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?posv

Solves a symmetric positive definite system of linear equations.

Syntax

Description

The `p?posv` routine computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and `sub(B)` denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor `sub(A)` as

$$\text{sub}(A) = U^T * U, \text{ if } \text{uplo} = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } \text{uplo} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of `sub(A)` is then used to solve the system of equations.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Must be ' <code>U</code> ' or ' <code>L</code> '.
	Indicates whether the upper or lower triangular part of <code>sub(A)</code> is stored.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix <code>sub(B)</code> ($nrhs \geq 0$).
<code>a</code>	(local) REAL for <code>psposv</code> DOUBLE PRECISION for <code>pdposv</code> COMPLEX for <code>pcposv</code> COMPLEX*16 for <code>pzposv</code> . Pointer into the local memory to an array of dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix <code>sub(A)</code> to be factored. If <code>uplo</code> = ' <code>U</code> ', the leading n -by- n upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo</code> = ' <code>L</code> ', the leading n -by- n lower triangular part of <code>sub(A)</code> contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix <code>A</code> , respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>A</code> .
<code>b</code>	(local) REAL for <code>psposv</code>

DOUBLE PRECISION for pdposv

COMPLEX for pcposv

COMPLEX*16 for pzposv.

Pointer into the local memory to an array of dimension ($11d_b, LOC(jb) + nrhs - 1$). On entry, the local pieces of the right hand sides distributed matrix sub(B).

ib, jb

(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

$descb$

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B .

Output Parameters

a

On exit, if $info = 0$, this array contains the local pieces of the factor U or L from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $L * L^H$.

b

On exit, if $info = 0$, $\text{sub}(B)$ is overwritten by the solution distributed matrix X .

$info$

(global) INTEGER.

If $info = 0$, the execution is successful.

If $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$: If $info = k$, the leading minor of order k , $A(ia:ia+k-1, ja:ja+k-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed.

p?posvx

Solves a symmetric or Hermitian positive definite system of linear equations.

Syntax

Fortran:

```

Description

The `p?posvx` routine uses the Cholesky factorization $A=U^T \cdot U$ or $A=L \cdot L^T$ to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1) \cdot X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$ a m -by- k matrix where y can be a , af , b and x .

The routine `p?posvx` performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(sr) \cdot A \cdot \text{diag}(sc) \cdot \text{inv}(\text{diag}(sc)) \cdot X = \text{diag}(sr) \cdot B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(sr) \cdot A \cdot \text{diag}(sc)$ and B by $\text{diag}(sr) \cdot B$.

- 2.** If $\text{fact} = \text{'N'}$ or 'E' , the Cholesky decomposition is used to factor the matrix A (after equilibration if $\text{fact} = \text{'E'}$) as
- $$A = U^T * U, \text{ if } \text{uplo} = \text{'U'}, \text{ or}$$
- $$A = L * L^T, \text{ if } \text{uplo} = \text{'L'},$$
- where U is an upper triangular matrix and L is a lower triangular matrix.
- 3.** The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
- 4.** The system of equations is solved for X using the factored form of A .
- 5.** Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
- 6.** If equilibration was used, the matrix X is premultiplied by $\text{diag}(sr)$ so that it solves the original system before equilibration.

Input Parameters

<i>fact</i>	(global) CHARACTER. Must be ' <i>F</i> ', ' <i>N</i> ', or ' <i>E</i> '.
	Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
	If $\text{fact} = \text{'F'}$: on entry, <i>af</i> contains the factored form of A . If <i>equed</i> = ' <i>Y</i> ', the matrix A has been equilibrated with scaling factors given by <i>s</i> . <i>a</i> and <i>af</i> will not be modified.
	If $\text{fact} = \text{'N'}$, the matrix A will be copied to <i>af</i> and factored.
	If $\text{fact} = \text{'E'}$, the matrix A will be equilibrated if necessary, then copied to <i>af</i> and factored.
<i>uplo</i>	(global) CHARACTER. Must be ' <i>U</i> ' or ' <i>L</i> '.
	Indicates whether the upper or lower triangular part of A is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrices B and X . ($nrhs \geq 0$).
<i>a</i>	(local) REAL for <i>psposvx</i> DOUBLE PRECISION for <i>pdpovx</i> COMPLEX for <i>pcposvx</i> DOUBLE COMPLEX for <i>pzposvx</i> . Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the symmetric/Hermitian matrix A , except if $\text{fact} = \text{'F'}$ and <i>equed</i> = ' <i>Y</i> ', then A must contain the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$. If <i>uplo</i> = ' <i>U</i> ', the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. A is not modified if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$ on exit.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .

af

(local)

REAL for `psposvx`

DOUBLE PRECISION for `pdpovsx`

COMPLEX for `pcposvx`

DOUBLE COMPLEX for `pzposvx`.

Pointer into the local memory to an array of local dimension (lld_af , $LOCc(ja+n-1)$).

If $fact = 'F'$, then af is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A . If $equed \neq 'N'$, then af is the factored form of the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$.

iaf, jaf

(global) INTEGER. The row and column indices in the global array af indicating the first row and the first column of the submatrix AF , respectively.

descaf

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix AF .

equed

(global) CHARACTER. Must be $'N'$ or $'Y'$.

equed is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);

If $equed = 'Y'$, equilibration was done and A has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$.

sr

(local)

REAL for `psposvx`

DOUBLE PRECISION for `pdpovsx`

COMPLEX for `pcposvx`

DOUBLE COMPLEX for `pzposvx`.

Array, size (lld_a).

The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $equed = 'N'$, s is not accessed.

If `fact = 'F'` and `equed = 'Y'`, each element of `s` must be positive.

b

(local)

REAL for `psposvx`DOUBLE PRECISION for `pdpovsx`COMPLEX for `pcposvx`DOUBLE COMPLEX for `pzposvx`.

Pointer into the local memory to an array of local dimension (`lld_b`, `LOCc(jb+nrhs-1)`). On entry, the *n*-by-*rhs* right-hand side matrix *B*.

ib, jb

(global) INTEGER. The row and column indices in the global array *b* indicating the first row and the first column of the submatrix *B*, respectively.

descb

(global and local) INTEGER. Array, dimension (`dlen_`). The array descriptor for the distributed matrix *B*.

x

(local)

REAL for `psposvx`DOUBLE PRECISION for `pdpovsx`COMPLEX for `pcposvx`DOUBLE COMPLEX for `pzposvx`.

Pointer into the local memory to an array of local dimension (`lld_x`, `LOCc(jx+nrhs-1)`).

ix, jx

(global) INTEGER. The row and column indices in the global array *x* indicating the first row and the first column of the submatrix *X*, respectively.

descx

(global and local) INTEGER array, dimension (`dlen_`). The array descriptor for the distributed matrix *X*.

work

(local)

REAL for `psposvx`DOUBLE PRECISION for `pdpovsx`COMPLEX for `pcposvx`DOUBLE COMPLEX for `pzposvx`.Workspace array, size (`lwork`).*lwork*

(local or global) INTEGER.

The dimension of the array *work*. *lwork* is local input and must be at least $\text{lwork} = \max(\text{p?pocon}(\text{lwork}), \text{p?porfs}(\text{lwork})) + \text{LOCr}(n_a)$.

*lwork = 3*desca(lld_)*.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

 $iwork$ (local) INTEGER. Workspace array, dimension ($lwork$). $lwork$

(local or global)

INTEGER. The dimension of the array $iwork$. $lwork$ is local input and must be at least $lwork = \text{desc}(1ld_1) lwork = \text{LOCr}(n_a)$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

 a

On exit, if $\text{fact} = 'E'$ and $\text{equed} = 'Y'$, a is overwritten by $\text{diag}(sr) * a * \text{diag}(sc)$.

 af

If $\text{fact} = 'N'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix A .

If $\text{fact} = 'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

 $equed$

If $\text{fact} \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in *Input Arguments* section).

 sr

This array is an output argument if $\text{fact} \neq 'F'$.

See the description of sr in *Input Arguments* section.

 sc

This array is an output argument if $\text{fact} \neq 'F'$.

See the description of sc in *Input Arguments* section.

 b

On exit, if $equed = 'N'$, b is not modified; if $\text{trans} = 'N'$ and $equed = 'R'$ or $'B'$, b is overwritten by $\text{diag}(r) * b$; if $\text{trans} = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$, b is overwritten by $\text{diag}(c) * b$.

 x

(local)

REAL for `psposvx`DOUBLE PRECISION for `pdposvx`COMPLEX for `pcposvx`DOUBLE COMPLEX for `pzposvx`.

If $info = 0$ the n -by- $nrhs$ solution matrix X to the original system of equations.

Note that A and B are modified on exit if $\text{equed} \neq 'N'$, and the solution to the equilibrated system is

```
inv(diag( $sc$ )) $*X$  if  $\text{trans} = 'N'$  and  $\text{equed} = 'C'$  or ' $B$ ', or  
inv(diag( $sr$ )) $*X$  if  $\text{trans} = 'T'$  or ' $C$ ' and  $\text{equed} = 'R'$  or ' $B$ '.
```

rcond

(global)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond=0$), the matrix is singular to working precision. This condition is indicated by a return code of $\text{info} > 0$.

ferr

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, size at least $\max(LOC, n_b)$. The estimated forward error bounds for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution, $ferr(j)$ bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest entry in $X(j)$. The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed.

berr

(local)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, size at least $\max(LOC, n_b)$. The componentwise relative backward error of each solution vector $X(j)$ (the smallest relative change in any entry of A or B that makes $X(j)$ an exact solution).

work(1)(local) On exit, *work(1)* returns the minimal and optimal *lwork*.*info*

(global) INTEGER.

If $\text{info}=0$, the execution is successful.< 0: if $\text{info} = -i$, the i -th argument had an illegal value> 0: if $\text{info} = i$, and $i \leq n$: if $\text{info} = i$, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.= $n+1$: $rcond$ is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

p?pbsv

Solves a symmetric/Hermitian positive definite banded system of linear equations.

Syntax

Fortran:

```
call pspbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pdpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

C:

```
void pspbsv (char *uplo , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs , float *a ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb , float *work ,
MKL_INT *lwork , MKL_INT *info );
void pdpbsv (char *uplo , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs , double *a ,

MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?pbsv routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth bw .

Cholesky factorization is used to factor a reordering of the matrix into L^*L' .

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'.
	Indicates whether the upper or lower triangular of A is stored.
	If <i>uplo</i> = 'U', the upper triangular A is stored
	If <i>uplo</i> = 'L', the lower triangular of A is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix A ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of subdiagonals in L or U . $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a</i>	(local). REAL for pspbsv DOUBLE PRECISON for pdpbsv

COMPLEX for `pcpbsv`

DOUBLE COMPLEX for `pzpbsv`.

Pointer into the local memory to an array with leading dimension $lld_a \geq (bw+1)$ (stored in `desca`). On entry, this array contains the local pieces of the distributed matrix `sub(A)` to be factored.

ja
 (global) INTEGER. The index in the global array *a* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

b
 (local)

REAL for `pspbsv`

DOUBLE PRECISON for `pdpbsv`

COMPLEX for `pcpbsv`

DOUBLE COMPLEX for `pzpbsv`.

Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.

ib
 (global) INTEGER. The row index in the global array *b* that points to the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb
 (global and local) INTEGER array of dimension *dlen*.

If 1D type (`dtype_b =502`), *dlen* ≥ 7 ;

If 2D type (`dtype_b =1`), *dlen* ≥ 9 .

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work
 (local).

REAL for `pspbsv`

DOUBLE PRECISON for `pdpbsv`

COMPLEX for `pcpbsv`

DOUBLE COMPLEX for `pzpbsv`.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork
 (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work(1)* and an error code is returned. $lwork \geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)$

Output Parameters

<i>a</i>	On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>b</i>	On exit, contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i>	On exit, <i>work</i> (1) contains the minimal <i>lwork</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?ptsv

Syntax

Solves a symmetric or Hermitian positive definite tridiagonal system of linear equations.

Fortran:

```
call psptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pdptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pcptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pzptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
```

C:

```
void psptsv (MKL_INT *n , MKL_INT *nrhs , float *d , float *e , MKL_INT *ja , MKL_INT
*desca , float *b , MKL_INT *ib , MKL_INT *descb , float *work , MKL_INT *lwork ,
MKL_INT *info );
void pdptsv (MKL_INT *n , MKL_INT *nrhs , double *d , double *e , MKL_INT *ja ,
MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb , double *work , MKL_INT
*lwork , MKL_INT *info );
void pcptsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *d , MKL_Complex8 *e ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *descb ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzptsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?ptsv` routine solves a system of linear equations

$$A(1:n, ja:ja+n-1)*X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real tridiagonal symmetric positive definite distributed matrix.

Cholesky factorization is used to factor a reordering of the matrix into $L*L'$.

Input Parameters

<code>n</code>	(global) INTEGER. The order of matrix A ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
<code>d</code>	(local) REAL for <code>psptsv</code> DOUBLE PRECISON for <code>pdptsv</code> COMPLEX for <code>pcptsv</code> DOUBLE COMPLEX for <code>pzptsv</code> . Pointer to local part of global vector storing the main diagonal of the matrix.
<code>e</code>	(local) REAL for <code>psptsv</code> DOUBLE PRECISON for <code>pdptsv</code> COMPLEX for <code>pcptsv</code> DOUBLE COMPLEX for <code>pzptsv</code> . Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d .
<code>ja</code>	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<code>desca</code>	(global and local) INTEGER array of dimension <code>dlen</code> . If 1d type (<code>dtype_a=501 or 502</code>), <code>dlen</code> ≥ 7 ; If 2d type (<code>dtype_a=1</code>), <code>dlen</code> ≥ 9 . The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
<code>b</code>	(local) REAL for <code>psptsv</code> DOUBLE PRECISON for <code>pdptsv</code> COMPLEX for <code>pcptsv</code> DOUBLE COMPLEX for <code>pzptsv</code> .

Pointer into the local memory to an array of local lead dimension $l1d_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.

ib (global) INTEGER. The row index in the global array b that points to the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).

descb (global and local) INTEGER array of dimension *dlen*.

If 1d type ($dtype_b = 502$), *dlen* ≥ 7 ;

If 2d type ($dtype_b = 1$), *dlen* ≥ 9 .

The array descriptor for the distributed matrix B .

Contains information of mapping of B to memory.

work (local).

REAL for psptsv

DOUBLE PRECISON for pdptsv

COMPLEX for pcptsv

DOUBLE COMPLEX for pzptsv.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. $lwork > (12 * \text{NPCOL} + 3 * nb) + \max((10 + 2 * \min(100, nrhs)) * \text{NPCOL} + 4 * nrhs, 8 * \text{NPCOL})$.

Output Parameters

d On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to *desca*(*nb*_).

e On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to *desca*(*nb*_).

b On exit, this contains the local piece of the solutions distributed matrix X .

work On exit, *work*(1) contains the minimal *lwork*.

info (local) INTEGER. If *info*=0, the execution is successful.

< 0: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0: If $info = k \leq \text{NPROCS}$, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If $info = k > \text{NPROCS}$, the submatrix stored on processor $info\text{-NPROCS}$ representing interactions with other processors was not positive definite, and the factorization was not completed.

p?gels

Solves overdetermined or underdetermined linear systems involving a matrix of full rank.

Syntax

Fortran:

```
call psgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pdgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pcgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pzgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```

Include Files

- C: mkl_scalapack.h

Description

The p?gels routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem
$$\text{minimize } ||\text{sub}(B) - \text{sub}(A) * X||$$
2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $\text{sub}(A) * X = \text{sub}(B)$.
3. If $trans = 'T'$ and $m \geq n$: find the minimum norm solution of an undetermined system $\text{sub}(A)^T * X = \text{sub}(B)$.
4. If $trans = 'T'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

```
minimize ||sub(B) - sub(A)T*X||,
```

where `sub(B)` denotes $B(ib:ib+m-1, jb:jb+nrhs-1)$ when `trans = 'N'` and $B(ib:ib+n-1, jb:jb+nrhs-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when `trans = 'N'`, the solution vectors are stored as the columns of the n -by- $nrhs$ right hand side matrix `sub(B)` and the m -by- $nrhs$ right hand side matrix `sub(B)` otherwise.

Input Parameters

<code>trans</code>	(global) CHARACTER. Must be ' <code>N</code> ', or ' <code>T</code> '. If <code>trans = 'N'</code> , the linear system involves matrix <code>sub(A)</code> ; If <code>trans = 'T'</code> , the linear system involves the transposed matrix A^T (for real flavors only).
<code>m</code>	(global) INTEGER. The number of rows in the distributed submatrix <code>sub(A)</code> ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the distributed submatrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides; the number of columns in the distributed submatrices <code>sub(B)</code> and <code>X</code> . ($nrhs \geq 0$).
<code>a</code>	(local) REAL for <code>psgels</code> DOUBLE PRECISION for <code>pdgels</code> COMPLEX for <code>pcgels</code> DOUBLE COMPLEX for <code>pzgels</code> . Pointer into the local memory to an array of dimension (<code>lld_a, LOCc(ja+n-1)</code>). On entry, contains the m -by- n matrix A .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix A , respectively.
<code>desca</code>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix A .
<code>b</code>	(local) REAL for <code>psgels</code> DOUBLE PRECISION for <code>pdgels</code> COMPLEX for <code>pcgels</code> DOUBLE COMPLEX for <code>pzgels</code> . Pointer into the local memory to an array of local dimension (<code>lld_b, LOCc(jb+nrhs-1)</code>). On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; <code>sub(B)</code> is m -by- $nrhs$ if <code>trans='N'</code> , and n -by- $nrhs$ otherwise.

ib, jb (global) INTEGER. The row and column indices in the global array *b* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

work (local)

REAL for psgels
DOUBLE PRECISION for pdgels
COMPLEX for pcgels
DOUBLE COMPLEX for pzgels.

Workspace array with dimension *lwork*.

lwork (local or global) INTEGER.

The dimension of the array *work lwork* is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then

```

ltau = numroc(ja+min(m,n)-1, nb_a, MYCOL, csrc_a, NPCOL),
lwf = nb_a * (mpa0 + nqa0 + nb_a)
lws = max((nb_a * (nb_a-1))/2, (nrhsqb0 + mpb0) * nb_a) +
      nb_a * nb_a
else
    ltau = numroc(ia+min(m,n)-1, mb_a, MYROW, rsrc_a, NPROW),
    lwf = mb_a * (mpa0 + nqa0 + mb_a)
    lws = max((mb_a * (mb_a-1))/2, (npb0 + max(nqa0 +
        numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW), mb_a, 0, 0,
        lcm), nrhsqb0)) * mb_a) + mb_a * mb_a
end if,
where lcm = lcm/NPROW with lcm = ilcm(NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icooffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol= indxg2p(ja, nb_a, MYROW, rsrc_a, NPROW)
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icooffa, nb_a, MYCOL, iacol, NPCOL),
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),

```

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW`, and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, If $m \geq n$, `sub(A)` is overwritten by the details of its *QR* factorization as returned by `p?geqrf`; if $m < n$, `sub(A)` is overwritten by details of its *LQ* factorization as returned by `p?gelqf`.

b

On exit, `sub(B)` is overwritten by the solution vectors, stored columnwise: if `trans = 'N'` and $m \geq n$, rows 1 to n of `sub(B)` contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column;

If `trans = 'N'` and $m < n$, rows 1 to n of `sub(B)` contain the minimum norm solution vectors;

If `trans = 'T'` and $m \geq n$, rows 1 to m of `sub(B)` contain the minimum norm solution vectors; if `trans = 'T'` and $m < n$, rows 1 to m of `sub(B)` contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column.

`work(1)`

On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then `info = - (i * 100 + j)`, if the i -th argument is a scalar and had an illegal value, then `info = -i`.

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

Fortran:

```
call pssyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
call pdsyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
```

C:

```
void pssyev (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT
*descz , float *work , MKL_INT *lwork , MKL_INT *info );
```

Description

The p?syev routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK routines.

In its present form, the routine assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* ='N', then only eigenvalues are computed.

If *jobz* ='V', then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

If *uplo* = 'U', *a* stores the upper triangular part of A .

If *uplo* = 'L', *a* stores the lower triangular part of A .

n (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

a (local)

REAL for pdssyev.

DOUBLE PRECISION for pdssyev.

Block cyclic array of global dimension (n, n) and local dimension (*lld_a*, LOC $c(ja+n-1)$). On entry, the symmetric matrix A .

If *uplo* = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix.

If *uplo* = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix A .

<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) REAL for pssyev. DOUBLE PRECISION for pdsyev. Array, size (<i>lwork</i>).
<i>lwork</i>	(local) INTEGER. See below for definitions of variables used to define <i>lwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lwork</i> $\geq 5*n + \text{sizesytrd} + 1$, where <i>sizesytrd</i> is the workspace for p?sytrd and is $\max(\text{NB} * (np + 1), 3 * \text{NB})$. If eigenvectors are requested (<i>jobz</i> = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is: <i>qrmem</i> = $2 * n - 2$ <i>lwmin</i> = $5 * n + n * ldc + \max(\text{sizemqrleft}, \text{qrmem}) + 1$ Variable definitions: <i>nb</i> = <i>desca(mb_)</i> = <i>desca(nb_)</i> = <i>descz(mb_)</i> = <i>descz(nb_)</i> ; <i>nn</i> = $\max(n, nb, 2)$; <i>desca(rsrcc_)</i> = <i>desca(rsrcc_)</i> = <i>descz(rsrcc_)</i> = <i>descz(csrc_)</i> = 0 <i>np</i> = <i>numroc(nn, nb, 0, 0, NPROW)</i> <i>nq</i> = <i>numroc(max(n, nb, 2), nb, 0, 0, NPCOL)</i> <i>nrc</i> = <i>numroc(n, nb, myprowc, 0, NPROCS)</i> <i>ldc</i> = $\max(1, nrc)$ <i>sizemqrleft</i> is the workspace for p?ormtr when its <i>side</i> argument is 'L'. <i>myprowc</i> is defined when a new context is created as follows: call blacs_get(<i>desca(ctxt_)</i> , 0, <i>contextc</i>) call blacs_gridinit(<i>contextc</i> , 'R', NPROCS, 1) call blacs_gridinfo(<i>contextc</i> , <i>nprowc</i> , <i>npcolc</i> , <i>myprowc</i> , <i>mypcolc</i>) If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). REAL for pssyev DOUBLE PRECISION for pdsyev Array, size (<i>n</i>). On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for pssyev DOUBLE PRECISION for pdsyev Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work(1)</i>	On output, <i>work(1)</i> returns the workspace needed to guarantee completion. If the input parameters are incorrect, <i>work(1)</i> may also be incorrect. If <i>jobz</i> = 'N' <i>work(1)</i> = minimal (optimal) amount of workspace If <i>jobz</i> = 'V' <i>work(1)</i> = minimal workspace required to generate all the eigenvectors.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge in ?steqr2 after a total of $30n$ iterations. If <i>info</i> = <i>n</i> +1, then p?syev has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?syev cannot be guaranteed.

p?syevd

Computes all eigenvalues and eigenvectors of a real symmetric matrix by using a divide and conquer algorithm.

Syntax

Fortran:

```
call pssyevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
iwork, liwork, info)
```

```
call pdsyevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
iwork, liwork, info)
```

C:

```
void pssyevd (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT
*descz , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT
*info );
```

```

Description

The p?syevd routine computes all eigenvalues and eigenvectors of a real symmetric matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

If *uplo* = 'U', a stores the upper triangular part of A .

If *uplo* = 'L', a stores the lower triangular part of A .

n (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

a (local).

REAL for pssyevd

DOUBLE PRECISION for pdssyevd.

Block cyclic array of global dimension (n, n) and local dimension (*lld_a*, *LOCc(ja+n-1)*). On entry, the symmetric matrix A .

If *uplo* = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix.

If *uplo* = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?syevd cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, dimension <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i> .
<i>work</i>	(local). REAL for pssyevd DOUBLE PRECISION for pdsyevd. Array, size <i>lwork</i> .
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . If eigenvalues are requested: $\text{lwork} \geq \max(1+6*n + 2*np*nq, \text{trilwmin}) + 2*n$ with $\text{trilwmin} = 3*n + \max(nb*(np + 1), 3*nb)$ $np = \text{numroc}(n, nb, myrow, iarow, NPROW)$ $nq = \text{numroc}(n, nb, mycol, iacol, NPCOL)$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.
<i>iwork</i>	(local) INTEGER. Workspace array, dimension <i>liwork</i> .
<i>liwork</i>	(local) INTEGER, dimension of <i>iwork</i> . $\text{liwork} = 7*n + 8*npcol + 2.$

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for pssyevd DOUBLE PRECISION for pdsyevd. Array, size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local).

REAL for pssyevd
 DOUBLE PRECISION for pdsyevd.
 Array, global dimension (n, n), local dimension ($lld_z, LOCo(jz+n-1)$).
 The z parameter contains the orthonormal eigenvectors of the matrix A .

work(1) On exit, returns adequate workspace to allow optimal performance.

iwork(1) (local).
 On exit, if $liwork > 0$, *iwork(1)* returns the optimal *liwork*.

info (global) INTEGER.
 If $info = 0$, the execution is successful.
 If $info < 0$:
 If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$. If the i -th argument is a scalar and had an illegal value, then $info = -i$.
 If $info > 0$:
 The algorithm failed to compute the $info/(n+1)$ -th eigenvalue while working on the submatrix lying in global rows and columns $\text{mod}(info, n+1)$.

p?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using Relatively Robust Representation.

Syntax

Fortran:

```
call pssyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,  

  iz, jz, descz, work, lwork, iwork, liwork, info )
call pdsyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,  

  iz, jz, descz, work, lwork, iwork, liwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

p?syevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK routines.

First, the matrix A is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w . The eigenvector matrix z is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	(global) CHARACTER*1
	Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) CHARACTER*1
	= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval [<i>vl</i> , <i>vu</i>] will be found. = 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>uplo</i>	(global) CHARACTER*1
	Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global) INTEGER
	The number of rows and columns of the matrix <i>a</i> . <i>n</i> ≥ 0
<i>a</i>	REAL for pssyevr DOUBLE PRECISION for pdsyevr
	Block cyclic array of global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_a</i> , <i>LOC_c(ja+n-1)</i>).
	This array contains the local pieces of the symmetric distributed matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>a</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>a</i> is used to define the elements of the symmetric matrix.
	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>a</i> , including the diagonal, is destroyed.
<i>ia</i>	(global) INTEGER
	Global row index of <i>a</i> , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>ja</i>	(global) INTEGER
	Global column index of <i>a</i> , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen_=9</i> .
	The array descriptor for the distributed matrix <i>a</i> .
<i>vl</i>	REAL for pssyevr DOUBLE PRECISION for pdsyevr

(global)

If *range*='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

vu

REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(global)

If *range*='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

il

(global) INTEGER

If *range*='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$.

Not referenced if *range* = 'A'.

iu

(global) INTEGER

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il,n) \leq iu \leq n$.

Not referenced if *range* = 'A'.

iz

(global) INTEGER

Global row index of *z*, which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

rz

(global) INTEGER

Global column index of *z*, which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

() INTEGER array of dimension *dlen_*.

The array descriptor for the distributed matrix *z*.

The context *descz(ctxt_)* must equal *desca(ctxt_)*. Also note the array alignment requirements specified below.

work

REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(local workspace) array, dimension (*lwork*)

lwork

(local) INTEGER

Size of *work*, must be at least 3.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$lwork \geq 2 + 5*n + \max(12 * nn, neig * (np0 + 1))$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$lwork \geq 2 + 5*n + \max(18*nn, np0 * mq0 + 2 * neig * neig) + (2 + \text{ceil}(neig, nprow*ncol))*nn$

Variable definitions:

$neig$ = number of eigenvectors requested

nb = $\text{desc}(mb_{_}) = \text{desc}(nb_{_}) = \text{descz}(mb_{_}) = \text{descz}(nb_{_})$

$nn = \max(n, neig, 2)$

$\text{desc}(rsrc_{_}) = \text{desc}(csrc_nb_{_}) = \text{descz}(rsrc_{_}) = \text{descz}(csrc_{_}) = 0$

$np0 = \text{numroc}(nn, neig, 0, 0, nprow)$

$mq0 = \text{numroc}(\max(neig, neig, 2), neig, 0, 0, npcol)$

$\text{ceil}(x, y)$ is a ScaLAPACK function returning $\text{ceiling}(x/y)$, and $nprow$ and $npcol$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pixerbla`.

$liwork$ (local) INTEGER

size of $iwork$

Let $nnp = \max(n, nprow*ncol + 1, 4)$. Then:

$liwork \geq 12*nnp + 2*n$ when the eigenvectors are desired

$liwork \geq 10*nnp + 2*n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

OUTPUT Parameters

m (global) INTEGER

Total number of eigenvalues found. $0 \leq m \leq n$.

nz (global) INTEGER

Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$

w REAL for `pssyevr`

DOUBLE PRECISION for `pdsyevr`

(global) array, dimension (n)

Upon successful exit, the first m entries contain the selected eigenvalues in ascending order.

<i>z</i>	REAL for pssyevr DOUBLE PRECISION for pdsyevr Block-cyclic array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOC_c(jz+n-1)</i>) On exit, contains local pieces of distributed matrix <i>Z</i> .
<i>work</i>	On return, <i>work</i> (1) contains the optimal amount of workspace required for efficient execution. If <i>jobz</i> ='N' <i>work</i> (1) = optimal amount of workspace required to compute the eigenvalues. If <i>jobz</i> ='V' <i>work</i> (1) = optimal amount of workspace required to compute eigenvalues and eigenvectors.
<i>iwork</i>	(local workspace) INTEGER array On return, <i>iwork</i> (1) contains the amount of integer workspace required.
<i>info</i>	(global) INTEGER = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> th-entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The distributed submatrices *a*(*ia*:*, *ja*:*) and *z*(*iz*:*iz*+*m*-1, *iz*:*iz*+*n*-1) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: *desc_a*(*m*_)=*desc_z*(*m*_)=*desc_a*(*n*_)=*desc_z*(*n*_)
2. Quadratic conformal blocking: *desc_a*(*mb*_)=*desc_a*(*nb*_)=*desc_z*(*mb*_)=*desc_z*(*nb*_), *desc_a*(*rsrc*_)=*desc_z*(*rsrc*_)
3. $\text{mod}(\text{ia}-1, \text{mb_a}) = \text{mod}(\text{iz}-1, \text{mb_z}) = 0$

p?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

Fortran:

```
call pssyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
call pdsyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
```

Description

The `p?syevx` routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScalAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be '`N`' or '`V`'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* = '`N`', then only eigenvalues are computed.

If *jobz* = '`V`', then eigenvalues and eigenvectors are computed.

range (global) CHARACTER*1. Must be '`A`', '`V`', or '`I`'.

If *range* = '`A`', all eigenvalues will be found.

If *range* = '`V`', all eigenvalues in the half-open interval $[vl, vu]$ will be found.

If *range* = '`I`', the eigenvalues with indices *il* through *iu* will be found.

uplo (global) CHARACTER*1. Must be '`U`' or '`L`'.

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

If *uplo* = '`U`', *a* stores the upper triangular part of A .

If *uplo* = '`L`', *a* stores the lower triangular part of A .

n (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

a (local). REAL for `pdssyevx`

DOUBLE PRECISION for `pdssyevx`.

Block cyclic array of global dimension (n, n) and local dimension $(lld_a, LOCc(ja+n-1))$. On entry, the symmetric matrix A .

If *uplo* = '`U`', only the upper triangular part of A is used to define the elements of the symmetric matrix.

If *uplo* = '`L`', only the lower triangular part of A is used to define the elements of the symmetric matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>vl, vu</i>	(global) REAL for pssyevx DOUBLE PRECISION for pdssyevx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; <i>vl</i> ≤ <i>vu</i> . Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: <i>il</i> ≥ 1 $\min(il, n) \leq iu \leq n$ Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). REAL for pssyevx DOUBLE PRECISION for pdssyevx. If <i>jobz</i> ='V', setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b),$ where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then <i>eps*norm(T)</i> will be used in its place, where <i>norm(T)</i> is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2*p?lamch('S')$ not zero. If this routine returns with $((\text{mod}(info, 2).ne.0).or. * (\text{mod}(info/8, 2).ne.0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2*p?lamch('S')$.
<i>orfac</i>	(global). REAL for pssyevx DOUBLE PRECISION for pdssyevx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within <i>tol=orfac*norm(A)</i> of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global array *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

REAL for pssyevx.

DOUBLE PRECISION for pdsyevx.

Array, size (*lwork*).

lwork

(local) INTEGER. The dimension of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lwork* $\geq 5*n + \max(5*nn, NB*(np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

lwork $\geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{ceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:

*(clustersize-1)*n*,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

{*w(k), ..., w(k+clustersize-1)* | *w(j+1) ≤ w(j)* + *orfac*2*norm(A)*},

where

neig = number of eigenvectors requested

nb = *desca(mb_)* = *desca(nb_)* = *descz(mb_)* = *descz(nb_)*;

nn = *max(n, nb, 2)*;

desca(rsra_) = *desca(nb_)* = *descz(rsra_)* = *descz(csrc_)* = 0;

np0 = *numroc(nn, nb, 0, 0, NPROW)*;

mq0 = *numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)*

ceil(x, y) is a ScaLAPACK function returning ceiling(*x/y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when `range='V'`, number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if `lwork` is large enough to compute the eigenvalues, `p?sygvx` computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

`lwork ≥ max(lwork, 5*n + nsytrd_lwopt),`

where `lwork`, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;
anb = pjlaenv(desca(ctxt_), 3, 'p?syttrd', 'L', 0, 0, 0, 0);
sqnpc = int(sqrt(dble(NPROW * NPCOL)));
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);
numroc is a ScaLAPACK tool functions;
pjlaenv is a ScaLAPACK environmental inquiry function
NPROW, MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.
```

For large `n`, no extra workspace is needed, however the biggest boost in performance comes for small `n`, so it is wise to provide the extra workspace (typically less than a megabyte per process).

If `clustersize > n/sqrt(NPROW*NPCOL)`, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, `clustersize = n-1`) `p?stein` will perform no better than `?stein` on single processor.

For `clustersize = n/sqrt(NPROW*NPCOL)` reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For `clustersize > n/sqrt(NPROW*NPCOL)` execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pixerbla`.

`iwork`

(local) INTEGER. Workspace array.

`liwork`

(local) INTEGER, dimension of `iwork`. `liwork ≥ 6*nnp`

Where: `nnp = max(n, NPROW*NPCOL + 1, 4)`

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

- a
On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.
- m
(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
- nz
(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$.
The number of columns of z that are filled.
If $jobz \neq 'V'$, nz is not referenced.
If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?syevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m.1e.descz(n_)$) and sufficient workspace to compute them. (See $lwork$). `p?syevx` is always able to detect insufficient space without computation unless `range.eq.'V'`.
- w
(global). REAL for `pssyevx`
DOUBLE PRECISION for `pdsyevx`.
Array, size (n). The first m elements contain the selected eigenvalues in ascending order.
- z
(local). REAL for `pssyevx`
DOUBLE PRECISION for `pdsyevx`.
Array, global dimension (n, n), local dimension ($lld_z, LOCC(jz+n-1)$).
If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.
If $jobz = 'N'$, then z is not referenced.
- $work(1)$
On exit, returns workspace adequate workspace to allow optimal performance.
- $iwork(1)$
On return, $iwork(1)$ contains the amount of integer workspace required.
- $ifail$
(global) INTEGER.
Array, size (n).
If $jobz = 'V'$, then on normal exit, the first m elements of $ifail$ are zero. If $(\text{mod}(info, 2) . ne. 0)$ on exit, then $ifail$ contains the indices of the eigenvectors that failed to converge.
If $jobz = 'N'$, then $ifail$ is not referenced.

iclustr

(global) INTEGER. Array, size (2*NPROW*NPCOL)

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*($2*i-1$) to *iclustr*($2*i$), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr()* is a zero terminated array. (*iclustr*($2*k$).ne.0. and. *iclustr*($2*k+1$).eq.0) if and only if k is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Array, size (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n) / gap(i)$ where C is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the i -th argument is an array and the j -entry had an illegal value, then *info* = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0: if (mod(*info*, 2).ne.0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U').

If (mod(*info*/2, 2).ne.0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4, 2).ne.0), then space limit prevented p?syevf from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8, 2).ne.0), then p?stebz failed to compute eigenvalues. Ensure *abstol*=2.0*p?lamch('U').

p?heev

Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

Syntax

Fortran:

```
call pcheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork,
lrwork, info)

call pzheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork,
lrwork, info)
```

C:

```
void pcheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *w , MKL_Complex8 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex8 *work , MKL_INT *lwork , float *rwork , MKL_INT
*lrwork , MKL_INT *info );

void pzheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *w , MKL_Complex16 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex16 *work , MKL_INT *lwork , double *rwork , MKL_INT
*lrwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?heev` routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. The routine assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters

`np` = the number of rows local to a given process.

`nq` = the number of columns local to a given process.

`jobz` (global) CHARACTER*1. Must be '`N`' or '`V`'.

Specifies if it is necessary to compute the eigenvectors:

If `jobz` = '`N`', then only eigenvalues are computed.

If `jobz` = '`V`', then eigenvalues and eigenvectors are computed.

`uplo` (global) CHARACTER*1. Must be '`U`' or '`L`'.

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

If `uplo` = '`U`', a stores the upper triangular part of A .

If `uplo` = '`L`', a stores the lower triangular part of A .

`n` (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

`a` (local).

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

Block cyclic array of global dimension (n, n) and local dimension $(lld_a,$ $LOCc(ja+n-1))$. On entry, the Hermitian matrix A .

If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the Hermitian matrix.

If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the Hermitian matrix.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

$desc_a$

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A . If $desc_a(ctxt_)$ is incorrect, p?heev cannot guarantee correct error reporting.

iz, jz

(global) INTEGER. The row and column indices in the global array z indicating the first row and the first column of the submatrix Z , respectively.

$desc_z$

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix Z . $desc_z(ctxt_)$ must equal $desc_a(ctxt_)$.

$work$

(local).

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

Array, size $lwork$.

$lwork$

(local) INTEGER. The dimension of the array $work$.

If only eigenvalues are requested ($jobz = 'N'$):

$lwork \geq \max(nb * (np0 + 1), 3) + 3*n$

If eigenvectors are requested ($jobz = 'V'$), then the amount of workspace required:

$lwork \geq (np0 + nq0 + nb) * nb + 3*n + n^2$

with $nb = desc_a(mb_) = desc_a(nb_) = nb = desc_z(mb_) = desc_z(nb_)$

$np0 = numroc(nn, nb, 0, 0, NPROW)$.

$nq0 = numroc(\max(n, nb, 2), nb, 0, 0, NPCOL)$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

$rwork$

(local).

REAL for pcheev

DOUBLE PRECISION for pzheev.

Workspace array, size $lrwork$.

$lrwork$

(local) INTEGER. The dimension of the array $rwork$.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lrwork* $\geq 2*n$.

If eigenvectors are requested (*jobz* = 'V'), then *lrwork* $\geq 2*n + 2*n-2$.

If *lrwork* = -1, then *lrwork* is global input and a workspace query is assumed; the routine only calculates the minimum size required for the *rwork* array. The required workspace is returned as the first element of *rwork*, and no error message is issued by *pixerbla*.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for <i>pcheev</i> DOUBLE PRECISION for <i>pzheev</i> . Array, size <i>n</i> . The first <i>m</i> elements contain the selected eigenvalues in ascending order.
<i>z</i>	(local). COMPLEX for <i>pcheev</i> DOUBLE COMPLEX for <i>pzheev</i> . Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work(1)</i>	On exit, returns adequate workspace to allow optimal performance. If <i>jobz</i> = 'N', then <i>work(1)</i> = minimal workspace only for eigenvalues. If <i>jobz</i> = 'V', then <i>work(1)</i> = minimal workspace required to generate all the eigenvectors.
<i>rwork(1)</i>	(local) COMPLEX for <i>pcheev</i> DOUBLE COMPLEX for <i>pzheev</i> . On output, <i>rwork(1)</i> returns workspace required to guarantee completion.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0:

If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$. If the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

If $\text{info} > 0$:

If $\text{info} = 1$ through n , the i -th eigenvalue did not converge in [?steqr2](#) after a total of $30*n$ iterations.

If $\text{info} = n+1$, then p?heev detected heterogeneity, and the accuracy of the results cannot be guaranteed.

p?heevd

Computes all eigenvalues and eigenvectors of a complex Hermitian matrix by using a divide and conquer algorithm.

Syntax

Fortran:

```
call pccheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
rwork, lrwork, iwork, liwork, info)
```

```
call pzcheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
rwork, lrwork, iwork, liwork, info)
```

C:

```
void pccheevd (char *jobz , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *w , MKL_Complex8 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex8 *work , MKL_INT *lwork , float *rwork , MKL_INT
*lrwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );

void pzcheevd (char *jobz , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *w , MKL_Complex16 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex16 *work , MKL_INT *lwork , double *rwork , MKL_INT
*lrwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

Include Files

Description

The p?heevd routine computes all eigenvalues and eigenvectors of a complex Hermitian matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$ (global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If $jobz = 'N'$, then only eigenvalues are computed.

If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.
 Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:
 If *uplo* = 'U', *a* stores the upper triangular part of *A*.
 If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n* \geq 0).

a (local).
 COMPLEX for pcheevd
 DOUBLE COMPLEX for pzheevd.
 Block cyclic array of global dimension (*n*, *n*) and local dimension (*lld_a*, *LOCc(ja+n-1)*). On entry, the Hermitian matrix *A*.
 If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.
 If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*. If *desca(ctxt_)* is incorrect, p?heevd cannot guarantee correct error reporting.

iz, jz (global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array, dimension *dlen_*. The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work (local).
 COMPLEX for pcheevd
 DOUBLE COMPLEX for pzheevd.
 Array, size *lwork*.

lwork (local) INTEGER. The dimension of the array *work*.
 If eigenvalues are requested:

$$\textit{lwork} = n + (\textit{nb0} + \textit{mq0} + \textit{nb}) * \textit{nb}$$

$$\text{with } \textit{np0} = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$$

$$\textit{mq0} = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

 $rwork$

(local).

REAL for pcheevd

DOUBLE PRECISION for pzheevd.

Workspace array, size $lrwork$. $lrwork$ (local) INTEGER. The dimension of the array $rwork$. $lrwork \geq 1 + 9*n + 3*np*nq,$ with $np = \text{numroc}(n, nb, myrow, irow, \text{NPROW})$ $nq = \text{numroc}(n, nb, mycol, iacol, \text{NPCOL})$ $iwork$ (local) INTEGER. Workspace array, dimension $liwork$. $liwork$ (local) INTEGER, dimension of $iwork$. $liwork = 7*n + 8*ncol + 2.$

Output Parameters

 a On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten. w

(global).

REAL for pcheevd

DOUBLE PRECISION for pzheevd.

Array, size n . If $info = 0$, w contains the eigenvalues in the ascending order. z

(local).

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

Array, global dimension (n, n) , local dimension $(lld_z, \text{LOCc}(jz+n-1))$.The z parameter contains the orthonormal eigenvectors of the matrix A . $work(1)$

On exit, returns adequate workspace to allow optimal performance.

 $rwork(1)$

(local)

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

On output, $rwork(1)$ returns workspace required to guarantee completion. $iwork(1)$

(local).

On return, *iwork*(1) contains the amount of integer workspace required.

info (global) INTEGER.
 If *info* = 0, the execution is successful.
 If *info* < 0:
 If the *i*-th argument is an array and the *j*-entry had an illegal value, then
 info = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal
 value, then *info* = -*i*.
 If *info* > 0:
 If *info* = 1 through *n*, the *i*-th eigenvalue did not converge.

p?heevr

Computes selected eigenvalues and, optionally,
 eigenvectors of a Hermitian matrix using Relatively
 Robust Representation.

Syntax

Fortran:

```
call pccheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
               iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
call pzheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
               iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* distributed in 2D blockcyclic format by calling the recommended sequence of ScalAPACK routines.

First, the matrix *A* is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in *w*. The eigenvector matrix *Z* is stored in 2D block-cyclic format distributed over all processors.

Input Parameters

<i>jobz</i>	(global) CHARACTER*1
	Specifies whether or not to compute the eigenvectors:
	= 'N': Compute eigenvalues only.
	= 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) CHARACTER*1
	= 'A': all eigenvalues will be found.
	= 'V': all eigenvalues in the interval [vl,vu] will be found.
	= 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.

<i>uplo</i>	(global) CHARACTER*1
	Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global) INTEGER
	The number of rows and columns of the matrix <i>A</i> . $n \geq 0$
<i>a</i>	COMPLEX for pcheevr COMPLEX*16 for pzheevr Block-cyclic array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_a</i> , <i>LOC_c(ja+n-1)</i>) Contains the local pieces of the Hermitian distributed matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>a</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>a</i> is used to define the elements of the Hermitian matrix.
<i>ia</i>	(global) INTEGER Global row index of <i>a</i> , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>ja</i>	(global) INTEGER Global column index of <i>a</i> , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen_</i> . (The ScaLAPACK descriptor length is <i>dlen_</i> = 9.) The array descriptor for the distributed matrix <i>a</i> . The descriptor stores details about the 2D block-cyclic storage, see the notes below. If <i>desca</i> is incorrect, p?heevr cannot work correctly. Also note the array alignment requirements specified below
<i>vl</i>	REAL for pcheevr DOUBLE PRECISION for pzheevr (global) If <i>range</i> ='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i i="" vu<=""></i>	REAL for pcheevr DOUBLE PRECISION for pzheevr (global) If <i>range</i> ='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i>	(global) INTEGER

If $\text{range} = \text{'I}'$, the index (from smallest to largest) of the smallest eigenvalue to be returned. $\text{il} \geq 1$.

Not referenced if $\text{range} = \text{'A'}$.

iu

(global) INTEGER

If $\text{range} = \text{'I}'$, the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(\text{il}, n) \leq \text{iu} \leq n$.

Not referenced if $\text{range} = \text{'A'}$.

iz

(global) INTEGER

Global row index of z , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global) INTEGER

Global column index of z , which points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

(global and local) INTEGER array of dimension dlen_z .

The array descriptor for the distributed matrix z . $\text{descz}(\text{ctxt}_\text{z})$ must equal $\text{desca}(\text{ctxt}_\text{z})$

work

COMPLEX for pccheevr

COMPLEX*16 for pzheevr

(local workspace) array, dimension (lwork)

lwork

(local) INTEGER

Size of work array, must be at least 3.

If only eigenvalues are requested:

$$\text{lwork} \geq n + \max(n * (\text{np00} + 1), n * 3)$$

If eigenvectors are requested:

$$\text{lwork} \geq n + (\text{np00} + \text{mq00} + n) * n$$

For definitions of np00 and mq00 , see lrwork .

For optimal performance, greater workspace is needed, i.e.

$$\text{lwork} \geq \max(\text{lwork}, \text{nhetrd_lwork})$$

Where lwork is as defined above, and

$$\text{nhetrd_lwork} = n + 2 * (\text{anb} + 1) * (4 * \text{nps} + 2) + (\text{nps} + 1) * \text{nps}$$

$$\text{ictxt} = \text{desca}(\text{ctxt}_\text{z})$$

$$\text{anb} = \text{pjlaenv}(\text{ictxt}, 3, \text{'PCHEATTRD'}, \text{'L'}, 0, 0, 0, 0, 0)$$

$$\text{sqnpc} = \sqrt{\text{real}(\text{nprow} * \text{npcol})}$$

$$\text{nps} = \max(\text{numroc}(n, 1, 0, 0, \text{sqnpc}), 2 * \text{anb})$$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

$rwork$

REAL for `pcheevr`

DOUBLE PRECISION for `pzheevr`

(local workspace) array, dimension ($lrwork$)

$lrwork$

(local) INTEGER

Size of $rwork$, must be at least 3.

See below for definitions of variables used to define $lrwork$.

If no eigenvectors are requested ($jobz = 'N'$) then

$$lrwork \geq 2 + 5 * n + \max(12 * n, nb * (np00 + 1))$$

If eigenvectors are requested ($jobz = 'V'$) then the amount of workspace required is:

$$\begin{aligned} lrwork \geq & 2 + 5 * n + \max(18 * n, np00 * mq00 + 2 * nb * nb) + \\ & (2 + \text{ceil}(neig, nprow * ncol)) * n \end{aligned}$$

Variable definitions:

$neig$ = number of eigenvectors requested

nb = $\text{desc}(mb_{_}) = \text{desc}(nb_{_}) = \text{desc}(mb_{_}) = \text{desc}(nb_{_})$

$nn = \max(n, nb, 2)$

$\text{desc}(rsrc_{_}) = \text{desc}(csrc_{_}) = \text{desc}(rsrc_{_}) = \text{desc}(csrc_{_}) = 0$

$np00 = \text{numroc}(nn, nb, 0, 0, nprow)$

$mq00 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, ncol)$

$\text{ceil}(x, y)$ is a ScaLAPACK function returning ceiling(x/y), and $nprow$ and $ncol$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by [pxerbla](#)

$iwork$

(local workspace) INTEGER array, dimension ($liwork$)

$liwork$

(local) INTEGER

size of $iwork$

Let $nnp = \max(n, nprow * ncol + 1, 4)$. Then:

$liwork \geq 12 * nnp + 2 * n$ when the eigenvectors are desired

$liwork \geq 10 * nnp + 2 * n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`

OUTPUT Parameters

a	The lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of a , including the diagonal, is destroyed.
m	(global) INTEGER Total number of eigenvalues found. $0 \leq m \leq n$.
nz	(global) INTEGER Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$
w	REAL for <code>pcheevr</code> DOUBLE PRECISION for <code>pzheevr</code> (global) array, dimension (n) On normal exit, the first m entries contain the selected eigenvalues in ascending order.
z	COMPLEX for <code>pcheevr</code> COMPLEX*16 for <code>pzheevr</code> (local) array, global dimension (n, n), local dimension ($lld_z, LOC_c(jz +n-1)$) If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If $jobz = 'N'$, then z is not referenced.
$work$	$work(1)$ returns workspace adequate workspace to allow optimal performance.
$rwork$	On return, $rwork(1)$ contains the optimal amount of workspace required for efficient execution. if $jobz='N'$ $rwork(1) =$ optimal amount of workspace required to compute the eigenvalues. if $jobz='V'$ $rwork(1) =$ optimal amount of workspace required to compute eigenvalues and eigenvectors.
$iwork$	On return, $iwork(1)$ contains the amount of integer workspace required.
$info$	(global) INTEGER = 0: successful exit

< 0: If the i -th argument is an array and the j -th entry had an illegal value, then $\text{info} = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $\text{desc}(m_*) = \text{desc}(m_*) = \text{desc}(n_*) = \text{desc}(n_*)$
2. Quadratic conformal blocking: $\text{desc}(mb_*) = \text{desc}(nb_*) = \text{desc}(mb_*) = \text{desc}(nb_*)$, $\text{desc}(rsrc_*) = \text{desc}(rsrc_*)$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

Fortran:

```
call pccheevx(jobz, range, uplo, n, a, ia, ja, desc, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr, gap, info)
call pzheevx(jobz, range, uplo, n, a, ia, ja, desc, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?heevx routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global) CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a</i>	(local). COMPLEX for pcheevx DOUBLE COMPLEX for pzheevx. Block cyclic array of global dimension (<i>n</i> , <i>n</i>) and local dimension (<i>lld_a</i> , LOC <i>c(ja+n-1)</i>). On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?heevx cannot guarantee correct error reporting.
<i>vl</i> , <i>vu</i>	(global) REAL for pcheevx DOUBLE PRECISION for pzheevx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i> , <i>iu</i>	(global)

INTEGER. If *range* = 'I', the indices of the smallest and largest eigenvalues to be returned.

Constraints:

il ≥ 1 ; $\min(il, n) \leq iu \leq n$.

Not referenced if *range* = 'A' or 'V'.

abstol

(global).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

If *jobz*='V', setting *abstol* to *p?lamch(context, 'U')* yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to *abstol*+*eps**max($|a|, |b|$), where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(*T*) will be used in its place, where norm(*T*) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2*p?lamch('S')$, not zero. If this routine returns with ((mod(*info*, 2).ne.0).or.(mod(*info*/8, 2).ne.0)), indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2*p?lamch('S')$.

orfac

(global). REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within *tol*=*orfac**norm(*A*) of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative.

orfac should be identical on all processes.

iz, *jz*

(global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Array, size *lwork*.

lwork

(local) INTEGER. The dimension of the array *work*.

If only eigenvalues are requested:

lwork $\geq n + \max(nb * (np0 + 1), 3)$

If eigenvectors are requested:

lwork $\geq n + (np0 + mq0 + nb) * nb$

with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$.

lwork $\geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{ceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$

For optimal performance, greater workspace is needed, that is

lwork $\geq \max(lwork, nhetrd_lwork)$

where *lwork* is as defined above, and $nhetrd_lwork = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$

```

ictxt = desca(ctxt_)

anb = pjlaenv(ictxt, 3, 'pchetrd', 'L', 0, 0, 0, 0)
sqnpc = sqrt(dble(NPROW * NPCOL))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2 * anb)

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

rwork

(local)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Workspace array, size *lrwork*.*lrwork*(local) INTEGER. The dimension of the array *work*.See below for definitions of variables used to define *lwork*.If no eigenvectors are requested (*jobz* = 'N'), then $lrwork \geq 5 * nn + 4 * n$.If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:
$$lrwork \geq 4 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{ceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$$
The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to *lrwork*:*(clustersize-1)*n*,where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:
$$\{w(k), \dots, w(k+clustersize-1) | w(j+1) \leq w(j) + orfac * 2 * \text{norm}(A)\}.$$

Variable definitions:

```

neig = number of eigenvectors requested;
nb = descra(mb_) = descra(nb_) = descz(mb_) = descz(nb_);
nn = max(n, NB, 2);
descra(rsra_) = descra(nb_) = descz(rsra_) = descz(csra_) = 0;
np0 = numroc(nn, nb, 0, 0, NPROW);
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
iceil(x, y) is a ScaLAPACK function returning ceiling(x/y)

```

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, p?heevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', p?heevx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?heevx to compute the eigenvalues, p?heevx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If *clustersize* $\geq n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, *clustersize* = *n*-1) p?stein will perform no better than ?stein on 1 processor.

For *clustersize* = *n*/ $\sqrt{NPROW \cdot NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* $> n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

liwork $\geq 6 * nnp$

Where: *nnp* = max(*n*, NPROW*NPCOL+1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
<i>nz</i>	(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of <i>z</i> that are filled. If <i>jobz</i> ≠ 'V', <i>nz</i> is not referenced. If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> unless the user supplies insufficient space and p?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <i>z</i> (<i>m.le.descz(n_)</i>) and sufficient workspace to compute them. (See <i>lwork</i>). p?heevx is always able to detect insufficient space without computation unless <i>range.eq.</i> 'V'.
<i>w</i>	(global). REAL for pcheevx DOUBLE PRECISION for pzheevx. Array, size (<i>n</i>). The first <i>m</i> elements contain the selected eigenvalues in ascending order.
<i>z</i>	(local). COMPLEX for pcheevx DOUBLE COMPLEX for pzheevx. Array, global dimension (<i>n, n</i>), local dimension (<i>lld_z, LOCC(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work(1)</i>	On exit, returns adequate workspace to allow optimal performance.
<i>rwork</i>	(local). REAL for pcheevx DOUBLE PRECISION for pzheevx. Array, size (<i>lwork</i>). On return, <i>rwork(1)</i> contains the optimal amount of workspace required for efficient execution. If <i>jobz</i> = 'N' <i>rwork(1)</i> = optimal amount of workspace required to compute eigenvalues efficiently. If <i>jobz</i> = 'V' <i>rwork(1)</i> = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality. If <i>range</i> = 'V', it is assumed that all eigenvectors may be required.

iwork(1) (local)
 On return, *iwork*(1) contains the amount of integer workspace required.

ifail (global) INTEGER.
 Array, size (*n*).
 If *jobz* = 'V', then on normal exit, the first *m* elements of *ifail* are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.
 If *jobz* = 'N', then *ifail* is not referenced.

iclustr (global) INTEGER.
 Array, size (2*NPROW*NPCOL).
 This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2*k) .ne. 0. and. *iclustr*(2*k +1) .eq. 0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap (global)
 REAL for pcheevx
 DOUBLE PRECISION for pzheevx.
 Array, size (NPROW*NPCOL)
 This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n) / \text{gap}(i)$ where *C* is a small constant.

info (global) INTEGER.
 If *info* = 0, the execution is successful.
 If *info* < 0:
 If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 If *info* > 0:
 If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')
 If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented `p?syevx` from computing all of the eigenvectors between v_l and v_u . The number of eigenvectors computed is returned in nz .

If $(\text{mod}(info/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues. Ensure $\text{abstol}=2.0 * \text{p?lamch}('U')$.

`p?gesvd`

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

Fortran:

```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?gesvd` routine computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array s in decreasing order and only the first $\min(m, n)$ columns of U and rows of $vt = V^T$ are computed.

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

$size = \min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

$jobu$ (global) CHARACTER*1. Specifies options for computing all or part of the matrix U .

If $jobu = 'V'$, the first $size$ columns of U (the left singular vectors) are returned in the array u ;

If $jobu = 'N'$, no columns of U (no left singular vectors) are computed.

$jobvt$

(global) CHARACTER*1.

Specifies options for computing all or part of the matrix V^T .

If $jobvt = 'V'$, the first $size$ rows of V^T (the right singular vectors) are returned in the array vt ;

If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.

m

(global) INTEGER. The number of rows of the matrix A ($m \geq 0$).

n

(global) INTEGER. The number of columns in A ($n \geq 0$).

a

(local). REAL for psgesvd

DOUBLE PRECISION for pdgesvd

COMPLEX for pcgesvd

COMPLEX*16 for pzgesvd

Block cyclic array, global dimension (m, n) , local dimension (mp, nq) .

$work(lwork)$ is a workspace array.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .

iu, ju

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix U , respectively.

<i>descu</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>U</i> .
<i>ivt, jvt</i>	(global) INTEGER. The row and column indices in the global array <i>vt</i> indicating the first row and the first column of the submatrix <i>VT</i> , respectively.
<i>descvt</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>VT</i> .
<i>work</i>	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd Workspace array, dimension (<i>lwork</i>)
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> ; $lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd),$ where <i>sizeb</i> = $\max(m, n)$, and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix <i>A</i> and to go from the bidiagonal matrix to the singular value decomposition <i>U S VT</i> . For <i>watobd</i> , the following holds: $watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d)),$ where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation $mp = \text{numroc}(m, mb, \text{MYROW}, \text{desca}(\text{ctxt}_{}), \text{NPROW}),$ $nq = \text{numroc}(n, nb, \text{MYCOL}, \text{desca}(lld_), \text{NPCOL}),$ the workspaces required for the above subprograms are $wp?lange = mp,$ $wp?lared1d = nq,$ $wp?lared2d = mp,$ $wp?gebrd = nb * (mp + nq + 1) + nq,$ where <i>nq</i> and <i>mp</i> refer, respectively, to the values obtained at <i>MYCOL</i> = 0 and <i>MYROW</i> = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0): $watobd \leq nb * (mp + nq + 1) + nq.$ In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor. For <i>wbdtosvd</i> , the following holds: $wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$ where

`wantu(wantvt) = 1`, if left/right singular vectors are wanted, and
`wantu(wantvt) = 0`, otherwise. `w?bdsqr`, `wp?ormbrqln`, and `wp?ormbrprt`
refer respectively to the workspace required for the subprograms `?bdsqr`,
`p?ormbr(qln)`, and `p?ormbr(prt)`, where `qln` and `prt` are the values of the
arguments `vect`, `side`, and `trans` in the call to `p?ormbr`. `nru` is equal to the
local number of rows of the matrix U when distributed 1-dimensional
"column" of processes. Analogously, `ncvt` is equal to the local number of
columns of the matrix VT when distributed across 1-dimensional "row" of
processes. Calling the LAPACK procedure `?bdsqr` requires

`w?bdsqr = max(1, 2*size + (2*size - 4)* max(wantu, wantvt))`
on every processor. Finally,

`wp?ormbrqln = max((nb*(nb-1))/2, (sizeq+mp)*nb)+nb*nb,`

`wp?ormbrprt = max((mb*(mb-1))/2, (sizep+nq)*mb)+mb*mb,`

If `lwork = -1`, then `lwork` is global input and a workspace query is
assumed; the routine only calculates the minimum size for the work array.
The required workspace is returned as the first element of `work` and no
error message is issued by `xerbla`.

<code>rwork</code>	<code>REAL for pcgesvd</code> <code>DOUBLE PRECISION for pzgesvd</code> Workspace array of size $1 + 4*sizeb$. Not used for <code>psgesvd</code> and <code>pdgesvd</code> .
--------------------	--

Output Parameters

<code>a</code>	On exit, the contents of <code>a</code> are destroyed.
<code>s</code>	(global). <code>REAL for psgesvd</code> and <code>pcgesvd</code> <code>DOUBLE PRECISION for pdgesvd</code> and <code>pzgesvd</code> Array of size <code>size</code> . Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.
<code>u</code>	(local). <code>REAL for psgesvd</code> <code>DOUBLE PRECISION for pdgesvd</code> <code>COMPLEX for pcgesvd</code> <code>COMPLEX*16 for pzgesvd</code> local dimension (<code>mp, sizeq</code>), global dimension (<code>m, size</code>) If <code>jobu = 'V'</code> , <code>u</code> contains the first $\min(m, n)$ columns of U . If <code>jobu = 'N'</code> or <code>'O'</code> , <code>u</code> is not referenced.
<code>vt</code>	(local). <code>REAL for psgesvd</code> <code>DOUBLE PRECISION for pdgesvd</code> <code>COMPLEX for pcgesvd</code> <code>COMPLEX*16 for pzgesvd</code> local dimension (<code>sizep, nq</code>), global dimension (<code>size, n</code>)

If $\text{jobvt} = \text{'V'}$, vt contains the first size rows of V^T if $\text{jobu} = \text{'N'}$, vt is not referenced.

work On exit, if $\text{info} = 0$, then $\text{work}(1)$ returns the required minimal size of lwork .

rwork On exit, if $\text{info} = 0$, then $\text{rwork}(1)$ returns the required size of rwork .

info (global) INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} < 0$, If $\text{info} = -i$, the i th parameter had an illegal value.

If $\text{info} > 0$ i , then if ?bdsqr did not converge,

If $\text{info} = \min(m, n) + 1$, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

Description

The `p?sygsvx` routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * \mathbf{x} = \lambda * \text{sub}(B) * \mathbf{x}, \text{sub}(A)^\top * \mathbf{x} = \lambda * \mathbf{x}, \text{or } \text{sub}(B) * \text{sub}(A) * \mathbf{x} = \lambda * \mathbf{x}.$$

Here \mathbf{x} denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A_{(ia:ia+n-1, ja:ja+n-1)}$ is assumed to symmetric, and $\text{sub}(B)$ denoting $B_{(ib:ib+n-1, jb:jb+n-1)}$ is also positive definite.

Input Parameters

<code>ibtype</code>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <code>ibtype</code> = 1, the problem type is $\text{sub}(A) * \mathbf{x} = \lambda * \text{sub}(B) * \mathbf{x}$; If <code>ibtype</code> = 2, the problem type is $\text{sub}(A)^\top * \mathbf{x} = \lambda * \mathbf{x}$; If <code>ibtype</code> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * \mathbf{x} = \lambda * \mathbf{x}$.
<code>jobz</code>	(global) CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. If <code>jobz</code> = ' <code>N</code> ', then compute eigenvalues only. If <code>jobz</code> = ' <code>V</code> ', then compute eigenvalues and eigenvectors.
<code>range</code>	(global) CHARACTER*1. Must be ' <code>A</code> ' or ' <code>V</code> ' or ' <code>I</code> '. If <code>range</code> = ' <code>A</code> ', the routine computes all eigenvalues. If <code>range</code> = ' <code>V</code> ', the routine computes eigenvalues in the interval: [<code>vl</code> , <code>vu</code>] If <code>range</code> = ' <code>I</code> ', the routine computes eigenvalues with indices <code>il</code> through <code>iu</code> .
<code>uplo</code>	(global) CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. If <code>uplo</code> = ' <code>U</code> ', arrays <code>a</code> and <code>b</code> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <code>uplo</code> = ' <code>L</code> ', arrays <code>a</code> and <code>b</code> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.
<code>n</code>	(global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$, $n \geq 0$.
<code>a</code>	(local) REAL for <code>pssygvx</code> DOUBLE PRECISION for <code>pdsygvx</code> . Pointer into the local memory to an array of dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$. If <code>uplo</code> = ' <code>U</code> ', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A . If $desca(ctxt_)$ is incorrect, $p?sygsvx$ cannot guarantee correct error reporting.

b

(local). REAL for $pssygvx$

DOUBLE PRECISION for $pdsygvx$.

Pointer into the local memory to an array of dimension (lld_b , $LOCc(jb + n - 1)$). On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(B)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(B)$ contains the upper triangular part of the matrix.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.

ib, jb

(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix B . $descb(ctxt_)$ must be equal to $desca(ctxt_)$.

vl, vu

(global)

REAL for $pssygvx$

DOUBLE PRECISION for $pdsygvx$.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu

(global)

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If $range = 'A'$ or ' V' , il and iu are not referenced.

abstol

(global)

REAL for $pssygvx$

DOUBLE PRECISION for $pdsygvx$.

If $jobz='V'$, setting $abstol$ to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$abstol + \text{eps} * \max(|a|, |b|),$$

where eps is the machine precision. If $abstol$ is less than or equal to zero, then $\text{eps} * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{p?lamch('S')}$ not zero. If this routine returns with $((\text{mod}(\text{info}, 2) .ne. 0) .or. * (\text{mod}(\text{info}/8, 2) .ne. 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * \text{p?lamch('S')}$.

orfac

(global).

REAL for pssygvx

DOUBLE PRECISION for pdsvyvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of $1.0e-3$ is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global array Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix Z . *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

REAL for pssygvx

DOUBLE PRECISION for pdsvyvx.

Workspace array, dimension (*lwork*)

lwork

(local) INTEGER.

Dimension of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5 * n + \max(5 * nn, NB * (np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{ceil}(neig, \text{NPROW} * \text{NPCOL}) * nn.$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

*(clustersize-1)*n,*

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{ w(k) , . . . , w(k+clustersize-1) | w(j+1) ≤ w(j) +  
orfac*2*norm(A) }
```

Variable definitions:

neig = number of eigenvectors requested,

nb = *desca(mb_)* = *desca(nb_)* = *descz(mb_)* = *descz(nb_)*,

nn = *max(n, nb, 2),*

desca(rsrcc_) = *desca(nb_)* = *descz(rsrcc_)* = *descz(csrrc_)* = 0,

np0 = *numroc(nn, nb, 0, 0, NPROW),*

mq0 = *numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)*

ceil(x, y) is a ScaLAPACK function returning ceiling(*x/y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

lwork ≥ max(*lwork*, 5*n + *nsytrd_lwopt*, *nsygst_lwopt*), where

lwork, as defined previously, depends upon the number of eigenvectors requested, and

nsytrd_lwopt = *n* + 2*(*anb*+1)*(4*nps+2) + (*nps*+3)**nps*

nsygst_lwopt = 2**np0***nb* + *nq0***nb* + *nb***nb*

anb = *pjlaenv(desca(ctxt_), 3, p?sytrd ', 'L', 0, 0, 0, 0)*

sqrnpc = int(sqrt(db1e(NPROW * NPCOL)))

nps = max(numroc(*n*, 1, 0, 0, *sqrnpc*), 2**anb*)

NB = *desca(mb_)*

np0 = *numroc(n, nb, 0, 0, NPROW)*

nq0 = *numroc(n, nb, 0, 0, NPCOL)*

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.

For large n , no extra workspace is needed, however the biggest boost in performance comes for small n , so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If $clustersize \geq n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on a single processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

$iwork$

(local) INTEGER. Workspace array.

$liwork$

(local) INTEGER, dimension of $iwork$.

$liwork \geq 6 * nnp$

Where:

$nnp = \max(n, NPROW \cdot NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit,

If $jobz = 'V'$, and if $info = 0$, `sub(A)` contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows:

```
for ibtype = 1 or 2,  $Z^T * sub(B) * Z = i$ ;
for ibtype = 3,  $Z^T * inv(sub(B)) * Z = i$ .
```

If $jobz = 'N'$, then on exit the upper triangle (if $uplo='U'$) or the lower triangle (if $uplo='L'$) of `sub(A)`, including the diagonal, is destroyed.

b

On exit, if $info \leq n$, the part of `sub(B)` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^T * U$ or $\text{sub}(B) = L * L^T$.

m

(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global) INTEGER.

Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p?sygvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (m.le.descz(*n_*)) and sufficient workspace to compute them. (See *lwork* below.) p?sygvx is always able to detect insufficient space without computation unless *range.eq.*'V'.

w

(global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Array, size (*n*). On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z

(local).

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

global dimension (*n*, *n*), local dimension (lld_z, locc(jz+n-1)).

If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work

If *jobz*='N' *work*(1) = optimal amount of workspace required to compute eigenvalues efficiently

If *jobz* = 'V' *work*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

ifail

(global) INTEGER.

Array, size (*n*).

ifail provides additional information when *info.ne.0*

If (mod(*info*/16, 2).ne.0) then *ifail*(1) indicates the order of the smallest minor which is not positive definite. If (mod(*info*, 2).ne.0) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and *jobz* = 'V', then the first *m* elements of *ifail* are set to zero.

iclustr

(global) INTEGER.

Array, size $(2 * \text{NPROW} * \text{NPCOL})$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*($2*i-1$) to *iclustr*($2*i$), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr()* is a zero terminated array.

$(\text{iclustr}(2*k) .ne. 0 .and. \text{iclustr}(2*k+1) .eq. 0)$ if and only if k is the number of clusters *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pssygvx

DOUBLE PRECISION for pdsgvxx.

Array, size $(\text{NPROW} * \text{NPCOL})$. This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n) / \text{gap}(i)$, where C is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the i -th argument is an array and the j -entry had an illegal value, then *info* = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) .ne. 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(\text{info}, 2, 2) .ne. 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) .ne. 0)$, then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *. The number of eigenvectors computed is returned in *nz*.*

If $(\text{mod}(\text{info}/8, 2) .ne. 0)$, then p?stebz failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2) .ne. 0)$, then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

p?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

Description

The p?hegvx routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$\text{sub}(A) \cdot x = \lambda \cdot \text{sub}(B) \cdot x, \quad \text{sub}(A) \cdot \text{sub}(B) \cdot x = \lambda \cdot x, \quad \text{or} \quad \text{sub}(B) \cdot \text{sub}(A) \cdot x = \lambda \cdot x.$$

Here $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ are assumed to be Hermitian and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

ibtype (global) INTEGER. Must be 1 or 2 or 3.

Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is

$$\text{sub}(A) \cdot x = \lambda \cdot \text{sub}(B) \cdot x;$$

If *ibtype* = 2, the problem type is

$$\text{sub}(A) \cdot \text{sub}(B) \cdot x = \lambda \cdot x;$$

If *ibtype* = 3, the problem type is

$$\text{sub}(B) \cdot \text{sub}(A) \cdot x = \lambda \cdot x.$$

jobz (global) CHARACTER*1. Must be 'N' or 'V'.

If *jobz* ='N', then compute eigenvalues only.

If *jobz* ='V', then compute eigenvalues and eigenvectors.

<i>range</i>	(global) CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [<i>vl</i> , <i i="" vu<="">] If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.</i>
<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of sub(<i>A</i>) and sub(<i>B</i>); If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of sub(<i>A</i>) and sub(<i>B</i>).
<i>n</i>	(global) INTEGER. The order of the matrices sub(<i>A</i>) and sub (<i>B</i>) (<i>n</i> ≥ 0).
<i>a</i>	(local) COMPLEX for pchegvx DOUBLE COMPLEX for pzhegvx. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> Hermitian distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?hegsv cannot guarantee correct error reporting.
<i>b</i>	(local). COMPLEX for pchegvx DOUBLE COMPLEX for pzhegvx. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> Hermitian distributed matrix sub(<i>B</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>B</i>) contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) INTEGER.

The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) INTEGER array, dimension ($dlen_$).

The array descriptor for the distributed matrix B . $descb(ctxt_)$ must be equal to $desca(ctxt_)$.

vl, vu

(global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu

(global)

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

(global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

If $jobz='V'$, setting $abstol$ to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$abstol + eps * \max(|a|, |b|)$,

where eps is the machine precision. If $abstol$ is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $((\text{mod}(info, 2) .ne. 0) .or. * (\text{mod}(info/8, 2) .ne. 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * p?lamch('S')$.

orfac

(global).

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see $lwork$), tol may be decreased until all eigenvectors to be

reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

COMPLEX for *pchegvx*

DOUBLE COMPLEX for *pzhegvx*.

Workspace array, dimension (*lwork*)

lwork

(local).

INTEGER. The dimension of the array *work*.

If only eigenvalues are requested:

lwork $\geq n + \max(NB * (np0 + 1), 3)$

If eigenvectors are requested:

lwork $\geq n + (np0 + mq0 + NB) * NB$

with *mq0* = *numroc(nn, NB, 0, 0, NPCOL)*.

For optimal performance, greater workspace is needed, that is

lwork $\geq \max(lwork, n, nhetrdr_lwopt, nhegst_lwopt)$

where *lwork* is as defined above, and

nhetrdr_lwork = $2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps;$

nhegst_lwopt = $2 * np0 * nb + mq0 * nb + nb * nb$

nb = *desca(mb_)*

np0 = *numroc(n, nb, 0, 0, NPROW)*

mq0 = *numroc(n, nb, 0, 0, NPCOL)*

ictxt = *desca(ctxt_)*

anb = *pjlaenv(ictxt, 3, 'p?hetrd', 'L', 0, 0, 0, 0)*

sqrnpc = *sqrt(dble(NPROW * NPCOL))*

nps = *max(numroc(n, 1, 0, 0, sqnpc), 2 * anb)*

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pixerbla.

rwork

(local)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Workspace array, size (*lrwork*).*lrwork*(local) INTEGER. The dimension of the array *rwork*.See below for definitions of variables used to define *lrwork*.If no eigenvectors are requested (*jobz* = 'N'), then *lrwork* $\geq 5*nn+4*n$ If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:*lrwork* $\geq 4*n + \max(5*nn, np0*mq0) + \text{ceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$ The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lrwork*:*(clustersize-1)*n*,where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:{*w(k), ..., w(k+clustersize-1)* | *w(j+1) ≤ w(j)+orfac*2*norm(A)*}

Variable definitions:

neig = number of eigenvectors requested;*nb* = *desca(mb_)* = *desca(nb_)* = *descz(mb_)* = *descz(nb_)*;*nn* = *max(n, nb, 2)*;*desca(rsra_)* = *desca(nb_)* = *descz(rsra_)* = *descz(csra_)* = 0 ;*np0* = *numroc(nn, nb, 0, 0, NPROW)*;*mq0* = *numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)*;*ceil(x, y)* is a ScaLAPACK function returning ceiling(*x/y*).When *lwork* is too small:If *lwork* is too small to guarantee orthogonality, p?hegvx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range='V'*, p?hegvx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range='V'* and as long as *lwork* is large enough to allow p?hegvx to compute the eigenvalues, p?hegvx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If $\text{clustersize} > n/\sqrt{(\text{NPROW} \times \text{NPCOL})}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $\text{clustersize} = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $\text{clustersize} = n/\sqrt{(\text{NPROW} \times \text{NPCOL})}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $\text{clustersize} > n/\sqrt{(\text{NPROW} \times \text{NPCOL})}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $\text{lwork} = -1$, then liwork is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pixerbla`.

$iwork$

(local) INTEGER. Workspace array.

$liwork$

(local) INTEGER, dimension of $iwork$.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

a

On exit, if $\text{jobz} = 'V'$, then if $\text{info} = 0$, `sub(A)` contains the distributed matrix Z of eigenvectors.

The eigenvectors are normalized as follows:

If $\text{ibtype} = 1$ or 2 , then $Z^H * \text{sub}(B) * Z = i$;

If $\text{ibtype} = 3$, then $Z^H * \text{inv}(\text{sub}(B)) * Z = i$.

If $\text{jobz} = 'N'$, then on exit the upper triangle (if $\text{uplo}='U'$) or the lower triangle (if $\text{uplo}='L'$) of `sub(A)`, including the diagonal, is destroyed.

b

On exit, if $\text{info} \leq n$, the part of `sub(B)` containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^H * U$, or $\text{sub}(B) = L * L^H$.

m

(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global) INTEGER. Total number of eigenvectors computed. $0 < nz < m$. The number of columns of z that are filled.

If $\text{jobz} \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and p?hegvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z (m. i.e. $descz(n_)$) and sufficient workspace to compute them. (See $lwork$ below.) The routine p?hegvx is always able to detect insufficient space without computation unless $range = 'V'$.

w

(global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Array, size (n). On normal exit, the first m entries contain the selected eigenvalues in ascending order.*z*

(local).

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

global dimension (n, n), local dimension ($lld_z, locc(jz+n-1)$).If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.If $jobz = 'N'$, then z is not referenced.*work*On exit, $work(1)$ returns the optimal amount of workspace.*rwork*On exit, $rwork(1)$ contains the amount of workspace required for optimal efficiencyIf $jobz='N'$ $rwork(1) =$ optimal amount of workspace required to compute eigenvalues efficientlyIf $jobz='V'$ $rwork(1) =$ optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.If $range='V'$, it is assumed that all eigenvectors may be required when computing optimal workspace.*ifail*

(global) INTEGER.

Array, size (n).*ifail* provides additional information when $info.ne.0$ If $(mod(info/16,2).ne.0)$, then $ifail(1)$ indicates the order of the smallest minor which is not positive definite.If $(mod(info,2).ne.0)$ on exit, then $ifail(1)$ contains the indices of the eigenvectors that failed to converge.If neither of the above error conditions are held, and $jobz = 'V'$, then the first m elements of $ifail$ are set to zero.*iclustr*

(global) INTEGER.

Array, size $(2 * \text{NPROW} * \text{NPCOL})$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*($2*i-1$) to *iclustr*($2*i$), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array. (*iclustr*($2*k$).ne.

$0.\text{and}. \text{clustr}(2*k+1).\text{eq.}0$) if and only if k is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

REAL for *pchegvx*

DOUBLE PRECISION for *pzhegvx*.

Array, size $(\text{NPROW} * \text{NPCOL})$.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n) / \text{gap}(i)$, where C is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the i -th argument is an array and the j -entry had an illegal value, then *info* = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If $(\text{mod}(\text{info}, 2).\text{ne.}0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(\text{info}, 2, 2).\text{ne.}0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2).\text{ne.}0)$, then space limit prevented *p?sygvyx* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2).\text{ne.}0)$, then *p?stebz* failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2).\text{ne.}0)$, then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary, Utility, and Redistribution/Copy Routines

5

This chapter describes the Intel® Math Kernel Library implementation of ScaLAPACK [Auxiliary Routines](#), [Utility Functions and Routines](#), and [Matrix Redistribution/Copy Routines](#). The library includes routines for both real and complex data.

NOTE

ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Routine naming conventions, mathematical notation, and matrix storage schemes used for ScaLAPACK auxiliary and utility routines are the same as described in previous chapters. Some routines and functions may have combined character codes, such as `sc` or `dz`. For example, the routine `psum1` uses a complex input array and returns a real value.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Auxiliary Routines

ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
b?laapp	s, d	Multiplies a matrix with an orthogonal matrix.
b?laexc	s, d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
b?treqc	s, d	Reorders the Schur factorization of a general matrix.
p?lacgv	c, z	Conjugates a complex vector.
p?max1	c, z	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>pamax</code> , but using the absolute value to the real part).
pmpcol	s, d	<i>Finds the collaborators of a process.</i>
pmpim2	s, d	Computes the eigenpair range assignments for all processes.

Routine Name	Data Types	Description
?combamax1	c, z	Finds the element with maximum real part absolute value and its corresponding global index.
p?sum1	sc, dz	Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.
p?dbtrsv	s, d, c, z	Computes an LU factorization of a general tridiagonal matrix with no pivoting. The routine is called by p?dbtrs.
p?dttrsv	s, d, c, z	Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrs.
p?gebal	s, d	Balances a general real matrix.
p?gebd2	s, d, c, z	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
p?gehd2	s, d, c, z	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
p?gelq2	s, d, c, z	Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).
p?geql2	s, d, c, z	Computes a QL factorization of a general rectangular matrix (unblocked algorithm).
p?geqr2	s, d, c, z	Computes a QR factorization of a general rectangular matrix (unblocked algorithm).
p?gerq2	s, d, c, z	Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).
p?getf2	s, d, c, z	Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s, d, c, z	Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s, d	Looks for two consecutive small subdiagonal elements.
p?lacp2	s, d, c, z	Copies all or part of a distributed matrix to another distributed matrix.
p?lacp3	s, d	Copies from a global parallel array into a local replicated array or vice versa.
p?lacpy	s, d, c, z	Copies all or part of one two-dimensional array to another.
p?laevswp	s, d, c, z	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
p?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Routine Name	Data Types	Description
p?laect	s, d, c, z	Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).
p?lamve	s, d	Copies all or part of one two-dimensional distributed array to another.
p?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
p?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
p?lansy, p?lanhe	s, d, c, z/c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
p?lantr	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
p?lapiv	s, d, c, z	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
p?laqge	s, d, c, z	Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.
p?laqr0	s, d	Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.
p?laqr1	s, d	Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.
p?laqr2	s, d	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
p?laqr3	s, d	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
p?laqr4	s, d	Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition.
p?laqr5	s, d	Performs a single small-bulge multi-shift QR sweep.
p?laqsy	s, d, c, z	Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.
p?lared1d	s, d	Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> .
p?lared2d	s, d	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
p?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.

Routine Name	Data Types	Description
p?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	c, z	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
p?larft	s, d, c, z	Forms the triangular vector T of a block reflector $H=I-VT\bar{V}^H$
p?larz	s, d, c, z	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	c, z	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzt	s, d, c, z	Forms the triangular factor T of a block reflector $H=I-VT\bar{V}^H$ as returned by p?tzrzf.
p?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as $C_{\text{to}}/C_{\text{from}}$.
p?laset	s, d, c, z	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β .
p?lasmsub	s, d	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
p?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
p?latra	s, d, c, z	Computes the trace of a general square distributed matrix.
p?latrd	s, d, c, z	Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	s, d, c, z	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices (local unblocked algorithm).
p?laum	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices.
p?lawil	s, d	Forms the Wilkinson transform.
p?org2l/p?ung2l	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).
p?org2r/p?ung2r	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).

Routine Name	Data Types	Description
p?orgr2/p?ungr2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?orm2l/p?unm2l	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).
p?orm2r/p?unm2r	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqr (unblocked algorithm).
p?orml2/p?unml2	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?pbtrs	s, d, c, z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.
p?pttrs	s, d, c, z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.
p?potf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rot	s, d	Applies a planar rotation to two distributed vectors.
p?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
p?systs2/p?hegs2	s, d, c, z	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?syt2/p?hetd2	s, d, c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trord	s, d	Reorders the Schur factorization of a general matrix.
p?trsen	s, d	Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.
p?trti2	s, d, c, z	Computes the inverse of a triangular matrix (local unblocked algorithm).
?lamsh	s, d	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laqr6	s, d	Performs a single small-bulge multi-shift QR sweep collecting the transformations.
?lar1va	s, d	<i>Computes scaled eigenvector corresponding to given eigenvalue.</i>
?laref	s, d	Applies Householder reflectors to matrices on either their rows or columns.
?larrb2	s, d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrd2	s, d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Routine Name	Data Types	Description
?larre2	s, d	Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.
?larre2a	s, d	<i>Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.</i>
?larrf2	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrv2	s, d	Computes the eigenvectors of the tridiagonal matrix $T = L^*D*L^T$ given L , D and the eigenvalues of L^*D*L^T .
?lasorte	s, d	Sorts eigenpairs by real and complex data types.
?lasrt2	s, d	Sorts numbers in increasing or decreasing order.
?stegr2	s, d	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
?stegr2a	s, d	Computes selected eigenvalues and initial representations needed for eigenvector computations.
?stegr2b	s, d	From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.
?stein2	s, d	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
?dbtf2	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).
?dbtrf	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).
?dttrf	s, d, c, z	Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
?dttrsv	s, d, c, z	Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.
?pttrsv	s, d, c, z	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by ?pttrf.
?steqr2	s, d	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

b?laapp*Multiplies a matrix with an orthogonal matrix.***Syntax****Fortran:**

```
call bslaapp( iside, m, n, nb, a, lda, nitraf, itraf, dtraf, work )
call bdlaapp( iside, m, n, nb, a, lda, nitraf, itraf, dtraf, work )
```

Include Files

- C: mkl_scalapack.h

Description

b?laapp computes

$$B = Q^T A \text{ or } B = A Q$$

where A is an m -by- n matrix and Q is an orthogonal matrix represented by the parameters in the arrays *itraf* and *dtraf* as described in [b?trexc](#).

This is an auxiliary routine called by [p?trord](#).

Input Parameters

<i>iside</i>	INTEGER	Specifies whether Q multiplies A from the left or right as follows: = 0: compute $B = Q^T A$; = 1: compute $B = A Q$.
<i>m</i>	INTEGER	The number of rows of A .
<i>n</i>	INTEGER	The number of columns of A .
<i>nb</i>	INTEGER	If <i>iside</i> = 0, the Q is applied block column-wise to the rows of A and <i>nb</i> specifies the maximal width of the block columns. If <i>iside</i> = 1, this variable is not referenced.
<i>a</i>	REAL for bslaapp DOUBLE PRECISION for bdlaapp	Array, dimension (<i>lda</i> , <i>n</i>) On entry, the matrix A .
<i>lda</i>	INTEGER	The leading dimension of the array <i>a</i> . <i>lda</i> $\geq \max(1,n)$.
<i>nitraf</i>	INTEGER	Length of the array <i>itraf</i> . <i>nitraf</i> ≥ 0 .
<i>itraf</i>	INTEGER array, length <i>nitraf</i>	List of parameters for representing the transformation matrix Q , see b?trexc .
<i>work</i>	(workspace) REAL array, dimension (<i>n</i>)	

OUTPUT Parameters

<i>a</i>	<i>a</i> is overwritten by <i>B</i> .
<i>dtraf</i>	REAL for bslaapp DOUBLE PRECISION for bdlaapp
	Array, length <i>k</i> . If <i>iside</i> =0, <i>k</i> = 3*(<i>n</i> / <i>nb</i>). If <i>iside</i> =1, <i>k</i> = 3* <i>nitrif</i> .
	List of parameters for representing the transformation matrix <i>Q</i> , see b?trexc

b?laexc

Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

Fortran:

```
call bslaexc( n, t, ldt, j1, n1, n2, itraf, dtraf, work, info )
call bdlaexc( n, t, ldt, j1, n1, n2, itraf, dtraf, work, info )
```

Include Files

- C: mkl_scalapack.h

Description

`b?laexc` swaps adjacent diagonal blocks T_{11} and T_{22} of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

In contrast to the LAPACK routine `?laexc`, the orthogonal transformation matrix Q is not explicitly constructed but represented by parameters contained in the arrays *itraf* and *dtraf*. See the description of [b?trexc](#) for more details.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

<i>n</i>	INTEGER The order of the matrix T . $n \geq 0$.
<i>t</i>	REAL for bslaexc DOUBLE PRECISION for bdlaexc Array, dimension (<i>ldt,n</i>) The upper quasi-triangular matrix T , in Schur canonical form.
<i>ldt</i>	INTEGER

The leading dimension of the array t . $\text{ldt} \geq \max(1, n)$.

j1 INTEGER

The index of the first row of the first block T_{11} .

n1 INTEGER

The order of the first block T_{11} . $n1 = 0, 1$ or 2 .

n2 INTEGER

The order of the second block T_{22} . $n2 = 0, 1$ or 2 .

work REAL for bsblaexc

DOUBLE PRECISION for bdlaexc

(Workspace) array, dimension (n)

OUTPUT Parameters

t The updated matrix T , in Schur canonical form.

itraf INTEGER array, length k , where

$k = 1$, if $n1+n2 = 2$;

$k = 2$, if $n1+n2 = 3$;

$k = 4$, if $n1+n2 = 4$.

List of parameters for representing the transformation matrix Q , see [b?trexc](#).

dtraf REAL for bsblaexc

DOUBLE PRECISION for bdlaexc

Array, length k , where

$k = 2$, if $n1+n2 = 2$;

$k = 5$, if $n1+n2 = 3$;

$k = 10$, if $n1+n2 = 4$.

List of parameters for representing the transformation matrix Q , see [b?trexc](#).

info INTEGER

= 0: successful exit

= 1: the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

b?trexc

Reorders the Schur factorization of a general matrix.

Syntax

Fortran:

```
call bstrexc( n, t, ldt, ifst, ilst, nitraf, itraf, ndtraf, dtraf, work, info )
call bdtrexc( n, t, ldt, ifst, ilst, nitraf, itraf, ndtraf, dtraf, work, info )
```

Include Files

- C: mkl_scalapack.h

Description

`b?trexc` reorders the real Schur factorization of a real matrix $A = Q * T * Q^T$, so that the diagonal block of T with row index `ifst` is moved to row `ilst`.

The real Schur form T is reordered by an orthogonal similarity transformation $Z^T * T * Z$. In contrast to the LAPACK routine `?trexc`, the orthogonal matrix Z is not explicitly constructed but represented by parameters contained in the arrays `itraf` and `dtraf`. See Application Notes for further details.

T must be in Schur canonical form (as returned by `?hseqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

<code>n</code>	INTEGER	
		The order of the matrix T . $n \geq 0$.
<code>t</code>	REAL for <code>bstrexc</code> DOUBLE PRECISION for <code>bdtrexc</code>	
		Array, dimension (<code>ldt,n</code>)
		The upper quasi-triangular matrix T , in Schur canonical form.
<code>ldt</code>	INTEGER	
		The leading dimension of the array <code>t</code> . $ldt \geq \max(1,n)$.
<code>ifst, ilst</code>	INTEGER	
		Specify the reordering of the diagonal blocks of T . The block with row index <code>ifst</code> is moved to row <code>ilst</code> , by a sequence of transpositions between adjacent blocks.
<code>nitraf</code>	INTEGER	
		Length of the array <code>itraf</code> .
		As a minimum requirement, $nitraf \geq \max(1, ilst-ifst)$.
		If there are 2-by-2 blocks in <code>t</code> then <code>nitraf</code> must be larger; a safe choice is $nitraf \geq \max(1,2* ilst-ifst)$.
<code>ndtraf</code>	INTEGER	
		Length of the array <code>dtraf</code> .
		As a minimum requirement, $ndtraf \geq \max(1,2* ilst-ifst)$.
		If there are 2-by-2 blocks in <code>t</code> then <code>ndtraf</code> must be larger; a safe choice is $ndtraf \geq \max(1,5* ilst-ifst)$.
<code>work</code>	REAL for <code>bstrexc</code>	

DOUBLE PRECISION for bdtrexc
 (Workspace) array, dimension (n)

OUTPUT Parameters

t	On exit, the reordered upper quasi-triangular matrix, in Schur canonical form.
$ifst, ilst$	If $ifst$ pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; $ilst$ always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). $1 \leq ifst \leq n; 1 \leq ilst \leq n.$
$nitraf$	Actual length of the array $itraf$.
$itraf$	INTEGER array, length $nitraf$ List of parameters for representing the transformation matrix Z . See Application Notes for further details.
$ndtraf$	Actual length of the array $dtraf$.
$dtraf$	REAL for bstrexc DOUBLE PRECISION for bdtrexc Array, length $ndtraf$ List of parameters for representing the transformation matrix Z . See Application Notes for further details.
$info$	INTEGER = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value = 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); t may have been partially reordered, and $ilst$ points to the first row of the current position of the block being moved. = 2: the 2 by 2 block to be reordered split into two 1 by 1 blocks and the second block failed to swap with an adjacent block. $ilst$ points to the first row of the current position of the whole block being moved.

Application Notes

The orthogonal transformation matrix Z is a product of $nitraf$ elementary orthogonal transformations. The parameters defining these transformations are stored in the arrays $itraf$ and $dtraf$ as follows:

Consider the i -th transformation acting on rows/columns $pos, pos+1, \dots$ If this transformation is

- a Givens rotation with cosine c and sine s then

$$itraf(i) = pos, dtraf(i) = c, dtraf(i+1) = s;$$

- a Householder reflector $H = I - \tau * v * v'$ with $v = [1; v2; v3]$ then

$$itraf(i) = n + pos, dtraf(i) = \tau, dtraf(i+1) = v2, dtraf(i+2) = v3;$$

- a Householder reflector $H = I - \tau * v * v'$ with $v = [v1; v2; 1]$ then

$$itraf(i) = 2*n + pos, dtraf(i) = v1, dtraf(i+1) = v2, dtraf(i+2) = \tau;$$

Note that the parameters in *dtraf* are stored consecutively.

p?lacgv

Conjugates a complex vector.

Syntax

Fortran:

```
call pclacgv(n, x, ix, jx, descx, incx)
call pzlacgv(n, x, ix, jx, descx, incx)
```

C:

```
void pclacgv (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pzlacgv (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lacgv routine conjugates a complex vector $\text{sub}(x)$ of length n , where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix:ix+n-1, jx)$ if $\text{incx} = 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of the distributed vector $\text{sub}(x)$.
<i>x</i>	(local). COMPLEX for pclacgv COMPLEX*16 for pzlacgv. Pointer into the local memory to an array of size $(\text{lld}_x, *)$. On entry the vector to be conjugated $x(i) = X(ix + (jx-1)*m_x + (i-1)*\text{incx})$, $1 \leq i \leq n$.
<i>ix</i>	(global) INTEGER. The row index in the global array x indicating the first row of $\text{sub}(x)$.
<i>jx</i>	(global) INTEGER. The column index in the global array x indicating the first column of $\text{sub}(x)$.
<i>descx</i>	(global and local) INTEGER. Array, size (<i>dlen_</i>). The array descriptor for the distributed matrix X .
<i>incx</i>	(global) INTEGER. The global increment for the elements of X . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	(local).
----------	----------

On exit, the conjugated vector.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS pamax, but using the absolute value to the real part).

Syntax

Fortran:

```
call pcmax1(n, amax, indx, x, ix, jx, descx, incx)
call pzmax1(n, amax, indx, x, ix, jx, descx, incx)
```

C:

```
void pcmax1 (MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , MKL_Complex8 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
void pzmax1 (MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , MKL_Complex16 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_scalapack.h

Description

The p?max1 routine computes the global index of the maximum element in absolute value of a distributed vector sub(x). The global index is returned in *indx* and the value is returned in *amax*, where sub(x) denotes $X(ix:ix+n-1, jx)$ if *incx* = 1, $X(ix, jx:jx+n-1)$ if *incx* = *m_x*.

Input Parameters

<i>n</i>	(global) pointer to INTEGER. The number of components of the distributed vector sub(x). $n \geq 0$.
<i>x</i>	(local) COMPLEX for pcmax1. COMPLEX*16 for pzmax1 Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x+ix+(n-1)*abs(incx))$. This array contains the entries of the distributed vector sub(x).
<i>ix</i>	(global) INTEGER. The row index in the global array X indicating the first row of sub(x).
<i>jx</i>	(global) INTEGER. The column index in the global array X indicating the first column of sub(x)
<i>descx</i>	(global and local) INTEGER. Array, size (<i>dlen_</i>). The array descriptor for the distributed matrix X.

incx (global) INTEGER. The global increment for the elements of X. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

amax (global output) pointer to REAL. The absolute value of the largest entry of the distributed vector sub(x) only in the scope of sub(x).

indx (global output) pointer to INTEGER. The global index of the element of the distributed vector sub(x) whose real part has maximum absolute value.

pmpcol

Finds the collaborators of a process.

Syntax

Fortran:

```
call pmpcol( myproc, nprocs, iil, needil, neediu, pmyils, pmyius, colbrt, frstcl,
lastcl )
```

Include Files

- C: mkl_scalapack.h

Description

Using the output from [pmpim2](#) and given the information on eigenvalue clusters, pmpcol finds the collaborators of *myproc*.

Input Parameters

myproc INTEGER
The processor number, $0 \leq \text{myproc} < \text{nprocs}$.

nprocs INTEGER
The total number of processors available.

iil INTEGER
The index of the leftmost eigenvalue in the eigenvalue cluster.

needil INTEGER
The leftmost position in the eigenvalue cluster needed by *myproc*.

neediu INTEGER
The rightmost position in the eigenvalue cluster needed by *myproc*.

pmyils INTEGER array
For each processor p , *pmyils*(p) is the index of the first eigenvalue in the eigenvalue cluster to be computed.
pmyils(p) equals zero if p stays idle.

pmyius INTEGER array
 For each processor p , $pmyius(p)$ is the index of the last eigenvalue in the eigenvalue cluster to be computed.
 $pmyius(p)$ equals zero if p stays idle.

OUTPUT Parameters

colbrt LOGICAL
 TRUE if $myproc$ collaborates.

frstcl, lastcl INTEGER
 First and last collaborator of $myproc$.
 $myproc$ collaborates with:
 $frstcl, \dots, myproc-1, myproc+1, \dots, lastcl$
 If $myproc = frstcl$, there are no collaborators on the left. If $myproc = lastcl$, there are no collaborators on the right.
 If $frstcl = 0$ and $lastcl = nprocs-1$, then $myproc$ collaborates with everybody

pmpim2

Computes the eigenpair range assignments for all processes.

Syntax

Fortran:

```
call pmpim2( il, iu, nprocs, pmyils, pmyius )
```

Include Files

- C: mkl_scalapack.h

Description

pmpim2 is the scheduling subroutine. It computes for all processors the eigenpair range assignments.

Input Parameters

il, iu INTEGER
 The range of eigenpairs to be computed.

nprocs INTEGER
 The total number of processors available.

Output Parameters

pmyils INTEGER array
 For each processor p , $pmyils(p)$ is the index of the first eigenvalue in a cluster to be computed.

$pmyils(p)$ equals zero if p stays idle.

$pmyius$

INTEGER array

For each processor p , $pmyius(p)$ is the index of the last eigenvalue in a cluster to be computed.

$pmyius(p)$ equals zero if p stays idle.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

Fortran:

```
call ccombamax1(v1, v2)
call zcombamax1(v1, v2)
```

C:

```
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2 );
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2 );
```

Include Files

- C: mkl_scalapack.h

Description

The ?combamax1 routine finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

v1

(local)

COMPLEX for ccombamax1

COMPLEX*16 for zcombamax1

Array, size 2. The first maximum absolute value element and its global index. $v1(1)=amax$, $v1(2)=indx$.

v2

(local)

COMPLEX for ccombamax1

COMPLEX*16 for zcombamax1

Array, size 2. The second maximum absolute value element and its global index. $v2(1)=amax$, $v2(2)=indx$.

Output Parameters

v1

(local).

The first maximum absolute value element and its global index.

$v1(1)=amax$, $v1(2)=indx$.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.

Syntax

Fortran:

```
call pscsum1(n, asum, x, ix, jx, descx, incx)
call pdzsum1(n, asum, x, ix, jx, descx, incx)
```

C:

```
void pscsum1 (MKL_INT *n , float *asum , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdzsum1 (MKL_INT *n , double *asum , MKL_Complex16 *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_scalapack.h

Description

The p?sum1 routine returns the sum of absolute values of a complex distributed vector sub(*x*) in *asum*, where sub(*x*) denotes $X(ix:ix+n-1, jx:jx)$, if *incx* = 1, $X(ix:ix, jx:jx+n-1)$, if *incx* = *m_x*.

Based on p?asum from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

<i>n</i>	(global) pointer to INTEGER. The number of components of the distributed vector sub(<i>x</i>). $n \geq 0$.
<i>x</i>	(local) COMPLEX for pscsum1 COMPLEX*16 for pdzsum1. Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x+ix+(n-1)*abs(incx))$. This array contains the entries of the distributed vector sub (<i>x</i>).
<i>ix</i>	(global) INTEGER. The row index in the global array <i>X</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) INTEGER. The column index in the global array <i>X</i> indicating the first column of sub(<i>x</i>)
<i>descx</i>	(local) INTEGER. Array, size 9. The array descriptor for the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>X</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> .

Output Parameters

<i>asum</i>	(local)
-------------	---------

Pointer to `REAL`. The sum of absolute values of the distributed vector $\text{sub}(x)$ only in its scope.

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The routine is called by p?dbtrs.

Syntax

Fortran:

```
call psdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

C:

```
void psdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );

void pddbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16
*work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?dbtrsv` routine solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ (for real flavors); } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ (for complex flavors),}$$

where $A(1 :n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code `PD@ (dom_pre) BTRF` and is stored in $A(1 :n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1 :n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`, and the choice of solving $A(1 :n, ja:ja+n-1)$ or $A(1 :n, ja:ja+n-1)^T$ is dictated by the user by the parameter `trans`.

Routine `p?dbtrf` must be called first.

Input Parameters

<code>uplo</code>	(global) CHARACTER. If <code>uplo='U'</code> , the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <code>uplo = 'L'</code> , the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>trans</code>	(global) CHARACTER. If <code>trans = 'N'</code> , solve with $A(1:n, ja:ja+n-1)$, if <code>trans = 'C'</code> , solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix A ; ($n \geq 0$).
<code>bwl</code>	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
<code>bwu</code>	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
<code>a</code>	(local). REAL for <code>psdbtrsv</code> DOUBLE PRECISION for <code>pddbtrsv</code> COMPLEX for <code>pcdbtrsv</code> COMPLEX*16 for <code>pzdbtrsv</code> . Pointer into the local memory to an array with first size $l/d_a \geq (bwl + bwu + 1)$ (stored in <code>desca</code>). On entry, this array contains the local pieces of the n -by- n unsymmetric banded distributed Cholesky factor L or $L^T * A(1 :n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<code>ja</code>	(global) INTEGER. The index in the global array <code>a</code> that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<code>desca</code>	(global and local) INTEGER array of size (<code>dlen_</code>). if 1d type (<code>dtype_a = 501</code> or <code>502</code>), <code>dlen \geq 7</code> ; if 2d type (<code>dtype_a = 1</code>), <code>dlen \geq 9</code> . The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
<code>b</code>	(local) REAL for <code>psdbtrsv</code> DOUBLE PRECISION for <code>pddbtrsv</code>

COMPLEX for pcdbtrsv

COMPLEX*16 for pzdbtrsv.

Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$.

ib (global) INTEGER. The row index in the global array *b* that points to the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb (global and local) INTEGER array of size (*dlen_*).
 if 1d type (*dtype_b* = 502), *dlen* ≥ 7 ;
 if 2d type (*dtype_b* = 1), *dlen* ≥ 9 . The array descriptor for the distributed matrix *B*. Contains information of mapping *B* to memory.

laf (local)
 INTEGER. Size of user-input Auxiliary Filling space *af*.
laf must be $\geq nb * (bwl + bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$. If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

work (local).
 REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv
 COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.
 Temporary workspace. This space may be overwritten in between calls to routines.
work must be the size given in *lwork*.

lwork (local or global) INTEGER.
 Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.
 $lwork \geq \max(bwl, bwu) * nrhs$.

Output Parameters

a (local).
 This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

b On exit, this contains the local piece of the solutions distributed matrix *X*.

af (local).
 REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv

COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.

Auxiliary Filling Space. Filling is created during the factorization routine p?dbtrf and this is stored in af. If a linear system is to be solved using p?dbtrf after the factorization routine, af must not be altered after the factorization.

work

On exit, work(1) contains the minimal lwork.

info

(local).

INTEGER. If info = 0, the execution is successful.

< 0: If the i-th argument is an array and the j-entry had an illegal value, then info = - (i*100+j), if the i-th argument is a scalar and had an illegal value, then info = -i.

p?dttrs

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges.
 The routine is called by p?dttrs.

Syntax

Fortran:

```
call psdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

C:

```
void psdttrs (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pddttrs (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdttrs (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8

MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?dttrs` routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ for real flavors; $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code `PS@(dom_pre)TTRF` and is stored in $A(1:n, ja:ja+n-1)$ and af .

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter `trans`.

Routine `p?dttrf` must be called first.

Input Parameters

`uplo`

(global) CHARACTER.

If `uplo='U'`, the upper triangle of $A(1:n, ja:ja+n-1)$ is stored,
if `uplo = 'L'`, the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

`trans`

(global) CHARACTER.

If `trans = 'N'`, solve with $A(1:n, ja:ja+n-1)$,
if `trans = 'C'`, solve with conjugate transpose $A(1:n, ja:ja+n-1)$.

`n`

(global) INTEGER. The order of the distributed submatrix A ; ($n \geq 0$).

`nrhs`

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. ($nrhs \geq 0$).

`d1`

(local).

REAL for `psdttrs`
DOUBLE PRECISION for `pddttrs`
COMPLEX for `pcdttrs`
COMPLEX*16 for `pzdttrs`.

Pointer to local part of global vector storing the lower diagonal of the matrix.

Globally, `d1(1)` is not referenced, and `d1` must be aligned with `d`.

Must be of size $\geq \text{desca}(\text{nb}__)$.

`d`

(local).

REAL for `psdttrs`
DOUBLE PRECISION for `pddttrs`
COMPLEX for `pcdttrs`

COMPLEX*16 **for** pzdttrs.

Pointer to local part of global vector storing the main diagonal of the matrix.

du
(local).

REAL **for** psdttrs
DOUBLE PRECISION **for** pddttrs
COMPLEX **for** pcdttrs
COMPLEX*16 **for** pzdttrs.

Pointer to local part of global vector storing the upper diagonal of the matrix.

Globally, *du*(*n*) is not referenced, and *du* must be aligned with *d*.

ja
(global) INTEGER. The index in the global array *a* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca
(global and local) INTEGER array of size (*dlen*_).
if 1d type (*dtype_a* = 501 or 502), *dlen* \geq 7;
if 2d type (*dtype_a* = 1), *dlen* \geq 9.
The array descriptor for the distributed matrix *A*. Contains information of mapping of *A* to memory.

b
(local)
REAL **for** psdttrs
DOUBLE PRECISION **for** pddttrs
COMPLEX **for** pcdttrs
COMPLEX*16 **for** pzdttrs.
Pointer into the local memory to an array of local lead dimension *lld_b* \geq *nb*. On entry, this array contains the local pieces of the right-hand sides *B*(*ib*:*ib+n-1*, 1 :*nrhs*).

ib
(global) INTEGER. The row index in the global array *b* that points to the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb
(global and local) INTEGER array of size (*dlen*_).
if 1d type (*dtype_b* = 502), *dlen* \geq 7;
if 2d type (*dtype_b* = 1), *dlen* \geq 9.
The array descriptor for the distributed matrix *B*. Contains information of mapping *B* to memory.

laf
(local).
INTEGER.
Size of user-input Auxiliary Filling space *af*.

laf must be $\geq 2 * (nb+2)$. If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

work (local).

REAL for psdttrs v

DOUBLE PRECISION for pddttrs v

COMPLEX for pcdttrs v

COMPLEX*16 for pzdttrs v.

Temporary workspace. This space may be overwritten in between calls to routines.

work must be the size given in *lwork*.

lwork

(local or global) INTEGER.

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

lwork $\geq 10 * npcol + 4 * nrhs$.

Output Parameters

d1 (local).

On exit, this array contains information containing the factors of the matrix.

d

On exit, this array contains information containing the factors of the matrix. Must be of size $\geq desca(nb_)$.

b

On exit, this contains the local piece of the solutions distributed matrix X.

af (local).

REAL for psdttrs v

DOUBLE PRECISION for pddttrs v

COMPLEX for pcdttrs v

COMPLEX*16 for pzdttrs v.

Auxiliary Filling Space. Filling is created during the factorization routine p?dttrf and this is stored in *af*. If a linear system is to be solved using p?dttrs after the factorization routine, *af* must not be altered after the factorization.

work

On exit, *work*(1) contains the minimal *lwork*.

info

(local). INTEGER.

If *info*=0, the execution is successful.

if *info*< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?gebal

Balances a general real matrix.

Syntax

Fortran:

```
call psgebal( job, n, a, desca, ilo, ihi, scale, info )
call pdgebal( job, n, a, desca, ilo, ihi, scale, info )
```

Include Files

- C: mkl_scalapack.h

Description

p?gebal balances a general real matrix A . This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first ilo to $ihi-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Input Parameters

<i>job</i>	(global) CHARACTER*1
	Specifies the operations to be performed on <i>a</i> :
	= 'N': none: simply set $ilo = 1$, $ihi = n$, $scale(i) = 1.0$ for $i = 1, \dots, n$;
	= 'P': permute only;
	= 'S': scale only;
	= 'B': both permute and scale.
<i>n</i>	(global) INTEGER
	The order of the matrix A ($n \geq 0$).
<i>a</i>	REAL for psgebal DOUBLE PRECISION for pdgebal (local) array, dimension ($desca(1\text{ld}_\text{c}), LOC_c(n)$) The input matrix A .
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen_</i> . The array descriptor for the distributed matrix A .

OUTPUT Parameters

<i>a</i>	On exit, <i>a</i> is overwritten by the balanced matrix. If <i>job</i> = 'N', <i>a</i> is not referenced. See Notes for further details.
<i>ilo, ihi</i>	(global) INTEGER

ilo and *ih*i are set to integers such that on exit $a(i,j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ih+1, \dots, n$.

If *job* = 'N' or 'S', *ilo* = 1 and *ih*i = *n*.

scale

REAL for psgebal

DOUBLE PRECISION for pdgebal

(global) array, dimension (*n*)

Details of the permutations and scaling factors applied to *a*. If *p(j)* is the index of the row and column interchanged with row and column *j* and *d(j)* is the scaling factor applied to row and column *j*, then

scale(j) = *p(j)* for *j* = 1, ..., *ilo*-1

= *d(j)* for *j* = *ilo*, ..., *ih*i

The order in which the interchanges are made is *n* to *ih*i+1, then 1 to *ilo*-1.

info

(global) INTEGER

= 0: successful exit.

< 0: if INFO = -*i*, the *i*-th argument had an illegal value.

Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T_2 \end{pmatrix}$$

where *T*1 and *T*2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices *ilo* and *ih*i mark the starting and ending columns of the submatrix *B*. Balancing consists of applying a diagonal similarity transformation *D*⁻¹ *B* *D* to make the 1-norms of each row of *B* and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T_1 & XD & Y \\ 0 & D^{-1}BD & D^{-1}Z \\ 0 & 0 & T_2 \end{pmatrix}$$

Information about the permutations *P* and the diagonal matrix *D* is returned in the vector *scale*.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

Fortran:

```
call psgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

C:

```
void psgebd2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );
void pdgebd2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tauq , double *taup , double *work ,
MKL_INT *lwork , MKL_INT *info );
void pcgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8 *taup ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?gebd2 routine reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$Q^T \text{sub}(A) P = B$.

If $m \geq n$, B is the upper bidiagonal; if $m < n$, B is the lower bidiagonal.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for psgebd2 DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Pointer into the local memory to an array of size ($l1d_a$, $LOCc(ja+n-1)$).

On entry, this array contains the local pieces of the general distributed matrix sub(A).

ia , ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

$work$

(local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

This is a workspace array of size ($lwork$).

$lwork$

(local or global) INTEGER.

The size of the array $work$.

$lwork$ is local input and must be at least $lwork \geq \max(mpa0, nqa0)$,

where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$,

$iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb, mycol, csrc_a, npcol)$,

$mpa0 = \text{numroc}(m+iroffa, nb, myrow, iarow, nprow)$,

$nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcol)$.

`indxg2p` and `numroc` are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

a

(local).

On exit, if $m \geq n$, the diagonal and the first superdiagonal of sub(A) are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array τ_{ap} , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array τ_{aq} , represent the

orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array τ_{up} , represent the orthogonal matrix P as a product of elementary reflectors. See *Applications Notes* below.

d

(local)

```
REAL for psgebd2
DOUBLE PRECISION for pdgebd2
COMPLEX for pcgebd2
COMPLEX*16 for pzgebd2.
```

Array, size $LOCc(ja+\min(m,n)-1)$ **if** $m \geq n$; $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d(i) = a(i,i)$. d is tied to the distributed matrix A .

e

(local)

```
REAL for psgebd2
DOUBLE PRECISION for pdgebd2
COMPLEX for pcgebd2
COMPLEX*16 for pzgebd2.
```

Array, size $LOCc(ja+\min(m,n)-1)$ **if** $m \geq n$; $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B :
if $m \geq n$, $e(i) = a(i, i+1)$ **for** $i = 1, 2, \dots, n-1$;
if $m < n$, $e(i) = a(i+1, i)$ **for** $i = 1, 2, \dots, m-1$. e is tied to the distributed matrix A .

tauq

(local).

```
REAL for psgebd2
DOUBLE PRECISION for pdgebd2
COMPLEX for pcgebd2
COMPLEX*16 for pzgebd2.
```

Array, size $LOCc(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . $tauq$ is tied to the distributed matrix A .

taup

(local).

```
REAL for psgebd2
DOUBLE PRECISION for pdgebd2
COMPLEX for pcgebd2
COMPLEX*16 for pzgebd2.
```

Array, size $LOCr(ia+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix P . $taup$ is tied to the distributed matrix A .

work

On exit, $work(1)$ returns the minimal and optimal $lwork$.

info (local)
 INTEGER.
 If *info* = 0, the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1)$$

Each *H(i)* and *G(i)* has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors. $v(1: i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$$A(ia+i-ia+m-1, a+i-1);$$

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

tauq is stored in *TAUQ(ja+i-1)* and *taup* in *TAUP(ia+i-1)*.

If $m < n$,

$v(1: i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i+1: ia+m-1, ja+i-1)$;

$u(1: i-1) = 0$, $u(i) = 1$, and $u(i+1 :n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$;

tauq is stored in *TAUQ(ja+i-1)* and *taup* in *TAUP(ia+i-1)*.

The contents of sub(*A*) on exit are illustrated by the following examples:

$$\begin{array}{l} m = 6 \text{ and } n = 5(m > n) : \\ \left[\begin{array}{cccccc} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{array} \right] \end{array} \quad \begin{array}{l} m = 5 \text{ and } n = 6(m < n) : \\ \left[\begin{array}{cccccc} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{array} \right] \end{array}$$

where *d* and *e* denote diagonal and off-diagonal elements of *B*, *vi* denotes an element of the vector defining *H(i)*, and *ui* an element of the vector defining *G(i)*.

p?gehd2

Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).

Syntax

Fortran:

```
call psgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pcgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgehd2 (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT
*info );
void pdgehd2 (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , double *a , MKL_INT *ia ,

- C: mkl_scalapack.h

Description

The p?gehd2 routine reduces a real/complex general distributed matrix sub(A) to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q' \cdot \text{sub}(A) \cdot Q = H$, where $\text{sub}(A) = A(ia+n-1 : ia+ n-1, ja+n-1 : ja+n-1)$.

Input Parameters

n (global) INTEGER. The order of the distributed submatrix A . ($n \geq 0$).

ilo, ihi (global) INTEGER. It is assumed that sub(A) is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+jlo-2$ and $ja+jhi:ja+n-1$. See *Application Notes* for further information.

If $n \geq 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.

a (local).

REAL for psgehd2

DOUBLE PRECISION for pdgehd2

COMPLEX for pcgehd2

COMPLEX*16 for pzgehd2.

Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOC}_c(ja+n-1))$.

On entry, this array contains the local pieces of the n -by- n general distributed matrix sub(A) to be reduced.

ia, ja (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. This is a workspace array of size (<i>lwork</i>). <i>lwork</i> (local or global) INTEGER. The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $npa0 = \text{numroc}(ihi+iroffa, nb, myrow, iarow, nprow)$. <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .
Output Parameters	
<i>a</i>	(local). On exit, the upper triangle and the first subdiagonal of sub(<i>A</i>) are overwritten with the upper Hessenberg matrix <i>H</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. Array, size $LOC_c(ja+n-2)$ The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of <i>tau</i> are set to zero. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) * H(ilo+1) * \dots * H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1: i)=0$, $v(i+1)=1$ and $v(ihi+1:n)=0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$, and τ in $\tau(ia+ilo+i-2)$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & a & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ a & a & a & a & a & a & a \end{bmatrix}$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

Fortran:

```
call psgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgelq2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgelq2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgelq2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzgelq2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?gelq2` routine computes an LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L^*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . Pointer into the local memory to an array of size (<code>lld_a, LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . This is a workspace array of size (<i>lwork</i>).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $\text{lwork} \geq nq0 + \max(1, mp0)$, where $\text{iroff} = \text{mod}(ia-1, mb_a)$, $\text{icoff} = \text{mod}(ja-1, nb_a)$, $\text{iarow} = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $\text{iacol} = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,

```

mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcol),
indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow,
and npcol can be determined by calling the subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a	(local).
	On exit, the elements on and below the diagonal of sub(A) contain the m by $\min(m,n)$ lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
tau	(local).
	REAL for psgelq2 DOUBLE PRECISION for pdgelq2 COMPLEX for pcgelq2 COMPLEX*16 for pzgelq2. Array, size $LOCr(ia+\min(m, n)-1)$. This array contains the scalar factors of the elementary reflectors. tau is tied to the distributed matrix A .
$work$	On exit, $work(1)$ returns the minimal and optimal $lwork$.
$info$	(local) INTEGER. If $info = 0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia+k-1)*H(ia+k-2)*\dots*H(ia)$ for real flavors, $Q = (H(ia+k-1))^H * (H(ia+k-2))^H * \dots * (H(ia))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - tau*v*v'$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1: i-1) = 0$ and $v(i) = 1$; $v(i+1: n)$ (for real flavors) or $\text{conjg}(v(i+1: n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i: ja+n-1)$, and tau in $TAU(ia+i-1)$.

p?geql2

Computes a *QL* factorization of a general rectangular matrix (unblocked algorithm).

Syntax

Fortran:

```
call psgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgeql2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeql2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgeql2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzgeql2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?geql2 routine computes a *QL* factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

m (global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n (global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

a (local).

REAL for psgeql2

DOUBLE PRECISION for pdgeql2

COMPLEX for pcgeql2

COMPLEX*16 for pzgeql2.

Pointer into the local memory to an array of size (*lld_a,LOCc(ja+n-1)*).

On entry, this array contains the local pieces of the m -by- n distributed matrix sub(A) which is to be factored.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix A .

work

(local).

REAL for *psgeql2*

DOUBLE PRECISION for *pdgeql2*

COMPLEX for *pcgeql2*

COMPLEX*16 for *pzgeql2*.

This is a workspace array of size (*lwork*).

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$,

where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,

$mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow)$,

$nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol)$,

indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

(local).

On exit,

if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ;

if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array *tau*, represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau

(local).

REAL for *psgeql2*

DOUBLE PRECISION for *pdgeql2*

COMPLEX for `pcgeql2`
 COMPLEX*16 for `pzgeql2`.

Array, size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. `tau` is tied to the distributed matrix `A`.

`work` On exit, `work(1)` returns the minimal and optimal `lwork`.

`info` (local). INTEGER.

If `info = 0`, the execution is successful. If `info < 0`: If the i -th argument is an array and the j -entry had an illegal value, then `info = - (i*100+j)`, if the i -th argument is a scalar and had an illegal value, then `info = -i`.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja)$, where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1: m) = 0$ and $v(m-k+i) = 1$; $v(1: m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $TAU(ja+n-k+i-1)$.

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

Fortran:

```
call psgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psgeqr2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeqr2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?geqr2` routine computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R$.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local). REAL for <code>psgeqr2</code> DOUBLE PRECISION for <code>pdgeqr2</code> COMPLEX for <code>pcgeqr2</code> COMPLEX*16 for <code>pzgeqr2</code> . Pointer into the local memory to an array of size ($lld_a, LOCc(ja+n-1)$). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
<code>desca</code>	(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .
<code>work</code>	(local). REAL for <code>psgeqr2</code> DOUBLE PRECISION for <code>pdgeqr2</code> COMPLEX for <code>pcgeqr2</code> COMPLEX*16 for <code>pzgeqr2</code> . This is a workspace array of size ($lwork$).
<code>lwork</code>	(local or global) INTEGER. The size of the array <code>work</code> . <code>lwork</code> is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iwoff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{idxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{idxg2p}(ja, nb_a, mycol, csrc_a, npcol)$, $mp0 = \text{numroc}(m+iwoff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol)$.

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

`a`

(local).

On exit, the elements on and above the diagonal of `sub(A)` contain the $\min(m,n)$ by n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array `tau`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

`tau`

(local).

REAL for `psgeqr2`

DOUBLE PRECISION for `pdgeqr2`

COMPLEX for `pcgeqr2`

COMPLEX*16 for `pzgeqr2`.

Array, size $LOCc(ja+\min(m,n)-1)$. This array contains the scalar factors of the elementary reflectors. `tau` is tied to the distributed matrix A .

`work`

On exit, `work(1)` returns the minimal and optimal `lwork`.

`info`

(local) INTEGER.

If `info = 0`, the execution is successful. If `info < 0`:

If the i -th argument is an array and the j -entry had an illegal value, then `info = - (i*100+j)`,

If the i -th argument is a scalar and had an illegal value, then `info = -i`.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(j) = I - tau * v * v',$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and tau in $TAU(ja+i-1)$.

p?gerq2

Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

Fortran:

```

call psgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)

```

C:

```

void psgerq2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgerq2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgerq2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
void pzgerq2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );

```

Include Files

Description

The p?gerq2 routine computes an *RQ* factorization of a real/complex distributed *m*-by-*n* matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

Input Parameters*m*

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n

(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

a

(local).

REAL for psgerq2

DOUBLE PRECISION for pdgerq2

COMPLEX for pcgerq2

COMPLEX*16 for pzgerq2.

Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOCc}(ja+n-1))$.

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix $\text{sub}(A)$ which is to be factored.

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *A*.

<i>work</i>	(local). REAL for psgerq2 DOUBLE PRECISION for pdgerq2 COMPLEX for pcgerq2 COMPLEX*16 for pzgerq2. This is a workspace array of size (<i>lwork</i>).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where $\begin{aligned} iroff &= \text{mod}(ia-1, mb_a), \quad icoff = \text{mod}(ja-1, nb_a), \\ iarow &= \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow), \\ iacol &= \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol), \quad mp0 = \\ &\text{numroc}(m+iroff, mb_a, myrow, iarow, nprow), \\ nq0 &= \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol), \\ \text{indxg2p} \text{ and } \text{numroc} &\text{ are ScaLAPACK tool functions; } myrow, mycol, nprow, \\ \text{and } npcol &\text{ can be determined by calling the subroutine blacs_gridinfo.} \end{aligned}$ <p>If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.</p>
Output Parameters	
<i>a</i>	(local). On exit, if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array <i>tau</i> , represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for psgerq2 DOUBLE PRECISION for pdgerq2 COMPLEX for pcgerq2 COMPLEX*16 for pzgerq2. Array, size $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER.

If $info = 0$, the execution is successful.

if $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$ for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - tau * v * v'$,

where tau is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or $\text{conjg}(v(1:n-k+i-1))$ for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and tau in $TAU(ia+m-k+i-1)$.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

Fortran:

```
call psgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pdgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pcgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pzgetf2(m, n, a, ia, ja, desca, ipiv, info)
```

C:

```
void psgetf2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_INT *info );
void pdgetf2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pcgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pzgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?getf2 routine computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L^* U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Input Parameters

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n

(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($nb_a - \text{mod}(ja-1, nb_a) \geq n \geq 0$).

a

(local).

REAL for psgetf2

DOUBLE PRECISION for pdgetf2

COMPLEX for pcgetf2

COMPLEX*16 for pzgetf2.

Pointer into the local memory to an array of size ($l1d_a, LOCr(ja+n-1)$).

On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *A*.

Output Parameters

ipiv

(local) INTEGER.

Array, size ($LOCr(m_a) + mb_a$). This array contains the pivoting information. $ipiv(i) \rightarrow$ The global row that local row *i* was swapped with. This array is tied to the distributed matrix *A*.

info

(local). INTEGER.

If $info = 0$: successful exit.

If $info < 0$:

- if the *i*-th argument is an array and the *j*-entry had an illegal value, then $info = -(i*100+j)$,
- if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$: If $info = k$, $u(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor *u* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?labrd

Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

Fortran:

```
call pslabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy,
jy, descy, work)

call pdlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy,
jy, descy, work)

call pclabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy,
jy, descy, work)

call pzlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy,
jy, descy, work)
```

C:

```
void pslabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *d , float *e , float *tauq , float *taup , float *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work );

void pdlabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tauq , double *taup ,
double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *y , MKL_INT *iy ,
MKL_INT *jy , MKL_INT *descy , double *work );

void pclabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8
*taup , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_Complex8
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );

void pzlabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq ,
MKL_Complex16 *taup , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_Complex16 *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?labrd` routine reduces the first nb rows and columns of a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q^* A * P$, and returns the matrices X and Y necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary routine called by `p?gebrd`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>nb</i>	(global) INTEGER. The number of leading rows and columns of $\text{sub}(A)$ to be reduced.
<i>a</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd. Pointer into the local memory to an array of size(<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix A.
<i>ix</i> , <i>jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix X.
<i>iy</i> , <i>jy</i>	(global) INTEGER. The row and column indices in the global array <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix Y.
<i>work</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd Workspace array, size (<i>lwork</i>) $lwork \geq nb_a + nq,$

```

with  $nq = \text{numroc}(n+\text{mod}(ia-1, nb\_y), nb\_y, mycol, iacol,$ 
 $npcol)$ 

 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$ 

 $\text{indxg2p}$  and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow$ ,  $mycol$ ,  $nprow$ , and  $npcol$  can be determined by calling the subroutine  $\text{blacs\_gridinfo}$ .

```

Output Parameters

- a* (local)
 On exit, the first nb rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged.
 If $m \geq n$, elements on and below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.
 If $m < n$, elements below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors. See *Application Notes* below.
- d* (local).
 REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd
 Array, size $\text{LOCr}(ia+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ja+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal distributed matrix B :
 $d(i) = A(ia+i-1, ja+i-1).$
d is tied to the distributed matrix *A*.
- e* (local).
 REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd
 Array, size $\text{LOCr}(ia+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ja+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B :
 if $m \geq n$, $E(i) = A(ia+i-1, ja+i)$ for $i = 1, 2, \dots, n-1$;
 if $m < n$, $E(i) = A(ia+i, ja+i-1)$ for $i = 1, 2, \dots, m-1$.
e is tied to the distributed matrix *A*.

<i>tauq, taup</i>	(local).
	REAL for pslabrd
	DOUBLE PRECISION for pdlabrd
	COMPLEX for pclabrd
	COMPLEX*16 for pzlabrd
	Array size $LOC_c(ja+\min(m, n)-1)$ for <i>tauq</i> , size $LOC_r(ia+\min(m, n)-1)$ for <i>taup</i> . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <i>Q</i> for <i>tauq</i> , <i>P</i> for <i>taup</i> . <i>tauq</i> and <i>taup</i> are tied to the distributed matrix <i>A</i> . See <i>Application Notes</i> below.
<i>x</i>	(local)
	REAL for pslabrd
	DOUBLE PRECISION for pdlabrd
	COMPLEX for pclabrd
	COMPLEX*16 for pzlabrd
	Pointer into the local memory to an array of size lld_x by <i>nb</i> . On exit, the local pieces of the distributed <i>m</i> -by- <i>nb</i> matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.
<i>y</i>	(local).
	REAL for pslabrd
	DOUBLE PRECISION for pdlabrd
	COMPLEX for pclabrd
	COMPLEX*16 for pzlabrd
	Pointer into the local memory to an array of size lld_y by <i>nb</i> . On exit, the local pieces of the distributed <i>n</i> -by- <i>nb</i> matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each *H(i)* and *G(i)* has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors.

If $m \geq n$, $v(1: i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1); u(1:i) = 0, u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; *tauq* is stored in *TAUQ(ja+i-1)* and *taup* in *TAUP(ia+i-1)*.

If $m < n$, $v(1: i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1); u(1:i-1) = 0, u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; *tauq* is stored in *TAUQ(ja+i-1)* and *taup* in *TAUP(ia+i-1)*. The elements of the vectors *v* and *u* together form the *m*-by-*nb* matrix *V* and the *nb*-by-*n* matrix *U'* which are necessary, with *X* and *Y*, to apply the transformation to the unreduced part of the matrix, using a block update of the form: $\text{sub}(A) := \text{sub}(A) - V * Y' - X * U'$. The contents of *sub(A)* on exit are illustrated by the following examples with *nb* = 2:

$$\begin{array}{ll}
 m = 6 \text{ and } n = 5(m > n): & m = 5 \text{ and } n = 6(m < n) : \\
 \left[\begin{array}{cccc} 1 & 1 & u_1 & v_1 \\ v_1 & 1 & 1 & u_2 \\ v_1 & v_2 & a & a \end{array} \right] & \left[\begin{array}{cccccc} 1 & u_1 & v_1 & u_1 & v_1 \\ 1 & 1 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{array} \right]
 \end{array}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

Fortran:

```
call psblacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pdblacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pclaon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pzlaon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
```

C:

```
void psblaon (MKL_INT *n , float *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , float *est ,
MKL_INT *kase );
void pdblaon (MKL_INT *n , double *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , double *est ,
MKL_INT *kase );
void pclaon (MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *est ,
MKL_INT *kase );
void pzlaon (MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *est ,
MKL_INT *kase );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lacon routine estimates the 1-norm of a square, real/unitary distributed matrix A. Reverse communication is used for evaluating matrix-vector products. x and v are aligned with the distributed matrix A, this information is implicitly contained within iv, ix, descv, and descx.

Input Parameters

n (global) INTEGER. The length of the distributed vectors v and x. $n \geq 0$.

<i>v</i>	(local). REAL for pslacon DOUBLE PRECISION for pdlacon COMPLEX for pclacon COMPLEX*16 for pzlacon. Pointer into the local memory to an array of size $LOCr(n+\text{mod}(iv-1, mb_v))$. On the final return, $v = a^*w$, where $\text{est} = \text{norm}(v)/\text{norm}(w)$ (w is not returned).
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix <i>V</i> , respectively.
<i>descv</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>x</i>	(local). REAL for pslacon DOUBLE PRECISION for pdlacon COMPLEX for pclacon COMPLEX*16 for pzlacon. Pointer into the local memory to an array of size $LOCr(n+\text{mod}(ix-1, mb_x))$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix <i>X</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>isgn</i>	(local). INTEGER. Array, size $LOCr(n+\text{mod}(ix-1, mb_x))$. <i>isgn</i> is aligned with <i>x</i> and <i>v</i> .
<i>kase</i>	(local). INTEGER. On the initial call to p?lacon, <i>kase</i> should be 0.

Output Parameters

<i>x</i>	(local). On an intermediate return, <i>X</i> should be overwritten by A^*X , if <i>kase</i> =1, A^*X , if <i>kase</i> =2, p?lacon must be re-called with all the other parameters unchanged.
<i>est</i>	(global). REAL for single precision flavors DOUBLE PRECISION for double precision flavors
<i>kase</i>	(local)

INTEGER. On an intermediate return, *kase* is 1 or 2, indicating whether *X* should be overwritten by A^*X , or A'^*X . On the final return from p?lacon, *kase* is again 0.

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

Fortran:

```
call psblaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
call pdblaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

C:

```
void psblaconsb (float *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *m ,
float *h44 , float *h33 , float *h43h34 , float *buf , MKL_INT *lwork );
void pdblaconsb (double *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *m ,
double *h44 , double *h33 , double *h43h34 , double *buf , MKL_INT *lwork );
```

Include Files

- C: mkl_scalapack.h

Description

The p?laconsb routine looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

Input Parameters

<i>a</i>	(global). REAL for psblaconsb DOUBLE PRECISION for pdblaconsb Array, size (<i>desca</i> (lld_),*). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER. The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>h44</i> , <i>h33</i> , <i>h43h34</i>	(global). REAL for psblaconsb DOUBLE PRECISION for pdblaconsb These three values are for the double shift QR iteration.

lwork (local or global) INTEGER.
 This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/\text{hbl})/\text{lcm}(\text{nproc}, \text{npcol}))$.
 Here lcm is least common multiple and $\text{nproc} * \text{npcol}$ is the logical grid size.

Output Parameters

m (global). On exit, this yields the starting location of the QR double shift.
 This will satisfy:
 $i \leq m \leq i-2$.

buf (local).
 REAL for pslaconsb
 DOUBLE PRECISION for pdlaconsb
 Array of size *lwork*.

lwork (local or global). On exit, *lwork* is the size of the work buffer.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

Fortran:

```
call pslacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

C:

```
void pslacp2 (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pdlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb );
void pzlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,

Include Files

- C: mkl_scalapack.h

Description

The `p?lacp2` routine copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, `p?lacp2` performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

`p?lacp2` requires that only dimension of the matrix operands is distributed.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local). REAL for <code>pslacp2</code> DOUBLE PRECISION for <code>pdlacp2</code> COMPLEX for <code>pclacp2</code> COMPLEX*16 for <code>pzlacp2</code> . Pointer into the local memory to an array of size (<code>lld_a, LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, size (<code>dlen_</code>). The array descriptor for the distributed matrix A .
<code>ib, jb</code>	(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of $\text{sub}(B)$, respectively.
<code>descb</code>	(global and local) INTEGER array, size (<code>dlen_</code>). The array descriptor for the distributed matrix B .

Output Parameters

<code>b</code>	(local). REAL for <code>pslacp2</code>
----------------	---

DOUBLE PRECISION for pdlacp2

COMPLEX for pclacp2

COMPLEX*16 for pzlacp2.

Pointer into the local memory to an array of size (lld_b , $LOCc(jb+n-1)$). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows:

```
if uplo = 'U',  $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ ,  $1 \leq i \leq j$ ,  $1 \leq j \leq n$ ;
if uplo = 'L',  $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ ,  $j \leq i \leq m$ ,  $1 \leq j \leq n$ ;
otherwise,  $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ ,  $1 \leq i \leq m$ ,  $1 \leq j \leq n$ .
```

p?lacp3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

Fortran:

```
call pslacp3(m, i, a, desca, b, ldb, ii, jj, rev)
call pdlacp3(m, i, a, desca, b, ldb, ii, jj, rev)
```

C:

```
void pslacp3 (MKL_INT *m , MKL_INT *i , float *a , MKL_INT *desca , float *b , MKL_INT
*ldb , MKL_INT *ii , MKL_INT *jj , MKL_INT *rev );
void pdlacp3 (MKL_INT *m , MKL_INT *i , double *a , MKL_INT *desca , double *b ,
MKL_INT *ldb , MKL_INT *ii , MKL_INT *jj , MKL_INT *rev );
```

Include Files

- C: mkl_scalapack.h

Description

This is an auxiliary routine that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Input Parameters

m

(global) INTEGER.

m is the order of the square submatrix that is copied.

m ≥ 0 . Unchanged on exit.

i

(global) INTEGER. $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.

a

(global). REAL for pslacp3

DOUBLE PRECISION for pdlacp3

Array, size ($desca(lld_), *$). On entry, the parallel matrix to be copied into or from.

desca (global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *A*.

b (local).
REAL for pslacp3
DOUBLE PRECISION for pdlacp3
Array, size *ldb* by *m*. If *rev* = 0, this is the global portion of the array *A*(*i*:*i+m-1*, *i*:*i+m-1*). If *rev* = 1, this is the unchanged on exit.

ldb (local)
INTEGER.
The leading dimension of *B*.

ii (global) INTEGER. By using *rev* 0 and 1, data can be sent out and returned again. If *rev* = 0, then *ii* is destination row index for the node(s) receiving the replicated *B*. If *ii* ≥ 0, *jj* ≥ 0, then node (*ii*, *jj*) receives the data. If *ii* = -1, *jj* ≥ 0, then all rows in column *jj* receive the data. If *ii* ≥ 0, *jj* = -1, then all cols in row *ii* receive the data. If *ii* = -1, *jj* = -1, then all nodes receive the data. If *rev* != 0, then *ii* is the source row index for the node(s) sending the replicated *B*.

jj (global) INTEGER. Similar description as *ii* above.

rev (global) INTEGER. Use *rev* = 0 to send global *A* into locally replicated *B* (on node (*ii*, *jj*)). Use *rev* != 0 to send locally replicated *B* from node (*ii*, *jj*) to its owner (which changes depending on its location in *A*) into the global *A*.

Output Parameters

a (global). On exit, if *rev* = 1, the copied data. Unchanged on exit if *rev* = 0.

b (local). If *rev* = 1, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

Fortran:

```
call pslacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

C:

```
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```

void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb );
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb );

```

Include Files

- C: mkl_scalapack.h

Description

The p?lacpy routine copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, p?lacpy performs a local copy $\text{sub}(B) := \text{sub}(A)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:
	= 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced;
	= 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
	Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of size (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

<i>desca</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix A.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of sub(<i>B</i>) respectively.
<i>descb</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix A.

Output Parameters

<i>b</i>	(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of size (<i>lld_b, LOCc(jb+n-1)</i>). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows: if <i>uplo</i> = 'U', <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 ≤ i ≤ j, 1 ≤ j ≤ n</i> ; if <i>uplo</i> = 'L', <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), j ≤ i ≤ m, 1 ≤ j ≤ n</i> ; otherwise, <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 ≤ i ≤ m, 1 ≤ j ≤ n</i> .
----------	--

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

Fortran:

```
call pslaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pdlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pclaevevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pzlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

C:

```
void pslaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , float *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *work , MKL_INT
*lwrook );
void pdlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , double *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *work , MKL_INT
*lwrook );
void pclaevevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , MKL_Complex8 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *rwork ,
MKL_INT *lrwork );
```

```
void pzlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , MKL_Complex16 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *rwork ,
MKL_INT *lrwork );
```

Include Files

- C: mkl_scalapack.h

Description

The p?laevswp routine moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

n (global) INTEGER.

The order of the matrix *A*. $n \geq 0$.

zin (local).

REAL for pslaevswp

DOUBLE PRECISION for pdlaevswp

COMPLEX for pclaevewp

COMPLEX*16 for pzlaevswp. Array, size (*ldzi*, *nvs(iam)*). The eigenvectors on input. Each eigenvector resides entirely in one process. Each process holds a contiguous set of *nvs(iam)* eigenvectors. The first eigenvector which the process holds is: sum for $i=[0, iam-1]$ of *nvs(i)*.

ldzi (local)

INTEGER. The leading dimension of the *zin* array.

iz, jz (global) INTEGER. The row and column indices in the global array *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *Z*.

nvs (global) INTEGER.

Array, size (*nprocs*+1)

nvs(i) = number of processes number of eigenvectors held by processes [0, *i*-1)

nvs(1) = number of eigen vectors held by[0, 1 -1] = 0

nvs(nprocs+1)= number of eigen vectors held by [0, *nprocs*)= total number of eigenvectors.

key (global) INTEGER.

Array, size (*n*). Indicates the actual index (after sorting) for each of the eigenvectors.

rwork (local).
 REAL for pslaevswp
 DOUBLE PRECISION for pdlaevswp
 COMPLEX for pclaevswp
 COMPLEX*16 for pzlaevswp. Array, size (*lrwork*).

lrwork (local)
 INTEGER. Size of *work*.

Output Parameters

z (local).
 REAL for pslaevswp
 DOUBLE PRECISION for pdlaevswp
 COMPLEX for pclaevswp
 COMPLEX*16 for pzlaevswp.
 Array, global size *n* by *n*, local size (*descz(dlen_)*, *nq*). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of *nb*.

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k-th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Syntax

Fortran:

```
call pslahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pdlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pclahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pzlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
```

C:

```
void pslahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *t , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work );
void pdlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *tau , double *t , double *y , MKL_INT *iy ,
MKL_INT *jy , MKL_INT *descy , double *work );
void pclahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *y ,
MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );
```

```
void pzlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lahrd` routine reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q^*A^*Q . The routine returns the matrices V and T which determine Q as a block reflector $I-V^*T^*V'$, and also the matrix $Y = A^*V^*T$.

This is an auxiliary routine called by `p?gehrd`. In the following comments `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<code>n</code>	(global) INTEGER.
	The order of the distributed submatrix <code>sub(A)</code> . $n \geq 0$.
<code>k</code>	(global) INTEGER.
	The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
<code>nb</code>	(global) INTEGER.
	The number of columns to be reduced.
<code>a</code>	(local). REAL for <code>pslahrd</code> DOUBLE PRECISION for <code>pdlahrd</code> COMPLEX for <code>pclahrd</code> COMPLEX*16 for <code>pzlahrd</code> . Pointer into the local memory to an array of size (<code>lld_a</code> , <code>LOCc(ja+n-k)</code>). On entry, this array contains the local pieces of the n -by- $(n-k+1)$ general distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array, size (<code>dlen_</code>). The array descriptor for the distributed matrix A .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the global array Y indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array, size (<code>dlen_</code>). The array descriptor for the distributed matrix Y .
<code>work</code>	(local).

```

REAL for pslahrd
DOUBLE PRECISION for pdlahrd
COMPLEX for pclahrd
COMPLEX*16 for pzlahrd.
Array, size (nb).

```

Output Parameters

a (local).
On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the k -th subdiagonal, with the array *tau*, represent the matrix Q as a product of elementary reflectors. The other columns of $A(ia:ia+n-1, ja:ja+n-k)$ are unchanged. (See *Application Notes* below.)

tau (local)
REAL for pslahrd
DOUBLE PRECISION for pdlahrd
COMPLEX for pclahrd
COMPLEX*16 for pzlahrd.
Array, size $LOC(ja+n-2)$. The scalar factors of the elementary reflectors (see *Application Notes* below). *tau* is tied to the distributed matrix *A*.

t (local) REAL for pslahrd
DOUBLE PRECISION for pdlahrd
COMPLEX for pclahrd
COMPLEX*16 for pzlahrd.
Array, size nb_a by nb_a The upper triangular matrix T .

y (local).
REAL for pslahrd
DOUBLE PRECISION for pdlahrd
COMPLEX for pclahrd
COMPLEX*16 for pzlahrd.
Pointer into the local memory to an array of size lId_y by nb_a . On exit, this array contains the local pieces of the n -by- nb distributed matrix Y . $lId_y \geq LOC(ia+n-1)$.

Application Notes

The matrix Q is represented as a product of nb elementary reflectors

$$Q = H(1)*H(2)*\dots*H(nb).$$

Each $H(i)$ has the form

$$H(i) = i - tau * v * v^T,$$

where τ_{ii} is a real/complex scalar, and v is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(ia+i+k:ia+n-1, ja+i-1)$, and τ_{ii} in $TAU(ja+i-1)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(ia:ia+n-1, ja:ja+n-k) := (I - V^*T^*V') * (A(ia:ia+n-1, ja:ja+n-k) - Y^*V')$. The contents of $A(ia:ia+n-1, ja:ja+n-k)$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(i)$.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).

Syntax

Fortran:

```
void pslaiect(float *sigma, int *n, float *d, int *count);
void pdlaiectb(float *sigma, int *n, float *d, int *count);
void pdlaiectl(float *sigma, int *n, float *d, int *count);
```

C:

```
void pslaiect (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectb (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectl (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
```

Include Files

- C: mkl_scalapack.h

Description

The p?laiect routine computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real routine pslaiect is assumed to be bit 32. Double precision routines pdlaiectb and pdlaiectl differ in the order of the double precision word storage and, consequently, in the signbit location. For pdlaiectb, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For pdlaiectl, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

<i>sigma</i>	REAL for pslaiect DOUBLE PRECISION for pdlaiectb/pdlaiectl. The shift. <i>p?laiect</i> finds the number of eigenvalues less than equal to <i>sigma</i> .
<i>n</i>	INTEGER. The order of the tridiagonal matrix <i>T</i> . $n \geq 1$.
<i>d</i>	REAL for pslaiect DOUBLE PRECISION for pdlaiectb/pdlaiectl. Array of size $(2n - 1)$. On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix <i>T</i> . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of <i>T</i> are in the entries $d(1), d(3), \dots, d(2n-1)$, while the squares of the off-diagonal entries are $d(2), d(4), \dots, d(2n-2)$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

<i>n</i>	INTEGER. The count of the number of eigenvalues of <i>T</i> less than or equal to <i>sigma</i> .
----------	--

p?lamve

Copies all or part of one two-dimensional distributed array to another.

Syntax

Fortran:

```
call pslamve( uplo, m, n, a, ia, ja, desca, b, ib, jb, descb, dwork )
call pdlamve( uplo, m, n, a, ia, ja, desca, b, ib, jb, descb, dwork )
```

Include Files

- C: mkl_scalapack.h

Description

p?lamve copies all or part of a distributed matrix *A* to another distributed matrix *B*. There is no alignment assumptions at all except that *A* and *B* are of the same size.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1 Specifies the part of the distributed matrix sub(<i>A</i>) to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of sub(<i>A</i>) is not referenced;
-------------	--

= 'L': Lower triangular part is copied; the strictly upper triangular part of sub(A) is not referenced;

Otherwise: All of the matrix sub(A) is copied.

m

(global) INTEGER

The number of rows to be operated on, which is the number of rows of the distributed submatrix sub(A). $m \geq 0$.

n

(global) INTEGER

The number of columns to be operated on, which is the number of columns of the distributed submatrix sub(A). $n \geq 0$.

a

REAL for pslamve

DOUBLE PRECISION for pdlamve

(local) pointer into the local memory to an array of dimension (lld_a , $\text{LOC}_c(j_a+n-1)$). This array contains the local pieces of the distributed matrix sub(A) to be copied from.

i_a

(global) INTEGER

The row index in the global array a indicating the first row of sub(A).

j_a

(global) INTEGER

The column index in the global array a indicating the first column of sub(A).

desc_a

(global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix A .

i_b

(global) INTEGER

The row index in the global array b indicating the first row of sub(B).

j_b

(global) INTEGER

The column index in the global array b indicating the first column of sub(B).

desc_b

(global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix B .

$dwork$

REAL for pslamve

DOUBLE PRECISION for pdlamve

(local workspace) array

If $\text{uplo} = 'U'$ or $\text{uplo} = 'L'$ and number of processors > 1, the length of $dwork$ is at least as large as the length of b .

Otherwise, $dwork$ is not referenced.

OUTPUT Parameters

b

REAL for pslamve

DOUBLE PRECISION for pdlamve
 (local) pointer into the local memory to an array of dimension (lld_b ,
 $LOC_c(jb+n-1)$). This array contains on exit the local pieces of the
 distributed matrix sub(B).

p?lange

Returns the value of the 1-norm, Frobenius norm,
 infinity-norm, or the largest absolute value of any
 element, of a general rectangular matrix.

Syntax

Fortran:

```
val = pslange(norm, m, n, a, ia, ja, desca, work)
val = pdlange(norm, m, n, a, ia, ja, desca, work)
val = pclange(norm, m, n, a, ia, ja, desca, work)
val = pzlange(norm, m, n, a, ia, ja, desca, work)
```

C:

```
float pslange (char *norm , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work );
double pdlange (char *norm , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
float pclange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );
double pzlange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

Description

The p?lange routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix sub(A) = $A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

norm (global) CHARACTER. Specifies what value is returned by the routine:
 = 'M' or 'm': val = max(abs(A_{ij})), largest absolute value of the matrix A , it's not a matrix norm.
 = '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': val = normF(A), Frobenius norm of the matrix A (square root of sum of squares).

m (global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(*A*). When *m* = 0, p?lange is set to zero. *m* ≥ 0.

n (global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(*A*). When *n* = 0, p?lange is set to zero. *n* ≥ 0.

a (local).

REAL for pslange

DOUBLE PRECISION for pdlange

COMPLEX for pclange

COMPLEX*16 for pzrange.

Pointer into the local memory to an array of size (*lld_a*, LOCc(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the global array *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *A*.

work (local).

REAL for pslange

DOUBLE PRECISION for pdlange

COMPLEX for pclange

COMPLEX*16 for pzrange.

Array size (*lwork*).

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

nq0 if *norm* = '1', 'O' or 'o',

mp0 if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

where

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprov*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

mp0 = numroc(*m+iroffa*, *mb_a*, *myrow*, *iarow*, *nprov*),

nq0 = numroc(*n+icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool routines; *myrow*, *mycol*, *nprov*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

`val`

REAL for `pslange/pclange`
DOUBLE PRECISION for `pdlange/pzlanh`
The value returned by the routine.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

Fortran:

```
val = pslanh(n, n, a, ia, ja, desca, work)
val = pdlanh(n, n, a, ia, ja, desca, work)
val = pclanh(n, n, a, ia, ja, desca, work)
val = pzlanh(n, n, a, ia, ja, desca, work)
```

C:

```
float pslanh (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );
double pdlanh (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *work );
float pclanh (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );
double pzlanh (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?lanhs` routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix `sub(A) = A(ia:ia+m-1, ja:ja+n-1)`.

Input Parameters

`norm`

CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm': `val = max(abs(Aij))`, largest absolute value of the matrix A .
= '1' or 'O' or 'o': `val = norm1(A)`, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': `val = normI(A)`, infinity norm of the matrix A (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(*A*). When *n* = 0, p?lanhs is set to zero. *n* ≥ 0 .

a

(local).

REAL for pslanh

DOUBLE PRECISION for pdlanh

COMPLEX for pclanh

COMPLEX*16 for pzlanh.

Pointer into the local memory to an array of size (*lld_a*, *LOCc(ja+n-1)*) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER.

The row and column indices in the global array *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix *A*.

work

(local).

REAL for pslanh

DOUBLE PRECISION for pdlanh

COMPLEX for pclanh

COMPLEX*16 for pzlanh.

Array, size (*lwork*).

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

nq0 if *norm* = '1', 'O' or 'o',

mp0 if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

where

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nrow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *ncol*),

mp0 = numroc(*m+iroffa*, *mb_a*, *myrow*, *iarow*, *nrow*),

nq0 = numroc(*n+icoffa*, *nb_a*, *mycol*, *iacol*, *ncol*),

indxg2p and numroc are ScaLAPACK tool routines; *myrow*, *imycol*, *nrow*, and *ncol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

`val` The value returned by the function.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

Fortran:

```
val = pslansy(norm, uplo, n, a, ia, ja, desca, work)
val = pdlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclansy(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhsy(norm, uplo, n, a, ia, ja, desca, work)
val = pclanhe(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhe(norm, uplo, n, a, ia, ja, desca, work)
```

C:

```
float pslansy (char *norm , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work );
double pdlansy (char *norm , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
float pclansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );
double pzlanhsy (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
float pclanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );
double pzlanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lansy` and `p?lanhe` routines return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

`norm` (global) CHARACTER. Specifies what value is returned by the routine:
 $= 'M'$ or '`m`': $val = \max(|A_{ij}|)$, largest absolute value of the matrix A , it is not a matrix norm.

= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo

(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced.

= 'U': Upper triangular part of $\text{sub}(A)$ is referenced,
= 'L': Lower triangular part of $\text{sub}(A)$ is referenced.

n

(global) INTEGER.

The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, $p?lansy$ is set to zero. $n \geq 0$.

a

(local).

```
REAL for pslansy
DOUBLE PRECISION for pdlansy
COMPLEX for pclansy, pclanhe
COMPLEX*16 for pzlanhs, pzlanhe.
```

Pointer into the local memory to an array of size ($lld_a, LOCc(ja+n-1)$) containing the local pieces of the distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

work

(local).

```
REAL for pslansy, pclansy, pclanhe
DOUBLE PRECISION for pdlansy, pzlanhs, pzlanhe
```

Array size ($lwork$).

$lwork \geq 0$ if $norm = 'M'$ or ' m ' (not referenced),
 $2 * nq0 + mp0 + ldw$ if $norm = '1'$, 'O' or 'o', 'I' or 'i',
where ldw is given by:

```
if( nprow.ne.npcol ) then
  ldw = mb_a * iceil(ceil(np0,mb_a), (lcm/nprow))
```

```

        else
          ldw = 0
        end if
        0 if norm = 'F', 'f', 'E' or 'e' (not referenced),
        where lcm is the least common multiple of nprow and npcol, lcm =
        ilcm( nprow, npcol ) and ceil(x,y) is a ScaLAPACK function that
        returns ceiling (x/y).
        iroffa = mod(ia-1, mb_a ), icoffa = mod( ja-1, nb_a ),
        iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
        iacol = indxg2p(ja, nb_a, mycol, csrc_a, ncol),
        mp0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
        nq0 = numroc(n+icoffa, nb_a, mycol, iacol, ncol),
        ilcm, ceil, indxg2p, and numroc are ScaLAPACK tool functions; myrow,
        mycol, nprow, and ncol can be determined by calling the subroutine
        blacs_gridinfo.

```

Output Parameters

<i>val</i>	The value returned by the routine.
------------	------------------------------------

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

Fortran:

```

val = pslantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pdlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pclantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pzlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)

```

C:

```

float pslantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
double pdlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
float pclantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
double pzlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );

```

Include Files

- C: mkl_scalapack.h

Description

The `p?lantr` routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $\text{val} = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A , it's not a matrix norm. = '1' or 'O' or 'o': $\text{val} = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $\text{val} = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $\text{val} = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$.
<i>diag</i>	(global) CHARACTER. Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal. = 'N': Non-unit diagonal. = 'U': Unit diagonal.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <code>p?lantr</code> is set to zero. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, <code>p?lantr</code> is set to zero. $n \geq 0$.
<i>a</i>	(local). REAL for <code>pslantr</code> DOUBLE PRECISION for <code>pdlantr</code> COMPLEX for <code>pclantr</code> COMPLEX*16 for <code>pzlantr</code> .

Pointer into the local memory to an array of size (lld_a , $LOCc(ja+n-1)$) containing the local pieces of the distributed matrix sub(A).

ia, ja

(global) INTEGER.

The row and column indices in the global array a indicating the first row and the first column of the submatrix sub(A), respectively.

desca

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

work

(local).

REAL for pslantr

DOUBLE PRECISION for pdlantr

COMPLEX for pclantr

COMPLEX*16 for pzlantr.

Array size ($iwork$).

$iwork \geq 0$ if $norm = 'M'$ or ' m ' (not referenced),

$nq0$ if $norm = '1'$, ' O ' or ' o ',

$mp0$ if $norm = 'I'$ or ' i ',

0 if $norm = 'F'$, ' f ', ' E ' or ' e ' (not referenced),

$iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,

$mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,

$nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol)$,

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

val

The value returned by the routine.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

Fortran:

```
call pslapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,
iwork)

call pdlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,
iwork)

call pclapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,
iwork)
```

```
call pzlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,
iwork)
```

C:

```
void pslapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pdlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pclapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT
*ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pzlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv ,
MKL_INT *ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lapiv routine applies either P (permutation matrix indicated by *ipiv*) or $\text{inv}(P)$ to a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This routine will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass *rowcol*='C' and *pivroc*='C'.

Input Parameters

<i>direc</i>	(global) CHARACTER*1.
	Specifies in which order the permutation is applied:
	= 'F' (Forward). Applies pivots forward from top of matrix. Computes $P * \text{sub}(A)$.
	= 'B' (Backward). Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$.
<i>rowcol</i>	(global) CHARACTER*1.
	Specifies if the rows or columns are to be permuted:
	= 'R' Rows will be permuted,
	= 'C' Columns will be permuted.
<i>pivroc</i>	(global) CHARACTER*1.
	Specifies whether <i>ipiv</i> is distributed over a process row or column:
	= 'R' <i>ipiv</i> is distributed over a process row,
	= 'C' <i>ipiv</i> is distributed over a process column.
<i>m</i>	(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, p?lapiv is set to zero. $m \geq 0$.

n (global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, p?lapiv is set to zero. $n \geq 0$.

a (local).

REAL for pslapiv

DOUBLE PRECISION for pdlapiv

COMPLEX for pclapiv

COMPLEX*16 for pzlapiv .

Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOCc}(\text{ja}+n-1))$ containing the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja (global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

ipiv (local) INTEGER.

Array, size ($lipiv$) ;

when $\text{rowcol}='R'$ or ' r ' :

$lipiv \geq \text{LOCr}(\text{ia}+m-1) + mb_a$ if $\text{pivroc}='C'$ or ' c ',

$lipiv \geq \text{LOCc}(m + \text{mod}(jp-1, nb_p))$ if $\text{pivroc}='R'$ or ' r ', and,

when $\text{rowcol}='C'$ or ' c ' :

$lipiv \geq \text{LOCr}(n + \text{mod}(ip-1, mb_p))$ if $\text{pivroc}='C'$ or ' c ',

$lipiv \geq \text{LOCc}(\text{ja}+n-1) + nb_a$ if $\text{pivroc}='R'$ or ' r '.

This array contains the pivoting information. $ipiv(i)$ is the global row (column), local row (column) i was swapped with. When $\text{rowcol}='R'$ or ' r ' and $\text{pivroc}='C'$ or ' c ', or $\text{rowcol}='C'$ or ' c ' and $\text{pivroc}='R'$ or ' r ', the last piece of this array of size mb_a (resp. nb_a) is used as workspace. In those cases, this array is tied to the distributed matrix A .

ip, jp (global) INTEGER. The row and column indices in the global array P indicating the first row and the first column of the submatrix $\text{sub}(P)$, respectively.

descip (global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed vector $ipiv$.

iwork (local). INTEGER.

Array, size (ldw), where ldw is equal to the workspace necessary for transposition, and the storage of the transposed $ipiv$:

Let lcm be the least common multiple of $nprow$ and $npcol$.

```

If( rowcol.eq.'r' .and. pivroc. eq.'r') then
    If( nprow.eq. npcol) then
        ldw = LOCr( n_p + mod(jp-1, nb_p) ) + nb_p
    else
        ldw = LOCr( n_p + mod(jp-1, nb_p) ) +
            nb_p * ceil( ceil(LOCc(n_p)/nb_p) / (lcm/npcol) )
    end if
else if( rowcol.eq.'c' .and. pivroc.eq.'c') then
    if( nprow.eq.
        npcol ) then
        ldw = LOCc( m_p + mod(ip-1, mb_p) ) + mb_p
    else
        ldw = LOCc( m_p + mod(ip-1, mb_p) ) +
            mb_p *ceil(ceil(LOCr(m_p)/mb_p) / (lcm/nprow) )
    end if
else
    iwork is not referenced.
end if.
```

Output Parameters

a (local).

On exit, the local pieces of the permuted distributed submatrix.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ .

Syntax

Fortran:

```
call pslaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pdlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pclaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)

Include Files

- C: mkl_scalapack.h

Description

The p?laqge routine equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors r and c computed by p?geequ.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for psraqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. Pointer into the local memory to an array of size (lld_a, LOCc(ja+n-1)). On entry, this array contains the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, size (dlen_). The array descriptor for the distributed matrix A .
<i>r</i>	(local). REAL for psraqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge.

Array, size $\text{LOC}_r(m_a)$. The row scale factors for $\text{sub}(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A .

c (local).

REAL **for** `pslaqge`
 DOUBLE PRECISION **for** `pdlaqge`
 COMPLEX **for** `pclaqge`
 COMPLEX*16 **for** `pzlaqge`.

Array, size $\text{LOC}_c(n_a)$. The row scale factors for $\text{sub}(A)$. c is aligned with the distributed matrix A , and replicated across every process column. c is tied to the distributed matrix A .

rowcnd (local).

REAL **for** `pslaqge`
 DOUBLE PRECISION **for** `pdlaqge`
 COMPLEX **for** `pclaqge`
 COMPLEX*16 **for** `pzlaqge`.

The global ratio of the smallest $r(i)$ to the largest $r(i)$, $ia \leq i \leq ia+m-1$.

colcnd (local).

REAL **for** `pslaqge`
 DOUBLE PRECISION **for** `pdlaqge`
 COMPLEX **for** `pclaqge`
 COMPLEX*16 **for** `pzlaqge`.

The global ratio of the smallest $c(i)$ to the largest $c(i)$, $ia \leq i \leq ia+n-1$.

amax (global). REAL **for** `pslaqge`

DOUBLE PRECISION **for** `pdlaqge`
 COMPLEX **for** `pclaqge`
 COMPLEX*16 **for** `pzlaqge`.

Absolute value of largest distributed submatrix entry.

Output Parameters

a (local).

On exit, the equilibrated distributed matrix. See `equed` for the form of the equilibrated distributed submatrix.

equed (global) CHARACTER.

Specifies the form of equilibration that was done.

= 'N': No equilibration

= 'R': Row equilibration, that is, $\text{sub}(A)$ has been pre-multiplied by `diag(r(ia:ia+m-1))`,

```
= 'C': column equilibration, that is, sub(A) has been post-multiplied by
diag(c(ja:ja+n-1)),
= 'B': Both row and column equilibration, that is, sub(A) has been
replaced by diag(r(ia:ia+m-1))* sub(A) * diag(c(ja:ja+n-1)).
```

p?laqr0

Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.

Syntax

Fortran:

```
call pslaqr0( wantt, wantz, n, ilo, ihi, h, desch, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, liwork, info, reclevel )
call pdlaqr0( wantt, wantz, n, ilo, ihi, h, desch, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, liwork, info, reclevel )
```

Include Files

- C: mkl_scalapack.h

Description

p?laqr0 computes the eigenvalues of a Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z*T*Z^T$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q * H * Q^T = (QZ) * T * (QZ)^T$.

Input Parameters

<i>wantt</i>	(global) LOGICAL = .TRUE. : the full Schur form T is required; = .FALSE. : only eigenvalues are required.
<i>wantz</i>	(global) LOGICAL = .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.
<i>n</i>	(global) INTEGER The order of the Hessenberg matrix H (and Z if <i>wantz</i>). $n \geq 0$.
<i>ilo, ihi</i>	(global) INTEGER It is assumed that <i>h</i> is already upper triangular in rows and columns 1: <i>ilo-1</i> and <i>ihi+1:n</i> . <i>ilo</i> and <i>ihi</i> are normally set by a previous call to p?gebal, and then passed to p?gehrd when the matrix output by <i>ihi</i> is reduced to Hessenberg form. Otherwise <i>ilo</i> and <i>ihi</i> should be set to 1 and <i>n</i> , respectively. If <i>n > 0</i> , then $1 \leq ilo \leq ihi \leq n$.

If $n = 0$, then $\text{ilo} = 1$ and $\text{ih} = 0$.

h	REAL for pslaqr0 DOUBLE PRECISION for pdlaqr0 (global) array, dimension ($\text{ld}_h, \text{LOC}_c(n)$) The upper Hessenberg matrix H .
desc_h	(global and local) INTEGER array of dimension $dlen_$. The array descriptor for the distributed matrix H .
$\text{ilo}_z, \text{ih}_z$	INTEGER Specify the rows of z to which transformations must be applied if want_z is .TRUE., $1 \leq \text{ilo}_z \leq \text{ilo}; \text{ih}_z \leq \text{ih}_z \leq n$.
z	REAL for pslaqr0 DOUBLE PRECISION for pdlaqr0 Array, dimension ($\text{ld}_z, \text{LOC}_c(n)$). If want_z is .TRUE., contains the matrix Z . If want_z is .FALSE., z is not referenced.
desc_z	(global and local) INTEGER array of dimension $dlen_$. The array descriptor for the distributed matrix Z .
work	REAL for pslaqr0 DOUBLE PRECISION for pdlaqr0 (local workspace) array, dimension(lwork)
lwork	(local) INTEGER The length of the workspace array work .
iwork	(local workspace) INTEGER array, dimension (liwork)
liwork	(local) INTEGER The length of the workspace array iwork .
reclevel	(local) INTEGER Level of recursion. $\text{reclevel} = 0$ must hold on entry.

OUTPUT Parameters

h	On exit, if want_t is .TRUE., h is upper quasi-triangular in rows and columns $\text{ilo}:ih$, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $h(i,i) = h(i+1,i+1)$ and $h(i+1,i)*h(i,i+1) < 0$. If $\text{info} = 0$ and want_t is .FALSE., the contents of h are unspecified on exit.
wr, wi	REAL for pslaqr0

DOUBLE PRECISION for pdlaqr0

The real and imaginary parts, respectively, of the computed eigenvalues ilo to ahi are stored in the corresponding elements of wr and wi . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi(i) > 0$ and $wi(i+1) < 0$. If $wantt$ is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h .

z Updated matrix with transformations applied only to the submatrix $z(ilo:ahi, ilo:ahi)$.

If $COMPZ = 'I'$, on exit, if $info = 0$, z contains the orthogonal matrix Z of the Schur vectors of H .

If $wantz$ is .TRUE., then $z(ilo:ahi, iloz:ihiz)$ is replaced by $z(ilo:ahi, iloz:ihiz)*U$, when U is the orthogonal/unitary Schur factor of $h(ilo:ahi, ilo:ahi)$.

If $wantz$ is .FALSE., then z is not defined.

$work(1)$ On exit, if $info = 0$, $work(1)$ returns the optimal $lwork$.

$iwork(1)$ On exit, if $info = 0$, $iwork(1)$ returns the optimal $liwork$.

$info$ INTEGER

> 0: if $info = i$, then the routine failed to compute all the eigenvalues. Elements $1:ilo-1$ and $i+1:n$ of wr and wi contain those eigenvalues which have been successfully computed.

> 0: if $wantt$ is .FALSE., then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through ilo of the final output value of h .

> 0: if $wantt$ is .TRUE., then $(\text{initial value of } h)*U = U*(\text{final value of } h)$, where U is an orthogonal/unitary matrix. The final value of h is upper Hessenberg and quasi-triangular/triangular in rows and columns $info+1$ through ahi .

> 0: if $wantz$ is .TRUE., then $(\text{final value of } z(ilo:ahi, iloz:ihiz)) = (\text{initial value of } z(ilo:ahi, iloz:ihiz))*U$, where U is the orthogonal/unitary matrix in the previous expression (regardless of the value of $wantt$).

> 0: if $wantz$ is .FALSE., then z is not accessed.

p?laqr1

Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.

Syntax

Fortran:

```
call pslaqr1( wantt, wantz, n, ilo, ahi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info )
```

```
call pdlaqr1( wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

`p?laqr1` is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns `ilo` to `ihi`.

This is a modified version of `p?lahqr` from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONSB) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of `p?lahqr` sometimes did not read out the converged eigenvalues correctly. This is now fixed.

Input Parameters

<code>wantt</code>	(global) LOGICAL
	= .TRUE. : the full Schur form T is required;
	= .FALSE.: only eigenvalues are required.
<code>wantz</code>	(global) LOGICAL
	= .TRUE. : the matrix of Schur vectors Z is required;
	= .FALSE.: Schur vectors are not required.
<code>n</code>	(global) LOGICAL
	The order of the Hessenberg matrix A (and Z if <code>wantz</code>). $n \geq 0$.
<code>ilo, ihi</code>	(global) INTEGER
	It is assumed that <code>a</code> is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $a(ilo,ilo-1) = 0$ (unless <code>ilo = 1</code>). <code>p?laqr1</code> works primarily with the Hessenberg submatrix in rows and columns <code>ilo</code> to <code>ihi</code> , but applies transformations to all of H if <code>wantt</code> is .TRUE..
	$1 \leq ilo \leq \max(1,ihi); ihi \leq n$.
<code>a</code>	REAL for pslaqr1 DOUBLE PRECISION for pdlaqr1
	(global) array, dimension (<code>desca(Ild_),LOC_c(n)</code>)
	On entry, the upper Hessenberg matrix A .
<code>desca</code>	(global and local) INTEGER array of dimension <code>dlen_</code> .
	The array descriptor for the distributed matrix A .

<i>iloz, ihiz</i>	(global) INTEGER Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n.$
<i>z</i>	REAL for pslaqr1 DOUBLE PRECISION for pdlaqr1 (global) array, dimension (<i>descz</i> (<i>lld_</i>), <i>LOC_c(n)</i>). If <i>wantz</i> is .TRUE., on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations accumulated by <i>p?hseqr</i> If <i>wantz</i> is .FALSE., <i>z</i> is not referenced.
<i>descz</i>	(global and local) INTEGER array of dimension <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	REAL for pslaqr1 DOUBLE PRECISION for pdlaqr1 (local output) array of size <i>lwork</i>
<i>lwork</i>	(local) INTEGER The size of the work array (<i>lwork</i> >=1). If <i>lwork</i> =-1, then a workspace query is assumed.
<i>iwork</i>	(global and local) INTEGER array of size <i>ilwork</i> This holds the some of the IBLK integer arrays.
<i>ilwork</i>	(local) INTEGER The size of the <i>iwork</i> array (<i>ilwork</i> ≥3).

OUTPUT Parameters

<i>a</i>	If <i>wantt</i> is .TRUE., <i>a</i> is upper quasi-triangular in rows and columns <i>ilo:ihiz</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> is .FALSE., the contents of <i>a</i> are unspecified on exit.
<i>wr, wi</i>	REAL for pslaqr1 DOUBLE PRECISION for pdlaqr1 (global replicated) array, dimension (<i>n</i>) The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihiz</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)th, with <i>wi(i)</i> > 0 and <i>wi(i+1)</i> < 0. If <i>wantt</i> is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>a</i> . <i>a</i> may be returned with larger diagonal blocks until the next release.

z On exit *z* is updated; transformations are applied only to the submatrix *z(iloz:ihiz,ilo:ihi)*.
If *wantz* is .FALSE., *z* is not referenced.

work(1) On exit, if *info* = 0, *work(1)* returns the optimal *lwork*.

info (global) INTEGER
< 0: parameter number -*info* incorrect or inconsistent
= 0: successful exit
> 0: p?laqr1 failed to compute all the eigenvalues *ilo* to *ihiz* in a total of $30*(ihiz-ilo+1)$ iterations; if *info* = *i*, elements *i+1:ihiz* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

Application Notes

This algorithm is very similar to p?lahqr. Unlike p?lahqr, instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires *a* and *z* to be distributed identically and have identical contexts.
- This release currently does not have a routine for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.
- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least $2*LCM(NPROW,NPCOL)$ bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.
- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK routine.
- For this release, it is assumed *rsrc_*=*csrc_*=0
- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this routine are subject to change.

p?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

Fortran:

```
call pslaqr2( wantt, wantz, n, ktop, kbot, nw, a, desca, iloz, ihiz, z, descz, ns, nd,
sr, si, t, ldt, v, ldv, wr, wi, work, lwork )
```

```
call pdlaqr2( wantt, wantz, n, ktop, kbot, nw, a, desca, iloz, ihiz, z, descz, ns, nd,
sr, si, t, ldt, v, ldv, wr, wi, work, lwork )
```

Include Files

- C: mkl_scalapack.h

Description

p?laqr2 accepts as input an upper Hessenberg matrix A and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output A is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of A . It is to be hoped that the final version of A has many zero subdiagonal entries.

This routine handles small deflation windows which is affordable by one processor. Normally, it is called by p?laqr1. All the inputs are assumed to be valid without checking.

Input Parameters

wantt	(global) LOGICAL
	If .TRUE., then the Hessenberg matrix A is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine).
	If .FALSE., then only enough of A is updated to preserve the eigenvalues.
wantz	(global) LOGICAL
	If .TRUE., then the orthogonal matrix Z is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine).
	If .FALSE., then z is not referenced.
n	(global) INTEGER
	The order of the matrix A and (if wantz is .TRUE.) the order of the orthogonal matrix Z .
ktop, kbot	(global) INTEGER
	It is assumed without a check that either $kbot = n$ or $A(kbot+1,kbot)=0$. $kbot$ and $ktop$ together determine an isolated block along the diagonal of the Hessenberg matrix. However, $A(ktop,ktop-1)=0$ is not essentially necessary if wantt is .TRUE. .
nw	(global) INTEGER
	Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$. Normally $nw \geq 3$ if p?laqr2 is called by p?laqr1.
a	REAL for pslaqr2 DOUBLE PRECISION for pdlaqr2 (local) array, dimension (desca(/ld_),LOC_c(n))
	The initial n -by- n section of a stores the Hessenberg matrix undergoing aggressive early deflation.
desca	(global and local) INTEGER array of dimension DLEN_.

The array descriptor for the distributed matrix A .

iloz, ihiz

(global) INTEGER

Specify the rows of z to which transformations must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ihiz \leq n$.

z

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

Array, dimension (*descz*(*ldz*),*LOCc*(*n*))

If *wantz* is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into *z*(*iloz*:*ihiz*, *kbot*:*ktop*) from the right.

If *wantz* is .FALSE., then *z* is unreferenced.

descz

(global and local) INTEGER array of dimension DLEN_.

The array descriptor for the distributed matrix Z .

t

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array, dimension *ldt***nw*.

ldt

(local) INTEGER

The leading dimension of the array *t*. *ldt* $\geq nw$.

v

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array, dimension *ldv***nw*.

ldv

(local) INTEGER

The leading dimension of the array *v*. *ldv* $\geq nw$.

wr, wi

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array, dimension *kbot*.

work

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array, dimension *lwork*.

lwork

(local) INTEGER

work(lwork) is a local array and *lwork* is assumed big enough so that *lwork* $\geq nw * nw$.

OUTPUT Parameters

<i>a</i>	On output <i>a</i> has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
<i>z</i>	
<i>ns</i>	(global) INTEGER The number of unconverged (ie approximate) eigenvalues returned in <i>sr</i> and <i>si</i> that may be used as shifts by the calling subroutine.
<i>nd</i>	(global) INTEGER The number of converged eigenvalues uncovered by this subroutine.
<i>sr, si</i>	REAL for pslaqr2 DOUBLE PRECISION for pdlaqr2 (global) array, dimension <i>kbot</i> On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in <i>sr(kbot-nd-ns+1)</i> through <i>sr(kbot-nd)</i> and <i>si(kbot-nd-ns+1)</i> through <i>si(kbot-nd)</i> , respectively. On processor #0, the real and imaginary parts of converged eigenvalues are stored in <i>sr(kbot-nd+1)</i> through <i>sr(kbot)</i> and <i>si(kbot-nd+1)</i> through <i>si(kbot)</i> , respectively. On other processors, these entries are set to zero.

p?laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

Fortran:

```
call pslaqr3( wantt, wantz, n, ktop, kbot, nw, h, desch, iloz, ihiz, z, descz, ns, nd,
sr, si, v, descv, nh, t, desct, nv, wv, descw, work, lwork, iwork, liwork, reclevel )
call pdlaqr3( wantt, wantz, n, ktop, kbot, nw, h, desch, iloz, ihiz, z, descz, ns, nd,
sr, si, v, descv, nh, t, desct, nv, wv, descw, work, lwork, iwork, liwork, reclevel )
```

Include Files

- C: mkl_scalapack.h

Description

This subroutine accepts as input an upper Hessenberg matrix *H* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *H* is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *H*. It is to be hoped that the final version of *H* has many zero subdiagonal entries.

Input Parameters

wantt (global) LOGICAL
 If .TRUE., then the Hessenberg matrix *h* is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine).
 If .FALSE., then only enough of *h* is updated to preserve the eigenvalues.

wantz (global) LOGICAL
 If .TRUE., then the orthogonal matrix *z* is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine).
 If .FALSE., then *z* is not referenced.

n (global) INTEGER
 The order of the matrix *H* and (if *wantz* is .TRUE.) the order of the orthogonal matrix *Z*.

ktop (global) INTEGER
 It is assumed that either *ktop* = 1 or *h(ktop,ktop-1)*=0. *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix.

kbot (global) INTEGER
 It is assumed without a check that either *kbot* = *n* or *h(kbot+1,kbot)*=0. *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix.

nw (global) INTEGER
 Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$.

h REAL for pslaqr3
 DOUBLE PRECISION for pdlaqr3
 (local) array, dimension (*desc*h**(*lld_*),*LOCc(n)*)
 The initial *n*-by-*n* section of *h* stores the Hessenberg matrix undergoing aggressive early deflation.

*desc*h** (global and local) INTEGER array of dimension *dlen_*.
 The array descriptor for the distributed matrix *h*.

iloz, ihiz (global) INTEGER
 Specify the rows of *z* to which transformations must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ihiz \leq n$.

z REAL for pslaqr3
 DOUBLE PRECISION for pdlaqr3
 Array, dimension (*desc*z**(*lld_*),*LOCc(n)*)

If `wantz` is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into $z(iloz:ihiz,kbot:ktop)$ from the right.

If `wantz` is .FALSE., then z is unreferenced.

`descz` (global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix z .

`v` REAL for `pslaqr3`

DOUBLE PRECISION for `pdlaqr3`

(global workspace) array, dimension ($descv(lld_), LOC_c(nw)$)

An nw -by- nw distributed work array.

`descv` (global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix v .

`nh` INTEGER scalar

The number of columns of t . $nh \geq nw$.

`t` REAL for `pslaqr3`

DOUBLE PRECISION for `pdlaqr3`

(global workspace) array, dimension ($desc(t)(lld_), LOC_c(nh)$)

`desc(t)` (global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix t .

`nv` (global) INTEGER

The number of rows of work array wv available for workspace. $nv \geq nw$.

`wv` (global workspace) REAL array, dimension

($descw(lld_), LOC_c(nw)$)

`descw` (global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the distributed matrix wv .

`work` (local workspace) REAL array, dimension $lwork$.

`lwork` (local) INTEGER

The dimension of the work array `work` ($lwork \geq 1$). $lwork = 2 * nw$ suffices, but greater efficiency may result from larger values of `lwork`.

If `lwork` = -1, then a workspace query is assumed; `p?laqr3` only estimates the optimal workspace size for the given values of n , nw , $ktop$ and $kbot$. The estimate is returned in `work(1)`. No error message related to `lwork` is issued by `xerbla`. Neither `h` nor `z` are accessed.

`iwork` (local workspace) INTEGER array, dimension ($liwork$)

`liwork` (local) INTEGER

The length of the workspace array $iwork$ ($liwork \geq 1$).

If $liwork=-1$, then a workspace query is assumed.

OUTPUT Parameters

h	On output h has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
z	IF $wantz$ is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into $z(iloz:ihiz,kbot:ktop)$ from the right. If $wantz$ is .FALSE., then z is unreferenced.
ns	(global) INTEGER The number of unconverged (ie approximate) eigenvalues returned in sr and si that may be used as shifts by the calling subroutine.
nd	(global) INTEGER The number of converged eigenvalues uncovered by this subroutine.
sr, si	REAL for pslaqr3 DOUBLE PRECISION for pdlaqr3 (global) array, dimension $kbot$ The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in $sr(kbot-nd-ns+1)$ through $sr(kbot-nd)$ and $si(kbot-nd-ns+1)$ through $si(kbot-nd)$, respectively. The real and imaginary parts of converged eigenvalues are stored in $sr(kbot-nd+1)$ through $sr(kbot)$ and $si(kbot-nd+1)$ through $si(kbot)$, respectively.
$work(1)$	On exit, if $info = 0$, $work(1)$ returns the optimal $lwork$
$iwork(1)$	On exit, if $info = 0$, $iwork(1)$ returns the optimal $liwork$

p?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition.

Syntax

Fortran:

```
call pslaqr4( wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, t,
              ldt, v, ldv, work, lwork, info )
call pdlaqr4( wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, t,
              ldt, v, ldv, work, lwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

`p?laqr4` is an auxiliary routine used to find the Schur decomposition and or eigenvalues of a matrix already in Hessenberg form from cols ilo to ih_i . This routine requires that the active block is small enough, i.e. $ih_i - ilo + 1 \leq ldt$, so that it can be solved by LAPACK. Normally, it is called by `p?laqr1`. All the inputs are assumed to be valid without checking.

Input Parameters

<code>wantt</code>	(global) LOGICAL = .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.
<code>wantz</code>	(global) LOGICAL = .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.
<code>n</code>	(global) INTEGER The order of the Hessenberg matrix A (and Z if <code>wantz</code>). $n \geq 0$.
<code>ilo, ih_i</code>	(global) INTEGER It is assumed that a is already upper quasi-triangular in rows and columns $ih_i + 1:n$, and that $a(ilo,ilo-1) = 0$ (unless $ilo = 1$). <code>p?laqr4</code> works primarily with the Hessenberg submatrix in rows and columns ilo to ih_i , but applies transformations to all of A if <code>wantt</code> is .TRUE.. $1 \leq ilo \leq \max(1,ih_i); ih_i \leq n$.
<code>a</code>	REAL for <code>pslaqr4</code> DOUBLE PRECISION for <code>pdlaqr4</code> (global) array, dimension (<code>desca(Ild_),LOC_c(n)</code>) The upper Hessenberg matrix A .
<code>desca</code>	(global and local) INTEGER array of dimension <code>dlen_</code> . The array descriptor for the distributed matrix a .
<code>iloz, ihiz</code>	(global) INTEGER Specify the rows of z to which transformations must be applied if <code>wantz</code> is .TRUE.. $1 \leq iloz \leq ilo; ih_i \leq ihiz \leq n$.
<code>z</code>	REAL for <code>pslaqr4</code> DOUBLE PRECISION for <code>pdlaqr4</code> (global) array. If <code>wantz</code> is .TRUE., on entry z must contain the current matrix Z of transformations accumulated by <code>p?hseqr</code> . If <code>wantz</code> is .FALSE., z is not referenced.
<code>descz</code>	(global and local) INTEGER array of dimension <code>dlen_</code> .

The array descriptor for the distributed matrix z .

t REAL for pslaqr4
 DOUBLE PRECISION for pdlaqr4
 (local workspace) array, dimension $l_{dt}*(i_{hi}-i_{lo}+1)$.

l_{dt} (local) INTEGER
 The leading dimension of the array t . $l_{dt} \geq i_{hi}-i_{lo}+1$.

v REAL for pslaqr4
 DOUBLE PRECISION for pdlaqr4
 (local workspace) array, dimension $l_{dv}*(i_{hi}-i_{lo}+1)$.

l_{dv} (local) INTEGER
 The leading dimension of the array v . $l_{dv} \geq i_{hi}-i_{lo}+1$.

$work$ REAL for pslaqr4
 DOUBLE PRECISION for pdlaqr4
 (local workspace) array, dimension l_{work} .

l_{work} (local) INTEGER
 The dimension of the work array $work$.
 $l_{work} \geq i_{hi}-i_{lo}+1$.

OUTPUT Parameters

a On exit, if $wantt$ is .TRUE., a is upper quasi-triangular in rows and columns $i_{lo}:i_{hi}$, with any 2-by-2 or larger diagonal blocks not yet in standard form. If $wantt$ is .FALSE., the contents of a are unspecified on exit.

wr, wi REAL for pslaqr4
 DOUBLE PRECISION for pdlaqr4
 (global replicated) array, dimension (n)
 The real and imaginary parts, respectively, of the computed eigenvalues i_{lo} to i_{hi} are stored in the corresponding elements of wr and wi . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi(i) > 0$ and $wi(i+1) < 0$. If $wantt$ is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in a . a may be returned with larger diagonal blocks until the next release.

z If $wantz$ is .TRUE., z is updated with transformations applied only to the submatrix $z(i_{lo}:i_{hi}, i_{lo}:i_{hi})$.

$info$ (global) INTEGER
 < 0: parameter number $-info$ incorrect or inconsistent;

= 0: successful exit;
> 0: p?laqr4 failed to compute all the eigenvalues ilo to ih_i in a total of $30*(ih_i-ilo+1)$ iterations; if $info = i$, elements $i+1:ih_i$ of wr and wi contain those eigenvalues which have been successfully computed.

p?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

Fortran:

```
call pslaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, desch, iloz,
ihiz, z, descz, work, lwork, iwork, liwork )

call pdlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, desch, iloz,
ihiz, z, descz, work, lwork, iwork, liwork )
```

Include Files

- C: mkl_scalapack.h

Description

This auxiliary subroutine called by p?laqr0 performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of h .

Input Parameters

<i>wantt</i>	(global) LOGICAL scalar
	<i>wantt</i> = .TRUE. if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to .FALSE. otherwise.
<i>wantz</i>	(global) LOGICAL scalar
	<i>wantz</i> = .TRUE. if the orthogonal Schur factor is being computed. <i>wantz</i> is set to .FALSE. otherwise.
<i>kacc22</i>	(global) INTEGER
	Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: p?laqr5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: p?laqr5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: p?laqr5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	(global) INTEGER scalar
	The order of the Hessenberg matrix h and, if <i>wantz</i> is .TRUE., the order of the orthogonal matrix Z .

<i>ktop, kbot</i>	(global) INTEGER scalar
	These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $ktop = 1$ or $h(ktop,ktop-1) = 0$ and either $kbot = n$ or $h(kbot+1,kbot) = 0$.
<i>nshfts</i>	(global) INTEGER scalar
	<i>nshfts</i> gives the number of simultaneous shifts. <i>nshfts</i> must be positive and even.
<i>sr, si</i>	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (global) Array of size (<i>nshfts</i>) <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.
<i>h</i>	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local) Array of size (<i>desch(lld_)</i> , <i>LOC_c(n)</i>) On input <i>h</i> contains a Hessenberg matrix.
<i>descch</i>	(global and local) INTEGER array of dimension <i>dlen_</i> . The array descriptor for the distributed matrix <i>h</i> .
<i>iloz, ihiz</i>	(global) INTEGER Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq iloz \leq ihiz \leq n$
<i>z</i>	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local) array of size (<i>descz(lld_)</i> , <i>LOC_c(n)</i>) If <i>wantz</i> = .TRUE., then the QR Sweep orthogonal similarity transformation is accumulated into <i>z(iloz:ihiz,kbot:ktop)</i> from the right. If <i>wantz</i> = .FALSE., then <i>z</i> is unreferenced.
<i>descz</i>	(global and local) INTEGER array of dimension <i>dlen_</i> . The array descriptor for the distributed matrix <i>z</i> .
<i>work</i>	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local workspace) array, dimension(<i>lwork</i>)
<i>lwork</i>	(local) INTEGER The size of the <i>work</i> array (<i>lwork</i> ≥ 1).

If $lwork=-1$, then a workspace query is assumed.

iwork (local workspace) INTEGER array, dimension (*lwork*)

lwork (local) INTEGER

The size of the *iwork* array ($lwork \geq 1$).

If $lwork=-1$, then a workspace query is assumed.

Output Parameters

h A multi-shift QR sweep with shifts $sr(j)+i*si(j)$ is applied to the isolated diagonal block in rows and columns *ktop* through *kbot*.

z If *wantz* is .TRUE., *z* is updated with transformations applied only to the submatrix $z(iloz:ihiz,kbot:ktop)$.

work(1) On exit, if *info* = 0, *work(1)* returns the optimal *lwork*.

iwork(1) On exit, if *info* = 0, *iwork(1)* returns the optimal *lwork*.

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.

Syntax

Fortran:

```
call pslaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pdlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pclaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pzlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
```

C:

```
void pslaqsy (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *sr , float *sc , float *scond , float *amax , char *equed );
void pdlaqsy (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char
*equed );
void pclaqsy (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , char *equed );
void pzlaqsy (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char
*equed );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?laqsy` routine equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors `sr` and `sc`. The scaling factors are computed by `p?poequ`.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<code>a</code>	(local). REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Pointer into the local memory to an array of size ($\text{lld}_a, \text{LOCc}(ja+n-1)$). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <code>uplo</code> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .
<code>sr</code>	(local) REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Array, DIMENSION $\text{LOCr}(m_a)$. The scale factors for $A(ia:ia+m-1, ja:ja+n-1)$. <code>sr</code> is aligned with the distributed matrix A , and replicated across every process column. <code>sr</code> is tied to the distributed matrix A .
<code>sc</code>	(local)

```

REAL for pslaqsy
DOUBLE PRECISION for pdlaqsy
COMPLEX for pclaqsy
COMPLEX*16 for pzlaqsy.

Array, DIMENSION LOCc(m_a). The scale factors for A (ia:ia+m-1, ja:ja+n-1). sr is aligned with the distributed matrix A, and replicated across every process column. sr is tied to the distributed matrix A.

scond
(global). REAL for pslaqsy
DOUBLE PRECISION for pdlaqsy
COMPLEX for pclaqsy
COMPLEX*16 for pzlaqsy.

Ratio of the smallest sr(i) (respectively sc(j)) to the largest sr(i) (respectively sc(j)), with ia ≤ i ≤ ia+n-1 and ja ≤ j ≤ ja+n-1.

amax
(global).

REAL for pslaqsy
DOUBLE PRECISION for pdlaqsy
COMPLEX for pclaqsy
COMPLEX*16 for pzlaqsy.

Absolute value of largest distributed submatrix entry.

```

Output Parameters

a

On exit,

if *equed* = 'Y', the equilibrated matrix:

$$\text{diag}(sr(ia:ia+n-1)) * \text{sub}(A) * \text{diag}(sc(ja:ja+n-1)).$$

equed

(global) CHARACTER*1.

Specifies whether or not equilibration was done.

= 'N': No equilibration.

= 'Y': Equilibration was done, that is, sub(A) has been replaced by:

$$\text{diag}(sr(ia:ia+n-1)) * \text{sub}(A) * \text{diag}(sc(ja:ja+n-1)).$$

p?lared1d

Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.

Syntax

Fortran:

```

call pslared1d(n, ia, ja, desc, bycol, byall, work, lwork)
call pdlared1d(n, ia, ja, desc, bycol, byall, work, lwork)

```

C:

```
void pslared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *bycol ,
float *byall , float *work , MKL_INT *lwork );
void pdlared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*bycol , double *byall , double *work , MKL_INT *lwork );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lared1d` routine redistributes a 1D array. It assumes that the input array `bycol` is distributed across rows and that all process column contain the same copy of `bycol`. The output array `byall` is identical on all processes and contains the entire array.

Input Parameters

`np` = Number of local rows in `bycol()`

`n` (global) INTEGER.

The number of elements to be redistributed. $n \geq 0$.

`ia, ja` (global) INTEGER. `ia, ja` must be equal to 1.

`desc` (local) INTEGER array, size 9. A 2D array descriptor, which describes `bycol`.

`bycol` (local).

REAL for `pslared1d`

DOUBLE PRECISION for `pdlared1d`

COMPLEX for `pclared1d`

COMPLEX*16 for `pzlated1d`.

Distributed block cyclic array global size (`n`), local size `np`. `bycol` is distributed across the process rows. All process columns are assumed to contain the same value.

`work` (local).

REAL for `pslared1d`

DOUBLE PRECISION for `pdlared1d`

COMPLEX for `pclared1d`

COMPLEX*16 for `pzlated1d`.

size (`lwork`). Used to hold the buffers sent from one process to another.

`lwork` (local)

INTEGER. The size of the `work` array. $lwork \geq \text{numroc}(n, \text{desc}(\text{nb}), 0, 0, npcol)$.

Output Parameters

`byall` (global). REAL for `pslared1d`

DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlated1d.

Global size (n), local size (n). $byall$ is exactly duplicated on all processes. It contains the same values as $bycol$, but it is replicated across all processes rather than being distributed.

p?lared2d

Redistributes an array assuming that the input array byrow is distributed across columns and that all process rows contain the same copy of byrow.

Syntax

Fortran:

```
call pslared2d(n, ia, ja, desc, byrow, byall, work, lwork)
call pdlared2d(n, ia, ja, desc, byrow, byall, work, lwork)
```

C:

```
void pslared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *byrow ,
float *byall , float *work , MKL_INT *lwork );
void pdlared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*byrow , double *byall , double *work , MKL_INT *lwork );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lared2d routine redistributes a 1D array. It assumes that the input array $byrow$ is distributed across columns and that all process rows contain the same copy of $byrow$. The output array $byall$ will be identical on all processes and will contain the entire array.

Input Parameters

np = Number of local rows in $byrow()$

n (global) INTEGER.
 The number of elements to be redistributed. $n \geq 0$.

ia, ja (global) INTEGER. ia, ja must be equal to 1.

$desc$ (local) INTEGER array, size ($dlen_$). A 2D array descriptor, which describes $byrow$.

$byrow$ (local).
 REAL for pslared2d
 DOUBLE PRECISION for pdlared2d
 COMPLEX for pclared2d
 COMPLEX*16 for pzlated2d.

Distributed block cyclic array global size (n), local size np . $bycol$ is distributed across the process columns. All process rows are assumed to contain the same value.

<i>work</i>	(local).
	REAL for pslared2d
	DOUBLE PRECISION for pdlared2d
	COMPLEX for pclared2d
	COMPLEX*16 for pzlared2d.
	size (<i>lwork</i>). Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local) INTEGER. The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}(nb_), 0, 0, npcol)$.

Output Parameters

<i>byall</i>	(global). REAL for pslared2d
	DOUBLE PRECISION for pdlared2d
	COMPLEX for pclared2d
	COMPLEX*16 for pzlared2d.
	Global size(n), local size (n). <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>bycol</i> , but it is replicated across all processes rather than being distributed.

p?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

Fortran:

```
call pslarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

C:

```
void pslarf (char *side , MKL_INT *m , MKL_INT *n , float *v , MKL_INT *iv , MKL_INT
*jv , MKL_INT *descv , MKL_INT *incv , float *tau , float *c , MKL_INT *ic , MKL_INT
*jc , MKL_INT *descc , float *work );
void pdlarf (char *side , MKL_INT *m , MKL_INT *n , double *v , MKL_INT *iv , MKL_INT
*jv , MKL_INT *descv , MKL_INT *incv , double *tau , double *c , MKL_INT *ic , MKL_INT
*jc , MKL_INT *descc , double *work );
void pclarf (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex8 *tau , MKL_Complex8 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work );
```

```
void pzlarf (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex16 *tau , MKL_Complex16 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work );
```

Include Files

- C: mkl_scalapack.h

Description

The p?larf routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v^* v,$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global). CHARACTER. = 'L': form $Q^* \text{sub}(C)$, = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>v</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Pointer into the local memory to an array of size (<i>lld_v</i> ,*) containing the local pieces of the distributed vectors V representing the Householder transformation Q , $v(iv:iv+m-1, jv)$ if <i>side</i> = 'L' and <i>incv</i> = 1, $v(iv, jv:jv+m-1)$ if <i>side</i> = 'L' and <i>incv</i> = <i>m_v</i> , $v(iv:iv+n-1, jv)$ if <i>side</i> = 'R' and <i>incv</i> = 1, $v(iv, jv:jv+n-1)$ if <i>side</i> = 'R' and <i>incv</i> = <i>m_v</i> . The vector v is the representation of Q . v is not used if $\tau = 0$.
<i>iv</i> , <i>jv</i>	(global) INTEGER. The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.

<i>descv</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix V.
<i>incv</i>	(global) INTEGER. The global increment for the elements of <i>v</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and <i>m_v</i> . <i>incv</i> must not be zero.
<i>tau</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzclarf. Array, size <i>LOCc(jv)</i> if <i>incv</i> = 1, and <i>LOCr(iv)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i> .
<i>c</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzclarf. Pointer into the local memory to an array of size (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>), containing the local pieces of sub(<i>C</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix sub(<i>C</i>), respectively.
<i>descC</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix C.
<i>work</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzclarf. Array, size (<i>lwork</i>). If <i>incv</i> = 1, if <i>side</i> = 'L', if <i>ivcol</i> = <i>iccol</i> , <i>lwork</i> ≥ <i>nqc0</i> else

```

lwork $\geq$ mpc0 + max( 1, nqc0 )
end if
else if side = 'R',
lwork $\geq$ nqc0 + max( max( 1, mpc0 ), numroc(numroc( n+
icoffc,nb_v,0,0,npcol),nb_v,0,0,lcmq ) )
end if
else if incv = m_v,
if side = 'L',
lwork $\geq$ mpc0 + max( max( 1, nqc0 ), numroc(
numroc(m+iroffc,mb_v,0,0,nprow ),mb_v,0,0, lcmp ) )
else if side = 'R',
if ivrow = icrow,
lwork $\geq$ mpc0
else
lwork $\geq$ nqc0 + max( 1, mpc0 )
end if
end if
end if,
where lcm is the least common multiple of nprow and npcol and lcm =
ilcm( nprow, npcol ), lcmp = lcm/nprow, lcmq = lcm/npcol,
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprow ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
mpc0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the subroutine
blacs_gridinfo.

```

Output Parameters

C

(local).

On exit, sub(*C*) is overwritten by the $Q^* \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C) * Q$ if *side* = 'R'.

p?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

Fortran:

```

Description

The p?larfb routine applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

<i>side</i>	(global) CHARACTER.
	if <i>side</i> = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left;
	if <i>side</i> = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right.
<i>trans</i>	(global) CHARACTER.
	if <i>trans</i> = 'N': no transpose, apply Q ;
	for real flavors, if <i>trans</i> ='T': transpose, apply Q^T
	for complex flavors, if <i>trans</i> = 'C': conjugate transpose, apply Q^H ;
<i>direct</i>	(global) CHARACTER. Indicates how Q is formed from a product of elementary reflectors.
	if <i>direct</i> = 'F': $Q = H(1)*H(2)*\dots*H(k)$ (Forward)

if *direct* = 'B': $Q = H(k) * \dots * H(2) * H(1)$ (Backward)
storev
 (global) CHARACTER.
 Indicates how the vectors that define the elementary reflectors are stored:
if *storev* = 'C': Columnwise
if *storev* = 'R': Rowwise.

m
 (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).

n
 (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).

k
 (global) INTEGER.
 The order of the matrix T .

v
 (local).
 REAL for `pstrarfb`
 DOUBLE PRECISION for `pdstrarfb`
 COMPLEX for `pclarfb`
 COMPLEX*16 for `pzclarfb`.
 Pointer into the local memory to an array of size
 $(\text{lld}_v, \text{LOC}_c(jv+k-1))$ if *storev* = 'C',
 $(\text{lld}_v, \text{LOC}_c(jv+m-1))$ if *storev* = 'R' and *side* = 'L',
 $(\text{lld}_v, \text{LOC}_c(jv+n-1))$ if *storev* = 'R' and *side* = 'R'.
 It contains the local pieces of the distributed vectors V representing the Householder transformation.
if *storev* = 'C' and *side* = 'L', $\text{lld}_v \geq \max(1, \text{LOC}_r(iv+m-1))$;
if *storev* = 'C' and *side* = 'R', $\text{lld}_v \geq \max(1, \text{LOC}_r(iv+n-1))$;
if *storev* = 'R', $\text{lld}_v \geq \text{LOC}_r(jv+k-1)$.

iv, jv
 (global) INTEGER.
 The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.

descv
 (global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix V .

c
 (local).
 REAL for `pstrarfb`
 DOUBLE PRECISION for `pdstrarfb`
 COMPLEX for `pclarfb`

`COMPLEX*16` **for** `pzlarfb`.

Pointer into the local memory to an array of size (`lld_c`, `LOCc(jc+n-1)`), containing the local pieces of $\text{sub}(C)$.

`ic, jc`

(global) `INTEGER`. The row and column indices in the global array C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

`descC`

(global and local) `INTEGER` array, size (`dlen_`). The array descriptor for the distributed matrix C .

`work`

(local).

`REAL` **for** `pslarfb`

`DOUBLE PRECISION` **for** `pdlarfb`

`COMPLEX` **for** `pclarfb`

`COMPLEX*16` **for** `pzlarfb`.

Workspace array, size (`lwork`).

If `storev = 'C'`,

if `side = 'L'`,

$lwork \geq (nqc0 + mpc0) * k$

else if `side = 'R'`,

$lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n + ioffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq), mpc0)) * k$

end if

else if `storev = 'R'`,

if `side = 'L'`,

$lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(\text{numroc}(m + iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, icmp), nqc0)) * k$

else if `side = 'R'`,

$lwork \geq (mpc0 + nqc0) * k$

end if

end if,

where

$lcmq = lcm / npcol$ with $lcm = \text{iclm}(nprow, npcol)$,

$iroffv = \text{mod}(iv-1, mb_v)$, $icoffv = \text{mod}(jv-1, nb_v)$,

$ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow)$,

$ivcol = \text{indxg2p}(jv, nb_v, mycol, csrc_v, npcol)$,

$MqV0 = \text{numroc}(m+icoffv, nb_v, mycol, ivcol, npcol)$,

$NpV0 = \text{numroc}(n+iroffv, mb_v, myrow, ivrow, nprow)$,

```

iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprov ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
MpC0 = numroc( m+iroffc, mb_c, myrow, icrow, nprov ),
NpC0 = numroc( n+icoffc, mb_c, myrow, icrow, nprov ),
NqC0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprov, and npcol can be determined by calling the subroutine
blacs_gridinfo.
```

Output Parameters

- t* (local).
 REAL for pslarfb
 DOUBLE PRECISION for pdlarfb
 COMPLEX for pclarfb
 COMPLEX*16 for pzlarfb.
 Array, size(*mb_v*, *mb_v*) if *storev* = 'R', and (*nb_v*, *nb_v*) if
 storev = 'C'. The triangular matrix *t* is the representation of the block
 reflector.
- c* (local).
 On exit, *sub(C)* is overwritten by the $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q'$. *Q'* is transpose (conjugate transpose) of *Q*.

p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

Syntax

Fortran:

```
call pclarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

C:

```
void pclarfc (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex8 *tau , MKL_Complex8 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work );
void pzlarfc (char *side , MKL_INT *m , MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv ,
MKL_INT *jv , MKL_INT *descv , MKL_INT *incv , MKL_Complex16 *tau , MKL_Complex16 *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?larfc` routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = i - \tau v^* v^* v,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<code>side</code>	(global) CHARACTER. if <code>side</code> = 'L': form $Q^H * \text{sub}(C)$; if <code>side</code> = 'R': form $\text{sub}(C) * Q^H$.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<code>v</code>	(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code> . Pointer into the local memory to an array of size (<code>lld_v,*</code>) containing the local pieces of the distributed vectors v representing the Householder transformation Q , <code>v(iv:iv+m-1, jv)</code> if <code>side</code> = 'L' and <code>incv</code> = 1, <code>v(iv, jv:jv+m-1)</code> if <code>side</code> = 'L' and <code>incv</code> = <code>m_v</code> , <code>v(iv:iv+n-1, jv)</code> if <code>side</code> = 'R' and <code>incv</code> = 1, <code>v(iv, jv:jv+n-1)</code> if <code>side</code> = 'R' and <code>incv</code> = <code>m_v</code> . The vector v is the representation of Q . v is not used if $\tau = 0$.
<code>iv, jv</code>	(global) INTEGER. The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.
<code>descv</code>	(global and local) INTEGER array, size (<code>dlen_</code>). The array descriptor for the distributed matrix V .
<code>incv</code>	(global) INTEGER. The global increment for the elements of v . Only two values of <code>incv</code> are supported in this version, namely 1 and <code>m_v</code> . <code>incv</code> must not be zero.
<code>tau</code>	(local)

COMPLEX for `pclarfc`
 COMPLEX*16 for `pzlarfc`.
 Array, size $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.
 τ is tied to the distributed matrix V .

c (local).

COMPLEX for `pclarfc`
 COMPLEX*16 for `pzlarfc`.

Pointer into the local memory to an array of size (lld_c , $LOCc(jc+n-1)$), containing the local pieces of $\text{sub}(C)$.

ic, jc (global) INTEGER.

The row and column indices in the global array C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

$desc_c$ (global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix C .

$work$ (local).

COMPLEX for `pclarfc`
 COMPLEX*16 for `pzlarfc`.

Workspace array, size ($lwork$).

```
If  $incv = 1$ ,
  if  $side = 'L'$ ,
    if  $ivcol = iccol$ ,
       $lwork \geq nqc0$ 
    else
       $lwork \geq mpc0 + \max( 1, nqc0 )$ 
    end if
  else if  $side = 'R'$ ,
     $lwork \geq nqc0 + \max( \max( 1, mpc0 ), \text{numroc}( \text{numroc}($ 
       $n+icoffc, nb\_v, 0, 0, npcol ), nb\_v, 0, 0, lcmq ) )$ 
  end if
  else if  $incv = m\_v$ ,
    if  $side = 'L'$ ,
       $lwork \geq mpc0 + \max( \max( 1, nqc0 ), \text{numroc}( \text{numroc}($ 
         $m+iroffc, mb\_v, 0, 0, nprow ), mb\_v, 0, 0, lcmq ) )$ 
    else if  $side = 'R'$ ,
      if  $ivrow = icrow$ ,
         $lwork \geq mpc0$ 
      else
```

```

lwork  $\geq nqc0 + \max( 1, mpc0 )$ 
end if
end if
end if,
where lcm is the least common multiple of nprow and npcol and lcm =
ilcm(nprow, npcol),
lcmp = lcm/nprow, lcmq = lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the subroutine
blacs_gridinfo.
```

Output Parameters

c

(local).

On exit, sub(*C*) is overwritten by the $Q^H * \text{sub}(C)$ if side = 'L', or $\text{sub}(C) * Q^H$ if side = 'R'.

p?larfg

Generates an elementary reflector (*Householder matrix*).

Syntax

Fortran:

```
call pslarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pdlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pclarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pzlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
```

C:

```
void pslarfg (MKL_INT *n , float *alpha , MKL_INT *iax , MKL_INT *jax , float *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *tau );
void pdlarfg (MKL_INT *n , double *alpha , MKL_INT *iax , MKL_INT *jax , double *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *tau );
void pclarfg (MKL_INT *n , MKL_Complex8 *alpha , MKL_INT *iax , MKL_INT *jax ,
MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx ,
MKL_Complex8 *tau );
```

```
void pzlarfg (MKL_INT *n , MKL_Complex16 *alpha , MKL_INT *iax , MKL_INT *jax ,
MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx ,
MKL_Complex16 *tau );
```

Include Files

- C: mkl_scalapack.h

Description

The p?larfg routine generates a real/complex elementary reflector H of order n , such that

$$H^* \text{sub}(X) = H^* \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, \quad H^* H = I,$$

where α is a scalar (a real scalar - for complex flavors), and $\text{sub}(X)$ is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if $incx = 1$ and $X(ix, jx:jx+n-2)$ if $incx = descx(m_)$. H is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 v')$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of $\text{sub}(X)$ are all zero (and $X(iax, jax)$ is real for complex flavors), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$.

Input Parameters

n	(global) INTEGER. The global order of the elementary reflector. $n \geq 0$.
iax, jax	(global) INTEGER. The global row and column indices in x of $X(iax, jax)$.
x	(local). REAL for pslarfg DOUBLE PRECISION for pdlarfg COMPLEX for pclarfg COMPLEX*16 for pzlarfg. Pointer into the local memory to an array of size ($lld_x, *$). This array contains the local pieces of the distributed vector $\text{sub}(X)$. Before entry, the incremented array $\text{sub}(X)$ must contain vector x .
ix, jx	(global) INTEGER.

The row and column indices in the global array X indicating the first row and the first column of $\text{sub}(X)$, respectively.

<i>descx</i>	(global and local) INTEGER. Array of size (<i>dlen_</i>). The array descriptor for the distributed matrix X .
<i>incx</i>	(global) INTEGER. The global increment for the elements of x . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>alpha</i>	(local) REAL for pslafg DOUBLE PRECISION for pdlafg COMPLEX for pclafg COMPLEX*16 for pzlafg. On exit, <i>alpha</i> is computed in the process scope having the vector $\text{sub}(X)$.
<i>x</i>	(local). On exit, it is overwritten with the vector v .
<i>tau</i>	(local). REAL for pslarfg DOUBLE PRECISION for pdlarfg COMPLEX for pclarfg COMPLEX*16 for pzlarfg. Array, size $LOCc(jx)$ if <i>incx</i> = 1, and $LOCr(ix)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix X .

p?larft

Forms the triangular vector T of a block reflector $H = I - V * T * V^H$.

Syntax

Fortran:

```
call pslarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

C:

```
void pslarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , float *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , float *tau , float *t , float *work );
```

```

void pdlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , double *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , double *tau , double *t , double *work );
void pclarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex8 *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex8 *tau , MKL_Complex8 *t ,
MKL_Complex8 *work );
void pzlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex16
*v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex16 *tau , MKL_Complex16
*t , MKL_Complex16 *work );

```

Include Files

- C: mkl_scalapack.h

Description

The p?larft routine forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $\text{direct} = \text{'F'}$, $H = H(1) * H(2) \dots * H(k)$, and T is upper triangular;

If $\text{direct} = \text{'B'}$, $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If $\text{storev} = \text{'C'}$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the distributed matrix V , and

$$H = I - V^* T^* V$$

If $\text{storev} = \text{'R'}$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the distributed matrix V , and

$$H = I - V'^* T^* V.$$

Input Parameters

direct

(global) CHARACTER*1.

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

if $\text{direct} = \text{'F'}$: $H = H(1) * H(2) * \dots * H(k)$ (forward)

if $\text{direct} = \text{'B'}$: $H = H(k) * \dots * H(2) * H(1)$ (backward).

storev

(global) CHARACTER*1.

Specifies how the vectors that define the elementary reflectors are stored (See Application Notes below):

if $\text{storev} = \text{'C'}$: columnwise;

if $\text{storev} = \text{'R'}$: rowwise.

n

(global) INTEGER.

The order of the block reflector H . $n \geq 0$.

k

(global) INTEGER.

The order of the triangular factor T , is equal to the number of elementary reflectors.

$$1 \leq k \leq mb_v (= nb_v).$$

<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Pointer into the local memory to an array of local size $(LOCr(iv+n-1), LOCc(jv+k-1))$ if <i>storev</i> = 'C', and $(LOCr(iv+k-1), LOCc(jv+n-1))$ if <i>storev</i> = 'R'. The distributed matrix <i>V</i> contains the Householder vectors. (See <i>Application Notes</i> below).
<i>iv</i> , <i>jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix sub(<i>V</i>), respectively.
<i>descv</i>	(local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>tau</i>	(local) REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Array, size $LOCr(iv+k-1)$ if <i>incv</i> = <i>m_v</i> , and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>V</i> .
<i>work</i>	(local). REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Workspace array, size $(k*(k-1)/2)$.

Output Parameters

<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft.
<i>t</i>	(local) REAL for pslarft

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

Array, size nb_v by nb_v if $storev = 'C'$, and (mb_v, mb_v) otherwise. It contains the k -by- k triangular factor of the block reflector associated with v . If $direct = 'F'$, t is upper triangular;

if $direct = 'B'$, t is lower triangular.

Application Notes

The shape of the matrix V and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$\begin{matrix} \text{v1} & \text{v2v} & \text{v3} \\ \text{v1} & \text{v2} & \text{v3} \\ 1 & \text{v2} & \text{v3} \\ 1 & \text{v3} \\ 1 \end{matrix}$

$\begin{matrix} \text{v1} & \text{v2v} & \text{v3} \\ \text{v1} & \text{v2} & \text{v3} \\ 1 & \text{v2} & \text{v3} \\ 1 & \text{v3} \\ 1 \end{matrix}$

$$\begin{aligned} & \text{direct} = 'B' \text{ and } storev = 'C' \\ & V(iv : iv + n - 1, \\ & \quad jv : jv + k - 1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ 1 & v3 \\ 1 \end{bmatrix} \end{aligned}$$

$$\begin{aligned} & \text{direct} = 'B' \text{ and } storev = 'R' \\ & V(iv : iv + k - 1, \\ & \quad jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 \\ v2 & v2 & v2 & 1 \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix} \end{aligned}$$

p?larz

Applies an elementary reflector as returned by p?tzrzf to a general matrix.

Syntax

Fortran:

```
call pslarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

The `p?larz` routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v^*,$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by [p?tzrzf](#).

Input Parameters

`side`

(global) CHARACTER.

if `side` = 'L': form $Q^* \text{sub}(C)$,

if `side` = 'R': form $\text{sub}(C)^* Q$, $Q = Q^T$ (for real flavors).

`m`

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).

`n`

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).

`l`

(global) INTEGER.

The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If `side` = 'L', $m \geq l \geq 0$,

if `side` = 'R', $n \geq l \geq 0$.

`v`

(local).

REAL for `pslarz`

DOUBLE PRECISION for `pdlarz`

COMPLEX for `pclarz`

COMPLEX*16 for `pzlarz`.

Pointer into the local memory to an array of size ($lld_v, *$) containing the local pieces of the distributed vectors v representing the Householder transformation Q ,

```
v(iv:iv+l-1, jv) if side = 'L' and incv = 1,  
v(iv, jv:jv+l-1) if side = 'L' and incv = m_v,  
v(iv:iv+l-1, jv) if side = 'R' and incv = 1,  
v(iv, jv:jv+l-1) if side = 'R' and incv = m_v.
```

The vector v in the representation of Q . v is not used if $tau = 0$.

iv, jv

(global) INTEGER. The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.

descv

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix V .

incv

(global) INTEGER.

The global increment for the elements of v . Only two values of $incv$ are supported in this version, namely 1 and m_v .

$incv$ must not be zero.

tau

(local)

```
REAL for pslarz  
DOUBLE PRECISION for pdlarz  
COMPLEX for pclarz  
COMPLEX*16 for pzlarz.
```

Array, size $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix V .

c

(local).

```
REAL for pslarz  
DOUBLE PRECISION for pdlarz  
COMPLEX for pclarz  
COMPLEX*16 for pzlarz.
```

Pointer into the local memory to an array of size ($lld_c, LOCc(jc+n-1)$), containing the local pieces of $\text{sub}(C)$.

ic, jc

(global) INTEGER.

The row and column indices in the global array C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix C .

work

(local).

```

REAL for pslarz
DOUBLE PRECISION for pdlarz
COMPLEX for pclarz
COMPLEX*16 for pzlarz.

Array, size (lwork)

If incv = 1,
  if side = 'L' ,
    if ivcol = iccol,
      lwork  $\geq NqC0$ 
    else
      lwork  $\geq MpC0 + \max(1, NqC0)$ 
    end if
  else if side = 'R' ,
    lwork  $\geq NqC0 + \max(\max(1, MpC0), \text{numroc}(\text{numroc}(n+icoffc, nb\_v, 0, 0, npcol), nb\_v, 0, 0, lcmq)))$ 
  end if
  else if incv = m_v,
    if side = 'L' ,
      lwork  $\geq MpC0 + \max(\max(1, NqC0), \text{numroc}(\text{numroc}(m+iroffc, mb\_v, 0, 0, nprow), mb\_v, 0, 0, lcm))$ 
    else if side = 'R' ,
      if ivrow = icrow,
        lwork  $\geq MpC0$ 
      else
        lwork  $\geq NqC0 + \max(1, MpC0)$ 
      end if
    end if
  end if.

```

Here lcm is the least common multiple of $nprow$ and $npcol$ and

$$\begin{aligned} lcm &= \text{ilcm}(nprow, npcol), lcm = lcm / nprow, \\ lcmq &= lcm / npcol, \\ iroffc &= \text{mod}(ic-1, mb_c), icoffc = \text{mod}(jc-1, nb_c), \\ icrow &= \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow), \\ iccol &= \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol), \\ mpco &= \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow), \\ nqco &= \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol), \end{aligned}$$

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `ncol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

`c` (local).

On exit, `sub(C)` is overwritten by the $Q^* \text{sub}(C)$ if `side = 'L'`, or `sub(C) * Q` if `side = 'R'`.

p?larzb

Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.

Syntax

Fortran:

```
call pslarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc,
descc, work)

Description

The `p?larzb` routine applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Q is a product of k elementary reflectors as returned by `p?tzrzf`.

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

Input Parameters

<code>side</code>	(global) CHARACTER. if <code>side</code> = ' <code>L</code> ': apply Q or Q^T (Q^H for complex flavors) from the Left; if <code>side</code> = ' <code>R</code> ': apply Q or Q^T (Q^H for complex flavors) from the Right.
<code>trans</code>	(global) CHARACTER. if <code>trans</code> = ' <code>N</code> ': No transpose, apply Q ; If <code>trans='T'</code> : Transpose, apply Q^T (real flavors); If <code>trans='C'</code> : Conjugate transpose, apply Q^H (complex flavors).
<code>direct</code>	(global) CHARACTER. Indicates how H is formed from a product of elementary reflectors. if <code>direct</code> = ' <code>F</code> ': $H = H(1)*H(2)*\dots*H(k)$ - forward (not supported) ; if <code>direct</code> = ' <code>B</code> ': $H = H(k)*\dots*H(2)*H(1)$ - backward.
<code>storev</code>	(global) CHARACTER. Indicates how the vectors that define the elementary reflectors are stored: if <code>storev</code> = ' <code>C</code> ': columnwise (not supported). if <code>storev</code> = ' <code>R</code> ': rowwise.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<code>k</code>	(global) INTEGER. The order of the matrix T . (= the number of elementary reflectors whose product defines the block reflector).
<code>l</code>	(global) INTEGER. The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <code>side</code> = ' <code>L</code> ', $m \geq l \geq 0$, if <code>side</code> = ' <code>R</code> ', $n \geq l \geq 0$.

<i>v</i>	(local). REAL for pslarzb DOUBLE PRECISION for pdlarzb COMPLEX for pclarzb COMPLEX*16 for pzlarzb. Pointer into the local memory to an array of size (<i>lld_v</i> , <i>LOCc(jv+m-1)</i>) if <i>side</i> = 'L', (<i>lld_v</i> , <i>LOCc(jv+m-1)</i>) if <i>side</i> = 'R'. It contains the local pieces of the distributed vectors <i>V</i> representing the Householder transformation as returned by p?tzrzf. $lld_v \geq LOCr(iv+k-1)$.
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>V</i> indicating the first row and the first column of the submatrix sub(<i>V</i>), respectively.
<i>descv</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>t</i>	(local) REAL for pslarzb DOUBLE PRECISION for pdlarzb COMPLEX for pclarzb COMPLEX*16 for pzlarzb. Array, DIMENSION <i>mb_v</i> by <i>mb_v</i> . The lower triangular matrix <i>T</i> in the representation of the block reflector.
<i>c</i>	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Pointer into the local memory to an array of size (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). On entry, the <i>m</i> -by- <i>n</i> distributed matrix sub(<i>C</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix sub(<i>C</i>), respectively.
<i>descC</i>	(global and local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local). REAL for pslarzb DOUBLE PRECISION for pdlarzb

```

Description

The p?larzc routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = i - \tau u^* v^* v,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by p?tzrzf.

Input Parameters

side

(global) CHARACTER.

```
if side = 'L': form  $Q^H * \text{sub}(C)$ ;
if side = 'R': form  $\text{sub}(C) * Q^H$ .
```

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).

l

(global) INTEGER.

The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors.

If $\text{side} = \text{'L'}$, $m \geq l \geq 0$,

if $\text{side} = \text{'R'}$, $n \geq l \geq 0$.

v

(local).

COMPLEX for `pclarzc`COMPLEX*16 for `pzlarzc`.

Pointer into the local memory to an array of size ($lld_v, *$) containing the local pieces of the distributed vectors v representing the Householder transformation Q ,

$v(iv:iv+l-1, jv)$ if $\text{side} = \text{'L'}$ and $\text{incv} = 1$,

$v(iv, jv:jv+l-1)$ if $\text{side} = \text{'L'}$ and $\text{incv} = m_v$,

$v(iv:iv+l-1, jv)$ if $\text{side} = \text{'R'}$ and $\text{incv} = 1$,

$v(iv, jv:jv+l-1)$ if $\text{side} = \text{'R'}$ and $\text{incv} = m_v$.

The vector v in the representation of Q . v is not used if $\tau_{au} = 0$.

iv, jv

(global) INTEGER.

The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.

descv

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix V .

incv

(global) INTEGER.

The global increment for the elements of v . Only two values of incv are supported in this version, namely 1 and m_v .

incv must not be zero.

tau

(local)

COMPLEX for `pclarzc`COMPLEX*16 for `pzlarzc`.

Array, size $\text{LOCc}(jv)$ if $\text{incv} = 1$, and $\text{LOCr}(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.

τ_{au} is tied to the distributed matrix V .

c

(local).

COMPLEX for `pclarzc`COMPLEX*16 for `pzlarzc`.

Pointer into the local memory to an array of size ($lld_c, \text{LOCc}(jc+n-1)$), containing the local pieces of $\text{sub}(C)$.

ic, jc

(global) INTEGER.

The row and column indices in the global array C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC (global and local) INTEGER array, size (*dlen_*). The array descriptor for the distributed matrix C .

work (local).

```

If incv = 1,
  if side = 'L' ,
    if ivcol = iccol,
      lwork ≥ nqc0
    else
      lwork ≥ mpc0 + max(1, nqc0)
    end if
  else if side = 'R' ,
    lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
      nb_v, 0, 0, lcmq) )
  end if
else if incv = m_v,
  if side = 'L' ,
    lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v, 0, 0,
nprow),
      mb_v, 0, 0, lcmp) )
  else if side = 'R',
    if ivrow = icrow,
      lwork ≥ mpc0
    else
      lwork ≥ nqc0 + max(1, mpc0)
    end if
  end if
end if

```

Here *lcm* is the least common multiple of *nprow* and *npcol*;

```

lcm = ilcm(nprow, npcol), lcmp = lcm/nprow, lcmq= lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc= mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),

```

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions;
`myrow`, `mycol`, `nprov`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

`c` (local).

On exit, $\text{sub}(C)$ is overwritten by the $Q^H \text{sub}(C)$ if `side = 'L'`, or $\text{sub}(C) * Q^H$ if `side = 'R'`.

p?larzt

Forms the triangular factor T of a block reflector $H=I-V*T*V^H$ as returned by `p?tzrzf`.

Syntax

Fortran:

```
call pslarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)

*t , MKL_Complex16 *work );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?larzt` routine forms the triangular factor T of a real/complex block reflector H of order greater than n , which is defined as a product of k elementary reflectors as returned by `p?tzrzf`.

If `direct = 'F'`, $H = H(1)*H(2)*...*H(k)$, and T is upper triangular;

If `direct = 'B'`, $H = H(k)*...*H(2)*H(1)$, and T is lower triangular.

If `storev = 'C'`, the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array `v`, and

$H = i - v * t * v'$.

If $storev = 'R'$, the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$$H = i - v^* t^* v$$

Currently, only $storev = 'R'$ and $direct = 'B'$ are supported.

Input Parameters

<i>direct</i>	(global) CHARACTER.
	Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
	if $direct = 'F'$: $H = H(1)*H(2)*\dots*H(k)$ (Forward, not supported)
	if $direct = 'B'$: $H = H(k)*\dots*H(2)*H(1)$ (Backward).
<i>storev</i>	(global) CHARACTER.
	Specifies how the vectors which defines the elementary reflectors are stored:
	if $storev = 'C'$: columnwise (not supported);
	if $storev = 'R'$: rowwise.
<i>n</i>	(global) INTEGER.
	The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global) INTEGER.
	The order of the triangular factor T (= the number of elementary reflectors).
	$1 \leq k \leq mb_v (= nb_v)$.
<i>v</i>	REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzclarzt.
	Pointer into the local memory to an array of local size ($LOCr(iv+k-1)$, $LOCc(jv+n-1)$).
	The distributed matrix V contains the Householder vectors. See <i>Application Notes</i> below.
<i>iv</i> , <i>jv</i>	(global) INTEGER. The row and column indices in the global array V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.
<i>descv</i>	(local) INTEGER array, size (<i>dlen_</i>). The array descriptor for the distributed matrix V .
<i>tau</i>	(local) REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt

`COMPLEX*16` for `pzlarzt`.

Array, DIMENSION $LOCr(iv+k-1)$ if $incv = m_v$, and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors.

τ is tied to the distributed matrix V .

$work$

(local).

`REAL` for `pslarzt`

`DOUBLE PRECISION` for `pdlarzt`

`COMPLEX` for `pclarzt`

`COMPLEX*16` for `pzlarzt`.

Workspace array, size $(k*(k-1)/2)$.

Output Parameters

v

`REAL` for `pslarzt`

`DOUBLE PRECISION` for `pdlarzt`

`COMPLEX` for `pclarzt`

`COMPLEX*16` for `pzlarzt`.

t

(local)

`REAL` for `pslarzt`

`DOUBLE PRECISION` for `pdlarzt`

`COMPLEX` for `pclarzt`

`COMPLEX*16` for `pzlarzt`.

Array, size mb_v by mb_v . It contains the k -by- k triangular factor of the block reflector associated with v . t is lower triangular.

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

```
direct='F' and storev='C'

$$\begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

v =   . . .
      . . .
      1 . .
          1 .
              1
```

direct='F' and storev='R':

$$\begin{bmatrix} & & & \overbrace{v_1 & v_1 & v_1 & v_1}^x & v_1 & \dots & 1 \\ v_1 & v_1 & v_1 & v_1 & v_1 & \dots & 1 \\ v_2 & v_2 & v_2 & v_2 & v_2 & \dots & 1 \\ v_3 & v_3 & v_3 & v_3 & v_3 & \dots & 1 \end{bmatrix}$$

direct='B' and storev='C':

$$\begin{array}{c} 1 \\ . \quad 1 \\ . \quad . \quad 1 \\ . \quad . \quad . \\ v = . \quad . \quad . \\ \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix} \end{array}$$

direct='B' and storev='R':

$$\begin{bmatrix} 1 & \dots & \overbrace{v_1 & v_1 & v_1 & v_1}^x & v_1 \\ . \quad 1 & \dots & v_2 & v_2 & v_2 & v_2 \\ . \quad . \quad 1 & \dots & v_3 & v_3 & v_3 & v_3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .

Syntax

Fortran:

```
call pslascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pdlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pclascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pzlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
```

C:

```
void pslascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pclascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pzlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lascl` routine multiplies the m -by- n real/complex distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto \cdot A(i, j) / cfrom$ does not over/underflow. `type` specifies that $\text{sub}(A)$ may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

<code>type</code>	(global) CHARACTER. <code>type</code> indicates the storage type of the input distributed matrix. if <code>type</code> = 'G': $\text{sub}(A)$ is a full matrix, if <code>type</code> = 'L': $\text{sub}(A)$ is a lower triangular matrix, if <code>type</code> = 'U': $\text{sub}(A)$ is an upper triangular matrix, if <code>type</code> = 'H': $\text{sub}(A)$ is an upper Hessenberg matrix.
<code>cfrom, cto</code>	(global) REAL for <code>pslascl/pclascl</code> DOUBLE PRECISION for <code>pdlascl/pzlascl</code> . The distributed matrix $\text{sub}(A)$ is multiplied by $cto/cfrom$. $A(i,j)$ is computed without over/underflow if the final result $cto \cdot A(i,j) / cfrom$ can be represented without over/underflow. <code>cfrom</code> must be nonzero.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local input/local output) REAL for <code>pslascl</code> DOUBLE PRECISION for <code>pdlascl</code> COMPLEX for <code>pclascl</code> COMPLEX*16 for <code>pzlascl</code> . Pointer into the local memory to an array of size <code>(lld_a, LOCc(ja+n-1))</code> . This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<code>ia, ja</code>	(global) INTEGER. The column and row indices in the global array A indicating the first row and column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER.

Array of size (*dlen_*). The array descriptor for the distributed matrix *A*.

Output Parameters

- a* (local).
On exit, this array contains the local pieces of the distributed matrix multiplied by *cto/cfrom*.
- info* (local)
INTEGER.
if *info* = 0: the execution is successful.
if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*),
if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

Fortran:

```
call pslaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pdlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pclaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pzlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
```

C:

```
void pslaset (char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float *beta ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdlaset (char *uplo , MKL_INT *m , MKL_INT *n , double *alpha , double *beta ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *alpha , MKL_Complex8
*beta , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzlaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *alpha ,
MKL_Complex16 *beta , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- C: mkl_scalapack.h

Description

The p?laset routine initializes an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia*:*ia+m-1*, *ja*:*ja+n-1*) to *beta* on the diagonal and *alpha* on the offdiagonals.

Input Parameters

- uplo* (global) CHARACTER.

Specifies the part of the distributed matrix $\text{sub}(A)$ to be set:

if $\text{uplo} = \text{'U'}$: upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed;

if $\text{uplo} = \text{'L'}$: lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed.

Otherwise: all of the matrix $\text{sub}(A)$ is set.

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

alpha

(global).

REAL for pslaset

DOUBLE PRECISION for pdlaset

COMPLEX for pclaset

COMPLEX*16 for pzaset.

The constant to which the offdiagonal elements are to be set.

beta

(global).

REAL for pslaset

DOUBLE PRECISION for pdlaset

COMPLEX for pclaset

COMPLEX*16 for pzaset.

The constant to which the diagonal elements are to be set.

Output Parameters

a

(local).

REAL for pslaset

DOUBLE PRECISION for pdlaset

COMPLEX for pclaset

COMPLEX*16 for pzaset.

Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOCc}(ja+n-1))$.

This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading m -by- n submatrix $\text{sub}(A)$ is set as follows:

if $\text{uplo} = \text{'U'}$, $A(ia+i-1, ja+j-1) = \text{alpha}$, $1 \leq i \leq j-1$, $1 \leq j \leq n$,

if $\text{uplo} = \text{'L'}$, $A(ia+i-1, ja+j-1) = \text{alpha}$, $j+1 \leq i \leq m$, $1 \leq j \leq n$,

otherwise, $A(ia+i-1, ja+j-1) = \text{alpha}$, $1 \leq i \leq m$, $1 \leq j \leq n$, $ia+i.\text{ne}.ja+j$, and, for all uplo , $A(ia+i-1, ja+i-1) = \text{beta}$, $1 \leq i \leq \min(m, n)$.

<i>ia</i> , <i>ja</i>	(global) INTEGER.
	The column and row indices in the global array <i>A</i> indicating the first row and column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER.
	Array of size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

Fortran:

```
call pslasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pdlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
```

C:

```
void pslasmsub (float *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *k ,
float *smlnum , float *buf , MKL_INT *lwork );
void pdlasmsub (double *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *k ,
double *smlnum , double *buf , MKL_INT *lwork );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lasmsub routine looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This routine does a global maximum and must be called by all processes.

Input Parameters

<i>a</i>	(global) REAL for pslasmsub DOUBLE PRECISION for pdlasmsub Array, size (<i>desca(lld_)</i> , *).
	On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER. The global location of the top of the unreduced submatrix of <i>A</i> .

Unchanged on exit.

smlnum

(global)

REAL for `pslasmsub`

DOUBLE PRECISION for `pdlasmsub`

On entry, a "small number" for the given matrix. Unchanged on exit. A suggested value for *smlnum* is `slamch('s') * (n/slamch('p'))` for `pslasmsub` or `dlamch('s') * (n/dlamch('p'))` for `pdlasmsub`. See `lamch`.

lwork

(global) INTEGER.

On exit, *lwork* is the size of the work buffer.

This must be at least $2 \cdot \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcol))$. Here `lcm` is least common multiple, and `nprow x npcol` is the logical grid size.

Output Parameters

k

(global) INTEGER.

On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $1 \leq m \leq i-1$.

buf

(local).

REAL for `pslasmsub`

DOUBLE PRECISION for `pdlasmsub`

Array of size *lwork*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

Fortran:

```
call pslassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pdlassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pclassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pzlassq(n, x, ix, jx, descx, incx, scale, sumsq)
```

C:

```
void pslassq (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *scale , float *sumsq );
void pdlassq (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *scale , double *sumsq );
void pclassq (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *scale , float *sumsq );
```

```
void pzlassq (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *scale , double *sumsq );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lassq routine returns the values *scl* and *sumsq* such that

$$scl^2 * sumsq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{sub}(X) = X(ix + (jx-1)*descx(m_)) + (i - 1)*incx)$ for pslassq/pdlassq ,

and $x(i) = \text{abs}(X(ix + (jx-1)*descx(m_)) + (i - 1)*incx)$ for pclassq/pzlassq.

For real routines pslassq/pdlassq the value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(x(i))).$$

For complex routines pclassq/pzlassq the value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value *scale* is assumed to be non-negative and *scl* returns the value

$$scl = \max_i (scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{imag}(x(i))))$$

For all routines p?lassq values *scale* and *sumsq* must be supplied in *scale* and *sumsq* respectively, and *scale* and *sumsq* are overwritten by *scl* and *ssq* respectively.

All routines p?lassq make only one pass through the vector sub(x).

Input Parameters

n (global) INTEGER.

The length of the distributed vector sub(*x*).

x REAL for pslassq

DOUBLE PRECISION for pdlassq

COMPLEX for pclassq

COMPLEX*16 for pzlassq.

The vector for which a scaled sum of squares is computed:

$x(ix + (jx-1)*m_x + (i - 1)*incx), 1 \leq i \leq n.$

ix (global) INTEGER.

The row index in the global array *X* indicating the first row of sub(*X*).

jx (global) INTEGER.

The column index in the global array *X* indicating the first column of sub(*X*).

descx (global and local) INTEGER array of size (*dlen*_).

The array descriptor for the distributed matrix X .

incx (global) INTEGER.

The global increment for the elements of X . Only two values of *incx* are supported in this version, namely 1 and m_x . The argument *incx* must not equal zero.

scale (local).

REAL for pslassq/pclassq

DOUBLE PRECISION for pdlassq/pzlassq.

On entry, the value *scale* in the equation above.

sumsq (local)

REAL for pslassq/pclassq

DOUBLE PRECISION for pdlassq/pzlassq.

On entry, the value *sumsq* in the equation above.

Output Parameters

scale (local).

On exit, *scale* is overwritten with *scl*, the scaling factor for the sum of squares.

sumsq (local).

On exit, *sumsq* is overwritten with the value *smsq*, the basic sum of squares from which *scl* has been factored out.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

Fortran:

```
call pslaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pdlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pclaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pzlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
```

C:

```
void pslaswp (char *direc , char *rowcol , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
void pdlaswp (char *direc , char *rowcol , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
void pclaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

```
void pzlaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?laswp` routine performs a series of row or column interchanges on the distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $\text{sub}(A)$. This routine assumes that the pivoting information has already been broadcast along the process row or column. Also note that this routine will only work for $k1-k2$ being in the same mb (or nb) block. If you want to pivot a full matrix, use `p?lapiv`.

Input Parameters

<code>direc</code>	(global) CHARACTER.
	Specifies in which order the permutation is applied:
	= 'F' - forward,
	= 'B' - backward.
<code>rowcol</code>	(global) CHARACTER.
	Specifies if the rows or columns are permuted:
	= 'R' - rows,
	= 'C' - columns.
<code>n</code>	(global) INTEGER.
	If <code>rowcol='R'</code> , the length of the rows of the distributed matrix $A(*, ja:ja+n-1)$ to be permuted;
	If <code>rowcol='C'</code> , the length of the columns of the distributed matrix $A(ia:ia+n-1, *)$ to be permuted;
<code>a</code>	(local)
	REAL for <code>pslaswp</code>
	DOUBLE PRECISION for <code>pdlaswp</code>
	COMPLEX for <code>pclaspw</code>
	COMPLEX*16 for <code>pzlaswp</code> .
	Pointer into the local memory to an array of size ($lld_a, *$). On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.
<code>ia</code>	(global) INTEGER.
	The row index in the global array A indicating the first row of $\text{sub}(A)$.
<code>ja</code>	(global) INTEGER.
	The column index in the global array A indicating the first column of $\text{sub}(A)$.
<code>desca</code>	(global and local) INTEGER array of size ($dlen_$).

The array descriptor for the distributed matrix A .

$k1$ (global) INTEGER.

The first element of $ipiv$ for which a row or column interchange will be done.

$k2$ (global) INTEGER.

The last element of $ipiv$ for which a row or column interchange will be done.

$ipiv$ (local)

INTEGER. Array, size $LOCr(m_a) + mb_a$ for row pivoting and $LOCr(n_a) + nb_a$ for column pivoting. This array is tied to the matrix A , $ipiv(k)=l$ implies rows (or columns) k and l are to be interchanged.

Output Parameters

A (local)

REAL for pslaswp

DOUBLE PRECISION for pdlaswp

COMPLEX for pcclaswp

COMPLEX*16 for pzblaswp.

On exit, the permuted distributed matrix.

p?latra

Computes the trace of a general square distributed matrix.

Syntax

Fortran:

```
val = pslatra(n, a, ia, ja, desca)
val = pdlatra(n, a, ia, ja, desca)
val = pclatra(n, a, ia, ja, desca)
val = pzlatra(n, a, ia, ja, desca)
```

C:

```
float pslatra (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
double pdlatra (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclatra (MKL_Complex8 * , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca );
void pzlatra (MKL_Complex16 * , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca );
```

Include Files

- C: mkl_scalapack.h

Description

This function computes the trace of an n -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local). REAL for pslatra DOUBLE PRECISION for pdlatra COMPLEX for pclatra COMPLEX*16 for pzlatra. Pointer into the local memory to an array of size (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) containing the local pieces of the distributed matrix, the trace of which is to be computed.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices respectively in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>val</i>	The value returned by the function.
------------	-------------------------------------

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

Fortran:

```
call pslatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pdlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pclatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pzlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
```

C:

```
void pslatrd (char *uplo , MKL_INT *n , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *d , float *e , float *tau , float *w , MKL_INT *iw ,
MKL_INT *jw , MKL_INT *descw , float *work );
```

```

void pdlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *w ,
MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , double *work );

void pclatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8
*w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex8 *work );

void pzlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau ,
MKL_Complex16 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex16 *work );

```

Include Files

- C: mkl_scalapack.h

Description

The p?latrd routine reduces nb rows and columns of a real symmetric or complex Hermitian matrix sub(A) = $A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q^* \text{sub}(A) Q$, and returns the matrices V and W , which are needed to apply the transformation to the unreduced part of sub(A).

If $uplo = U$, p?latrd reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = L$, p?latrd reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by p?syrtd/p?hetrd.

Input Parameters

uplo

(global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(A) is stored:

= 'U': Upper triangular
= 'L': Lower triangular.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed submatrix sub(A). $n \geq 0$.

nb

(global) INTEGER.

The number of rows and columns to be reduced.

a

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Pointer into the local memory to an array of size(lld_a, LOCc(ja+n-1)).

On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix sub(A).

If $uplo = \text{U}$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If $uplo = \text{L}$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia

(global) INTEGER.

The row index in the global array A indicating the first row of $\text{sub}(A)$.*ja*

(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.*desca*(global and local) INTEGER array of size ($dlen_$). The array descriptor for the distributed matrix A .*iw*

(global) INTEGER.

The row index in the global array W indicating the first row of $\text{sub}(W)$.*jw*

(global) INTEGER.

The column index in the global array W indicating the first column of $\text{sub}(W)$.*descw*(global and local) INTEGER array of size ($dlen_$). The array descriptor for the distributed matrix W .*work*

(local)

```
REAL for pslatrd  
DOUBLE PRECISION for pdlatrd  
COMPLEX for pclatrd  
COMPLEX*16 for pzlatrd.
```

Workspace array of size (nb_a).

Output Parameters

a

(local)

On exit, if $uplo = \text{'U'}$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $\text{sub}(A)$; the elements above the diagonal with the array τau represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if $uplo = \text{'L'}$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $\text{sub}(A)$; the elements below the diagonal with the array τau represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

d

(local)

REAL for pslatrd/pclatrd

DOUBLE PRECISION for pdlatrd/pzlatrd.

Array, size $\text{LOCc}(ja+n-1)$.

The diagonal elements of the tridiagonal matrix T : $d(i) = a(i, i)$. d is tied to the distributed matrix A .

e

(local)

REAL for pslatrd/pclatrd

DOUBLE PRECISION for pdlatrd/pzlatrd.

Array, size $\text{LOCc}(ja+n-1)$ if $\text{uplo} = \text{'U'}$, $\text{LOCc}(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e(i) = a(i, i + 1)$ if $\text{uplo} = \text{'U'}$,

$e(i) = a(i + 1, i)$ if $\text{uplo} = \text{L}$.

e is tied to the distributed matrix A .

tau

(local)

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Array, size $\text{LOCc}(ja+n-1)$. This array contains the scalar factors tau of the elementary reflectors. tau is tied to the distributed matrix A .

w

(local)

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Pointer into the local memory to an array of size l/d_w by nb_w . This array contains the local pieces of the n -by- nb_w matrix w required to update the unreduced part of $\text{sub}(A)$.

Application Notes

If $\text{uplo} = \text{'U'}$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v'$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and tau in $tau(ja+i-1)$.

If $\text{uplo} = \text{L}$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1: ia+n-1, ja+i-1)$, and τ in $\tau(ia+i-1)$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$\text{sub}(A) := \text{sub}(A) - vw' - wv'$.

The contents of a on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$:

$$\begin{array}{ll} \text{if } \text{uplo}=\text{U}: & \text{if } \text{uplo}=\text{L}: \\ \left[\begin{array}{ccccc} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & d & 1 & \\ & & & d & \end{array} \right] & \left[\begin{array}{ccccc} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{array} \right] \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

Fortran:

```
call pslatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pdlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pclatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pzlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)
```

C:

```

Description

The p?latrs routine solves a triangular system of equations $Ax = sb$, $A^T x = sb$ or $A^H x = sb$, where s is a scale factor set to prevent overflow. The description of the routine will be extended in the future releases.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to Ax . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where s - is a scale factor
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$
<i>a</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs Array, size <i>lda</i> by <i>n</i> . Contains the triangular matrix A . If <i>uplo</i> = U, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

If $diag = 'U'$, the diagonal elements of a are also not referenced and are assumed to be 1.

ia, ja

(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

x

REAL for pslatrs/pclatrs

DOUBLE PRECISION for pdlatrs/pzlatrs

Array, size (n). On entry, the right hand side b of the triangular system.

ix

(global) INTEGER. The row index in the global array x indicating the first row of $\text{sub}(x)$.

jx

(global) INTEGER.

The column index in the global array x indicating the first column of $\text{sub}(x)$.

descx

(global and local) INTEGER.

Array, size ($dlen_$). The array descriptor for the distributed matrix X .

cnorm

REAL for pslatrs/pclatrs

DOUBLE PRECISION for pdlatrs/pzlatrs.

Array, size (n). If $normin = 'Y'$, $cnorm$ is an input argument and $cnorm(j)$ contains the norm of the off-diagonal part of the j -th column of A . If $trans = 'N'$, $cnorm(j)$ must be greater than or equal to the infinity-norm, and if $trans = 'T'$ or ' C' , $cnorm(j)$ must be greater than or equal to the 1-norm.

work

(local).

REAL for pslatrs

DOUBLE PRECISION for pdlatrs

COMPLEX for pclatrs

COMPLEX*16 for pzlatrs.

Temporary workspace.

Output Parameters

X

On exit, x is overwritten by the solution vector x .

scale

REAL for pslatrs/pclatrs

DOUBLE PRECISION for pdlatrs/pzlatrs.

Array, size lda by n . The scaling factor s for the triangular system as described above.

If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $AX = 0$.

$cnorm$

If $normin = 'N'$, $cnorm$ is an output argument and $cnorm(j)$ returns the 1-norm of the off-diagonal part of the j -th column of A .

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

Fortran:

```
call pslatrz(m, n, l, a, ia, ja, desca, tau, work)
call pdlatrz(m, n, l, a, ia, ja, desca, tau, work)
call pclatrz(m, n, l, a, ia, ja, desca, tau, work)
call pzlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

C:

```
void pslatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work );
void pdlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work );
void pclatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work );
void pzlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?latrz` routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = [A(ia:ia+m-1, ja:ja+m-1) A(ia:ia+m-1, ja+n-1:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $\text{sub}(A)$ is factored as

$\text{sub}(A) = (R \ 0) * Z$,

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. $m \geq 0$.

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.

l (global) INTEGER.

The number of columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$.

a (local)

REAL for pslatrz
DOUBLE PRECISION for pdlatrz
COMPLEX for pclatrz
COMPLEX*16 for pzlatrz.

Pointer into the local memory to an array of size (*lld_a*, *LOCc(ja+n-1)*). On entry, the local pieces of the m -by- n distributed matrix $\text{sub}(A)$, which is to be factored.

ia (global) INTEGER.

The row index in the global array *A* indicating the first row of $\text{sub}(A)$.

ja (global) INTEGER.

The column index in the global array *A* indicating the first column of $\text{sub}(A)$.

desca (global and local) INTEGER array of size (*dlen_*).

The array descriptor for the distributed matrix *A*.

work (local)

REAL for pslatrz
DOUBLE PRECISION for pdlatrz
COMPLEX for pclatrz
COMPLEX*16 for pzlatrz.

Workspace array, size (*lwork*).

lwork $\geq nq0 + \max(1, mp0)$, where
iroff = mod(*ia*-1, *mb_a*),
icoff = mod(*ja*-1, *nb_a*),
iarow = idxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nproc*),
iacol = idxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *ncol*),
mp0 = numroc(*m+iroff*, *mb_a*, *myrow*, *iarow*, *nproc*),
nq0 = numroc(*n+icoff*, *nb_a*, *mycol*, *iacol*, *ncol*),
numroc, *idxg2p*, and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nproc*, and *ncol* can be determined by calling the subroutine *blacs_gridinfo*.

Output Parameters

a

On exit, the leading m -by- m upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix R , and elements $n-l+1$ to n of the first m rows of $\text{sub}(A)$, with the array τ_{au} , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.

tau

(local)

REAL for pslatrz

DOUBLE PRECISION for pdlatrz

COMPLEX for pclatrz

COMPLEX*16 for pzlatrz.

Array, size ($\text{LOC}_r(ja+m-1)$). This array contains the scalar factors of the elementary reflectors. τ_{au} is tied to the distributed matrix A .

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex routines, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau_{\text{au}} * u(k) * u(k)', \quad u(k) = \begin{bmatrix} I \\ 0 \\ z(k) \end{bmatrix}$$

τ_{au} is a scalar and $z(k)$ is an $(n-m)$ -element vector. τ_{au} and $z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ_{au} is returned in the k -th element of τ_{au} and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $a(k, m+1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$.

Z is given by

$Z = Z(1)Z(2)\dots Z(m)$.

p?lauu2

Computes the product U^*U' or L'^*L , where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

Fortran:

```
call pslauu2(uplo, n, a, ia, ja, desca)
call pdlauu2(uplo, n, a, ia, ja, desca)
call pclauu2(uplo, n, a, ia, ja, desca)
```

```
call pzlaau2(uplo, n, a, ia, ja, desca)
```

C:

```
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
void pzlaau2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lauu2 routine computes the product U^*U' or L^*L' , where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or 'u', then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$.

If $uplo = 'L'$ or '', then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this routine, the matrix to operate on should be strictly local to one process.

Input Parameters

uplo (global) CHARACTER*1.
Specifies whether the triangular factor stored in the *matrix* $\text{sub}(A)$ is upper or lower triangular:
= U: upper triangular
= L: lower triangular.

n (global) INTEGER.
The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.

a (local)
REAL for pslauu2
DOUBLE PRECISION for pdlauu2
COMPLEX for pclauu2
COMPLEX*16 for pzlaau2.
Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOCc}(ja+n-1))$.
On entry, the local pieces of the triangular factor U or L .

ia (global) INTEGER.
The row index in the global array *A* indicating the first row of $\text{sub}(A)$.

<i>ja</i>	(global) INTEGER.
	The column index in the global array A indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) INTEGER array of size (<i>dlen_</i>). The array descriptor for the distributed matrix A .

Output Parameters

<i>a</i>	(local)
	On exit, if <i>uplo</i> = 'U', the upper triangle of the distributed matrix $\text{sub}(A)$ is overwritten with the upper triangle of the product U^*U' ; if <i>uplo</i> = 'L', the lower triangle of $\text{sub}(A)$ is overwritten with the lower triangle of the product L'^*L .

p?lauum

Computes the product U^*U' or L'^*L , where U and L are upper or lower triangular matrices.

Syntax

Fortran:

```
call pslauum(uplo, n, a, ia, ja, desca)
call pdlauum(uplo, n, a, ia, ja, desca)
call pclauum(uplo, n, a, ia, ja, desca)
call pzlaum(uplo, n, a, ia, ja, desca)
```

C:

```
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
void pclauum (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
void pzlaum (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lauum routine computes the product U^*U' or L'^*L , where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the triangular factor stored in the matrix sub(<i>A</i>) is upper or lower triangular: = 'U': upper triangular = 'L': lower triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$.
<i>a</i>	(local) REAL for pslauum DOUBLE PRECISION for pdlauum COMPLEX for pclauum COMPLEX*16 for pzlaum. Pointer into the local memory to an array of size (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the local pieces of the triangular factor <i>U</i> or <i>L</i> .
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of size (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = 'U', the upper triangle of the distributed matrix sub(<i>A</i>) is overwritten with the upper triangle of the product <i>U</i> * <i>U</i> ' ; if <i>uplo</i> = 'L', the lower triangle of sub(<i>A</i>) is overwritten with the lower triangle of the product <i>L</i> ' * <i>L</i> .
----------	--

p?lawil

Forms the Wilkinson transform.

Syntax

Fortran:

```
call pslawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pdlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
```

C:

```
void pslawil (MKL_INT *ii , MKL_INT *jj , MKL_INT *m , float *a , MKL_INT *desca ,
float *h44 , float *h33 , float *h43h34 , float *v );
void pdlawil (MKL_INT *ii , MKL_INT *jj , MKL_INT *m , double *a , MKL_INT *desca ,
double *h44 , double *h33 , double *h43h34 , double *v );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lawil` routine gets the transform given by $h44$, $h33$, and $h43h34$ into v starting at row m .

Input Parameters

<i>ii</i>	(global) INTEGER. Row owner of $h(m+2, m+2)$.
<i>jj</i>	(global) INTEGER. Column owner of $h(m+2, m+2)$.
<i>m</i>	(global) INTEGER. On entry, the location from where the transform starts (row m). Unchanged on exit.
<i>a</i>	(global) REAL for <code>pslawil</code> DOUBLE PRECISION for <code>pdlawil</code> Array, size (<code>desca(lld_)</code> ,*). On entry, the Hessenberg matrix. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER Array of size (<code>dlen_</code>). The array descriptor for the distributed matrix A . Unchanged on exit.
<i>h43h34</i>	(global) REAL for <code>pslawil</code> DOUBLE PRECISION for <code>pdlawil</code> These three values are for the double shift QR iteration. Unchanged on exit.

Output Parameters

<i>v</i>	(global) REAL for <code>pslawil</code> DOUBLE PRECISION for <code>pdlawil</code> Array of size 3 that contains the transform on output.
----------	--

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

Fortran:

```
call psorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

Description

The p?org2l/p?ung2l routine generates an m -by- n real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$$Q = H(k) * \dots * H(2) * H(1) \text{ as returned by p?geqlf.}$$

Input Parameters

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $m \geq n \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.

a

REAL for psorg21
 DOUBLE PRECISION for pdorg21
 COMPLEX for pcung21
 COMPLEX*16 for pzung21.
 Pointer into the local memory to an array, size (*lld_a*, *LOCc(ja+n-1)*).
 On entry, the *j*-th column must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-k$, as returned by [p?geqlf](#) in the *k* columns of its *distributed matrix* argument $A(ia:*, ja+n-k:ja+n-1)$.

ia

(global) INTEGER.
 The row index in the global array *A* indicating the first row of sub(*A*).

ja

(global) INTEGER.
 The column index in the global array *A* indicating the first column of sub(*A*).

desca

(global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix *A*.

tau

(local)
 REAL for psorg21
 DOUBLE PRECISION for pdorg21
 COMPLEX for pcung21
 COMPLEX*16 for pzung21.
 Array, size *LOCc(ja+n-1)*.
 This array contains the scalar factor $\tau_{au}(j)$ of the elementary reflector $H(j)$, as returned by [p?geqlf](#).

work

(local)
 REAL for psorg21
 DOUBLE PRECISION for pdorg21
 COMPLEX for pcung21
 COMPLEX*16 for pzung21.
 Workspace array, size (*lwork*).

lwork

(local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where
 $iroffa = \text{mod}(ia-1, mb_a),$
 $icoffa = \text{mod}(ja-1, nb_a),$
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol),$

```

mpa0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nqa0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol).

indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow,
and npcol can be determined by calling the subroutine blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and optimal size for all
work arrays. Each of these values is returned in the first entry of the
corresponding work array, and no error message is issued by pxerbla.

```

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the m -by- n distributed matrix Q .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?org2r/p?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqr (unblocked algorithm).

Syntax

Fortran:

```

call psorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)

```

C:

```

void psorg2r (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorg2r (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcung2r (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzung2r (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );

```

Include Files

Description

The `p?org2r/p?ung2r` routine generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m :

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?geqrf`.

Input Parameters

`m`

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.

`n`

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $m \geq n \geq 0$.

`k`

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.

`a`

REAL for `psorg2r`

DOUBLE PRECISION for `pdorg2r`

COMPLEX for `pcung2r`

COMPLEX*16 for `pzung2r`.

Pointer into the local memory to an array, size (`lld_a`, `LOCc(ja+n-1)`).

On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by `p?geqrf` in the k columns of its *distributed matrix* argument $A(ia:*, ja:ja+k-1)$.

`ia`

(global) INTEGER.

The row index in the global array A indicating the first row of $\text{sub}(A)$.

`ja`

(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.

`desca`

(global and local) INTEGER array of size (`dlen_`).

The array descriptor for the distributed matrix A .

`tau`

(local)

REAL for `psorg2r`

DOUBLE PRECISION for `pdorg2r`

COMPLEX for `pcung2r`

`COMPLEX*16` for `pzung2r`.

Array, size $LOCc(ja+k-1)$.

This array contains the scalar factor $\tau(j)$ of the elementary reflector $H(j)$, as returned by `p?geqrf`. This array is tied to the distributed matrix A .

`work`

(local)

`REAL` for `psorg2r`

`DOUBLE PRECISION` for `pdorg2r`

`COMPLEX` for `pcung2r`

`COMPLEX*16` for `pzung2r`.

Workspace array, size ($lwork$).

`lwork`

(local or global) `INTEGER`.

The dimension of the array `work`.

$lwork$ is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$,

where

```
iroffa = mod(ia-1, mb_a , icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
mpa0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nqa0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol).
```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

`a`

On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

`work`

On exit, `work(1)` returns the minimal and optimal $lwork$.

`info`

(local) `INTEGER`.

= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
then `info = - (i*100+j)`,

if the i -th argument is a scalar and had an illegal value,
then `info = -i`.

p?orgl2/p?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

Fortran:

```
call psorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

C:

```
void psorgl2 (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgl2 (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcungl2 (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzungl2 (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Description

The p?orgr2/p?ungr2 routine generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1)^H * H(2)^H * \dots * H(k)^H$ (for real flavors);

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors) as returned by [p?gerqf](#).

Input Parameters

m	(global) INTEGER.
	The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER.
	The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) INTEGER.
	The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungqr2 COMPLEX*16 for pzungr2. Pointer into the local memory to an array, size (lld_a , $LOCc(ja+n-1)$). On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the k rows of its <i>distributed matrix</i> argument $A(ia+m-k:ia+m-1, ja:*)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).
ja	(global) INTEGER. The column index in the global array A indicating the first column of sub(A).
$desca$	(global and local) INTEGER array of size ($dlen_$). The array descriptor for the distributed matrix A .
tau	(local) REAL for psorgr2

DOUBLE PRECISION for pdorgqr2

COMPLEX for pcungqr2

COMPLEX*16 for pzungr2.

Array, size $LOC_r(ja+m-1)$. This array contains the scalar factors $tau(i)$ of the elementary reflectors $H(i)$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

work

(local)

REAL for psorgqr2

DOUBLE PRECISION for pdorgqr2

COMPLEX for pcungqr2

COMPLEX*16 for pzungr2.

Workspace array, size (*lwork*).

lwork

(local or global) INTEGER.

The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,

$mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,

$nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol)$.

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,

then *info* = - (i*100+j),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -i.

p?orm2l/p?unm2l

Multiples a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

Fortran:

```
call psorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,

Description

The p?orm2l/p?unm2l routine overwrites the general real/complex m -by- n distributed matrix sub $(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by [p?geqlf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

side	(global) CHARACTER. = ' L ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = ' R ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
trans	(global) CHARACTER. = ' N ': apply Q (no transpose) = ' T ': apply Q^T (transpose, for real flavors) = ' C ': apply Q^H (conjugate transpose, for complex flavors)
m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l . Pointer into the local memory to an array, $\text{size}(\text{lld}_a, \text{LOC}_c(ja+k-1))$. On entry, the j -th row must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If $\text{side} = 'L'$, $\text{lld}_a \geq \max(1, \text{LOC}_r(ia+m-1))$, if $\text{side} = 'R'$, $\text{lld}_a \geq \max(1, \text{LOC}_r(ia+n-1))$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of $\text{sub}(A)$.
ja	(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.

descA (global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix A .

tau (local)

```
REAL for psorm2l
DOUBLE PRECISION for pdorm2l
COMPLEX for pcunm2l
COMPLEX*16 for pzunm2l.
```

Array, size $LOC_C(ja+n-1)$. This array contains the scalar factor $\tau_{au}(j)$ of the elementary reflector $H(j)$, as returned by [p?geqlf](#). This array is tied to the distributed matrix A .

c (local)

```
REAL for psorm2l
DOUBLE PRECISION for pdorm2l
COMPLEX for pcunm2l
COMPLEX*16 for pzunm2l.
```

Pointer into the local memory to an array, size (*lld_c*, $LOC_C(jc+n-1)$). On entry, the local pieces of the distributed matrix $\text{sub}(C)$.

ic (global) INTEGER.

The row index in the global array C indicating the first row of $\text{sub}(C)$.

jc (global) INTEGER.

The column index in the global array C indicating the first column of $\text{sub}(C)$.

descC (global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix C .

work (local)

```
REAL for psorm2l
DOUBLE PRECISION for pdorm2l
COMPLEX for pcunm2l
COMPLEX*16 for pzunm2l.
```

Workspace array, size (*lwork*).

On exit, *work*(1) returns the minimal and optimal *lwork*.

lwork (local or global) INTEGER.

The dimension of the array *work*.

lwork is local input and must be at least

```
if side = 'L', lwork ≥ mpc0 + max(1, nqc0),
if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n
+icoffc, nb_a, 0, 0, ncol), nb_a, 0, 0, lcmq)),
```

where

```

lcmq = lcm/npcol,
lcm = iclm(nprow, npcol),
iroffc = mod(ic-1, mb_c),
icooffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
Mqc0 = numroc(m+icooffc, nb_c, mycol, icrow, nprow),
Npc0 = numroc(n+iroffc, mb_c, myrow, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the subroutine
blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i*100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

```

If side = 'L', ( mb_a.eq.mb_c .AND. iroffa.eq.iroffc .AND. iarow.eq.icrow )
If side = 'R', ( mb_a.eq.nb_c .AND. iroffa.eq.iroffc ).
```

p?orm2r/p?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqr (unblocked algorithm).

Syntax

Description

The p?orm2r/p?unm2r routine overwrites the general real/complex m -by- n distributed matrix sub $(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by p?geqrf . Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

side (global) CHARACTER.

= 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,
 = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.

trans

(global) CHARACTER.
 = 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q .

```
If side = 'L', m ≥ k ≥ 0;  
if side = 'R', n ≥ k ≥ 0.
```

a

(local)

```
REAL for psorm2r  
DOUBLE PRECISION for pdorm2r  
COMPLEX for pcunm2r  
COMPLEX*16 for pzunm2r.
```

Pointer into the local memory to an array, size(*lld_a*, *LOCc(ja+k-1)*).

On entry, the *j*-th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by [p?geqrf](#) in the *k* columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.

```
If side = 'L', lld_a ≥ max(1, LOCr(ia+m-1)),  
if side = 'R', lld_a ≥ max(1, LOCr(ia+n-1)).
```

ia

(global) INTEGER.

The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja

(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.

desca

(global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix A .

tau

(local)

REAL **for** psorm2r
 DOUBLE PRECISION **for** pdorm2r
 COMPLEX **for** pcunm2r
 COMPLEX*16 **for** pzunm2r.

Array, size $LOC_C(ja+k-1)$. This array contains the scalar factors $\tau_{au}(j)$ of the elementary reflector $H(j)$, as returned by [p?geqrf](#). This array is tied to the distributed matrix A .

c
 (local)
 REAL **for** psorm2r
 DOUBLE PRECISION **for** pdorm2r
 COMPLEX **for** pcunm2r
 COMPLEX*16 **for** pzunm2r.
 Pointer into the local memory to an array, size ($l1d_c$, $LOC_C(jc+n-1)$).
 On entry, the local pieces of the distributed matrix sub (C).

ic
 (global) INTEGER.
 The row index in the global array C indicating the first row of sub(C).

jc
 (global) INTEGER.
 The column index in the global array C indicating the first column of sub(C).

descC
 (global and local) INTEGER array of size ($dlen_$).
 The array descriptor for the distributed matrix C .

work
 (local)
 REAL **for** psorm2r
 DOUBLE PRECISION **for** pdorm2r
 COMPLEX **for** pcunm2r
 COMPLEX*16 **for** pzunm2r.
 Workspace array, size ($lwork$).

lwork
 (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least

```
if side = 'L', lwork ≥ mpc0 + max(1, nqc0),
if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n
+icoffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),
```

 where

$$lcmq = lcm/npcol,$$

$$lcm = iclm(nprow, npcol),$$

$$iroffc = \text{mod}(ic-1, mb_c),$$

```

 $icoffc = \text{mod}(jc-1, nb\_c),$ 
 $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow),$ 
 $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npcol),$ 
 $Mqc0 = \text{numroc}(m+icoffc, nb\_c, mycol, icrow, nprow),$ 
 $Npc0 = \text{numroc}(n+iroffc, mb\_c, myrow, iccol, npcol),$ 
ilcm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

c On exit, *c* is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.
= 0: successful exit
< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
then *info* = - (*i**100+*j*),
if the *i*-th argument is a scalar and had an illegal value,
then *info* = -*i*.

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', $(mb_a.eq.mb_c .AND. iroffa.eq.iroffc .AND. iarow.eq.icrow)$
If *side* = 'R', $(mb_a.eq.nb_c .AND. iroffa.eq.iroffc)$.

p?orml2/p?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

$\text{sub}(C)^*Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C)^*Q^T / \text{sub}(C)^*Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k)^* \dots ^* H(2)^* H(1)$ (for real flavors)

$Q = (H(k))^H \star \dots \star (H(2))^H \star (H(1))^H$ (for complex flavors)

as returned by p?gelqf . Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER.
	= 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,
	= 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER.

= 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q .

If $\text{side} = 'L'$, $m \geq k \geq 0$;

if $\text{side} = 'R'$, $n \geq k \geq 0$.

a

(local)

REAL for psorml2

DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2

COMPLEX*16 for pzunml2.

Pointer into the local memory to an array, size

(*lld_a*, $\text{LOCc}(ja+m-1)$ if $\text{side}='L'$,

(*lld_a*, $\text{LOCc}(ja+n-1)$ if $\text{side}='R'$,

where $\text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1))$.

On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gelqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia

(global) INTEGER.

The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja

(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.

desca

(global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix A .

tau

(local)

REAL for psorml2

DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2

COMPLEX*16 **for** pzunml2.
 Array, size $\text{LOCc}(ia+k-1)$. This array contains the scalar factors $\tau(i)$ of the elementary reflector $H(i)$, as returned by [p?gelqf](#). This array is tied to the distributed matrix A .

c
 (local)
 REAL **for** psorml2
 DOUBLE PRECISION **for** pdorml2
 COMPLEX **for** pcunml2
 COMPLEX*16 **for** pzunml2.
 Pointer into the local memory to an array, size (lld_c , $\text{LOCc}(jc+n-1)$). On entry, the local pieces of the distributed matrix sub (C).

ic
 (global) INTEGER.
 The row index in the global array C indicating the first row of sub(C).

jc
 (global) INTEGER.
 The column index in the global array C indicating the first column of sub(C).

descC
 (global and local) INTEGER array of size ($dlen_$). The array descriptor for the distributed matrix C .

work
 (local)
 REAL **for** psorml2
 DOUBLE PRECISION **for** pdorml2
 COMPLEX **for** pcunml2
 COMPLEX*16 **for** pzunml2.
 Workspace array, size ($lwork$).

lwork
 (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least

$$\text{if } side = 'L', lwork \geq mqc0 + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + ioffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm)) ,$$

$$\text{if } side = 'R', lwork \geq nqc0 + \max(1, mqc0) ,$$
 where

$$lcm = lcm / nprow,$$

$$lcm = iclm(nprow, nqcol),$$

$$iroffc = \text{mod}(ic-1, mb_c),$$

$$icoffc = \text{mod}(jc-1, nb_c),$$

$$icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$$

$$iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, nqcol),$$

$$Mpc0 = \text{numroc}(m + icoffc, mb_c, mycol, icrow, nprow),$$

$Nqc0 = \text{numroc}(n+iroffc, nb_c, myrow, iccol, npcol),$
ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprov*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', $(nb_a.eq.mb_c .AND. icoffa.eq.iroffc)$
If *side* = 'R', $(nb_a.eq.nb_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol)$.

p?ormr2/p?unmr2

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors)

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors)

as returned by p?gerqf . Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER.
= 'L':	apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,
= 'R':	apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER.
= 'N':	apply Q (no transpose)
= 'T':	apply Q^T (transpose, for real flavors)
= 'C':	apply Q^H (conjugate transpose, for complex flavors)

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q .

If $\text{side} = 'L'$, $m \geq k \geq 0$;

if $\text{side} = 'R'$, $n \geq k \geq 0$.

a

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array, size

$(\text{lld}_a, \text{LOCc}(ja+m-1)$ if $\text{side}='L'$,

$(\text{lld}_a, \text{LOCc}(ja+n-1)$ if $\text{side}='R'$,

where $\text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1))$.

On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gerqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia

(global) INTEGER.

The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja

(global) INTEGER.

The column index in the global array A indicating the first column of $\text{sub}(A)$.

desca

(global and local) INTEGER array of size (*dlen_*). The array descriptor for the distributed matrix A .

tau

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Array, size $\text{LOCc}(ia+k-1)$. This array contains the scalar factors $\tau(i)$ of the elementary reflector $H(i)$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

c	(local) REAL for psormr2 DOUBLE PRECISION for pdormr2 COMPLEX for pcunmr2 COMPLEX*16 for pzunmr2. Pointer into the local memory to an array, size($l1d_c$, $\text{LOCc}(jc+n-1)$). On entry, the local pieces of the distributed matrix sub (C).
ic	(global) INTEGER. The row index in the global array C indicating the first row of sub(C).
jc	(global) INTEGER. The column index in the global array C indicating the first column of sub(C).
desc_C	(global and local) INTEGER array of size ($dlen_$). The array descriptor for the distributed matrix C .
$work$	(local) REAL for psormr2 DOUBLE PRECISION for pdormr2 COMPLEX for pcunmr2 COMPLEX*16 for pzunmr2. Workspace array, size ($lwork$).
$lwork$	(local or global) INTEGER. The dimension of the array $work$. $lwork$ is local input and must be at least $\text{if } side = 'L', lwork \geq mpc0 + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm)),$ $\text{if } side = 'R', lwork \geq nqc0 + \max(1, mpc0),$ where $lcm = lcm(nprow, npcol),$ $irow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$ $icol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol),$ $Mpc0 = \text{numroc}(m + iroffc, mb_c, myrow, icrow, nprow),$ $Nqc0 = \text{numroc}(n + icoffc, nb_c, mycol, iccol, npcol),$

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprov`, and `ncol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pixerbla`.

Output Parameters

<code>c</code>	On exit, <code>c</code> is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = - (i*100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

NOTE

The distributed submatrices `A(ia:*, ja:*)` and `C(ic:ic+m-1, jc:jc+n-1)` must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, (`nb_a.eq.mb_c .AND. icooffa.eq.iroffc`)
If `side = 'R'`, (`nb_a.eq.nb_c .AND. icooffa.eq.icooffc .AND. iacol.eq.iccol`).

p?pbtrs

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.

Syntax

Fortran:

```
call pspbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

```
call pdpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

```
call pcpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

```
call pzpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

C:

Description

The `p?pbtrs` routine solves a banded triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$

or

$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs)$ for real flavors,

$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code `p?pbtrf` and is stored in $A(1:n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

Routine `p?pbtrf` must be called first.

Input Parameters

`uplo`

(global) CHARACTER. Must be 'U' or 'L'.

If `uplo` = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

If `uplo` = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

`trans`

(global) CHARACTER. Must be 'N' or 'T' or 'C'.

If `trans` = 'N', solve with $A(1:n, ja:ja+n-1)$;

If `trans` = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$.

If `trans` = 'C' for complex flavors, solve with conjugate transpose ($A(1:n, ja:ja+n-1)^H$).

`n`

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.

`bw`

(global) INTEGER.

The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.

nrhs

(global) INTEGER.

The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.

a

(local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

Pointer into the local memory to an array with the first size $lld_a \geq (bw + 1)$, stored in *desca*.

On entry, this array contains the local pieces of the n -by- n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$.

This local portion is stored in the packed banded format used in LAPACK. See the *Application Notes* below and the ScaLAPACK manual for more detail on the format of distributed matrices.

ja

(global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array, size (*dlen*). The array descriptor for the distributed matrix *A*.

If 1D type (*dtype_a* = 501), then *dlen* ≥ 7 ;

If 2D type (*dtype_a* = 1), then *dlen* ≥ 9 .

Contains information on mapping of *A* to memory. (See ScaLAPACK manual for full description and options.)

b

(local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

Pointer into the local memory to an array of local lead size $lld_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

ib

(global) INTEGER. The row index in the global array *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) INTEGER array, size (*dlen*). The array descriptor for the distributed matrix *B*.

If 1D type (*dtype_b* = 502), then *dlen* ≥ 7 ;

If 2D type (*dtype_b* = 1), then *dlen* \geq 9.

Contains information on mapping of *B* to memory. Please, see ScaLAPACK manual for full description and options.

laf

(local)

INTEGER. The size of user-input auxiliary Fillin space *af*. Must be *laf* \geq (*nb*+2**bw*) * *bw*. If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work

(local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between calls to routines.

lwork

(local or global) INTEGER. The size of the user-input workspace *work*, must be at least *lwork* \geq *bw***nrhs*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

af

(local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

The array *af* is of size *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?pbtrf](#) and this is stored in *af*. If a linear system is to be solved using [p?pbtrs](#) after the factorization routine, *af* must not be altered after the factorization.

b

On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1)

On exit, *work*(1) contains the minimum value of *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,

then *info* = -(*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

Application Notes

If the factorization routine and the solve routine are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization routine and the solve routine.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix *A* one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into *P* pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

1. **Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space *af*. Mathematically, this is equivalent to reordering the matrix *A* as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of *A* in memory.
2. **Reduced System Phase:** A small ($bw^*(P-1)$) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space *af*. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
3. **Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsV

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf .

Syntax

Fortran:

```
call pspttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pdpttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pcpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,

Description

The p?ptttrs routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1)^{*}X = B(jb:jb+n-1, 1:nrhs)$

or

$A(1:n, ja:ja+n-1)^T*X = B(jb:jb+n-1, 1:nrhs)$ for real flavors,

$A(1:n, ja:ja+n-1)^H*X = B(jb:jb+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code p?pttrf and is stored in $A(1:n, ja:ja+n-1)$ and af. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to uplo.

Routine p?pttrf must be called first.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;
	If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) CHARACTER. Must be 'N' or 'C'.
	If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$;
	If <i>trans</i> = 'C' (for complex flavors), solve with conjugate transpose ($A(1:n, ja:ja+n-1)^H$).
<i>n</i>	(global) INTEGER.
	The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<i>nrhs</i>	(global) INTEGER.
	The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.
<i>d</i>	(local)
	REAL for psptttrs
	DOUBLE PRECISION for pdptttrs
	COMPLEX for pcptttrs

COMPLEX*16 for `pzpttrs`.

Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq \text{desc}(nb_)$.

e

(local)

REAL for `pspttrs`

DOUBLE PRECISION for `pdpttrs`

COMPLEX for `pcpttrs`

COMPLEX*16 for `pzpttrs`.

Pointer to the local part of the global vector storing the upper diagonal of the matrix; must be of size $\geq \text{desc}(nb_)$. Globally, $du(n)$ is not referenced, and du must be aligned with d .

ja

(global) **INTEGER**. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desc

(global and local) **INTEGER array**, size (*dlen_*). The array descriptor for the distributed matrix *A*.

If 1D type (*dtype_a* = 501 or 502), then *dlen* ≥ 7 ;

If 2D type (*dtype_a* = 1), then *dlen* ≥ 9 .

Contains information on mapping of *A* to memory. See ScaLAPACK manual for full description and options.

b

(local)

REAL for `pspttrs`

DOUBLE PRECISION for `pdpttrs`

COMPLEX for `pcpttrs`

COMPLEX*16 for `pzpttrs`.

Pointer into the local memory to an array of local lead size $lld_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

ib

(global) **INTEGER**. The row index in the global array *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) **INTEGER array**, size (*dlen_*). The array descriptor for the distributed matrix *B*.

If 1D type (*dtype_b* = 502), then *dlen* ≥ 7 ;

If 2D type (*dtype_b* = 1), then *dlen* ≥ 9 .

Contains information on mapping of *B* to memory. See ScaLAPACK manual for full description and options.

laf

(local)

INTEGER. The size of user-input auxiliary Fillin space *af*. Must be $laf \geq (nb+2 * bw) * bw$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between calls to routines.

lwork

(local or global) INTEGER. The size of the user-input workspace *work*, must be at least $lwork \geq (10+2*\min(100, nrhs))*npcol+4*nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

d, e

(local).

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

On exit, these arrays contain information on the factors of the matrix.

af

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

The array *af* is of size *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?pbtrf](#) and this is stored in *af*. If a linear system is to be solved using [p?pttrs](#) after the factorization routine, *af* must not be altered after the factorization.

b

On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1)

On exit, *work*(1) contains the minimum value of *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
then *info* = -(*i**100+*j*),

if the i -th argument is a scalar and had an illegal value,
then $\text{info} = -i$.

p?potf2

*Computes the Cholesky factorization of a symmetric/
Hermitian positive definite matrix (local unblocked
algorithm).*

Syntax

Fortran:

```
call pspotf2(uplo, n, a, ia, ja, desca, info)
call pdpotf2(uplo, n, a, ia, ja, desca, info)
call pcpotf2(uplo, n, a, ia, ja, desca, info)
call pzpotf2(uplo, n, a, ia, ja, desca, info)
```

C:

MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `p?potf2` routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(\text{ia}: \text{ia}+n-1, \text{ja}: \text{ja}+n-1)$.

The factorization has the form

$\text{sub}(A) = U' * U$, if $\text{uplo} = 'U'$, or $\text{sub}(A) = L * L'$, if $\text{uplo} = 'L'$,

where U is an upper triangular matrix, L is lower triangular. X' denotes transpose (conjugate transpose) of X .

Input Parameters

<code>uplo</code>	(global) CHARACTER.
	Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix A is stored.
	= ' <code>U</code> ': upper triangle of $\text{sub}(A)$ is stored;
	= ' <code>L</code> ': lower triangle of $\text{sub}(A)$ is stored.

`n` (global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed submatrix sub (A). $n \geq 0$.

a

(local)
 REAL for pspotf2
 DOUBLE PRECISION for pdpotf2
 COMPLEX for pcpotf2
 COMPLEX*16 for pzpotf2.

Pointer into the local memory to an array of size ($l1d_a$, $LOCc(ja+n-1)$) containing the local pieces of the n -by- n symmetric distributed matrix sub(A) to be factored.

If $uplo = 'U'$, the leading n -by- n upper triangular part of sub(A) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of sub(A) contains the lower triangular matrix and the strictly upper triangular part of sub(A) is not referenced.

ia, ja

(global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the sub(A), respectively.

desca

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

Output Parameters

a

(local)
 On exit,
 if $uplo = 'U'$, the upper triangular part of the distributed matrix contains the Cholesky factor U ;
 if $uplo = 'L'$, the lower triangular part of the distributed matrix contains the Cholesky factor L .

info

(local) INTEGER.
 = 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = -(i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.
 > 0: if $info = k$, the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rot

Applies a planar rotation to two distributed vectors.

Syntax

Fortran:

```
call psrot( n, x, ix, jx, descx, incx, y, iy, jy, descy, incy, cs, sn, work, lwork,
info )
call pdrot( n, x, ix, jx, descx, incx, y, iy, jy, descy, incy, cs, sn, work, lwork,
info )
```

Include Files

- C: mkl_scalapack.h

Description

p?rot applies a planar rotation defined by *cs* and *sn* to the two distributed vectors sub(*x*) and sub(*y*).

Input Parameters

<i>n</i>	(global) INTEGER	The number of elements to operate on when applying the planar rotation to <i>x</i> and <i>y</i> ($n \geq 0$).
<i>x</i>	REAL for psrot DOUBLE PRECISION for pdrot (local) array of dimension ($(jx-1)*descx(m_)$ + <i>ix</i> + ($n - 1$)*abs(<i>incx</i>))	This array contains the entries of the distributed vector sub(<i>x</i>).
<i>ix</i>	(global) INTEGER	The global row index of the submatrix of the distributed matrix <i>x</i> to operate on. If <i>incx</i> = 1, then it is required that <i>ix</i> = <i>iy</i> . $1 \leq ix \leq descx(m_)$.
<i>jx</i>	(global) INTEGER	The global column index of the submatrix of the distributed matrix <i>x</i> to operate on. If <i>incx</i> = <i>descx(m_)</i> , then it is required that <i>jx</i> = <i>jy</i> . $1 \leq ix \leq descx(n_)$.
<i>descx</i>	(global and local) INTEGER array of dimension 9	The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER	The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>descx(m_)</i> . Moreover, it must hold that <i>incx</i> = <i>descx(m_)</i> if <i>incy</i> = <i>descy(m_)</i> and that <i>incx</i> = 1 if <i>incy</i> = 1.
<i>y</i>	REAL for psrot DOUBLE PRECISION for pdrot (local) array of dimension ($(jy-1)*descy(m_)$ + <i>iy</i> + ($n - 1$)*abs(<i>incy</i>))	

This array contains the entries of the distributed vector $\text{sub}(y)$.

i_y

(global) INTEGER

The global row index of the submatrix of the distributed matrix *y* to operate on. If *incy* = 1, then it is required that *i_y* = *i_x*. $1 \leq i_y \leq \text{descy}(m_)$.

j_y

(global) INTEGER

The global column index of the submatrix of the distributed matrix *y* to operate on. If *incy* = $\text{descx}(m_)$, then it is required that *j_y* = *j_x*. $1 \leq j_y \leq \text{descy}(n_)$.

descy

(global and local) INTEGER array of dimension 9

The array descriptor of the distributed matrix *y*.

incy

(global) INTEGER

The global increment for the elements of *y*. Only two values of *incy* are supported in this version, namely 1 and $\text{descy}(m_)$. Moreover, it must hold that *incy* = $\text{descy}(m_)$ if *incx* = $\text{descx}(m_)$ and that *incy* = 1 if *incx* = 1.

cs, sn

(global)

REAL for psrot

DOUBLE PRECISION for pdrot

The parameters defining the properties of the planar rotation. It must hold that $0 \leq cs, sn \leq 1$ and that $sn^2 + cs^2 = 1$. The latter is hardly checked in finite precision arithmetics.

work

REAL for psrot

DOUBLE PRECISION for pdrot

(local workspace) array of dimension *lwork*

lwork

(local) INTEGER

The length of the workspace array *work*.

If *incx* = 1 and *incy* = 1, then *lwork* = $2 * \text{descx}(mb_)$

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by [pxerbla](#).

OUTPUT Parameters

x

y

work(1)

On exit, if *info* = 0, *work(1)* returns the optimal *lwork*

info

(global) INTEGER

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?rscl

Multiples a vector by the reciprocal of a real scalar.

Syntax

Fortran:

```
call psrscl(n, sa, sx, ix, jx, descx, incx)
call pdrscl(n, sa, sx, ix, jx, descx, incx)
call pcsrcscl(n, sa, sx, ix, jx, descx, incx)
call pzdrscl(n, sa, sx, ix, jx, descx, incx)
```

C:

```
void psrscl (MKL_INT *n , float *sa , float *sx , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdrscl (MKL_INT *n , double *sa , double *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pcsrcscl (MKL_INT *n , float *sa , MKL_Complex8 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pzdrscl (MKL_INT *n , double *sa , MKL_Complex16 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_scalapack.h

Description

The p?rscl routine multiplies an n -element real/complex vector $\text{sub}(x)$ by the real scalar $1/a$. This is done without overflow or underflow as long as the final result $\text{sub}(x)/a$ does not overflow or underflow.

$\text{sub}(x)$ denotes $x(ix:ix+n-1, jx:jx)$, if $incx = 1$,

and $x(ix:ix, jx:jx+n-1)$, if $incx = m_x$.

Input Parameters

n (global) INTEGER.

The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.

sa REAL for psrscl/pcsrcscl

DOUBLE PRECISION for pdrscl/pzdrscl.

The scalar a that is used to divide each component of the vector x . This parameter must be ≥ 0 .

sx REAL for psrscl

DOUBLE PRECISION for pdrscl
 COMPLEX for pcsrcsl
 COMPLEX*16 for pzdrscl.

Array containing the local pieces of a distributed matrix of size of at least $((j_x-1)*m_x + i_x + (n-1)*\text{abs}(incx))$. This array contains the entries of the distributed vector sub(x).

i_x (global) INTEGER. The row index of the submatrix of the distributed matrix X to operate on.

j_x (global) INTEGER. The column index of the submatrix of the distributed matrix X to operate on.

descx (global and local) INTEGER. Array of size 9. The array descriptor for the distributed matrix X .

incx (global) INTEGER. The increment for the elements of X . This version supports only two values of *incx*, namely 1 and *m_x*.

Output Parameters

s_x On exit, the result x/a .

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).

Syntax

Fortran:

```
call pssygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pdsygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pchegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pzhegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
```

C:

```
void pssygs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *info );
void pdsygs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb , MKL_INT *info );
```

```
void pchegs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
void pzhegs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?sygs2/p?hegs2 routine reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ - for real flavors, and
 $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ - for complex flavors.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) * x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$U * \text{sub}(A) * U^T$ or $L^{**} T * \text{sub}(A) * L$ - for real flavors and
 $U * \text{sub}(A) * U^H$ or $L^{**} H * \text{sub}(A) * L$ - for complex flavors.

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ (for real flavors), or as $U^H * U$ or $L * L^H$ (for complex flavors) by p?potrf.

Input Parameters

<i>ibtype</i>	(global) INTEGER. = 1: compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real subroutines, and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex subroutines; = 2 or 3: compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$ for real subroutines, and $U * \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex subroutines.
<i>uplo</i>	(global) CHARACTER Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized. = 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real subroutines) or as $U^H * U$ (for complex subroutines).

= 'L': Lower triangular of sub(A) is stored and sub(B) is factorized as L^*L^T (for real subroutines) or as L^*L^H (for complex subroutines)

n (global) INTEGER.

The order of the matrices sub(A) and sub(B). $n \geq 0$.

a (local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array, size (lld_a , $LOCc(ja+n-1)$).

On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix sub(A).

If $uplo = 'U'$, the leading n -by- n upper triangular part of sub(A) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(A) is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of sub(A) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(A) is not referenced.

ia, ja

(global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the sub(A), respectively.

desca

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

B

(local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array, size (lld_b , $LOCc(jb+n-1)$).

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of sub(B) as returned by [p?potrf](#).

ib, jb

(global) INTEGER.

The row and column indices in the global array B indicating the first row and the first column of the sub(B), respectively.

descb

(global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix B .

Output Parameters

a

(local)

On exit, if $info = 0$, the transformed matrix is stored in the same format as $\text{sub}(A)$.

info INTEGER.
 $= 0$: successful exit.
 < 0 : if the i -th argument is an array and the j -entry had an illegal value,
then $info = - (i * 100)$,
if the i -th argument is a scalar and had an illegal value,
then $info = -i$.

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

Fortran:

```
call pssytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pchetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?sytd2/p?hetd2 routine reduces a real symmetric/complex Hermitian matrix $\text{sub}(A)$ to symmetric/Hermitian tridiagonal form T by an orthogonal/unitary similarity transformation:

$$Q^* \text{sub}(A) * Q = T, \text{ where } \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1).$$

Input Parameters

uplo (global) CHARACTER.
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored:
 $= 'U'$: upper triangular
 $= 'L'$: lower triangular

n (global) INTEGER.
The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.

a (local)
REAL for pssytd2
DOUBLE PRECISION for pdsytd2

COMPLEX for `pchetd2`
 COMPLEX*16 for `pzhetd2`.
 Pointer into the local memory to an array, size (`lld_a`, `LOCc(ja+n-1)`).
 On entry, this array contains the local pieces of the n -by- n symmetric/
 Hermitian distributed matrix sub(A).
 If `uplo` = 'U', the leading n -by- n upper triangular part of sub(A) contains
 the upper triangular part of the matrix, and the strictly lower triangular part
 of sub(A) is not referenced.
 If `uplo` = 'L', the leading n -by- n lower triangular part of sub(A) contains
 the lower triangular part of the matrix, and the strictly upper triangular part
 of sub(A) is not referenced.

`ia, ja`
 (global) INTEGER.
 The row and column indices in the global array A indicating the first row
 and the first column of the sub(A), respectively.

`desca`
 (global and local) INTEGER array, size (`dlen_`). The array descriptor for the
 distributed matrix A .

`work`
 (local)
 REAL for `pssytd2`
 DOUBLE PRECISION for `pdsytd2`
 COMPLEX for `pchetd2`
 COMPLEX*16 for `pzhetd2`.
 The array `work` is a temporary workspace array of size `/work`.

Output Parameters

`a`
 On exit, if `uplo` = 'U', the diagonal and first superdiagonal of sub(A) are
 overwritten by the corresponding elements of the tridiagonal matrix T , and
 the elements above the first superdiagonal, with the array `tau`, represent
 the orthogonal/unitary matrix Q as a product of elementary reflectors;
 if `uplo` = 'L', the diagonal and first subdiagonal of A are overwritten by
 the corresponding elements of the tridiagonal matrix T , and the elements
 below the first subdiagonal, with the array `tau`, represent the orthogonal/
 unitary matrix Q as a product of elementary reflectors. See the *Application
 Notes* below.

`d`
 (local)
 REAL for `pssytd2/pchetd2`
 DOUBLE PRECISION for `pdsytd2/pzhetd2`.
 Array, size (`LOCc(ja+n-1)`). The diagonal elements of the tridiagonal
 matrix T :
 $d(i) = a(i,i); d$ is tied to the distributed matrix A .

`e`
 (local)
 REAL for `pssytd2/pchetd2`

DOUBLE PRECISION for `pdsytd2/pzhetd2`.

`Array, size(LOCc(ja+n-1))`,

if `uplo = 'U'`, `LOCc(ja+n-2)` otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e(i) = a(i,i+1)$ if `uplo = 'U'`,

$e(i) = a(i+1,i)$ if `uplo = 'L'`.

e is tied to the distributed matrix A .

`tau`

(local)

REAL for `pssytd2`

DOUBLE PRECISION for `pdsytd2`

COMPLEX for `pchetd2`

COMPLEX*16 for `pzhetd2`.

`Array, size(LOCc(ja+n-1))`.

The scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

`work(1)`

On exit, `work(1)` returns the minimal and optimal value of `lwork`.

`lwork`

(local or global) INTEGER.

The dimension of the workspace array `work`.

`lwork` is local input and must be at least $lwork \geq 3n$.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

`info`

(local) INTEGER.

= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
then $info = -(i*100)$,

if the i -th argument is a scalar and had an illegal value,

then $info = -i$.

Application Notes

If `uplo = 'U'`, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $TAU(ja+i-1)$.

If `uplo = 'L'`, the matrix Q is represented as a product of elementary reflectors

$Q = H(1) * H(2) * \dots * H(n-1)$.

Each $H(i)$ has the form

$H(i) = I - tau * v * v'$,

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and tau in $TAU(ja+i-1)$.

The contents of sub (A) on exit are illustrated by the following examples with $n = 5$:

$$\begin{array}{c} \text{if } uplo='U': \\ \left[\begin{array}{ccccc} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{array} \right] \\ \\ \text{if } uplo='L': \\ \left[\begin{array}{ccccc} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{array} \right] \end{array}$$

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE

The distributed submatrix sub(A) must verify some alignment properties, namely the following expression should be true:

($mb_a.eq.nb_a .AND. iroffa.eq.icoffa$) with $iroffa = \text{mod}(ia - 1, mb_a)$ and $icoffa = \text{mod}(ja - 1, nb_a)$.

p?trord

Reorders the Schur factorization of a general matrix.

Syntax

Fortran:

```
call pstrord( compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m,
work, lwork, iwork, liwork, info )
call pdtrord( compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m,
work, lwork, iwork, liwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

p?trord reorders the real Schur factorization of a real matrix $A = Q * T^* Q^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

T must be in Schur form (as returned by p?lahqr), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This subroutine uses a delay and accumulate procedure for performing the off-diagonal updates.

Input Parameters

<i>compg</i>	(global) CHARACTER*1 = 'V': update the matrix q of Schur vectors; = 'N': do not update q .												
<i>select</i>	(global) INTEGER array, dimension (n) <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, <i>select(j)</i> must be set to 1. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either <i>select(j)</i> or <i>select(j+1)</i> or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.												
<i>para</i>	(global) INTEGER*6 Block parameters: <table border="0"> <tr> <td><i>para(1)</i></td><td>maximum number of concurrent computational windows allowed in the algorithm; $0 < para(1) \leq \min(nprow, ncol)$ must hold;</td></tr> <tr> <td><i>para(2)</i></td><td>number of eigenvalues in each window; $0 < para(2) < para(3)$ must hold;</td></tr> <tr> <td><i>para(3)</i></td><td>window size; $para(2) < para(3) < desc(m_b)$ must hold;</td></tr> <tr> <td><i>para(4)</i></td><td>minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para(4) \leq 100$ must hold;</td></tr> <tr> <td><i>para(5)</i></td><td>width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para(5) \leq desc(m_b)$ must hold.</td></tr> <tr> <td><i>para(6)</i></td><td>the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para(6) \leq para(2)$ must hold.</td></tr> </table>	<i>para(1)</i>	maximum number of concurrent computational windows allowed in the algorithm; $0 < para(1) \leq \min(nprow, ncol)$ must hold;	<i>para(2)</i>	number of eigenvalues in each window; $0 < para(2) < para(3)$ must hold;	<i>para(3)</i>	window size; $para(2) < para(3) < desc(m_b)$ must hold;	<i>para(4)</i>	minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para(4) \leq 100$ must hold;	<i>para(5)</i>	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para(5) \leq desc(m_b)$ must hold.	<i>para(6)</i>	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para(6) \leq para(2)$ must hold.
<i>para(1)</i>	maximum number of concurrent computational windows allowed in the algorithm; $0 < para(1) \leq \min(nprow, ncol)$ must hold;												
<i>para(2)</i>	number of eigenvalues in each window; $0 < para(2) < para(3)$ must hold;												
<i>para(3)</i>	window size; $para(2) < para(3) < desc(m_b)$ must hold;												
<i>para(4)</i>	minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para(4) \leq 100$ must hold;												
<i>para(5)</i>	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para(5) \leq desc(m_b)$ must hold.												
<i>para(6)</i>	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para(6) \leq para(2)$ must hold.												
<i>n</i>	(global) INTEGER The order of the globally distributed matrix T . $n \geq 0$.												
<i>t</i>	REAL for pstrord DOUBLE PRECISION for pdtrord (local) array, dimension ($\text{lld}_t, \text{LOC}_c(n)$). The local pieces of the global distributed upper quasi-triangular matrix T , in Schur form.												
<i>it, jt</i>	(global) INTEGER												

The row and column index in the global array t indicating the first column of T . $it = jt = 1$ must hold (see Application Notes).

desc_t (global and local) INTEGER array of dimension *dlen_*.

The array descriptor for the global distributed matrix t .

q REAL for pstrord

DOUBLE PRECISION for pdtrord

(local) array, dimension ($\text{ld}_q, \text{LOC}_c(n)$).

On entry, if $\text{comp}_q = 'V'$, the local pieces of the global distributed matrix Q of Schur vectors.

If $\text{comp}_q = 'N'$, *q* is not referenced.

iq, jq (global) INTEGER

The column index in the global array *q* indicating the first column of Q . $iq = jq = 1$ must hold (see Application Notes).

desc_q (global and local) INTEGER array of dimension *dlen_*.

The array descriptor for the global distributed matrix *q*.

work REAL for pstrord

DOUBLE PRECISION for pdtrord

(local workspace) array, dimension (*lwork*)

lwork (local) INTEGER

The dimension of the array *work*.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [pxerbla](#).

iwork (local workspace) INTEGER array, dimension (*liwork*)

liwork (local) INTEGER

The dimension of the array *iwork*.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by [pxerbla](#)

OUTPUT Parameters

select (global) INTEGER array, dimension (*n*)

The (partial) reordering is displayed.

<i>t</i>	On exit, <i>t</i> is overwritten by the local pieces of the reordered matrix <i>T</i> , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.
<i>q</i>	On exit, if <i>compq</i> = 'V', <i>q</i> has been postmultiplied by the global orthogonal transformation matrix which reorders <i>t</i> ; the leading <i>m</i> columns of <i>q</i> form an orthonormal basis for the specified invariant subspace. If <i>compq</i> = 'N', <i>q</i> is not referenced.
<i>wr, wi</i>	REAL for pstrord DOUBLE PRECISION for pdtrord (global) array, dimension (<i>n</i>) The real and imaginary parts, respectively, of the reordered eigenvalues of <i>t</i> . The eigenvalues are in principle stored in the same order as on the diagonal of <i>t</i> , with <i>wr</i> (<i>i</i>) = <i>t</i> (<i>i,i</i>) and, if <i>t</i> (<i>i:i+1,i:i+1</i>) is a 2-by-2 diagonal block, <i>wi</i> (<i>i</i>) > 0 and <i>wi</i> (<i>i+1</i>) = - <i>wi</i> (<i>i</i>). Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
<i>m</i>	(global) INTEGER The dimension of the specified invariant subspace. $0 \leq m \leq n$.
<i>work(1)</i>	On exit, if <i>info</i> = 0, <i>work(1)</i> returns the optimal <i>lwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, <i>iwork(1)</i> returns the optimal <i>liwork</i> .
<i>info</i>	(global) INTEGER = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *1000+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: here we have several possibilities <ul style="list-style-type: none">• Reordering of <i>t</i> failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); <i>t</i> may have been partially reordered, and <i>wr</i> and <i>wi</i> contain the eigenvalues in the same order as in <i>t</i>. On exit, <i>info</i> = {the index of <i>t</i> where the swap failed}.• A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block. On exit, <i>info</i> = {the index of <i>t</i> where the swap failed}.• If <i>info</i> = <i>n</i>+1, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- $\text{desc}(\text{mb}_\perp) = \text{desc}(\text{nb}_\perp) = \text{descq}(\text{mb}_\perp) = \text{descq}(\text{nb}_\perp)$
- $\text{desc}(\text{rsr}_\perp) = \text{descq}(\text{rsr}_\perp)$
- $\text{desc}(\text{csr}_\perp) = \text{descq}(\text{csr}_\perp)$

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of t and q , i.e., $it = jt = iq = jq = 1$ must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

p?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

Fortran:

```
call pstrsen( job, compq, select, para, n, t, it, jt, desc, q, iq, jq, descq, wr,
              wi, m, s, sep, work, lwork, iwork, liwork, info )
call pdtrsen( job, compq, select, para, n, t, it, jt, desc, q, iq, jq, descq, wr,
              wi, m, s, sep, work, lwork, iwork, liwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

[p?trsen](#) reorders the real Schur factorization of a real matrix $A = Q*T^TQ^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace. The reordering is performed by [p?trord](#).

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur form (as returned by [p?lahqr](#)), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

Input Parameters

<i>job</i>	(global) CHARACTER*1
	Specifies whether condition numbers are required for the cluster of eigenvalues (<i>s</i>) or the invariant subspace (<i>sep</i>):
= 'N':	no condition numbers are required;
= 'E':	only the condition number for the cluster of eigenvalues is computed (<i>s</i>);

= 'V': only the condition number for the invariant subspace is computed (*sep*);
 = 'B': condition numbers for both the cluster and the invariant subspace are computed (*s* and *sep*).

compq

(global) CHARACTER*1
 = 'V': update the matrix *q* of Schur vectors;
 = 'N': do not update *q*.

select

(global) LOGICAL array, dimension (*n*)

select specifies the eigenvalues in the selected cluster. To select a real eigenvalue *w(j)*, *select(j)* must be set to .TRUE.. To select a complex conjugate pair of eigenvalues *w(j)* and *w(j+1)*, corresponding to a 2-by-2 diagonal block, either *select(j)* or *select(j+1)* or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

para

(global) INTEGER*6

Block parameters:

<i>para(1)</i>	maximum number of concurrent computational windows allowed in the algorithm; $0 < \text{para}(1) \leq \min(\text{NPROW}, \text{NPCOL})$ must hold;
<i>para(2)</i>	number of eigenvalues in each window; $0 < \text{para}(2) < \text{para}(3)$ must hold;
<i>para(3)</i>	window size; $\text{para}(2) < \text{para}(3) < \text{desc}(mb_)$ must hold;
<i>para(4)</i>	minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq \text{para}(4) \leq 100$ must hold;
<i>para(5)</i>	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < \text{para}(5) \leq \text{desc}(mb_)$ must hold.
<i>para(6)</i>	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size $0 < \text{para}(6) \leq \text{para}(2)$ must hold;

n

(global) INTEGER

The order of the globally distributed matrix *t*. $n \geq 0$.

t

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local) array, dimension (*lld_t,LOC_c(n)*).

The local pieces of the global distributed upper quasi-triangular matrix T , in Schur form.

it, jt

(global) INTEGER

The row and column index in the global array t indicating the first column of T . $it = jt = 1$ must hold (see Application Notes).

$desc_t$

(global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the global distributed matrix t .

q

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local) array, dimension ($\text{lld}_q, \text{LOC}_c(n)$).

On entry, if $\text{compq} = 'V'$, the local pieces of the global distributed matrix Q of Schur vectors.

If $\text{compq} = 'N'$, q is not referenced.

iq, jq

(global) INTEGER

The column index in the global array q indicating the first column of Q . $iq = jq = 1$ must hold (see Application Notes).

$desc_q$

(global and local) INTEGER array of dimension $dlen_$.

The array descriptor for the global distributed matrix q .

$work$

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local workspace) array, dimension ($lwork$)

$lwork$

(local) INTEGER

The dimension of the array $work$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [pxerbla](#).

$iwork$

(local workspace) INTEGER array, dimension ($liwork$)

$liwork$

(local) INTEGER

The dimension of the array $iwork$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [pxerbla](#).

OUTPUT Parameters

<i>t</i>	<i>t</i> is overwritten by the local pieces of the reordered matrix T , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.
<i>q</i>	On exit, if <i>compq</i> = 'V', <i>q</i> has been postmultiplied by the global orthogonal transformation matrix which reorders <i>t</i> ; the leading <i>m</i> columns of <i>q</i> form an orthonormal basis for the specified invariant subspace. If <i>compq</i> = 'N', <i>q</i> is not referenced.
<i>wr, wi</i>	REAL for pstrsen DOUBLE PRECISION for pdtrsen (global) array, dimension (<i>n</i>) The real and imaginary parts, respectively, of the reordered eigenvalues of <i>t</i> . The eigenvalues are in principle stored in the same order as on the diagonal of <i>t</i> , with <i>wr</i> (<i>i</i>) = <i>t</i> (<i>i,i</i>) and, if <i>t</i> (<i>i:i+1,i:i+1</i>) is a 2-by-2 diagonal block, <i>wi</i> (<i>i</i>) > 0 and <i>wi</i> (<i>i+1</i>) = - <i>wi</i> (<i>i</i>). Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
<i>m</i>	(global) INTEGER The dimension of the specified invariant subspace. $0 \leq m \leq n$.
<i>s</i>	REAL for pstrsen DOUBLE PRECISION for pdtrsen (global) If <i>job</i> = 'E' or 'B', <i>s</i> is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. <i>s</i> cannot underestimate the true reciprocal condition number by more than a factor of $\text{sqrt}(n)$. If <i>m</i> = 0 or <i>n</i> , <i>s</i> = 1. If <i>job</i> = 'N' or 'V', <i>s</i> is not referenced.
<i>sep</i>	REAL for pstrsen DOUBLE PRECISION for pdtrsen (global) If <i>job</i> = 'V' or 'B', <i>sep</i> is the estimated reciprocal condition number of the specified invariant subspace. If <i>m</i> = 0 or <i>n</i> , <i>sep</i> = <i>norm(t)</i> . If <i>job</i> = 'N' or 'E', <i>sep</i> is not referenced.
<i>work(1)</i>	On exit, if <i>info</i> = 0, <i>work(1)</i> returns the optimal <i>lwork</i> .
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, <i>iwork(1)</i> returns the optimal <i>liwork</i> .
<i>info</i>	(global) INTEGER = 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*1000+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0: here we have several possibilities

- Reordering of t failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); t may have been partially reordered, and wr and wi contain the eigenvalues in the same order as in t .

On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$.

- If $info = n+1$, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- $desc(m_b) = desc(t) = descq(m_b) = descq(n_b)$
- $desc(r_src) = descq(r_src)$
- $desc(c_src) = descq(c_src)$

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of t and q , i.e., $it = jt = iq = jq = 1$ must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in $para$ should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

Fortran:

```
call pstrti2(uplo, diag, n, a, ia, ja, desca, info)
call pdtrti2(uplo, diag, n, a, ia, ja, desca, info)
call pctrti2(uplo, diag, n, a, ia, ja, desca, info)
call pztrti2(uplo, diag, n, a, ia, ja, desca, info)
```

C:

```
void pstrti2 (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdtrti2 (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
void pctrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pztrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The p?trti2 routine computes the inverse of a real/complex upper or lower triangular block matrix sub (A) = $A(ia:ia+n-1, ja:ja+n-1)$.

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

uplo

(global) CHARACTER*1.

Specifies whether the matrix sub (A) is upper or lower triangular.

= 'U': sub (A) is upper triangular

= 'L': sub (A) is lower triangular.

diag

(global) CHARACTER*1.

Specifies whether or not the matrix A is unit triangular.

= 'N': sub (A) is non-unit triangular

= 'U': sub (A) is unit triangular.

n

(global) INTEGER.

The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub (A). $n \geq 0$.

a

(local)

REAL for pstrti2

DOUBLE PRECISION for pdtrti2

COMPLEX for pctrti2

COMPLEX*16 for pztrti2.

Pointer into the local memory to an array, size(*l1d_a*, LOCc(*ja+n-1*)).

On entry, this array contains the local pieces of the triangular matrix sub(A).

If *uplo* = 'U', the leading n -by- n upper triangular part of the matrix sub(A) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(A) is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of the matrix sub(A) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(A) is not referenced. If $diag = 'U'$, the diagonal elements of sub(A) are not referenced either and are assumed to be 1.

ia, ja (global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the sub(A), respectively.

$desca$ (global and local) INTEGER array, size ($dlen_$). The array descriptor for the distributed matrix A .

Output Parameters

a On exit, the (triangular) inverse of the original matrix, in the same storage format.

$info$ INTEGER.

= 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = - (i*100)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

Fortran:

```
call slamsh(s, lds, nbudge, jblk, h, ldh, n, ulp)
call dlamsh(s, lds, nbudge, jblk, h, ldh, n, ulp)
```

C:

```
void slamsh (float *s , MKL_INT *lds , MKL_INT *nbudge , MKL_INT *jblk , float *h ,
MKL_INT *ldh , MKL_INT *n , float *ulp );
void dlamsh (double *s , MKL_INT *lds , MKL_INT *nbudge , MKL_INT *jblk , double *h ,
MKL_INT *ldh , MKL_INT *n , double *ulp );
```

Include Files

- C: mkl_scalapack.h

Description

The ?lamsh routine sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The subroutine should only be called when there are multiple shifts/bulges ($nbulge > 1$) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

<i>s</i>	(local) INTEGER. REAL for slamsh DOUBLE PRECISION for dlamsh Array, size (<i>lds</i> ,*).
	On entry, the matrix of shifts. Only the 2×2 diagonal of <i>s</i> is referenced. It is assumed that <i>s</i> has <i>jblk</i> double shifts (size 2).
<i>lds</i>	(local) INTEGER. On entry, the leading dimension of <i>S</i> ; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$.
<i>nbulge</i>	(local) INTEGER. On entry, the number of bulges to send through <i>h</i> (>1). <i>nbulge</i> should be less than the maximum determined (<i>jblk</i>). $1 < nbulge \leq jblk \leq lds/2$.
<i>jblk</i>	(local) INTEGER. On entry, the leading dimension of <i>S</i> ; unchanged on exit.
<i>h</i>	(local) INTEGER. REAL for slamsh DOUBLE PRECISION for dlamsh Array, size <i>lds</i> by <i>n</i> . On entry, the local matrix to apply the shifts on. <i>h</i> should be aligned so that the starting row is 2.
<i>ldh</i>	(local) INTEGER. On entry, the leading dimension of <i>H</i> ; unchanged on exit.
<i>n</i>	(local) INTEGER. On entry, the size of <i>H</i> . If all the bulges are expected to go through, <i>n</i> should be at least $4nbulge+2$. Otherwise, <i>nbulge</i> may be reduced by this routine.
<i>ulp</i>	(local) REAL for slamsh DOUBLE PRECISION for dlamsh

On entry, machine precision. Unchanged on exit.

Output Parameters

<i>s</i>	On exit, the data is rearranged in the best order for applying.
<i>nbulge</i>	On exit, the maximum number of bulges that can be sent through.
<i>h</i>	On exit, the data is destroyed.

?laqr6

Performs a single small-bulge multi-shift QR sweep collecting the transformations.

Syntax

Fortran:

```
call slaqr6( job, wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz,
ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
call dlaqr6( job, wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz,
ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

Include Files

- C: mkl_scalapack.h

Description

This auxiliary subroutine called by [p?laqr5](#) performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix $h(ktop:kbot, ktop:kbot)$, collecting the transformations in the matrix V or accumulating the transformations in the matrix z (see below).

This is a modified version of [?laqr5](#) from LAPACK 3.1.

Input Parameters

<i>job</i>	CHARACTER scalar
	Set the kind of job to do in ?laqr6, as follows:
<i>job</i> = 'I':	Introduce and chase bulges in submatrix
<i>job</i> = 'C':	Chase bulges from top to bottom of submatrix
<i>job</i> = 'O':	Chase bulges off submatrix
<i>wantt</i>	LOGICAL scalar
	<i>wantt</i> = .TRUE. if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to .FALSE. otherwise.
<i>wantz</i>	LOGICAL scalar
	<i>wantz</i> = .TRUE. if the orthogonal Schur factor is being computed. <i>wantz</i> is set to .FALSE. otherwise.
<i>kacc22</i>	INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates.

= 0: ?laqr6 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.

= 1: ?laqr6 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

= 2: ?laqr6 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

n

INTEGER scalar

n is the order of the Hessenberg matrix *h* upon which this subroutine operates.

ktop, kbot

INTEGER scalar

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either *ktop* = 1 or *h(ktop,ktop-1)* = 0 and either *kbot* = *n* or *h(kbot+1,kbot)* = 0.

nshfts

INTEGER scalar

nshfts gives the number of simultaneous shifts. *nshfts* must be positive and even.

sr, si

REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size (*nshfts*)

sr contains the real parts and *si* contains the imaginary parts of the *nshfts* shifts of origin that define the multi-shift QR sweep.

h

REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size (*ldh,n*)

On input *h* contains a Hessenberg matrix.

ldh

INTEGER scalar

ldh is the leading dimension of *h* just as declared in the calling procedure. *ldh* $\geq \max(1,n)$.

iloz, ihiz

INTEGER scalar

Specify the rows of *z* to which transformations must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ihiz \leq n$

z

REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size (*ldz,ktop*)

If *wantz* = .TRUE., then the QR sweep orthogonal similarity transformation is accumulated into *z(iloz:ihiz,kbot:ktop)* from the right.

If $wantz = .FALSE.$, then z is unreferenced.

ldz

INTEGER scalar

ldz is the leading dimension of z just as declared in the calling procedure.
 $ldz \geq n$.

v

REAL for `slaqr6`

DOUBLE PRECISION for `dlaqr6`

(workspace) array of size ($ldv, nshfts/2$)

ldv

INTEGER scalar

ldv is the leading dimension of v as declared in the calling procedure.
 $ldv \geq 3$.

u

REAL for `slaqr6`

DOUBLE PRECISION for `dlaqr6`

(workspace) array of size ($ldu, 3*nshfts-3$)

ldu

INTEGER scalar

ldu is the leading dimension of u just as declared in the in the calling subroutine. $ldu \geq 3*nshfts-3$.

nh

INTEGER scalar

nh is the number of columns in array wh available for workspace. $nh \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

wh

REAL for `slaqr6`

DOUBLE PRECISION for `dlaqr6`

(workspace) array of size ($ldwh, nh$)

$ldwh$

INTEGER scalar

Leading dimension of wh just as declared in the calling procedure.
 $ldwh \geq 3*nshfts-3$.

nv

INTEGER scalar

nv is the number of rows in wv available for workspace. $nv \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

wv

REAL for `slaqr6`

DOUBLE PRECISION for `dlaqr6`

(workspace) array of size ($ldwv, 3*nshfts-3$)

$ldwv$

INTEGER scalar

$ldwv$ is the leading dimension of wv as declared in the in the calling subroutine. $ldwv \geq nv$.

OUTPUT Parameters

<i>h</i>	A multi-shift QR sweep with shifts $sr(j)+i*si(j)$ is applied to the isolated diagonal block in rows and columns k_{top} through k_{bot} .
<i>z</i>	If <i>wantz</i> is .TRUE., then the QR sweep orthogonal/unitary similarity transformation is accumulated into $z(iloz:ihiz,kbot:ktop)$ from the right. If <i>wantz</i> is .FALSE., then <i>z</i> is unreferenced.

Application Notes

Notes

Based on contributions by Karen Braman and Ralph Byers, Department of Mathematics, University of Kansas, USA Robert Granat, Department of Computing Science and HPC2N, Umeå University, Sweden

?lar1va

Computes scaled eigenvector corresponding to given eigenvalue.

Syntax

Fortran:

```
call slar1va(n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
call dlar1va(n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

Include Files

- C: mkl_scalapack.h

Description

?slar1va computes the (scaled) *r*-th column of the inverse of the submatrix in rows *b1* through *bn* of the tridiagonal matrix $L D L^T - \lambda I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, *r* corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform, $L D L^T - \lambda I = L_+ D_+ L_+^T$,
2. Progressive qd transform, $L D L^T - \lambda I = U_- D_- U_-^T$,
3. Computation of the diagonal elements of the inverse of $L D L^T - \lambda I$ by combining the above transforms, and choosing *r* as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled) *r*-th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

<i>n</i>	INTEGER
	The order of the matrix $L D L^T$.

<i>b1</i>	INTEGER
	First index of the submatrix of $L D L^T$.

<i>bn</i>	INTEGER
	Last index of the submatrix of $L D L^T$.
<i>lambda</i>	REAL for slarlva DOUBLE PRECISION for dlarlva
	The shift λ . In order to compute an accurate eigenvector, <i>lambda</i> should be a good approximation to an eigenvalue of $L D L^T$.
<i>l</i>	REAL for slarlva DOUBLE PRECISION for dlarlva Array, dimension ($n-1$)
	The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix <i>l</i> , in elements 1 to $n-1$.
<i>d</i>	REAL for slarlva DOUBLE PRECISION for dlarlva Array, dimension (n)
	The n diagonal elements of the diagonal matrix <i>d</i> .
<i>ld</i>	REAL for slarlva DOUBLE PRECISION for dlarlva Array, dimension ($n-1$)
	The $n-1$ elements $l(i)*d(i)$.
<i>lld</i>	REAL for slarlva DOUBLE PRECISION for dlarlva Array, dimension ($n-1$)
	The $n-1$ elements $l(i)*l(i)*d(i)$.
<i>pivmin</i>	REAL for slarlva DOUBLE PRECISION for dlarlva
	The minimum pivot in the Sturm sequence.
<i>gaptol</i>	REAL for slarlva DOUBLE PRECISION for dlarlva
	Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.
<i>z</i>	REAL for slarlva DOUBLE PRECISION for dlarlva Array, dimension (n)
	On input, all entries of <i>z</i> must be set to 0.
<i>wantnc</i>	LOGICAL

Specifies whether *negcnt* has to be computed.

r

INTEGER

The twist index for the twisted factorization used to compute *z*.

On input, $0 \leq r \leq n$. If *r* is input as 0, *r* is set to the index where $(L D L^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, *r* is unchanged.

Ideally, *r* designates the position of the maximum entry in the eigenvector.

work

REAL for slarlva

DOUBLE PRECISION for dlarlva

(workspace) array, dimension ($4 * n$)

OUTPUT Parameters

z

On output, *z* contains the (scaled) *r*-th column of the inverse. The scaling is such that *z(r)* equals 1.

negcnt

INTEGER

If *wantnc* is .TRUE., then *negcnt* = the number of pivots < *pivmin* in the matrix factorization $L D L^T$, and *negcnt* = -1 otherwise.

ztz

REAL for slarlva

DOUBLE PRECISION for dlarlva

The square of the 2-norm of *z*.

mingma

REAL for slarlva

DOUBLE PRECISION for dlarlva

The reciprocal of the largest (in magnitude) diagonal element of the inverse of $L D L^T - \sigma I$.

r

On output, *r* contains the twist index used to compute *z*.

isuppz

INTEGER array, dimension (2)

The support of the vector in *z*, i.e., the vector *z* is nonzero only in elements *isuppz(1)* through *isuppz(2)*.

nrminv

REAL for slarlva

DOUBLE PRECISION for dlarlva

nrminv = $1/\text{SQRT}(ztz)$

resid

REAL for slarlva

DOUBLE PRECISION for dlarlva

The residual of the FP vector.

resid = $\text{ABS}(mingma)/\text{SQRT}(ztz)$

rqcorr

REAL for slarlva

DOUBLE PRECISION for dlarlva
 The Rayleigh Quotient correction to *lambda*.

?laref

Applies Householder reflectors to matrices on either their rows or columns.

Syntax

Fortran:

```
call slaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)

call dlaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)
```

C:

```
void slaref (char *type , float *a , MKL_INT *lda , MKL_INT *wantz , float *z ,
MKL_INT *ldz , MKL_INT *block , MKL_INT *irow1 , MKL_INT *icoll , MKL_INT *istart ,
MKL_INT *istop , MKL_INT *itmp1 , MKL_INT *itmp2 , MKL_INT *liloz , MKL_INT *lihiz ,
float *vecs , float *v2 , float *v3 , float *t1 , float *t2 , float *t3 );

void dlaref (char *type , double *a , MKL_INT *lda , MKL_INT *wantz , double *z ,
MKL_INT *ldz , MKL_INT *block , MKL_INT *irow1 , MKL_INT *icoll , MKL_INT *istart ,
MKL_INT *istop , MKL_INT *itmp1 , MKL_INT *itmp2 , MKL_INT *liloz , MKL_INT *lihiz ,
double *vecs , double *v2 , double *v3 , double *t1 , double *t2 , double *t3 );
```

Include Files

- C: mkl_scalapack.h

Description

The ?laref routine applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

type (global) CHARACTER*1.
 If *type* = 'R', apply reflectors to the rows of the matrix (apply from left). Otherwise, apply reflectors to the columns of the matrix. Unchanged on exit.

a (global) REAL for slaref
 DOUBLE PRECISION for dlaref
 Array, size (*lda*, *).
 On entry, the matrix to receive the reflections.

lda (local) INTEGER.
 On entry, the leading dimension of *A*; unchanged on exit.

wantz (global) LOGICAL.

If *wantz* = .TRUE., apply any column reflections to *Z* as well.

If *wantz* = .FALSE., do no additional work on *Z*.

z (global) REAL for slaref

DOUBLE PRECISION for dlaref

Array, size (*ldz*, *).

On entry, the second matrix to receive column reflections.

ldz (local) INTEGER.

On entry, the leading dimension of *Z*; unchanged on exit.

block (global) LOGICAL.

= .TRUE. : apply several reflectors at once and read their data from the *vecs* array;

= .FALSE. : apply the single reflector given by *v2*, *v3*, *t1*, *t2*, and *t3*.

irow1 (local) INTEGER.

On entry, the local row element of the matrix *A*.

icoll (local) INTEGER.

On entry, the local column element of the matrix *A*.

istart (global) INTEGER.

Specifies the "number" of the first reflector.

istart is used as an index into *vecs* if *block* is set. *istart* is ignored if *block* is .FALSE. .

istop (global) INTEGER.

Specifies the "number" of the last reflector.

istop is used as an index into *vecs* if *block* is set. *istop* is ignored if *block* is .FALSE. .

itmp1 (local) INTEGER.

Starting range into *A*. For rows, this is the local first column. For columns, this is the local first row.

itmp2 (local) INTEGER.

Ending range into *A*. For rows, this is the local last column. For columns, this is the local last row.

liloz, *lihiz* (local). INTEGER.

Serve the same purpose as *itmp1*, *itmp2* but for *Z* when *wantz* is set.

vecs (global)

REAL for slaref

DOUBLE PRECISION for dlaref.

Array of size $3 * n$ (matrix size). This array holds the size 3 reflectors one after another and is only accessed when *block* is .TRUE..

```
v2,v3,t1,t2,t3          (global) INTEGER.  
REAL for slaref  
DOUBLE PRECISION for dlaref.
```

These parameters hold information on a single size 3 Householder reflector and are read when *block* is .FALSE., and overwritten when *block* is .TRUE..

Output Parameters

<i>a</i>	On exit, the updated matrix.
<i>z</i>	Changed only if <i>wantz</i> is set. If <i>wantz</i> is .FALSE., <i>z</i> is not referenced.
<i>irow1</i>	Undefined.
<i>icoll</i>	Undefined.
<i>v2,v3,t1,t2,t3</i>	These parameters are read when <i>block</i> is .FALSE., and overwritten when <i>block</i> is .TRUE..

?larrb2

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

Fortran:

```
call slarrb2( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,  
iwork, pivmin, lgpvmn, lgspdm, twist, info )  
call dlarrb2( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,  
iwork, pivmin, lgpvmn, lgspdm, twist, info )
```

Include Files

- C: mkl_scalapack.h

Description

Given the relatively robust representation (RRR) $L D L^T$, ?larrb2 does "limited" bisection to refine the eigenvalues of $L D L^T$, $w(ifirst - offset)$ through $w(ilast - offset)$, to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals $[left, right]$ are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively.

NOTE

There are very few minor differences between `?larrb` from LAPACK and this current subroutine `?larrb2`. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using `?larrb2` is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses `?larrb`. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

Input Parameters

<i>n</i>	INTEGER	
		The order of the matrix.
<i>d</i>	REAL for <code>slarrb2</code> DOUBLE PRECISION for <code>dlarrb2</code>	
		Array, dimension (<i>n</i>)
		The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>lld</i>	REAL for <code>slarrb2</code> DOUBLE PRECISION for <code>dlarrb2</code>	
		Array, dimension (<i>n</i> -1)
		The (<i>n</i> -1) elements $l_i^* l_i^* d(i)$.
<i>ifirst</i>	INTEGER	
		The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER	
		The index of the last eigenvalue to be computed.
<i>rtol1, rtol2</i>	REAL for <code>slarrb2</code> DOUBLE PRECISION for <code>dlarrb2</code>	
		Tolerance for the convergence of the bisection intervals.
		An interval $[left, right]$ has converged if $right - left < \max(rtolt * gap, rtolt * \max(left , right))$ where <i>gap</i> is the (estimated) distance to the nearest eigenvalue.
<i>offset</i>	INTEGER	
		Offset for the arrays <i>w</i> , <i>wgap</i> and <i>werr</i> , i.e., the <i>ifirst</i> - <i>offset</i> through <i>ilast</i> - <i>offset</i> elements of these arrays are to be used.
<i>w</i>	REAL for <code>slarrb2</code> DOUBLE PRECISION for <code>dlarrb2</code>	
		Array, dimension (<i>n</i>)
		On input, <i>w</i> (<i>ifirst</i> - <i>offset</i>) through <i>w</i> (<i>ilast</i> - <i>offset</i>) are estimates of the eigenvalues of $L D L^T$ indexed <i>ifirst</i> through <i>ilast</i> .

<i>wgap</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 Array, dimension ($n-1$) On input, the (estimated) gaps between consecutive eigenvalues of $L D L^T$, i.e., $wgap(I - \text{offset})$ is the gap between eigenvalues I and $I + 1$. Note that if $\text{ifirst} = \text{ilast}$ then $wgap(\text{ifirst} - \text{offset})$ must be set to zero.
<i>werr</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 Array, dimension (n) On input, $werr(\text{ifirst} - \text{offset})$ through $werr(\text{ilast} - \text{offset})$ are the errors in the estimates of the corresponding elements in w .
<i>work</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 (workspace) array, dimension ($4*n$) Workspace.
<i>iwork</i>	(workspace) INTEGER array, dimension ($2*n$) Workspace.
<i>pivmin</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 The minimum pivot in the sturm sequence.
<i>lgpvmn</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 Logarithm of $pivmin$, precomputed.
<i>lgspdm</i>	REAL for slarrb2 DOUBLE PRECISION for dlarrb2 Logarithm of the spectral diameter, precomputed.
<i>twist</i>	INTEGER The twist index for the twisted factorization that is used for the <i>negcount</i> . $twist = n$: Compute <i>negcount</i> from $L D L^T - \lambda I = L_+ D_+ L_+^T$ $twist = 1$: Compute <i>negcount</i> from $L D L^T - \lambda I = U_- D_- U_-^T$ $twist = r$, $1 < r < n$: Compute <i>negcount</i> from $L D L^T - \lambda I = N_r \Delta_r N_r^T$

OUTPUT Parameters

w On output, the eigenvalue estimates in w are refined.

wgap On output, the eigenvalue gaps in $wgap$ are refined.

werr On output, the errors in *werr* are refined.

info INTEGER

Error flag.

?larrd2

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

Fortran:

```
call slarrd2( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplitt,
isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, dol, dou, info )
call dlarrd2( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplitt,
isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, dol, dou, info )
```

Include Files

- C: mkl_scalapack.h

Description

?larrd2 computes the eigenvalues of a symmetric tridiagonal matrix T to limited initial accuracy. This is an auxiliary code to be called from ?larre2a.

?larrd2 has been created using the LAPACK code ?larrd which itself stems from ?stebz. The motivation for creating ?larrd2 is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, ?larrd2 can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

Input Parameters

<i>range</i>	CHARACTER
= 'A': ("All")	all eigenvalues will be found.
= 'V': ("Value")	all eigenvalues in the half-open interval (<i>vl</i> , <i>vu</i>] will be found.
= 'I': ("Index")	the <i>il</i> -th through <i>iu</i> -th eigenvalues (of the entire matrix) will be found.
<i>order</i>	CHARACTER
= 'B': ("By Block")	the eigenvalues will be grouped by split-off block (see <i>iblock</i> , <i>isplit</i>) and ordered from smallest to largest within the block.
= 'E': ("Entire matrix")	the eigenvalues for the entire matrix will be ordered from smallest to largest.
<i>n</i>	INTEGER
	The order of the tridiagonal matrix T . $n \geq 0$.
<i>vl</i> , <i>vu</i>	REAL for slarrd2

DOUBLE PRECISION for `dlarrd2`

If `range='V'`, the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to `vl`, or greater than `vu`, will not be returned. $vl < vu$.

Not referenced if `range = 'A'` or `'I'`.

`il, iu`

INTEGER

If `range='I'`, the indices (in ascending order) of the smallest and largest eigenvalues to be returned.

$1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$ if $n = 0$.

Not referenced if `range = 'A'` or `'V'`.

`gers`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

Array, dimension (2^*n)

The n Gershgorin intervals (the i -th Gershgorin interval is $(gers(2*i-1), gers(2*i))$).

`reltol`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

The minimum relative width of an interval. When an interval is narrower than `reltol` times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

`d`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

Array, dimension (n)

The n diagonal elements of the tridiagonal matrix T .

`e`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

Array, dimension ($n-1$)

The $(n-1)$ off-diagonal elements of the tridiagonal matrix T .

`e2`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

Array, dimension ($n-1$)

The $(n-1)$ squared off-diagonal elements of the tridiagonal matrix T .

`pivmin`

REAL for `slarrd2`

DOUBLE PRECISION for `dlarrd2`

The minimum pivot allowed in the sturm sequence for T .

`nsplit`

INTEGER

The number of diagonal blocks in the matrix T .

$1 \leq nsplit \leq n$.

isplit

INTEGER Array, dimension (n)

The splitting points, at which T breaks up into submatrices.

The first submatrix consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, etc., and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.

(Only the first $nsplit$ elements will actually be used, but since the user cannot know a priori what value $nsplit$ will have, n words must be reserved for *isplit*.)

work

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

(workspace) array, dimension ($4*n$)

iwork

(workspace) INTEGER array, dimension ($3*n$)

dol, dou

INTEGER

Specifying an index range $dol:dou$ allows the user to work on only a selected part of the representation tree.

Otherwise, the setting $dol=1, dou=n$ should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *W*.

OUTPUT Parameters

m

INTEGER

The actual number of eigenvalues found. $0 \leq m \leq n$.

(See also the description of *info=2,3*.)

w

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array, dimension (n)

On exit, the first *m* elements of *w* will contain the eigenvalue approximations. ?larrd2 computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue *j*. The eigenvalue approximation is given as the interval midpoint $w(j) = (a_j + b_j)/2$. The corresponding error is bounded by $werr(j) = \text{abs}(a_j - b_j)/2$.

werr

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array, dimension (n)

The error bound on the corresponding eigenvalue approximation in *w*.

<i>wl, wu</i>	REAL for slarrd2 DOUBLE PRECISION for dlarrd2
	The interval (<i>wl, wu</i>] contains all the wanted eigenvalues.
	If <i>range</i> ='V', then <i>wl</i> = <i>vl</i> and <i>wu</i> = <i>vu</i> .
	If <i>range</i> ='A', then <i>wl</i> and <i>wu</i> are the global Gershgorin bounds on the spectrum.
	If <i>range</i> ='I', then <i>wl</i> and <i>wu</i> are computed by SLAEBZ from the index range specified.
<i>iblock</i>	INTEGER Array, dimension (<i>n</i>) At each row/column <i>j</i> where <i>e(j)</i> is zero or small, the matrix <i>T</i> is considered to split into a block diagonal matrix. On exit, if <i>info</i> = 0, <i>iblock(i)</i> specifies to which block (from 1 to the number of blocks) the eigenvalue <i>w(i)</i> belongs. (?larrd2 may use the remaining <i>n-m</i> elements as workspace.)
<i>indexw</i>	INTEGER Array, dimension (<i>n</i>) The indices of the eigenvalues within each block (submatrix); for example, <i>indexw(i)=j</i> and <i>iblock(i)=k</i> imply that the <i>i</i> -th eigenvalue <i>w(i)</i> is the <i>j</i> -th eigenvalue in block <i>k</i> .
<i>info</i>	INTEGER = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value > 0: some or all of the eigenvalues failed to converge or were not computed: <ul style="list-style-type: none">• =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.• =2 or 3: <i>range</i>='I' only: Not all of the eigenvalues <i>il:iu</i> were found.• = 4: <i>range</i>='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

?larre2

Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

Fortran:

```
call slarre2( range, n, vl, vu, il, iu, d, e, e2, rtoll, rtol2, spltol, nsplit, isplit, m, dol, dou, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
call dlarre2( range, n, vl, vu, il, iu, d, e, e2, rtoll, rtol2, spltol, nsplit, isplit, m, dol, dou, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

Include Files

- C: mkl_scalapack.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , ?larre2 sets, via ?larra, "small" off-diagonal elements to zero. For each block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the root RRR, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then returned to ?stegr2 to compute the eigenvectors T .

?larre2 is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, ?larre2 can skip over blocks which contain none of the eigenvalues from *d0l* to *dou* for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

Input Parameters

<i>range</i>	CHARACTER
	= 'A': ("All") all eigenvalues will be found.
	= 'V': ("Value") all eigenvalues in the half-open interval (<i>vl</i> , <i>vu</i>] will be found.
	= 'I': ("Index") the <i>il</i> -th through <i>iu</i> -th eigenvalues (of the entire matrix) will be found.
<i>n</i>	INTEGER
	The order of the matrix. <i>n</i> > 0.
<i>vl</i> , <i>vu</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2 If <i>range</i> ='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , will not be returned. <i>vl</i> < <i>vu</i> .
<i>il</i> , <i>iu</i>	INTEGER If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$.
<i>d</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2 Array, dimension (<i>n</i>) The <i>n</i> diagonal elements of the tridiagonal matrix T .
<i>e</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2

Array, dimension (n)

The first ($n-1$) entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.

$e2$

REAL for slarre2

DOUBLE PRECISION for dlarre2

Array, dimension (n)

The first ($n-1$) entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.

$rto11, rto12$

REAL for slarre2

DOUBLE PRECISION for dlarre2

Parameters for bisection.

An interval $[left, right]$ has converged if $right-left < \max(rto11*gap, rto12*\max(|left|, |right|))$

$spltol$

REAL for slarre2

DOUBLE PRECISION for dlarre2

The threshold for splitting.

dol, dou

INTEGER

Specifying an index range $dol:dou$ allows the user to work on only a selected part of the representation tree. Otherwise, the setting $dol=1$, $dou=n$ should be applied.

Note that dol and dou refer to the order in which the eigenvalues are stored in w .

$work$

REAL for slarre2

DOUBLE PRECISION for dlarre2

Workspace array, dimension ($6*n$)

$iwork$

INTEGER workspace array, dimension ($5*n$)

OUTPUT Parameters

vl, vu

If $range='I'$ or $'A'$, ?larre2 contains bounds on the desired part of the spectrum.

d

The n diagonal elements of the diagonal matrices D_i .

e

e contains the subdiagonal elements of the unit bidiagonal matrices L_i . The entries $e(isplit(i))$, $1 \leq i \leq nsplit$, contain the base points σ_i on output.

$e2$

The entries $e2(isplit(i))$, $1 \leq i \leq nsplit$, are set to zero.

$nsplit$

INTEGER

The number of blocks T splits into. $1 \leq nsplit \leq n$.

<i>isplit</i>	INTEGER Array, dimension (<i>n</i>) The splitting points, at which <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc., and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= <i>n</i> .
<i>m</i>	INTEGER The total number of eigenvalues (of all $L_i D_i L_i^T$) found.
<i>w</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2 Array, dimension (<i>n</i>) The first <i>m</i> elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i D_i L_i^T$, are sorted in ascending order (?larre2 may use the remaining <i>n-m</i> elements as workspace). Note that immediately after exiting this routine, only the eigenvalues from position <i>dol:dou</i> in <i>w</i> might rely on this processor when the eigenvalue computation is done in parallel.
<i>werr</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2 Array, dimension (<i>n</i>) The error bound on the corresponding eigenvalue in <i>w</i> . Note that immediately after exiting this routine, only the uncertainties from position <i>dol:dou</i> in <i>werr</i> might rely on this processor when the eigenvalue computation is done in parallel.
<i>wgap</i>	REAL for slarre2 DOUBLE PRECISION for dlarre2 Array, dimension (<i>n</i>) The separation from the right neighbor eigenvalue in <i>w</i> . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block we store the left gap Note that immediately after exiting this routine, only the gaps from position <i>dol:dou</i> in <i>wgap</i> might rely on this processor when the eigenvalue computation is done in parallel.
<i>iblock</i>	INTEGER Array, dimension (<i>n</i>) The indices of the blocks (submatrices) associated with the corresponding eigenvalues in <i>w</i> ; <i>iblock</i> (<i>i</i>)=1 if eigenvalue <i>w</i> (<i>i</i>) belongs to the first block from the top, <i>iblock</i> (<i>i</i>)=2 if <i>w</i> (<i>i</i>) belongs to the second block, and so on.
<i>indexw</i>	INTEGER Array, dimension (<i>n</i>)

The indices of the eigenvalues within each block (submatrix); for example, $indexw(i) = 10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10th eigenvalue in block 2.

gers REAL for slarre2
 DOUBLE PRECISION for dlarre2
 Array, dimension (2^*n)
 The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$).

pivmin REAL for slarre2
 DOUBLE PRECISION for dlarre2
 The minimum pivot in the sturm sequence for T .

info INTEGER
 = 0: successful exit
 > 0: A problem occurred in ?larre2.
 < 0: One of the called subroutines signaled an internal problem.
 Needs inspection of the corresponding parameter *info* for further information.
 =-1: Problem in ?larrd .
 =-2: Not enough internal iterations to find the base representation.
 =-3: Problem in ?larrb when computing the refined root representation for ?lasq2.
 =-4: Problem in ?larrb when performing bisection on the desired part of the spectrum.
 =-5: Problem in ?lasq2
 =-6: Problem in ?lasq2

?larre2a

Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

Fortran:

```
call slarre2a( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
isplit, m, dol, dou, needil, neediu, w, werr, wgap, iblock, indexw, gers, sdiam,
pivmin, work, iwork, minrgp, info )  

call dlarre2a( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
isplit, m, dol, dou, needil, neediu, w, werr, wgap, iblock, indexw, gers, sdiam,
pivmin, work, iwork, minrgp, info )
```

Include Files

- C: mkl_scalapack.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , ?larre2a sets any "small" off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

NOTE

The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by *range*). However, to reduce work and improve scalability, only the eigenvalues *d0l* to *d0u* are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from *d0l* to *d0u* are skipped. The DQDS algorithm (subroutine ?1asq2) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Input Parameters

<i>range</i>	CHARACTER
	= 'A': ("All") all eigenvalues will be found.
	= 'V': ("Value") all eigenvalues in the half-open interval (<i>vl</i> , <i>vu</i>] will be found.
	= 'I': ("Index") the <i>i1</i> -th through <i>iu</i> -th eigenvalues (of the entire matrix) will be found.
<i>n</i>	INTEGER
	The order of the matrix. <i>n</i> > 0.
<i>vl</i> , <i>vu</i>	REAL for slarre2a DOUBLE PRECISION for dlarre2a If <i>range</i> ='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , will not be returned. <i>vl</i> < <i>vu</i> . If <i>range</i> ='I' or ='A', ?larre2a computes bounds on the desired part of the spectrum.
<i>i1</i> , <i>iu</i>	INTEGER If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq i1 \leq iu \leq n$.
<i>d</i>	REAL for slarre2a DOUBLE PRECISION for dlarre2a Array, dimension (<i>n</i>) On entry, the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .

e

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
Array, dimension (n)
The first ($n-1$) entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.

e2

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
Array, dimension (n)
The first ($n-1$) entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.

rto11, rto12

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
Parameters for bisection.
An interval $[left, right]$ has converged if $right - left < \max(rto11 * gap, rto12 * \max(|left|, |right|))$

spltol

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
The threshold for splitting.

dol, dou

INTEGER
If the user wants to work on only a selected part of the representation tree, he can specify an index range $dol:dou$.
Otherwise, the setting $dol=1, dou=n$ should be applied.
Note that dol and dou refer to the order in which the eigenvalues are stored in w .

work

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
Workspace array, dimension ($6*n$)

iwork

INTEGER workspace array, dimension ($5*n$)

minrgp

REAL for slarre2a
DOUBLE PRECISION for dlarre2a
The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

OUTPUT Parameters

vl, vu

REAL for slarre2a
DOUBLE PRECISION for dlarre2a

If `range='V'`, the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to `vl`, or greater than `vu`, are not returned. $vl < vu$.

If `range='I'` or `range='A'`, ?larre2a computes bounds on the desired part of the spectrum.

d

The n diagonal elements of the diagonal matrices D_i .

e

e contains the subdiagonal elements of the unit bidiagonal matrices L_i . The entries $e(isplit(i))$, $1 \leq i \leq nsplit$, contain the base points σ_i on output.

e2

The entries $e2(isplit(i))$,
 $1 \leq i \leq nsplit$, have been set to zero.

nsplit

INTEGER

The number of blocks T splits into. $1 \leq nsplit \leq n$.

isplit

INTEGER array, dimension (n)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, etc., and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.

m

INTEGER

The total number of eigenvalues (of all $L_i D_i L_i^T$) found.

needil, neediu

INTEGER

The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree.

w

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array, dimension (n)

The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i D_i L_i^T$, are sorted in ascending order (?larre2a may use the remaining $n-m$ elements as workspace).

Note that immediately after exiting this routine, only the eigenvalues from position `dol:dou` in *w* rely on this processor because the eigenvalue computation is done in parallel.

werr

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array, dimension (n)

The error bound on the corresponding eigenvalue in *w*.

Note that immediately after exiting this routine, only the uncertainties from position `dol:dou` in *werr* are reliable on this processor because the eigenvalue computation is done in parallel.

wgap

REAL for slarre2a
 DOUBLE PRECISION for dlarre2a
 Array, dimension (n)
 The separation from the right neighbor eigenvalue in w . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.
 Exception: at the right end of a block we store the left gap
 Note that immediately after exiting this routine, only the gaps from position $dol:dou$ in *wgap* are reliable on this processor because the eigenvalue computation is done in parallel.

iblock

INTEGER Array, dimension (n)
 The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $iblock(i)=2$ if $w(i)$ belongs to the second block, etc.

indexw

INTEGER Array, dimension (n)
 The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in block 2.

gers

REAL for slarre2a
 DOUBLE PRECISION for dlarre2a
 Array, dimension (2^*n)
 The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$).

pivmin

REAL for slarre2a
 DOUBLE PRECISION for dlarre2a
 The minimum pivot in the sturm sequence for T .

info

INTEGER
 = 0: successful exit
 > 0: A problem occurred in ?larre2a.
 < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.
 =-1: Problem in ?larrd2.
 =-2: Not enough internal iterations to find base representation.
 =-3: Problem in ?larrb2 when computing the refined root representation.
 =-4: Problem in ?larrb2 when performing bisection on the desired part of the spectrum.
 = -9 Problem: $m < dou-dol+1$, that is the code found fewer eigenvalues than it was supposed to.

?larrf2

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax**Fortran:**

```
call slarrf2( n, d, l, ld, clstrt, clegend, clmid1, clmid2, w, wgap, werr, trymid,
spdiam, clgap1, clgapr, pivmin, sigma, dplus, lplus, work, info )
```

```
call dlarrf2( n, d, l, ld, clstrt, clegend, clmid1, clmid2, w, wgap, werr, trymid,
spdiam, clgap1, clgapr, pivmin, sigma, dplus, lplus, work, info )
```

Include Files

- C: mkl_scalapack.h

Description

Given the initial representation $L D L^T$ and its cluster of close eigenvalues (in a relative measure), $w(c1strt)$, $w(c1strt+1)$, ..., $w(clegend)$, ?larrf2 finds a new relatively robust representation $L D L^T - \sigma I = L_+ D_+ L_+^T$ such that at least one of the eigenvalues of $L_+ D_+ L_+^T$ is relatively isolated.

This is an enhanced version of ?larrf that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

Input Parameters

<i>n</i>	INTEGER	
		The order of the matrix (subblock, if the matrix was split).
<i>d</i>	REAL for slarrf2 DOUBLE PRECISION for dlarrf2	
		Array, dimension (<i>n</i>)
		The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	REAL for slarrf2 DOUBLE PRECISION for dlarrf2	
		Array, dimension (<i>n</i> -1)
		The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	REAL for slarrf2 DOUBLE PRECISION for dlarrf2	
		Array, dimension (<i>n</i> -1)
		The (<i>n</i> -1) elements <i>l</i> (<i>i</i>)* <i>d</i> (<i>i</i>).
<i>clstrt</i>	INTEGER	
		The index of the first eigenvalue in the cluster.
<i>clegend</i>	INTEGER	

The index of the last eigenvalue in the cluster.

clmid1, clmid2

INTEGER

The index of a middle eigenvalue pair with large gap.

w

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array, dimension $\geq (clend-clstrt+1)$

The eigenvalue approximations of $L D L^T$ in ascending order. *w*(*clstrt*) through *w*(*clend*) form the cluster of relatively close eigenvalues.

wgap

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array, dimension $\geq (clend-clstrt+1)$

The separation from the right neighbor eigenvalue in *w*.

werr

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array, dimension $\geq (clend-clstrt+1)$

werr contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in *w*.

spdiam

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Estimate of the spectral diameter obtained from the Gershgorin intervals

clgap1, clgapr

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Absolute gap on each end of the cluster.

Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.

pivmin

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

The minimum pivot allowed in the sturm sequence.

work

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Workspace array, dimension $(2*n)$

OUTPUT Parameters

wgap

Contains refined values of its input approximations. Very small gaps are unchanged.

sigma

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

The shift (σ) used to form $L_+ D_+ L_+^T$.

dplus

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array, dimension (n)

The n diagonal elements of the diagonal matrix D_+ .

lplus

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array, dimension ($n-1$)

The first $(n-1)$ elements of *lplus* contain the subdiagonal elements of the unit bidiagonal matrix L_+ .

?larrv2

Computes the eigenvectors of the tridiagonal matrix $T = L^* D^* L^T$ given L , D and the eigenvalues of $L^* D^* L^T$.

Syntax

Fortran:

```
call slarrv2( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, needil, neediu, minrgp,
rtol1, rtol2, w, werr, wgap, iblock, indexw, gers, sdiam, z, ldz, isuppz, work, iwork,
vstart, finish, maxcls, ndepth, parity, zoffset, info )
call dlarrv2( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, needil, neediu, minrgp,
rtol1, rtol2, w, werr, wgap, iblock, indexw, gers, sdiam, z, ldz, isuppz, work, iwork,
vstart, finish, maxcls, ndepth, parity, zoffset, info )
```

Include Files

- C: mkl_scalapack.h

Description

?larrv2 computes the eigenvectors of the tridiagonal matrix $T = L^* D^* L^T$ given L , D and approximations to the eigenvalues of $L^* D^* L^T$. The input eigenvalues should have been computed by ?larre2a or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional INTEGER parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant when both eigenvalues and eigenvectors are computed (stegr2b parameter *jobz* = 'V'). ?larrv2 only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.

- The additional arguments `vstart`, `finish`, `ndepth`, `parity`, `zoffset` are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable `finish` is true, the computation has ended. All eigenpairs between `d0l` and `d0u` have been computed. `m` is set to `d0u - d0l + 1`.
- ?larrv2 needs more workspace in `z` than the sequential SLARRV. It is used to store the conformal embedding of the local representation tree.

Input Parameters

`n`

INTEGER

The order of the matrix. $n \geq 0$.`vl, vu`

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. `vu` is currently not used but kept as parameter in case needed.

`d`

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (n)The n diagonal elements of the diagonal matrix `d`. On exit, `d` is overwritten.`l`

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (n)

The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L are in elements 1 to $n-1$ of `l` (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by ?larre. On exit, `l` is overwritten.

`pivmin`

DOUBLE PRECISION

The minimum pivot allowed in the sturm sequence.

`isplit`INTEGER array, dimension (n)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to `isplit(1)`, the second of rows/columns `isplit(1) + 1` through `isplit(2)`, etc.

`m`

INTEGER

The total number of input eigenvalues. $0 \leq m \leq n$.`d0l, d0u`

INTEGER

If the user wants to compute only selected eigenvectors from all the eigenvalues supplied, he can specify an index range $dol:dou$. Or else the setting $dol=1, dou=m$ should be applied. Note that dol and dou refer to the order in which the eigenvalues are stored in w . If the user wants to compute only selected eigenpairs, then the columns $dol-1$ to $dou+1$ of the eigenvector space z contain the computed eigenvectors. All other columns of z are set to zero.

If $dol > 1$, then $z(:,dol-1-zoffset)$ is used.

If $dou < m$, then $z(:,dou+1-zoffset)$ is used.

needil, neediu

INTEGER

Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree.

When $dol \leq needil \leq neediu \leq dou$, all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.

minrgp

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

rto11, rto12

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Parameters for bisection. An interval $[left,right]$ has converged if $right-left < \max(rto11*gap, rto12*\max(|left|,|right|))$

w

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (n)

The first m elements of w contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array w from ?stegr2a is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.

werr

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (n)

The first m elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in w .

wgap

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

	Array, dimension (n)
	The separation from the right neighbor eigenvalue in w .
<i>iblock</i>	INTEGER Array, dimension (n)
	The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $iblock(i)=2$ if $w(i)$ belongs to the second block, etc.
<i>indexw</i>	INTEGER Array, dimension (n)
	The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10th eigenvalue in the second block.
<i>gers</i>	REAL for slarrv2 DOUBLE PRECISION for dlarrv2
	Array, dimension (2^*n)
	The n Gershgorin intervals (the i -th Gershgorin interval is $(gers(2*i-1), gers(2*i))$). The Gershgorin intervals should be computed from the original unshifted matrix.
	Not used but kept as parameter for possible future use.
<i>sdiam</i>	REAL for slarrv2 DOUBLE PRECISION for dlarrv2
	Array, dimension (n)
	The spectral diameters for all unreduced blocks.
<i>ldz</i>	INTEGER
	The leading dimension of the array z . $ldz \geq 1$, and if <code>stegr2b</code> parameter $jobz = 'V'$, $ldz \geq \max(1,n)$.
<i>work</i>	REAL for slarrv2 DOUBLE PRECISION for dlarrv2
	(workspace) array, dimension (12^*n)
<i>iwork</i>	(workspace) INTEGER Array, dimension (7^*n)
<i>vstart</i>	LOGICAL .TRUE. on initialization, set to .FALSE. afterwards.
<i>finish</i>	LOGICAL A flag that indicates whether all eigenpairs have been computed.
<i>maxcls</i>	INTEGER The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	INTEGER

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

<i>parity</i>	INTEGER
	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>zoffset</i>	INTEGER

Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion.

OUTPUT Parameters

needil, *neediu*

w Unshifted eigenvalues for which eigenvectors have already been computed.

werr Contains refined values of its input approximations.

wgap Contains refined values of its input approximations. Very small gaps are changed.

z REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (*ldz*, max(1,*m*))

If *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w(i)*.

In the distributed version, only a subset of columns is accessed, see *dol*, *dou*, and *zoffset*.

isuppz

INTEGER array, dimension (2*max(1,*m*))

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*(2*i-1) through *isuppz*(2*i).

vstart

.TRUE. on initialization, set to .FALSE. afterwards.

finish

A flag that indicates whether all eigenpairs have been computed.

maxcls

The largest cluster worked on by this processor in the representation tree.

ndepth

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

info

INTEGER

= 0: successful exit

> 0: A problem occurred in ?larrv2.

< 0: One of the called subroutines signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in `?larrb2` when refining a child's eigenvalues.

=-2: Problem in `?larrf2` when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to $1/\text{minrgp}$, be aware that decreasing *minrgp* might be reduce precision.

=-3: Problem in `?larrb2` when refining a single eigenvalue after the Rayleigh correction was rejected.

= 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

Fortran:

```
call slasorte(s, lds, j, out, info)
call dlasorte(s, lds, j, out, info)
```

C:

```
void slasorte (float *s , MKL_INT *lds , MKL_INT *j , float *out , MKL_INT *info );
void dlasorte (double *s , MKL_INT *lds , MKL_INT *j , double *out , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `?lasorte` routine sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This routine does no parallel work and makes no calls.

Input Parameters

s (local) INTEGER.
 REAL for `slasorte`
 DOUBLE PRECISION for `dlasorte`
 Array, size (*lds*).
 On entry, a matrix already in Schur form.

lds (local) INTEGER.
 On entry, the leading dimension of the array *s*; unchanged on exit.

j (local) INTEGER.

On entry, the order of the matrix S ; unchanged on exit.

out

(local) INTEGER.

REAL for slasorte

DOUBLE PRECISION for dlasorte

Array, size $(2*j)$. The work buffer required by the routine.

info

(local) INTEGER.

Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix S was not originally in Schur form. 0 indicates successful completion.

Output Parameters

s

On exit, the diagonal blocks of S have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.

out

Work buffer.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

Fortran:

```
call slasrt2(id, n, d, key, info)
call dlasrt2(id, n, d, key, info)
```

C:

```
void slasrt2 (char *id , MKL_INT *n , float *d , MKL_INT *key , MKL_INT *info );
void dlasrt2 (char *id , MKL_INT *n , double *d , MKL_INT *key , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?lasrt2 routine is modified LAPACK routine [?lasrt](#), which sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of STACK limits n to about 2^{32} .

Input Parameters

id

CHARACTER*1.

= 'I': sort d in increasing order;

= 'D': sort d in decreasing order.

n

INTEGER. The length of the array d .

d

REAL for slasrt2

DOUBLE PRECISION for dlasrt2.

Array, size (n).

On entry, the array to be sorted.

key INTEGER.

Array, size (n).

On entry, *key* contains a key to each of the entries in $d()$.

Typically, $key(i) = i$ for all i .

Output Parameters

D On exit, *d* has been sorted into increasing order
 $(d(1) \leq \dots \leq d(n))$ or into decreasing order
 $(d(1) \geq \dots \geq d(n))$, depending on *id*.

info INTEGER.
= 0: successful exit
< 0: if *info* = - i , the i -th argument had an illegal value.

key On exit, *key* is permuted in exactly the same manner as *d()* was permuted from input to output. Therefore, if $key(i) = i$ for all i upon input, then $d_{\text{out}}(i) = d_{\text{in}}(key(i))$.

?stegr2

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

Fortran:

```
call sstegr2( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz, work,
lwork, iwork, liwork, dol, zoffset, info )
call dstegr2( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz, work,
lwork, iwork, liwork, dol, zoffset, info )
```

Include Files

- C: mkl_scalapack.h

Description

?stegr2 computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

?stegr2 has been adapted from LAPACK's ?stegr. Please note the following crucial changes.

1. The calling sequence has two additional INTEGER parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. ?steqr2 only computes the eigenpairs corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenpairs belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be fully accurate.
2. *m* is not the number of eigenvalues specified by *range*, but is $m = dou - dol + 1$. This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case *m* refers to the number of eigenvalues computed on this processor.
3. The arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Input Parameters

<i>jobz</i>	CHARACTER*1
	= 'N': Compute eigenvalues only;
	= 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1
	= 'A': all eigenvalues will be found.
	= 'V': all eigenvalues in the half-open interval (<i>vl</i> , <i>vu</i>] will be found.
	= 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>n</i>	INTEGER
	The order of the matrix. $n \geq 0$.
<i>d</i>	REAL for ssteqr2 DOUBLE PRECISION for dstegr2 Array, dimension (<i>n</i>) On entry, the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> . Overwritten on exit.
<i>e</i>	REAL for ssteqr2 DOUBLE PRECISION for dstegr2 Array, dimension (<i>n</i>) On entry, the (<i>n</i> -1) subdiagonal elements of the tridiagonal matrix <i>T</i> in elements 1 to <i>n</i> -1 of <i>e</i> . <i>e</i> (<i>n</i>) need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>vl</i>	REAL for ssteqr2 DOUBLE PRECISION for dstegr2
<i>vu</i>	REAL for ssteqr2 DOUBLE PRECISION for dstegr2 If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for eigenvalues. <i>vl</i> < <i>vu</i> . Not referenced if <i>range</i> = 'A' or 'I'.

<i>il, iu</i>	INTEGER
	If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 ≤ <i>il</i> ≤ <i>iu</i> ≤ <i>n</i> , if <i>n</i> > 0. Not referenced if <i>range</i> = 'A' or 'V'.
<i>ldz</i>	INTEGER
	The leading dimension of the array <i>z</i> . <i>ldz</i> ≥ 1, and if <i>jobz</i> = 'V', then <i>ldz</i> ≥ $\max(1, n)$.
<i>nzc</i>	INTEGER
	The number of eigenvectors to be held in the array <i>z</i> . If <i>range</i> = 'A', then <i>nzc</i> ≥ $\max(1, n)$. If <i>range</i> = 'V', then <i>nzc</i> ≥ the number of eigenvalues in (<i>vl</i> , <i>vu</i>]. If <i>range</i> = 'I', then <i>nzc</i> ≥ <i>iu</i> - <i>il</i> +1. If <i>nzc</i> = -1, then a workspace query is assumed; the routine calculates the number of columns of the array <i>z</i> that are needed to hold the eigenvectors. This value is returned as the first entry of the <i>z</i> array, and no error message related to <i>nzc</i> is issued.
<i>lwork</i>	INTEGER
	The dimension of the array <i>work</i> . <i>lwork</i> ≥ $\max(1, 18 * n)$ if <i>jobz</i> = 'V', and <i>lwork</i> ≥ $\max(1, 12 * n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.
<i>liwork</i>	INTEGER
	The dimension of the array <i>iwork</i> . <i>liwork</i> ≥ $\max(1, 10 * n)$ if the eigenvectors are desired, and <i>liwork</i> ≥ $\max(1, 8 * n)$ if only the eigenvalues are to be computed. If <i>liwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.
<i>dol, dou</i>	INTEGER
	From the eigenvalues <i>w</i> (1: <i>m</i>), only eigenvectors <i>z</i> (:, <i>dol</i>) to <i>z</i> (:, <i>dou</i>) are computed. If <i>dol</i> > 1, then <i>z</i> (:, <i>dol</i> -1- <i>zoffset</i>) is used and overwritten. If <i>dou</i> < <i>m</i> , then <i>z</i> (:, <i>dou</i> +1- <i>zoffset</i>) is used and overwritten.
<i>zoffset</i>	INTEGER
	Offset for storing the eigenpairs when <i>z</i> is distributed in 1D-cyclic fashion

OUTPUT Parameters

m

INTEGER

Globally summed over all processors, *m* equals the total number of eigenvalues found. $0 \leq m \leq n$. If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il+1*. The local output equals *m* = *dou - dol + 1*.

*w*REAL array, dimension (*n*) for `ssteqr2`DOUBLE PRECISION array, dimension (*n*) for `dstegr2`Array, dimension (*n*)

The first *m* elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this routine, only the eigenvalues from position *dol:dou* are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the *w* array. This information is communicated in the ScalAPACK driver.

*z*REAL for `ssteqr2`DOUBLE PRECISION for `dstegr2`Array, dimension (*ldz, max(1,m)*)

If *jobz* = 'V', and if *info* = 0, then the first *m* columns of *z* contain some of the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w(i)*.

If *jobz* = 'N', then *z* is not referenced.

Note: the user must ensure that at least $\max(1,m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and can be computed with a workspace query by setting *nzc* = -1, see below.

*isuppz*INTEGER array, dimension ($2*\max(1,m)$)

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th computed eigenvector is nonzero only in elements *isuppz(2*i-1)* through *isuppz(2*i)*. This is relevant in the case when the matrix is split. *isuppz* is only set if *n>2*.

*work*On exit, if *info* = 0, *work(1)* returns the optimal (and minimal) *lwork*.*iwork*On exit, if *info* = 0, *iwork(1)* returns the optimal *liwork*.*info*

INTEGER

On exit, *info*

= 0: successful exit

other:if *info* = *-i*, the *i*-th argument had an illegal valueif *info* = 10X, internal error in `?larre2`,if *info* = 20X, internal error in `?larrv`.

Here, the digit $X = \text{ABS}(\text{iinfo}) < 10$, where iinfo is the nonzero error code returned by `?larre2` or `?larryv`, respectively.

?stegr2a

Computes selected eigenvalues and initial representations needed for eigenvector computations.

Syntax

Fortran:

```
call sstegr2a( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, work, lwork,
iwork, liwork, dol, dou, needil, neediu, inderr, nsplit, pivmin, scale, wl, wu, info )
call dstegr2a( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, work, lwork,
iwork, liwork, dol, dou, needil, neediu, inderr, nsplit, pivmin, scale, wl, wu, info )
```

Include Files

- C: mkl_scalapack.h

Description

`?stegr2a` computes selected eigenvalues and initial representations needed for eigenvector computations in `?stegr2b`. It is invoked in the ScalAPACK MRRR driver `p?syevr` and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, `?stegr2a` implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of `?stegr2a`, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, `?stegr2b`.

Please note:

- The calling sequence has two additional INTEGER parameters, (compared to LAPACK's `?stegr`), these are `dol` and `dou` and should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case `jobz = 'V'`.

Globally invoked over all processors, `?stegr2a` computes all the eigenvalues specified by `range`.

`?stegr2a` locally only computes the eigenvalues corresponding to eigenvalues `dol` through `dou` in `w`. (That is, instead of computing the eigenvectors belonging to `w(1)` through `w(m)`, only the eigenvectors belonging to eigenvalues `w(dol)` through `w(dou)` are computed. In this case, only the eigenvalues `dol:dou` are guaranteed to be fully accurate.

- `m` is not the number of eigenvalues specified by `range`, but it is $m = dou - dol + 1$. Instead, `m` refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in `?stegr2a` itself (this is done later in `?stegr2b`), the interface

If `jobz = 'V'` then, depending on `range` and `dol, dou`, `?stegr2a` might need more workspace in `z` than the original `?stegr`. In particular, the arrays `w` and `z` might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Input Parameters

<code>jobz</code>	CHARACTER*1
	= 'N': Compute eigenvalues only;
	= 'V': Compute eigenvalues and eigenvectors.

<i>range</i>	CHARACTER*1
	= 'A': all eigenvalues will be found.
	= 'V': all eigenvalues in the half-open interval (<i>vl</i> , <i>vu</i>] will be found.
	= 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>n</i>	INTEGER
	The order of the matrix. <i>n</i> ≥ 0.
<i>d</i>	REAL for ssteigr2a DOUBLE PRECISION for dstegr2a Array, dimension (<i>n</i>)
	The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> . Overwritten on exit.
<i>e</i>	REAL for ssteigr2a DOUBLE PRECISION for dstegr2a Array, dimension (<i>n</i>)
	On entry, the (<i>n</i> -1) subdiagonal elements of the tridiagonal matrix <i>T</i> in elements 1 to <i>n</i> -1 of <i>e</i> . <i>e</i> (<i>n</i>) need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>vl</i> , <i>vu</i>	REAL for ssteigr2a DOUBLE PRECISION for dstegr2a If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for eigenvalues. <i>vl</i> < <i>vu</i> . Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i> , <i>iu</i>	INTEGER If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 ≤ <i>il</i> ≤ <i>iu</i> ≤ <i>n</i> , if <i>n</i> > 0. Not referenced if <i>range</i> = 'A' or 'V'.
<i>ldz</i>	INTEGER The leading dimension of the array <i>z</i> . <i>ldz</i> ≥ 1, and if <i>jobz</i> = 'V', then <i>ldz</i> ≥ max(1, <i>n</i>).
<i>nzc</i>	INTEGER The number of eigenvectors to be held in the array <i>z</i> . If <i>range</i> = 'A', then <i>nzc</i> ≥ max(1, <i>n</i>). If <i>range</i> = 'V', then <i>nzc</i> ≥ the number of eigenvalues in (<i>vl</i> , <i>vu</i>]. If <i>range</i> = 'I', then <i>nzc</i> ≥ <i>iu</i> - <i>il</i> +1. If <i>nzc</i> = -1, then a workspace query is assumed; the routine calculates the number of columns of the array <i>z</i> that are needed to hold the eigenvectors. This value is returned as the first entry of the <i>z</i> array, and no error message related to <i>nzc</i> is issued.

lwork

INTEGER

The dimension of the array *work*. $lwork \geq \max(1, 18*n)$ if *jobz* = 'V', and $lwork \geq \max(1, 12*n)$ if *jobz* = 'N'.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued.

liwork

INTEGER

The dimension of the array *iwork*. $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued.

dol, dou

INTEGER

From all the eigenvalues $w(1:m)$, only eigenvalues $w(dol:dou)$ are computed.

OUTPUT Parameters

m

INTEGER

Globally summed over all processors, *m* equals the total number of eigenvalues found. $0 \leq m \leq n$.

If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il+1*.

The local output equals *m* = *dou - dol + 1*.

w

REAL for ssteqr2a

DOUBLE PRECISION for dstegr2a

Array, dimension (*n*)

The first *m* elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this routine, only the eigenvalues from position *dol:dou* are reliable on this processor because the eigenvalue computation is done in parallel. The other entries outside *dol:dou* are very crude preliminary approximations. Other processors hold reliable information on these other parts of the *w* array.

This information is communicated in the ScaLAPACK driver.

z

REAL for ssteqr2a

DOUBLE PRECISION for dstegr2a

Array, dimension (*ldz, max(1,m)*)

?steqr2a does not compute eigenvectors, this is done in ?steqr2b. The argument *z* as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this subroutine is meant to be used when eigenvectors are computed.

<i>work</i>	On exit, if <i>info</i> = 0, <i>work</i> (1) returns the optimal (and minimal) <i>lwork</i> .
<i>iwork</i>	On exit, if <i>info</i> = 0, <i>iwork</i> (1) returns the optimal <i>liwork</i> .
<i>needil</i> , <i>neediu</i>	INTEGER The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.
<i>inderr</i>	INTEGER <i>inderr</i> points to the place in the work space where the eigenvalue uncertainties (errors) are stored.
<i>nsplit</i>	INTEGER The number of blocks into which <i>T</i> splits. $1 \leq nsplit \leq n$.
<i>pivmin</i>	REAL for <i>ssteqr2a</i> DOUBLE PRECISION for <i>dsteqr2a</i> The minimum pivot in the sturm sequence for <i>T</i> .
<i>scale</i>	REAL for <i>ssteqr2a</i> DOUBLE PRECISION for <i>dsteqr2a</i> The scaling factor for the tridiagonal <i>T</i> .
<i>wl</i> , <i>wu</i>	REAL for <i>ssteqr2a</i> DOUBLE PRECISION for <i>dsteqr2a</i> The interval (<i>wl</i> , <i>wu</i>] contains all the wanted eigenvalues. It is either given by the user or computed in ?larre2a .
<i>info</i>	INTEGER On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 10 <i>x</i> , internal error in ?larre2a , Here, the digit <i>x</i> = <i>abs</i> (<i>iinfo</i>) < 10, where <i>iinfo</i> is the nonzero error code returned by ?larre2a .

?steqr2b

From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.

Syntax

Fortran:

```
call sstegr2b( jobz, n, d, e, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork,
dol, dou, needil, neediu, indwlc, pivmin, scale, wl, wu, vstart, finish, maxcls,
ndepth, parity, zoffset, info )

call dstegr2b( jobz, n, d, e, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork,
dol, dou, needil, neediu, indwlc, pivmin, scale, wl, wu, vstart, finish, maxcls,
ndepth, parity, zoffset, info )
```

Include Files

- C: mkl_scalapack.h

Description

?stegr2b should only be called after a call to ?stegr2a. From eigenvalues and initial representations computed by ?stegr2a, ?stegr2b computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy $m \geq dol \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'. ?stegr2b only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.)
- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is true, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to *dou* - *dol* + 1.
- ?stegr2b needs more workspace in *z* than the sequential ?stegr. It is used to store the conformal embedding of the local representation tree.

Input Parameters

<i>jobz</i>	CHARACTER*1
	= 'N': Compute eigenvalues only;
	= 'V': Compute eigenvalues and eigenvectors.
<i>n</i>	INTEGER
	The order of the matrix. <i>n</i> ≥ 0 .
<i>d</i>	REAL for sstegr2b DOUBLE PRECISION for dstegr2b Array, dimension (<i>n</i>) The <i>n</i> diagonal elements of the tridiagonal matrix T. Overwritten on exit.
<i>e</i>	REAL for sstegr2b DOUBLE PRECISION for dstegr2b

Array, dimension (n)

The ($n-1$) subdiagonal elements of the tridiagonal matrix T in elements 1 to $n-1$ of e . $e(n)$ need not be set on input, but is used internally as workspace. Overwritten on exit.

m

INTEGER

The total number of eigenvalues found in ?steqr2a. $0 \leq m \leq n$.

w

REAL for ssteqr2b

DOUBLE PRECISION for dstegr2b

Array, dimension (n)

The first m elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from $dol:dou$, are reliable on this processor. (It does not need to know about any others anyway.)

ldz

INTEGER

The leading dimension of the array z . $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1,n)$.

nzc

INTEGER

The number of eigenvectors to be held in the array z .

$lwork$

INTEGER

The dimension of the array $work$. $lwork \geq \max(1,18*n)$

if $jobz = 'V'$, and $lwork \geq \max(1,12*n)$ if $jobz = 'N'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.

$liwork$

INTEGER

The dimension of the array $iwork$. $liwork \geq \max(1,10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1,8*n)$ if only the eigenvalues are to be computed.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.

dol, dou

INTEGER

From the eigenvalues $w(1:m)$, only eigenvectors $z(:,dol)$ to $z(:,dou)$ are computed.

If $dol > 1$, then $z(:,dol-1-zoffset)$ is used and overwritten.

If $dou < m$, then $z(:,dou+1-zoffset)$ is used and overwritten.

$needil, neediu$

INTEGER

Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by [?larre2a](#), modified in the course of the algorithm.

pivmin

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The minimum pivot in the sturm sequence for T .*scale*

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The scaling factor for T . Used for unscaling the eigenvalues at the very end of the algorithm.*wl, wu*

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The interval $(wl, wu]$ contains all the wanted eigenvalues.*vstart*

LOGICAL

.TRUE. on initialization, set to .FALSE. afterwards.

finish

LOGICAL

Indicates whether all eigenpairs have been computed.

maxcls

INTEGER

The largest cluster worked on by this processor in the representation tree.

ndepth

INTEGER

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity

INTEGER

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

zoffset

INTEGER

Offset for storing the eigenpairs when z is distributed in 1D-cyclic fashion.

OUTPUT Parameters

z

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

Array, dimension ($ldz, \max(1,m)$)

If $jobz = 'V'$, and if $info = 0$, then a subset of the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

See $d01$, $d02$ for more information.

<i>isuppz</i>	INTEGER array, dimension (2*max(1, <i>m</i>)) The support of the eigenvectors in <i>z</i> , i.e., the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th computed eigenvector is nonzero only in elements <i>isuppz</i> (2*i-1) through <i>isuppz</i> (2*i). This is relevant in the case when the matrix is split. <i>isuppz</i> is only set if <i>n</i> >2.
<i>work</i>	On exit, if <i>info</i> = 0, <i>work</i> (1) returns the optimal (and minimal) <i>lwork</i> .
<i>iwork</i>	On exit, if <i>info</i> = 0, <i>iwork</i> (1) returns the optimal <i>liwork</i> .
<i>needil</i> , <i>neediu</i>	Modified in the course of the algorithm.
<i>indwl</i> c	REAL for <i>ssteigr2b</i> DOUBLE PRECISION for <i>dsteigr2b</i> Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)
<i>vstart</i>	.TRUE. on initialization, set to .FALSE. afterwards.
<i>finish</i>	Indicates whether all eigenpairs have been computed
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>info</i>	INTEGER On exit, <i>info</i> = 0: successful exit other:if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 20 <i>x</i> , internal error in ?larrv2 . Here, the digit <i>x</i> = abs(<i>iinfo</i>) < 10, where <i>iinfo</i> is the nonzero error code returned by ?larrv2

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

Fortran:

```
call sstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
call dstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
```

C:

```
void sstein2 (MKL_INT *n , float *d , float *e , MKL_INT *m , float *w , MKL_INT
*iblock , MKL_INT *isplit , float *orfac , float *z , MKL_INT *ldz , float *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
void dstein2 (MKL_INT *n , double *d , double *e , MKL_INT *m , double *w , MKL_INT
*iblock , MKL_INT *isplit , double *orfac , double *z , MKL_INT *ldz , double *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The `?stein2` routine is a modified LAPACK routine `?stein`. It computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>m</i>	INTEGER. The number of eigenvectors to be found ($0 \leq m \leq n$).
<i>d</i> , <i>e</i> , <i>w</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) , size (<i>n</i>). The <i>n</i> diagonal elements of the tridiagonal matrix T . <i>e</i> (*) , size (<i>n</i>). The (<i>n</i> -1) subdiagonal elements of the tridiagonal matrix T , in elements 1 to <i>n</i> -1. <i>e</i> (<i>n</i>) need not be set. <i>w</i> (*) , size (<i>n</i>). The first <i>m</i> elements of <i>w</i> contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array <i>w</i> from <code>?stebz</code> with ORDER = 'B' is expected here). The dimension of <i>w</i> must be at least <code>max(1, n)</code> .
<i>iblock</i>	INTEGER. Array, size (<i>n</i>). The submatrix indices associated with the corresponding eigenvalues in <i>w</i> ; <i>iblock</i> (<i>i</i>) = 1, if eigenvalue <i>w</i> (<i>i</i>) belongs to the first submatrix from the top, <i>iblock</i> (<i>i</i>) = 2, if eigenvalue <i>w</i> (<i>i</i>) belongs to the second submatrix, etc. (The output array <i>iblock</i> from <code>?stebz</code> is expected here).
<i>isplit</i>	INTEGER. Array, size (<i>n</i>).

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit(1)$, the second submatrix consists of rows/columns $isplit(1)+1$ through $isplit(2)$, etc. (The output array $isplit$ from ?stebz is expected here).

<i>orfac</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within $orfac * T $ of each other are to be orthogonalized.
<i>ldz</i>	INTEGER. The leading dimension of the output array z ; $ldz \geq \max(1, n)$.
<i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, size $(5n)$.
<i>iwork</i>	INTEGER. Workspace array, size (n) .

Output Parameters

<i>z</i>	REAL for sstein2 DOUBLE PRECISION for dstein2 Array, size ldz by m . The computed eigenvectors. The eigenvector associated with the eigenvalue $w(i)$ is stored in the i -th column of z . Any vector that fails to converge is set to its current iterate after $maxits$ iterations.
<i>ifail</i>	INTEGER. Array, size (m) . On normal exit, all elements of <i>ifail</i> are zero. If one or more eigenvectors fail to converge after $maxits$ iterations, then their indices are stored in the array <i>ifail</i> .
<i>info</i>	INTEGER. <i>info</i> = 0, the exit is successful. <i>info</i> < 0: if <i>info</i> = $-i$, the i -th had an illegal value. <i>info</i> > 0: if <i>info</i> = i , then i eigenvectors failed to converge in $maxits$ iterations. Their indices are stored in the array <i>ifail</i> .

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

Fortran:

```
call sdbtf2(m, n, kl, ku, ab, ldab, info)
```

```
call ddbtf2(m, n, kl, ku, ab, ldab, info)
call cdbtf2(m, n, kl, ku, ab, ldab, info)
call zdbtf2(m, n, kl, ku, ab, ldab, info)
```

C:

```
void sdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT
*ldab , MKL_INT *info );
void ddbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab ,
MKL_INT *ldab , MKL_INT *info );
void cdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab ,
MKL_INT *ldab , MKL_INT *info );
void zdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab ,
MKL_INT *ldab , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?dbtf2 routine computes an LU factorization of a general real/complex m -by- n band matrix A without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of A ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ($ku \geq 0$).
<i>ab</i>	REAL for sdbtf2 DOUBLE PRECISION for ddbtf2 COMPLEX for cdbtf2 COMPLEX*16 for zdbtf2. Array, size <i>ldab</i> by <i>n</i> . The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl of the array need not be set. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: $ab(kl+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . ($ldab \geq 2kl + ku + 1$)

Output Parameters

ab

On exit, details of the factorization: U is stored as an upper triangular band matrix with k_l+ku superdiagonals in rows 1 to k_l+ku+1 , and the multipliers used during the factorization are stored in rows k_l+ku+2 to $2*k_l+ku+1$. See the *Application Notes* below for further details.

info

INTEGER.

= 0: successful exit

< 0: if *info* = - *i*, the *i*-th argument had an illegal value,

> 0: if *info* = + *i*, $u(i,i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $k_l = 2$, $ku = 1$:

Original Matrix	LU Factorization
.....
.....
.....
.....
.....
.....

The routine does not use array elements marked *; elements marked + need not be set on entry, but the routine requires them to store elements of U , because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

Fortran:

```
call sdbtrf(m, n, kl, ku, ab, ldab, info)
call ddbtrf(m, n, kl, ku, ab, ldab, info)
call cdbtrf(m, n, kl, ku, ab, ldab, info)
call zdbtrf(m, n, kl, ku, ab, ldab, info)
```

C:

```
void sdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT *ldab , MKL_INT *info );
void ddbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab ,
MKL_INT *ldab , MKL_INT *info );
void cdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab ,
MKL_INT *ldab , MKL_INT *info );
void zdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab ,
MKL_INT *ldab , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

This routine computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>k1</i>	INTEGER. The number of sub-diagonals within the band of A ($k1 \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ($ku \geq 0$).
<i>ab</i>	REAL for sdbtrf DOUBLE PRECISION for ddbtrf COMPLEX for cdbtrf COMPLEX*16 for zdbtrf. Array, size l_{dab} by n . The matrix A in band storage, in rows $k1+1$ to $2k1+ku+1$; rows 1 to $k1$ of the array need not be set. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: $ab(k1+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+k1)$.
<i>l_{dab}</i>	INTEGER. The leading dimension of the array <i>ab</i> . $(l_{dab} \geq 2k1 + ku + 1)$

Output Parameters

<i>ab</i>	On exit, details of the factorization: U is stored as an upper triangular band matrix with $k1+ku$ superdiagonals in rows 1 to $k1+ku+1$, and the multipliers used during the factorization are stored in rows $k1+ku+2$ to $2*k1+ku+1$. See the <i>Application Notes</i> below for further details.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = $-i$, the i -th argument had an illegal value, > 0: if <i>info</i> = $+i$, $u(i, i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $k1 = 2$, $ku = 1$:

The routine does not use array elements marked *.

?dttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

Fortran:

```
call sdttrf(n, dl, d, du, info)
call ddttrf(n, dl, d, du, info)
call cdttrf(n, dl, d, du, info)
call zdttrf(n, dl, d, du, info)
```

C:

```
void sdttrf (MKL_INT *n , float *dl , float *d , float *du , MKL_INT *info );
void ddttrf (MKL_INT *n , double *dl , double *d , double *du , MKL_INT *info );
void cdttrf (MKL_INT *n , MKL_Complex8 *dl , MKL_Complex8 *d , MKL_Complex8 *du ,
MKL_INT *info );
void zdttrf (MKL_INT *n , MKL_Complex16 *dl , MKL_Complex16 *d , MKL_Complex16 *du ,
MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?dttrf routine computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L \cdot U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>dl, d, du</i>	REAL for sdttrf DOUBLE PRECISION for ddttrf COMPLEX for cdttrf COMPLEX*16 for zdttrf. Arrays containing elements of A .

The array dl of size $(n - 1)$ contains the sub-diagonal elements of A .

The array d of size n contains the diagonal elements of A .

The array du of size $(n - 1)$ contains the super-diagonal elements of A .

Output Parameters

dl	Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
d	Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
du	Overwritten by the $(n-1)$ elements of the first super-diagonal of U .
$info$	<p>INTEGER.</p> <p>= 0: successful exit</p> <p>< 0: if $info = - i$, the i-th argument had an illegal value,</p> <p>> 0: if $info = i$, $u(i,i)$ is exactly 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.</p>

?dttrs

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

Fortran:

```
call sdtrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call ddtrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call cdtrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call zdtrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
```

C:

```
void sdtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , float *b , MKL_INT *ldb , MKL_INT *info );
void ddtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , double *b , MKL_INT *ldb , MKL_INT *info );
void cdtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*dl , MKL_Complex8 *d , MKL_Complex8 *du , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT
*info );
void zdtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*dl , MKL_Complex16 *d , MKL_Complex16 *du , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT
*info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?dttrs_V routine solves one of the following systems of linear equations:

$$L^*X = B, L^T*X = B, \text{ or } L^H*X = B,$$

$$U^*X = B, U^T*X = B, \text{ or } U^H*X = B$$

with factors of the tridiagonal matrix A from the LU factorization computed by [?dttrf](#).

Input Parameters

uplo

CHARACTER*1.

Specifies whether to solve with L or U .

trans

CHARACTER. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If *trans* = 'N', then $A^*X=B$ is solved for X (no transpose).

If *trans* = 'T', then $A^T*X = B$ is solved for X (transpose).

If *trans* = 'C', then $A^H*X = B$ is solved for X (conjugate transpose).

n

INTEGER. The order of the matrix A ($n \geq 0$).

nrhs

INTEGER. The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$).

dl,d,du,b

REAL for sdttrs_V

DOUBLE PRECISION for ddttrs_V

COMPLEX for cdtrs_V

COMPLEX*16 for zdtrs_V.

Arrays of sizes: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, nrhs)$.

The array *dl* contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A .

The array *d* contains n diagonal elements of the upper triangular matrix U from the LU factorization of A .

The array *du* contains the $(n - 1)$ elements of the first super-diagonal of U .

On entry, the array *b* contains the right-hand side matrix B .

ldb

INTEGER. The leading dimension of the array *b*; $ldb \geq \max(1, n)$.

Output Parameters

b

Overwritten by the solution matrix X .

info

INTEGER. If *info*=0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

?pttrsV

*Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $L^*D^*L^H$ factorization computed by ?pttrf.*

Syntax

Fortran:

```
call spttrsv(trans, n, nrhs, d, e, b, ldb, info)
call dpttrsv(trans, n, nrhs, d, e, b, ldb, info)
call cpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
call zpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
```

C:

```
void spttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , float *b , MKL_INT *ldb , MKL_INT *info );
void dpttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , double *e , double *b , MKL_INT *ldb , MKL_INT *info );
void cpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , MKL_Complex8 *e , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT *info );
void zpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?pttrsV routine solves one of the triangular systems:

$L^T X = B$, or $L^H X = B$ for real flavors,

or

$L^H X = B$, or $L^H X = B$,

$U^H X = B$, or $U^H X = B$ for complex flavors,

where L (or U for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix A such that

$A = L^*D^*L^H$ (computed by [spttrf/dpttrf](#))

or

$A = U^H D^* U$ or $A = L^* D^* L^H$ (computed by [cpttrf/zpttrf](#)).

Input Parameters

uplo

CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:

If $uplo = 'U'$, e is the superdiagonal of U , and $A = U^H D^* U$ or $A = L^* D^* L^H$;

if $uplo = 'L'$, e is the subdiagonal of L , and $A = L^*D*L^H$.

The two forms are equivalent, if A is real.

trans

CHARACTER.

Specifies the form of the system of equations:

for real flavors:

if $trans = 'N'$: $L*X = B$ (no transpose)

if $trans = 'T'$: $L^T*X = B$ (transpose)

for complex flavors:

if $trans = 'N'$: $U*X = B$ or $L^H*X = B$ (no transpose)

if $trans = 'C'$: $U^H*X = B$ or $L^H*X = B$ (conjugate transpose).

n

INTEGER. The order of the tridiagonal matrix A . $n \geq 0$.

nrhs

INTEGER. The number of right hand sides, that is, the number of columns of the matrix B . $nrhs \geq 0$.

d

REAL array, size (n). The n diagonal elements of the diagonal matrix D from the factorization computed by [?pttrf](#).

e

COMPLEX array, size ($n-1$). The ($n-1$) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by [?pttrf](#). See *uplo*.

b

COMPLEX array, size ldb by $nrhs$.

On entry, the right hand side matrix B .

ldb

INTEGER.

The leading dimension of the array b .

$ldb \geq \max(1, n)$.

Output Parameters

b

On exit, the solution matrix X .

info

INTEGER.

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

Fortran:

```
call ssteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

```
call dsteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

C:

```
void ssteqr2 (char *compz , MKL_INT *n , float *d , float *e , float *z , MKL_INT
*ldz , MKL_INT *nr , float *work , MKL_INT *info );
void dsteqr2 (char *compz , MKL_INT *n , double *d , double *e , double *z , MKL_INT
*ldz , MKL_INT *nr , double *work , MKL_INT *info );
```

Include Files

- C: mkl_scalapack.h

Description

The ?steqr2 routine is a modified version of LAPACK routine ?steqr. The ?steqr2 routine computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. ?steqr2 is modified from ?steqr to allow each ScalAPACK process running ?steqr2 to perform updates on a distributed matrix Q. Proper usage of ?steqr2 can be gleaned from examination of ScalAPACK routine p?syev.

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix <i>T</i> .
<i>n</i>	INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).
<i>d</i> , <i>e</i> , <i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> contains the diagonal elements of <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the $(n-1)$ subdiagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>work</i> is a workspace array. The dimension of <i>work</i> is $\max(1, 2*n-2)$. If <i>compz</i> = 'N', then <i>work</i> is not referenced.
<i>z</i>	(local) REAL for ssteqr2 DOUBLE PRECISION for dsteqr2 Array, global size <i>n</i> by <i>n</i> , local size <i>ldz</i> by <i>nr</i> . If <i>compz</i> = 'V', then <i>z</i> contains the orthogonal matrix used in the reduction to tridiagonal form.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> . Constraints: $ldz \geq 1$, $ldz \geq \max(1, n)$, if eigenvectors are desired.

nr INTEGER. $nr = \max(1, numroc(n, nb, myprow, 0, nprocs))$.
If $compz = 'N'$, then nr is not referenced.

Output Parameters

d REAL array, size (n), for `ssteqr2`.
DOUBLE PRECISION array, size (n), for `dsteqr2`.
On exit, the eigenvalues in ascending order, if $info = 0$.
See also *info*.

e REAL array, size ($n-1$), for `ssteqr2`.
DOUBLE PRECISION array, size ($n-1$), for `dsteqr2`.
On exit, *e* has been destroyed.

z (local)
REAL for `ssteqr2`
DOUBLE PRECISION for `dsteqr2`
Array, global size n by n , local size ldz by nr .
On exit, if $info = 0$, then,
if $compz = 'V'$, *z* contains the orthonormal eigenvectors of the original symmetric matrix, and if $compz = 'I'$, *z* contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $compz = 'N'$, then *z* is not referenced.

info INTEGER.
 $info = 0$, the exit is successful.
 $info < 0$: if $info = -i$, the i -th had an illegal value.
 $info > 0$: the algorithm has failed to find all the eigenvalues in a total of $30n$ iterations;
if $info = i$, then i elements of *e* have not converged to zero; on exit, *d* and *e* contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
<code>p?labad</code>	<code>s, d</code>	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<code>p?lachkieee</code>	<code>s, d</code>	Performs a simple check for the features of the IEEE standard. (C interface function).

Routine Name	Data Types	Description
p?lamch	s, d	Determines machine parameters for floating-point arithmetic.
p?lasnbt	s, d	Computes the position of the sign bit of a floating-point number. (C interface function).

See Also

[pxerbla](#) Error handling routine called by ScalAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

Fortran:

```
call pslabad(ictxt, small, large)
call pdlabad(ictxt, small, large)
```

C:

```
void pslabad (MKL_INT *ictxt , float *small , float *large );
void pdlabad (MKL_INT *ictxt , double *small , double *large );
```

Include Files

- C: mkl_scalapack.h

Description

The p?labad routine takes as input the values computed by p?lamch for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by p?lamch. This subroutine is needed because p?lamch does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this routine performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

<i>ictxt</i>	(global) INTEGER. The BLACS context handle in which the computation takes place.
<i>small</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad. On entry, the underflow threshold as computed by p?lamch.
<i>large</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad.

On entry, the overflow threshold as computed by `p?lamch`.

Output Parameters

<i>small</i>	(local).
	On exit, if $\log_{10}(large)$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	(local).
	On exit, if $\log_{10}(large)$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

`p?lachkieee`

Performs a simple check for the features of the IEEE standard. (C interface function).

Syntax

Fortran:

```
void pslachkieee(int *isieee, float *rmax, float *rmin);
void pdlachkieee(int *isieee, float *rmax, float *rmin);
```

C:

```
void pslachkieee (MKL_INT *isieee , float *rmax , float *rmin );
void pdlachkieee (MKL_INT *isieee , float *rmax , float *rmin );
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?lachkieee` routine performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, `p?lachkieee` may not return.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code. This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

<i>rmax</i>	(local).
	REAL for <code>pslachkieee</code>
	DOUBLE PRECISION for <code>pdlachkieee</code>
	The overflow threshold (= <code>?lamch ('O')</code>).
<i>rmin</i>	(local).
	REAL for <code>pslachkieee</code>
	DOUBLE PRECISION for <code>pdlachkieee</code>
	The underflow threshold (= <code>?lamch ('U')</code>).

Output Parameters

isieee (local). INTEGER.

On exit, *isieee* = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, *isieee* = 0 implies that some the features of the IEEE standard that we rely on are missing.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

Fortran:

```
val = pslamch(ictxt, cmach)
```

```
val = pdlamch(ictxt, cmach)
```

C:

```
float pslamch (MKL_INT *ictxt , char *cmach );
```

```
double pdlamch (MKL_INT *ictxt , char *cmach );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lamch routine determines single precision machine parameters.

Input Parameters

ictxt (global). INTEGER. The BLACS context handle in which the computation takes place.

cmach (global) CHARACTER*1.

Specifies the value to be returned by p?lamch:

```
= 'E' or 'e', p?lamch := eps
= 'S' or 's' , p?lamch := sfmin
= 'B' or 'b', p?lamch := base
= 'P' or 'p', p?lamch := eps*base
= 'N' or 'n', p?lamch := t
= 'R' or 'r', p?lamch := rnd
= 'M' or 'm', p?lamch := emin
= 'U' or 'u', p?lamch := rmin
= 'L' or 'l', p?lamch := emax
= 'O' or 'o', p?lamch := rmax,
```

where

```

eps = relative machine precision
sfmin = safe minimum, such that 1/sfmin does not overflow
base = base of the machine
prec = eps*base
t = number of (base) digits in the mantissa
rnd = 1.0 when rounding occurs in addition, 0.0 otherwise
emin = minimum exponent before (gradual) underflow
rmin = underflow threshold - base^(emin-1)
emax = largest exponent before overflow
rmax = overflow threshold - (base^emax) * (1-eps)

```

Output Parameters

<i>val</i>	Value returned by the routine.
------------	--------------------------------

p?lasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

Fortran:

```
void pslasnbt(int *ieflag);
void pdlASNBT(int *ieflag);
```

C:

```
void pslasnbt (MKL_INT *ieflag );
void pdlASNBT (MKL_INT *ieflag );
```

Include Files

- C: mkl_scalapack.h

Description

The p?lasnbt routine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

<i>ieflag</i>	INTEGER.
---------------	----------

This flag indicates the position of the signbit of any single/double precision floating point number.

ieflag = 0, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

ieflag = 1 indicates that the signbit is the 32-nd bit for a single precision routine.

In the case of a double precision routine:

ieflag = 1 indicates that the signbit is the 32-nd bit (Big Endian).

ieflag = 2 indicates that the signbit is the 64-th bit (Little Endian).

Matrix Redistribution/Copy Routines

This section describes ScaLAPACK redistribution/copy routines. Summary information about these routines is given in the following table:

ScaLAPACK Redistribution/Copy Routines

Routine Name	Data Types	Description
p?gemr2d	s, d, c, z, i	Copies a submatrix from one general rectangular matrix to another.
p?trmr2d	s, d, c, z, i	Copies a submatrix from one trapezoidal matrix to another.

See Also

[pxerbla](#) Error handling routine called by ScaLAPACK routines.

p?gemr2d

Copies a submatrix from one general rectangular matrix to another.

Syntax

Fortran:

```
call psgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pdgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pcgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pzgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pigemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
```

C:

```
void psgemr2d (MKL_INT *m, MKL_INT *n, float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *ictxt );
void pdgemr2d (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,

Description

The `p?gemr2d` routine copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?trmr2d`, these routines are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B . The general rules for which parameters need to be set are:

- All calling processes must have the correct m and n .
- Processes in context A must correctly define all parameters describing A .
- Processes in context B must correctly define all parameters describing B .
- Processes which are not members of context A must pass `descA(ctxt_) = -1` and need not set other parameters describing A .
- Processes which are not members of context B must pass `descB(ctxt_) = -1` and need not set other parameters describing B .

Because of its generality, `p?gemr2d` can be used for many operations not usually associated with copy routines. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this routine can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this routine requires an array descriptor with `dtype_ = 1`.

Input Parameters

m	(global) INTEGER. The number of rows of matrix A to be copied ($m \geq 0$).
n	(global) INTEGER. The number of columns of matrix A to be copied ($n \geq 0$).
$nrhs$	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
a	(local) REAL for <code>psgemr2d</code> DOUBLE for <code>pdgemr2d</code> COMPLEX for <code>pcgemr2d</code> DOUBLE COMPLEX for <code>pzgemr2d</code> INTEGER for <code>pigemr2d</code> .

Pointer into the local memory to array of size lld_a by $LOCc(ja+n-1)$ containing the source matrix A .

ia, ja (global) INTEGER. The row and column indices in the array A indicating the first row and the first column, respectively, of the submatrix of A) to copy. $1 \leq ia \leq total_rows_in_a - m + 1$, $1 \leq ja \leq total_columns_in_a - n + 1$.

desca (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

Only $desca(dtype__) = 1$ is supported, so $dlen_ = 9$.

If the calling process is not part of the context of A , $desca(ctxt_)$ must be equal to -1.

ib, jb (global) INTEGER. The row and column indices in the array B indicating the first row and the first column, respectively, of the submatrix B to which to copy the matrix. $1 \leq ib \leq total_rows_in_b - m + 1$, $1 \leq jb \leq total_columns_in_b - n + 1$.

descb (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .

Only $descb(dtype__) = 1$ is supported, so $dlen_ = 9$.

If the calling process is not part of the context of B , $descb(ctxt_)$ must be equal to -1.

ictxt (global) INTEGER.

The context encompassing at least the union of all processes in context A and context B . All processes in the context $ictxt$ must call this routine, even if they do not own a piece of either matrix.

Output Parameters

b REAL for psgemr2d
 DOUBLE for pdgemr2d
 COMPLEX for pcgemr2d
 DOUBLE COMPLEX for pzgemr2d
 INTEGER for pigemr2d.
 Pointer into the local memory to array of size lld_b by $LOCc(jb+nrhs-1)$.
 Overwritten by the submatrix from A .

p?trmr2d

Copies a submatrix from one trapezoidal matrix to another.

Syntax

Fortran:

```
call pstrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pdtrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
```

```
call pctrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pztrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)

Description

The `p?trmr2d` routine copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?gemr2d`, these routines are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

The `p?trmr2d` routine assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B . The general rules for which parameters need to be set are:

- All calling processes must have the correct m and n .
- Processes in context A must correctly define all parameters describing A .
- Processes in context B must correctly define all parameters describing B .
- Processes which are not members of context A must pass `desca(ctxt_) = -1` and need not set other parameters describing A .
- Processes which are not members of context B must pass `descb(ctxt_) = -1` and need not set other parameters describing B .

Because of its generality, `p?trmr2d` can be used for many operations not usually associated with copy routines. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for

instance, this routine can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this routine requires an array descriptor with $dtype_ = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether to copy the upper or lower part of the matrix or submatrix.
	<i>uplo</i> = 'U' Copy the upper triangular part.
	<i>uplo</i> = 'L' Copy the lower triangular part.
<i>diag</i>	(global) CHARACTER*1. Specifies whether to copy the diagonal of the matrix or submatrix.
	<i>diag</i> = 'U' Do not copy the diagonal.
	<i>diag</i> = 'N' Copy the diagonal.
<i>m</i>	(global) INTEGER. The number of rows of matrix <i>A</i> to be copied ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns of matrix <i>A</i> to be copied ($n \geq 0$).
<i>a</i>	(local) REAL for pstrmr2d DOUBLE for pdtrmr2d COMPLEX for pcstrmr2d DOUBLE COMPLEX for pzstrmr2d INTEGER for pitrnr2d. Pointer into the local memory to array of size <i>lld_a</i> by <i>LOCc(ja+n-1)</i> containing the source matrix <i>A</i> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the array <i>A</i> indicating the first row and the first column, respectively, of the submatrix of <i>A</i> to copy. $1 \leq ia \leq total_rows_in_a - m + 1$, $1 \leq ja \leq total_columns_in_a - n + 1$.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen</i> . The array descriptor for the distributed matrix <i>A</i> . Only <i>desca(dtype_)</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>A</i> , <i>desca(ctxt_)</i> must be equal to -1.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the array <i>B</i> indicating the first row and the first column, respectively, of the submatrix <i>B</i> to which to copy the matrix. $1 \leq ib \leq total_rows_in_b - m + 1$, $1 \leq jb \leq total_columns_in_b - n + 1$.

<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . Only <i>descb(dtype_)</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>B</i> , <i>descb(ctxt_)</i> must be equal to -1.
<i>ictxt</i>	(global) INTEGER. The context encompassing at least the union of all processes in context <i>A</i> and context <i>B</i> . All processes in the context <i>ictxt</i> must call this routine, even if they do not own a piece of either matrix.

Output Parameters

<i>b</i>	REAL for pstrmr2d DOUBLE for pdtrmr2d COMPLEX for pcstrmr2d DOUBLE COMPLEX for pzstrmr2d INTEGER for pitrnr2d. Pointer into the local memory to array of size <i>lld_b</i> by <i>LOCc(jb+nrhs-1)</i> . Overwritten by the submatrix from <i>A</i> .

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes

- the direct sparse solver based on PARDISO* which is referred to here as [Intel MKL PARDISO](#);
- the alternative interface for the direct sparse solver which is referred to here as the [DSS interface](#);
- [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI);
- and [two preconditioners](#) based on the incomplete LU factorization technique.

Intel MKL PARDISO – Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel MKL PARDISO solver. The interface is Fortran, but it can be called from C or C++ programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems.

The Intel MKL PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

The following table lists the names of the Intel MKL PARDISO routines and describes their general use.

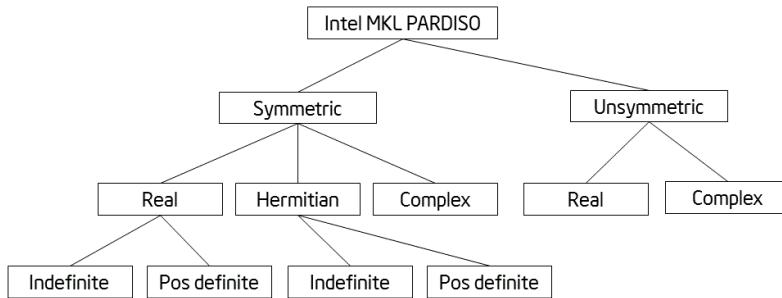

Intel MKL PARDISO Routines

Routine	Description
pardisoinit	Initializes Intel MKL PARDISO with default parameters depending on the matrix type.
pardiso	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.
pardiso_64	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.
pardiso_getenv	Retrieves additional values from the Intel MKL PARDISO handle.
pardiso_setenv	Sets additional values in the Intel MKL PARDISO handle.
mkl_pardiso_pivot	Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine.

Routine	Description
<code>pardiso_getdiag</code>	Returns diagonal elements of initial and factorized matrix.
<code>pardiso_handle_store</code>	Store internal structures from <code>pardiso</code> to a file.
<code>pardiso_handle_restore</code>	Restore <code>pardiso</code> internal structures from a file.
<code>pardiso_handle_delete</code>	Delete files with <code>pardiso</code> internal structure data.
<code>pardiso_handle_store_64</code>	Store internal structures from <code>pardiso_64</code> to a file.
<code>pardiso_handle_restore_64</code>	Restore <code>pardiso_64</code> internal structures from a file.
<code>pardiso_handle_delete_64</code>	Delete files with <code>pardiso_64</code> internal structure data.

The Intel MKL PARDISO solver supports a wide range of real and complex sparse matrix types (see the figure below).

Sparse Matrices That Can Be Solved with the Intel MKL PARDISO Solver

The Intel MKL PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

You can find code examples that use Intel MKL PARDISO routines to solve systems of linear equations in the `examples` folder of the Intel MKL installation directory:

- Fortran examples: `examples/solverf/source`
- C examples: `examples/solverc/source`

Supported Matrix Types

The analysis steps performed by Intel MKL PARDISO depend on the structure of the input matrix A .

Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2

Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of X is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1×1 and 2×2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and optional iterative refinement.

Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)^T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$$\text{alpha} = \text{eps} * \|A2\|_{\text{inf}},$$

where eps is the machine precision, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $\|A2\|_{\text{inf}}$ is the infinity norm of A . Any tiny pivots encountered during elimination are set to the sign $(1_{II}) * \text{eps} * \|A2\|_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Sparse Data Storage

Sparse data storage in Intel MKL PARDISO follows the 3-array variation of the compressed sparse row (CSR3) format described in [Sparse Matrix Storage Format](#) with the Intel MKL PARDISO parameters *ja* standing for *columns*, *ia* for *rowIndex*, and *a* for *values*. The algorithms in Intel MKL PARDISO require column indices *ja* to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

CAUTION

Intel MKL PARDISO column indices ja must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ([iparm\(27\)](#))

NOTE

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel MKL PARDISO creates internal copies of arrays ia , ja , and a full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

Storage of Matrices

By default, Intel MKL PARDISO stores matrices in RAM. However, you can specify that Intel MKL PARDISO store matrices on disk by setting [iparm\(60\)](#). This is referred to as in-core (IC) and out-of-core (OOC), respectively.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

These variables specify the path and filename as follows:

`<MKL_PARDISO_OOC_CFG_PATH>/<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Linux* OS and OS X*, and
`<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Windows* OS.

By default, the name of the file is `pardiso_ooc.cfg` and it is placed in the current directory.

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is not set or if it is set to 1, then all files are deleted. If it is set to 0, then all files are stored.

By default, the OOC version of Intel MKL PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables `MKL_PARDISO_OOC_MAX_CORE_SIZE`, `MKL_PARDISO_OOC_MAX_SWAP_SIZE`, `MKL_PARDISO_OOC_KEEP_FILE`, and `MKL_PARDISO_OOC_PATH`, create the configuration file with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` is the directory for storing data, `ooc_file` is the file name without any extension, N is the maximum size of RAM in megabytes available for Intel MKL PARDISO (default value is 2000 MB), K is the maximum swap size in megabytes available for Intel MKL PARDISO (default value is 0 MB). Do not set $N+K$ greater than the size of the RAM plus the size of the swap. Be sure to allow enough free memory for the operating system and any other processes which are necessary.

CAUTION

The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line.

For Linux* OS and OS X*:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

NOTE

The values specified in a command line have higher priorities: if a variable is changed in the configuration file and in the command line, OOC version of Intel MKL PARDISO uses only the value defined in the command line.

Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel MKL PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel MKL PARDISO. You can select the method using the *iparm*(4) input parameter. The *iparm*(20) parameter returns the error status after running Intel MKL PARDISO.

Single and Double Precision Computations

Intel MKL PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

Separate Forward and Backward Substitution

The solver execution step (see *parameter phase* = 33 below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix A (*mtype* = 2) is factored by Intel MKL PARDISO as $A = L^T L$. In this case the solution of the system $A^T x = b$ can be found as sequence of substitutions: $L^T y = b$ (forward substitution, *phase* = 331) and $L^T x = y$ (backward substitution, *phase* = 333).

A real nonsymmetric matrix A (*mtype* = 11) is factored by Intel MKL PARDISO as $A = L^T U$. In this case the solution of the system $A^T x = b$ can be found by the following sequence: $L^T y = b$ (forward substitution, *phase* = 331) and $U^T x = y$ (backward substitution, *phase* = 333).

Solving a system with a real symmetric indefinite matrix A (*mtype* = -2) is slightly different from the cases above. Intel MKL PARDISO factors this matrix as $A = LDL^T$, and the solution of the system $A^T x = b$ can be calculated as the following sequence of substitutions: $L^T y = b$ (forward substitution, *phase* = 331), $D^T v = y$

(diagonal substitution, $\text{phase} = 332$), and finally $L^T x = v$ (backward substitution, $\text{phase} = 333$). Diagonal substitution makes sense only for symmetric indefinite matrices ($mtype = -2, -4, 6$). For matrices of other types a solution can be found as described in the first two examples.

CAUTION

The number of refinement steps ([iparm\(8\)](#)) must be set to zero if a solution is calculated with separate substitutions ($\text{phase} = 331, 332, 333$), otherwise Intel MKL PARDISO produces the wrong result.

NOTE

Different pivoting ([iparm\(21\)](#)) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ($\text{phase}=33$) regardless of the pivoting used.

Callback Function for Pivoting Control

In-core Intel MKL PARDISO allows you to control pivoting with a callback routine, [mkl_pardiso_pivot](#). You can then use the [pardiso_getdiag](#) routine to access the diagonal elements. Set [iparm\(56\)](#) to 1 in order to use the callback functionality.

[pardiso](#)

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

Fortran:

```
call pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl,
b, x, error)
```

C:

```
void pardiso (_MKL_DSS_HANDLE_t pt, MKL_INT *maxfct, MKL_INT *mnum, MKL_INT *mtype,
MKL_INT *phase, MKL_INT *n, void *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *perm, MKL_INT
*nrhs, MKL_INT *iparm, MKL_INT *msglvl, void *b, void *x, MKL_INT *error);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

Description

The routine `pardiso` calculates the solution of a set of sparse linear equations

$A \cdot X = B$

with single or multiple right-hand sides, using a parallel LU , LDL , or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ vectors or matrices.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters**NOTE**

The types given for parameters in this section are specified in FORTRAN 77 notation. See [Intel MKL PARDISO Parameters in Tabular Form](#) for detailed description of types of Intel MKL PARDISO parameters in Fortran 90 and C notations.

<i>pt</i>	INTEGER for 32-bit or 64-bit architectures INTEGER*8 for 64-bit architectures Array with dimension of 64. Handle to internal data structure. The entries must be set to zero prior to the first call to <code>pardiso</code> . Unique for factorization.
-----------	---

CAUTION

After the first call to `pardiso` do not directly modify *pt*, as that could cause a serious memory leak.

Use the `pardiso_handle_store` or `pardiso_handle_store_64` routine to store the content of *pt* to a file. Restore the contents of *pt* from the file using `pardiso_handle_restore` or `pardiso_handle_restore_64`. Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

<i>maxfct</i>	INTEGER Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver. <code>pardiso</code> can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers <i>pt</i> .
---------------	--

<i>mnum</i>	INTEGER Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$. In most applications this value is 1.
-------------	---

<i>mtype</i>	INTEGER Defines the matrix type, which influences the pivoting method. The Intel MKL PARDISO solver supports the following matrices:
--------------	---

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase

INTEGER

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel MKL PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [Separate Forward and Backward Substitution](#)).

- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like <i>phase</i> =33, but only forward substitution
332	like <i>phase</i> =33, but only diagonal substitution (if available)

<i>phase</i>	Solver Execution Steps
333	like <i>phase</i> =33, but only backward substitution
0	Release internal memory for <i>L</i> and <i>U</i> matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

If *iparm*(36) = 0, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If *iparm*(36) = 2, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling *pardiso*. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix *S* with your own.

NOTE

For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel MKL PARDISO phase 332 implementation.

n

INTEGER

Number of equations in the sparse linear systems of equations *A***X* = *B*.
Constraint: *n* > 0.

a

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The size of *a* is the same as that of *ja* and the coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) format with increasing values of *ja* for each row. Refer to *values* array description in [Storage Formats for the Direct Sparse Solvers](#) for more details.

ia

INTEGER

Array, dimension $(n+1)$. For $i \leq n$, $ia(i)$ points to the first column index of row i in the array ja in compressed sparse row format. That is, $ia(i)$ gives the index of the element in array a that contains the first non-zero element from row i of A . The last element $ia(n+1)$ is taken to be equal to the number of non-zero elements in A , plus one. Refer to `rowIndex` array description in [Storage Formats for the Direct Sparse Solvers](#) for more details. The array ia is also accessed in all phases of the solution process.

Indexing of ia is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [`iparm\(35\)`](#).

ja

INTEGER

Array $ja(*)$ contains column indices of the sparse matrix A stored in compressed sparse row format. It is important that the indices are in increasing order per row. The array ja is also accessed in all phases of the solution process. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for `columns` array in [Storage Formats for the Direct Sparse Solvers](#).

Indexing of ja is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [`iparm\(35\)`](#).

perm

INTEGER

Array, dimension (n) . Depending on the value of [`iparm\(5\)`](#) and [`iparm\(31\)`](#), either holds the permutation vector of size n or specifies elements used for computing a partial solution.

- If $iparm(5) = 1$, $iparm(31) = 0$, and $iparm(36) = 0$, $perm$ specifies the fill-in reducing ordering to the solver. Let A be the original matrix and $C = P^* A^* P^T$ be the permuted matrix. Row (column) i of C is the $perm(i)$ row (column) of A . The array $perm$ is also used to return the permutation vector calculated during fill-in reducing ordering stage.

NOTE

Be aware that setting $iparm(5) = 1$ prevents use of a parallel algorithm for the solve step.

- If $iparm(5) = 2$, $iparm(31) = 0$, and $iparm(36) = 0$, the computed permutation vector is returned in the $perm$ array.
- If $iparm(5) = 0$, $iparm(31) > 0$, and $iparm(36) = 0$, $perm$ specifies elements of the right-hand side to use or of the solution to compute for a partial solution.
- If $iparm(5) = 0$, $iparm(31) = 0$, and $iparm(36) > 0$, $perm$ specifies elements for a Schur complement.

See [`iparm\(5\)`](#) and [`iparm\(31\)`](#) for more details.

Indexing of $perm$ is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [`iparm\(35\)`](#).

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, dimension (64). This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver.

See [pardiso iparm Parameter](#) for more details about the *iparm* parameters.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then pardiso generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

Array, dimension (*n*, *nrhs*). On entry, contains the right-hand side vector/ matrix *B*, which is placed in memory contiguously. The *b*(*i*+(*k*-1)×*nrhs*) must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.

Output Parameters

(See also [Intel MKL PARDISO Parameters in Tabular Form](#).)

pt

Handle to internal data structure.

iparm

On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See [pardiso iparm Parameter](#) for more details about the *iparm* parameters.

b

On output, the array is replaced with the solution if *iparm*(6) = 1.

x

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel MKL PARDISO (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel MKL PARDISO (*iparm*(28)=1)

Array, dimension ($n, nrhs$). If `iparm(6) = 0` it contains solution vector/matrix X , which is placed contiguously in memory. The $x(i + (k-1) \times n)$ element must hold the i -th component of the k -th solution vector. Note that x is only accessed in the solution phase.

`error`

INTEGER

The error indicator according to the below table:

<code>error</code>	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files
-12	(<code>pardiso_64</code> only) <code>pardiso_64</code> called from 32-bit library

pardisoinit

Initialize Intel MKL PARDISO with default parameters in accordance with the matrix type.

Syntax

Fortran:

```
call pardisoinit (pt, mtype, iparm)
```

C:

```
void pardisoinit (_MKL_DSS_HANDLE_t pt, MKL_INT *mtype, MKL_INT *iparm);
```

Include Files

- **Fortran:** `mkl.fi`
- **Fortran 90:** `mkl_pardiso.f90`
- **C:** `mkl.h`

Description

This function initializes Intel MKL PARDISO internal address pointer *pt* with zero values (as needed for the very first call of *pardiso*) and sets default *iparm* values in accordance with the matrix type. Intel MKL supplies the *pardisoinit* routine to be compatible with PARDISO 3.2 or lower.

NOTE

An alternative way to set default *iparm* values is to call *pardiso* in the analysis phase with *iparm(1)=0*. In this case you must initialize the internal address pointer *pt* with zero values manually.

NOTE

The *pardisoinit* routine initializes only the in-core version of Intel MKL PARDISO. Switching on the out-of core version of Intel MKL PARDISO as well as changing default *iparm* values can be done after the call to *pardisoinit* but before the first call to *pardiso*.

Input Parameters

NOTE

Parameters types in this section are specified in FORTRAN 77 notation. See [Intel MKL PARDISO Parameters in Tabular Form](#) section for detailed description of types of Intel MKL PARDISO parameters in C/ Fortran 90 notations.

mtype

INTEGER

This scalar value defines the matrix type. Based on this value *pardisoinit* sets default values for the *iparm* array. Refer to the section [Intel MKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel MKL PARDISO

Output Parameters

pt

INTEGER for 32-bit or 64-bit architectures

INTEGER*8 for 64-bit architectures

Array with a dimension of 64. Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The *pardisoinit* routine nullifies the array *pt*.

NOTE

It is very important that the pointer *pt* is initialized with zero before the first call of Intel MKL PARDISO. After that first call you should never modify the pointer, because it could cause a serious memory leak or a crash.

iparm

INTEGER

Array with a dimension of 64. This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver. The pardisoinit routine fills-in the *iparm* array with the default values. Refer to the section [Intel MKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel MKL PARDISO.

[pardiso_64](#)

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.

Syntax

Fortran:

```
call pardiso_64 (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm,
msglvl, b, x, error)
```

C:

```
void pardiso_64 (_MKL_DSS_HANDLE_t pt, long long int *maxfct, long long int *mnum, long
long int *mtype, long long int *phase, long long int *n, void *a, long long int *ia,
long long int *ja, long long int *perm, long long int *nrhs, long long int *iparm, long
long int *msglvl, void *b, void *x, long long int *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

`pardiso_64` is an alternative ILP64 (64-bit integer) version of the `pardiso` routine (see [Description](#) section for more details). The interface of `pardiso_64` is the same as the interface of `pardiso`, but it accepts and returns all INTEGER data as INTEGER*8.

Use `pardiso_64` when `pardiso` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (`pardiso_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `pardiso_64` may perform slower than regular `pardiso` on the reordering and symbolic factorization phase.

NOTE

`pardiso_64` is supported only in the 64-bit libraries. If `pardiso_64` is called from the 32-bit libraries, it returns `error == -12`.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The input parameters of `pardiso_64` are the same as the [input parameters of `pardiso`](#), but `pardiso_64` accepts all INTEGER data as `INTEGER*8`.

Output Parameters

The output parameters of `pardiso_64` are the same as the [output parameters of `pardiso`](#), but `pardiso_64` returns all INTEGER data as `INTEGER*8`.

`pardiso_getenv`, `pardiso_setenv`

Retrieves additional values from or sets additional values in the Intel MKL PARDISO handle.

Syntax

Fortran:

```
error = pardiso_getenv(handle, param, value)
error = pardiso_setenv(handle, param, value)
```

C:

```
MKL_INT pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM
*param, char *value);

MKL_INT pardiso_setenv (_MKL_DSS_HANDLE_t handle , const enum PARDISO_ENV_PARAM *param,
const char *value);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

NOTE

`pardiso_setenv` requires the `value` parameter to be converted to the string in C notation if it is called from Fortran. You can do this using `mkl_cvt_to_null_terminated_str` subroutine declared in the `mkl_dss.f77` or `mkl_dss.f90` include files (see the example below).

Description

These functions operate with the Intel MKL PARDISO handle. The `pardiso_getenv` routine retrieves additional values from the Intel MKL PARDISO handle, and `pardiso_setenv` sets specified values in the Intel MKL PARDISO handle.

These functions enable retrieving and setting the name of the Intel MKL PARDISO OOC file.

To retrieve the Intel MKL PARDISO OOC file name, you can apply this function to any properly-created handle.

To set the the Intel MKL PARDISO OOC file name in the handle you must call the function before the reordering stage. This is because the OOC file name is stored in the handle after the reordering stage and it is not changed during further computations.

NOTE

A 1024-byte internal buffer is used inside Intel MKL PARDISO for storing the OOC file name. Allocate a 1024-byte buffer for passing to the `pardiso_getenv` function as the `value` parameter.

Input Parameters

<i>handle</i>	Fortran: MKL_FORTRAN_HANDLE Intel MKL PARDISO handle for which to set and from which to retrieve information. (See DSS Interface Description for structure description)
<i>param</i>	Fortran: INTEGER. Specifies the required parameter. The only value is <code>PARDISO_OOC_FILE_NAME</code> , defined in the corresponding include file.
<i>value</i>	Fortran: CHARACTER array. Input parameter for <code>pardiso_setenv</code> . Contains the name of the OOC file that must be used in the handle.

Output Parameters

<i>handle</i>	Output parameter for <code>pardiso_setenv</code> . Data object of the MKL_DSS_HANDLE type (see DSS Interface Description).
<i>value</i>	Output parameter for <code>pardiso_getenv</code> . Contains the name of the OOC file that must be used in the handle.

Example (FORTRAN 90)

```

INCLUDE 'mkl_pardiso.f90'
INCLUDE 'mkl_dss.f90'
PROGRAM pardiso_sym_f90
USE mkl_pardiso
USE mkl_dss

INTEGER*8 pt(64)
CHARACTER*1024 file_name
INTEGER buff(256), bufLen, error

pt(1:64) = 0

file_name = 'pardiso_ooc_file'
bufLen = len_trim(file_name)
call mkl_cvt_to_null_terminated_str(buff, bufLen, trim(file_name))
error = pardiso_setenv(pt, PARDISO_OOC_FILE_NAME, buff)

! call pardiso() here

END PROGRAM

```

mkl_pardiso_pivot

Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine.

Syntax

Fortran:

```
call mkl_pardiso_pivot (ai, bi, eps)
```

C:

```
void mkl_pardiso_pivot (void *ai, void *bi, void *eps);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel MKL PARDISO determines that a diagonal element `bi` is a pivot if `bi < eps`, and if so, replaces it with `eps`. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

NOTE

To use this routine, you must set `iparm(56)` to 1 before the main `pardiso` loop.

NOTE

This routine is only available for in-core Intel MKL PARDISO.

Input Parameters

<code>ai</code>	DOUBLE PRECISION - for real types of matrices (<code>mtype=2, -2, 4, and 6</code>) and for double precision Intel MKL PARDISO (<code>iparm(28)=0</code>)
	Diagonal element of initial matrix corresponding to pivot element.
<code>bi</code>	DOUBLE PRECISION - for real types of matrices (<code>mtype=2, -2, 4, and 6</code>) and for double precision Intel MKL PARDISO (<code>iparm(28)=0</code>)
	Diagonal element of factorized matrix that could be chosen as a pivot element.
<code>eps</code>	DOUBLE PRECISION
	Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by <code>iparm(10)</code> .

Output Parameters

<code>bi</code>	In case element is chosen as a pivot, value with which to replace the pivot.
-----------------	--

`pardiso_getdiag`

Returns diagonal elements of initial and factorized matrix.

Syntax

Fortran:

```
call pardiso_getdiag (pt, df, da, mnum, error)
```

C:

```
void pardiso_getdiag (_MKL_DSS_HANDLE_t pt, void *df, void *da, MKL_INT *mnum,
MKL_INT *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

NOTE

In order to use this routine, you must set [iparm\(56\)](#) to 1 before the main pardiso loop.

Input Parameters

<i>pt</i>	INTEGER for 32-bit or 64-bit architectures INTEGER*8 for 64-bit architectures Array with a dimension of 64. Handle to internal data structure for the Intel MKL PARDISO solver. The entries must be set to zero prior to the first call to pardiso. Unique for factorization.
<i>mnum</i>	INTEGER Indicates the actual matrix for the solution phase of the Intel MKL PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: $1 \leq mnum \leq maxfct$. In most applications this value is 1.

Output Parameters

<i>df</i>	DOUBLE PRECISION - for real types of matrices and for double precision Intel MKL PARDISO (iparm(28)=0) REAL - for real types of matrices and for single precision Intel MKL PARDISO (iparm(28)=1) DOUBLE COMPLEX - for complex types of matrices and for double precision Intel MKL PARDISO (iparm(28)=0) COMPLEX - for complex types of matrices and for single precision Intel MKL PARDISO (iparm(28)=1) Array with a dimension of <i>n</i> . Contains diagonal elements of the factorized matrix after factorization.
<i>da</i>	DOUBLE PRECISION - for real types of matrices and for double precision Intel MKL PARDISO (iparm(28)=0)

REAL - for real types of matrices and for single precision Intel MKL PARDISO (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices and for double precision Intel MKL PARDISO (*iparm*(28)=0)

COMPLEX - for complex types of matrices and for single precision Intel MKL PARDISO (*iparm*(28)=1)

Array with a dimension of *n*. Contains diagonal elements of the initial matrix.

error

INTEGER

The error indicator.

error	Information
0	no error
-1	Diagonal information not turned on before pardiso main loop (<i>iparm</i> (56)=0).

[pardiso_handle_store](#)

Store internal structures from pardiso to a file.

Syntax

Fortran:

```
call pardiso_handle_store (pt, dirname, error)
```

C:

```
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, char *dirname, MKL_INT *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restore` routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

pt

INTEGER for 32-bit or 64-bit architectures

INTEGER*8 for 64-bit architectures

Array with a dimension of 64. Handle to internal data structure.

dirname

CHARACTER

String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

Output Parameters

`error` INTEGER

The error indicator.

<code>error</code>	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for writing.
-11	Error while writing to file.
-13	Wrong file format.

pardiso_handle_restore

Restore pardiso internal structures from a file.

Syntax

Fortran:

```
call pardiso_handle_restore (pt, dirname, error)
```

C:

```
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, char *dirname, MKL_INT *error);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

Input Parameters

`dirname` CHARACTER

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

pt INTEGER for 32-bit or 64-bit architectures
 INTEGER*8 for 64-bit architectures
 Array with a dimension of 64. Handle to internal data structure.

error INTEGER

The error indicator.

error	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

pardiso_handle_delete

Delete files with pardiso internal structure data.

Syntax

Fortran:

```
call pardiso_handle_delete (dirname, error)
```

C:

```
void pardiso_handle_delete (char *dirname, MKL_INT *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This function deletes files generated with `pardiso_handle_store` that contain Intel MKL PARDISO internal structures.

Input Parameters

dirname CHARACTER

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error INTEGER

The error indicator.

error	Information
0	No error.
-10	Cannot delete files.

[pardiso_handle_store_64](#)

Store internal structures from pardiso_64 to a file.

Syntax

Fortran:

```
call pardiso_handle_store_64 (pt, dirname, error)
```

C:

```
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, char *dirname, MKL_INT *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the [pardiso_64](#) routine. The [pardiso_handle_restore_64](#) routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

pt INTEGER*8 for 64-bit architectures
 Array with a dimension of 64. Handle to internal data structure.

dirname CHARACTER
 String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named handle.pds in the directory.

Output Parameters

error INTEGER
 The error indicator.

error	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for writing.

error	Information
-11	Error while writing to file.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.
-13	Wrong file format.

pardiso_handle_restore_64

Restore pardiso_64 internal structures from a file.

Syntax

Fortran:

```
call pardiso_handle_restore_64 (pt, dirname, error)
```

C:

```
void pardiso_handle_restore_64 (_MKL_DSS_HANDLE_t pt, char *dirname, MKL_INT *error);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store_64` after a phase of the `pardiso_64` routine and continue execution of the next phase.

Input Parameters

<i>dirname</i>	CHARACTER
	String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Input Parameters

<i>pt</i>	INTEGER for 32-bit or 64-bit architectures INTEGER*8 for 64-bit architectures
	Array with a dimension of 64. Handle to internal data structure.

error INTEGER

The error indicator.

error Information

0	No error.
-2	Not enough memory.

error	Information
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

pardiso_handle_delete_64

Syntax

Delete files with `pardiso_64` internal structure data.

Fortran:

```
call pardiso_handle_delete_64 (dirname, error)
```

C:

```
void pardiso_handle_delete_64 (char *dirname, MKL_INT *error);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

Description

This function deletes files generated with `pardiso_handle_dump_64` that contain Intel MKL PARDISO internal structures.

Input Parameters

<i>dirname</i>	CHARACTER
	String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error	Information
0	No error.
-10	Cannot delete files.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.

Intel MKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel MKL PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/ Out
<i>pt(64)</i>	FORTRAN 77: INTEGER on 32-bit architectures, INTEGER*8 on 64- bit architectures Fortran 90: TYPE (MKL_PARDISO_HANDLE) , INTENT (INOUT) C: void*	Solver internal data address pointer	0	Must be initialized with zeros and never be modified later	in/ out
<i>maxfct</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: MKL_INT*	Maximal number of factors in memory	>0	Generally used value is 1	in
<i>mnum</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: MKL_INT*	The number of matrix (from 1 to <i>maxfct</i>) to solve	[1: <i>maxfct</i>]	Generally used value is 1	in
<i>mtype</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: MKL_INT*	Matrix type	1 2 -2 3 4 -4 6 11 13	Real and structurally symmetric Real and symmetric positive definite Real and symmetric indefinite Complex and structurally symmetric Complex and Hermitian positive definite Complex and Hermitian indefinite Complex and symmetric matrix Real and nonsymmetric matrix Complex and nonsymmetric matrix	in
<i>phase</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: MKL_INT*	Controls the execution of the solver For <i>iparm(36) ></i> 0, phases 331, 332, and 333	11 12 13	Analysis Analysis, numerical factorization Analysis, numerical factorization, solve	in

Parameter	Type	Description	Values	Comments	In/ Out
		perform a different decomposition. See the <i>phase</i> parameter of pardiso for details.	22 23 33 331 332 333 0 -1	Numerical factorization Numerical factorization, solve Solve, iterative refinement <i>phase</i> =33, but only forward substitution <i>phase</i> =33, but only diagonal substitution <i>phase</i> =33, but only backward substitution Release internal memory for L and U of the matrix number <i>mnum</i> Release all internal memory for all matrices	
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: MKL_INT*	Number of equations in the sparse linear system $A*X = B$	>0		in
<i>a (*)</i>	FORTRAN 77: PARDISO_DATA_TYPE 1) Fortran 90: PARDISO_DATA_TYPE 1), INTENT(IN) C: void*	Contains the non-zero elements of the coefficient matrix <i>A</i>	*	The size of <i>a</i> is the same as that of <i>ja</i> , and the coefficient matrix can be either real or complex. The matrix must be stored in the 3-array variation of compressed sparse row (CSR3) format with increasing values of <i>ja</i> for each row	in
<i>ia (n+1)</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: MKL_INT*	<i>rowIndex</i> array in CSR3 format	>=0	<i>ia (i)</i> gives the index of the element in array <i>a</i> that contains the first non-zero element from row <i>i</i> of <i>A</i> . The last element <i>ia (n+1)</i> (for one-based indexing) or <i>ia (n)</i> (for zero-based indexing) is taken to be equal to the number of non-zero elements in <i>A</i> , plus one. Note: <i>iparm(35)</i> indicates whether row/column indexing starts from 1 or 0.	in

Parameter	Type	Description	Values	Comments	In/ Out
$ja(*)$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: MKL_INT*	$columns$ array in CSR3 format	$>=0$	The column indices for each row of A must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in a and ja . Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system. Note: iparm(35) indicates whether row/column indexing starts from 1 or 0.	in
$perm(n)$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(INOUT) C: MKL_INT*	Holds the permutation vector of size n or specifies elements used for computing a partial solution	$>=0$	You can apply your own fill-in reducing ordering (iparm(5) = 1) or return the permutation from the solver (iparm(5) = 2). Let $C = P^* A^* P^T$ be the permuted matrix. Row (column) i of C is the $perm(i)$ row (column) of A . The numbering of the array must describe a permutation. To specify elements for a partial solution, set $iparm(5) = 0$, $iparm(31) > 0$, and $iparm(36) = 0$. To specify elements for a Schur complement, set $iparm(5) = 0$, $iparm(31) = 0$, and $iparm(36) > 0$. Note: iparm(35) indicates whether row/column indexing starts from 1 or 0.	in/ out
$nrhs$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: MKL_INT*	Number of right-hand sides that need to be solved for	$>=0$	Generally used value is 1 To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.	in

Parameter	Type	Description	Values	Comments	In/ Out
<i>iparm(64)</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(INOUT) C: MKL_INT*	This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver (see pardiso iparm Parameter for more details)	*	If <i>iparm(1)=0</i> , Intel MKL PARDISO fills <i>iparm(2)</i> through <i>iparm(64)</i> with default values and uses them.	in/ out
<i>msglvl</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: MKL_INT*	Message level information	0 1	Intel MKL PARDISO generates no output Intel MKL PARDISO prints statistical information	in
<i>b(n*nrhs)</i>	FORTRAN 77: PARDISO_DATA_TYPE vectors 1) Fortran 90: PARDISO_DATA_TYPE 1), INTENT(INOUT) C: void*	Right-hand side	*	On entry, contains the right-hand side vector/matrix <i>B</i> , which is placed contiguously in memory. The <i>b(i+(k-1)*nrhs)</i> element must hold the <i>i</i> -th component of <i>k</i> -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase. On output, the array is replaced with the solution if <i>iparm(6)=1</i> .	in/ out
<i>x(n*nrhs)</i>	FORTRAN 77: PARDISO_DATA_TYPE 1) Fortran 90: PARDISO_DATA_TYPE 1), INTENT(OUT) C: void*	Solution vectors	*	On output, if <i>iparm(6)=0</i> , contains solution vector/matrix <i>X</i> which is placed contiguously in memory. The <i>x(i+(k-1)*nrhs)</i> element must hold the <i>i</i> -th component of <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.	out
<i>error</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(OUT) C: MKL_INT*	Error indicator	0 -1 -2 -3 -4 -5	No error Input inconsistent Not enough memory Reordering problem Zero pivot, numerical factorization or iterative refinement problem Unclassified (internal) error	out

Parameter	Type	Description	Values	Comments	In/ Out
			-6	Reordering failed (matrix types 11 and 13 only)	
			-7	Diagonal matrix is singular	
			-8	32-bit integer overflow problem	
			-9	Not enough memory for OOC	
			-10	Problems with opening OOC temporary files	
			-11	Read/write problems with the OOC data file	

¹⁾ See description of `PARDISO_DATA_TYPE` in [PARDISO_DATA_TYPE](#).

pardiso iparm Parameter

The following table describes all individual components of the Intel MKL PARDISO `iparm()` parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description						
<code>iparm(1)</code>	Use default values.						
<code>input</code>	<table> <tr> <td>0</td> <td><code>iparm(2) - iparm(64)</code> are filled with default values.</td> </tr> <tr> <td>$\neq 0$</td> <td>You must supply all values in components <code>iparm(2) - iparm(64)</code>.</td> </tr> </table>	0	<code>iparm(2) - iparm(64)</code> are filled with default values.	$\neq 0$	You must supply all values in components <code>iparm(2) - iparm(64)</code> .		
0	<code>iparm(2) - iparm(64)</code> are filled with default values.						
$\neq 0$	You must supply all values in components <code>iparm(2) - iparm(64)</code> .						
<code>iparm(2)</code>	Fill-in reducing ordering for the input matrix.						
<code>input</code>	<p>CAUTION</p> <p>You can control the parallel execution of the solver by explicitly setting the <code>MKL_NUM_THREADS</code> environment variable. If fewer threads are available than specified, the execution may slow down instead of speeding up. If <code>MKL_NUM_THREADS</code> is not defined, then the solver uses all available processors.</p> <table> <tr> <td>0</td> <td>The minimum degree algorithm [Li99].</td> </tr> <tr> <td>2*</td> <td>The nested dissection algorithm from the METIS package [Karypis98].</td> </tr> <tr> <td>3</td> <td>The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel MKL PARDISO Phase 1 takes significant time.</td> </tr> </table>	0	The minimum degree algorithm [Li99] .	2*	The nested dissection algorithm from the METIS package [Karypis98] .	3	The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel MKL PARDISO Phase 1 takes significant time.
0	The minimum degree algorithm [Li99] .						
2*	The nested dissection algorithm from the METIS package [Karypis98] .						
3	The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel MKL PARDISO Phase 1 takes significant time.						
<code>iparm(3)</code>	Reserved. Set to zero.						
<code>iparm(4)</code>	Preconditioned CGS/CG.						
<code>input</code>	This parameter controls preconditioned CGS [Sonn89] for nonsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. <code>iparm(4)</code> has the form $iparm(4) = 10 * L + K$.						
$K=0$	The factorization is always computed as required by <code>phase</code> .						
$K=1$	CGS iteration replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.						

Component	Description								
K=2	CGS iteration for symmetric matrices replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.								
	The value L controls the stopping criterion of the Krylow-Subspace iteration: $\text{eps}_{\text{CGS}} = 10^{-L}$ is used in the stopping criterion $\ dx_i\ / \ dx_0\ < \text{eps}_{\text{CGS}}$ where $\ dx_i\ = \ \text{inv}(L^*U)^*r_i\ $ and r_i is the residue at iteration i of the preconditioned Krylow-Subspace iteration. A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If $\text{phase} = 23$, then the factorization for a given A is automatically recomputed in cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using $\text{phase} = 33$ results in an error message ($\text{error} = -4$) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from iparm(20) . The default is $\text{iparm}(4)=0$, and other values are only recommended for an advanced user. $\text{iparm}(4)$ must be greater or equal to zero.								
	Examples:								
	<table> <thead> <tr> <th><code>iparm(4)</code></th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>31</td> <td>LU-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices</td> </tr> <tr> <td>61</td> <td>LU-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices</td> </tr> <tr> <td>62</td> <td>LU-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices</td> </tr> </tbody> </table>	<code>iparm(4)</code>	Description	31	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices	61	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices	62	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices
<code>iparm(4)</code>	Description								
31	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices								
61	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices								
62	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices								
<code>iparm(5)</code>	User permutation.								
input	This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel MKL PARDISO. This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P^*A^*P^T$), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <code>perm</code> parameter.								
CAUTION									
You can only set one of <code>iparm(5)</code> , <code>iparm(31)</code> , and <code>iparm(36)</code> , so be sure that the <code>iparm(31)</code> (partial solution) and the <code>iparm(36)</code> (Schur complement) parameters are 0 if you set <code>iparm(5)</code> .									
0*	User permutation in the <code>perm</code> array is ignored.								
1	Intel MKL PARDISO uses the user supplied fill-in reducing permutation from the <code>perm</code> array. <code>iparm(2)</code> is ignored.								
NOTE									
Setting <code>iparm(5) = 1</code> prevents use of a parallel algorithm for the solve step.									

Component	Description
2	Intel MKL PARDISO returns the permutation vector computed at phase 1 in the <i>perm</i> array.
<i>iparm(6)</i> input	Write solution on <i>x</i> . NOTE The array <i>x</i> is always used.
0*	The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.
1	The solver stores the solution on the right-hand side <i>b</i> .
<i>iparm(7)</i> output	Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.
<i>iparm(8)</i> input	Iterative refinement step. On entry to the solve and iterative refinement step, <i>iparm(8)</i> must be set to the maximum number of iterative refinement steps that the solver performs. 0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization. >0 Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm(8)</i> steps of iterative refinement. The solver might stop the process before the maximum number of steps if <ul style="list-style-type: none"> • a satisfactory level of accuracy of the solution in terms of backward error is achieved, • or if it determines that the required accuracy cannot be reached. In this case Intel MKL PARDISO returns -4 in the <i>error</i> parameter. The number of executed iterations is reported in <i>iparm(7)</i> . <0 Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of <i>iparm(8)=0</i>) and the number of executed iterations is reported in <i>iparm(7)</i> .
<i>iparm(9)</i>	Reserved. Set to zero.
<i>iparm(10)</i> input	Pivoting perturbation. This parameter instructs Intel MKL PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with $\text{eps} = 10^{-\text{iparm}(10)}$. The magnitude of the potential pivot is tested against a constant threshold of $\text{alpha} = \text{eps} * \ A2\ _{\text{inf}}$,

Component	Description
	where $\text{eps} = 10^{(-\text{iparm}(10))}$, $A2 = P^* P_{\text{MPS}}^* D_r^* A^* D_c^* P$, and $\ A2\ _{\text{inf}}$ is the infinity norm of the scaled and permuted matrix A. Any tiny pivots encountered during elimination are set to the sign $(\text{LII})^* \text{eps} * \ A2\ _{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-\text{iparm}(10))}$.
13*	The default value for nonsymmetric matrices ($mtype = 11$, $mtype=13$), $\text{eps} = 10^{-13}$.
8*	The default value for symmetric indefinite matrices ($mtype = -2$, $mtype=-4$, $mtype=6$), $\text{eps} = 10^{-8}$.
<i>iparm(11)</i>	Scaling vectors.
input	<p>Intel MKL PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric matrices ($mtype = 11$ or $mtype = 13$). The scaling can also be used for symmetric indefinite matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$) when the symmetric weighted matchings are applied (<i>iparm(13)</i> = 1).</p> <p>Use <i>iparm(11)</i> = 1 (scaling) and <i>iparm(13)</i> = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix A in array <i>a</i> in case of scaling and symmetric weighted matching.</p>
0*	Disable scaling. Default for symmetric indefinite matrices.
1*	<p>Enable scaling. Default for nonsymmetric matrices.</p> <p>Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices ($mtype = 11$, $mtype = 13$). The scaling can also be used for symmetric indefinite matrices ($mtype = -2$, $mtype = -4$, $mtype = 6$) when the symmetric weighted matchings are applied (<i>iparm(13)</i> = 1).</p> <p>Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix A in case of scaling.</p>
<i>iparm(12)</i>	Solve with transposed or conjugate transposed matrix A.
input	<p>NOTE For real matrices the terms <i>transposed</i> and <i>conjugate transposed</i> are equivalent.</p>
0*	Solve a linear system $AX = B$.
1	Solve a conjugate transposed system $A^H X = B$ based on the factorization of the matrix A.
2	Solve a transposed system $A^T X = B$ based on the factorization of the matrix A.
<i>iparm(13)</i>	Improved accuracy using (non-) symmetric weighted matching.
input	Intel MKL PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.
0*	Disable matching. Default for symmetric indefinite matrices.

Component	Description				
1*	<p>Enable matching. Default for nonsymmetric matrices.</p> <p>Maximum weighted matching algorithm to permute large elements close to the diagonal.</p> <p>It is recommended to use <code>iparm(11) = 1</code> (scaling) and <code>iparm(13) = 1</code> (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p> <p>Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix A in case of symmetric weighted matching.</p>				
<code>iparm(14)</code>	Number of perturbed pivots.				
<code>output</code>	After factorization, contains the number of perturbed pivots for the matrix types: 11, 13, -2, -4 and -6.				
<code>iparm(15)</code>	Peak memory on symbolic factorization.				
<code>output</code>	The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.				
<code>iparm(16)</code>	Permanent memory on symbolic factorization.				
<code>output</code>	Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.				
<code>iparm(17)</code>	Size of factors/Peak memory on numerical factorization and solution.				
<code>output</code>	This parameter provides the size in kilobytes of the total memory consumed by in-core Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1. See <code>iparm(63)</code> for the OOC mode. The total peak memory consumed by Intel MKL PARDISO is $\max(iparm(15), iparm(16)+iparm(17))$.				
<code>iparm(18)</code>	Report the number of non-zero elements in the factors.				
<code>input/output</code>	<table border="0"> <tr> <td><0</td> <td>Enable reporting if <code>iparm(18) < 0</code> on entry. The default value is -1.</td> </tr> <tr> <td>≥ 0</td> <td>Disable reporting.</td> </tr> </table>	<0	Enable reporting if <code>iparm(18) < 0</code> on entry. The default value is -1.	≥ 0	Disable reporting.
<0	Enable reporting if <code>iparm(18) < 0</code> on entry. The default value is -1.				
≥ 0	Disable reporting.				
<code>iparm(19)</code>	Report number of floating point operations (in 10^6 floating point operations) that are necessary to factor the matrix A .				
<code>input/output</code>	<table border="0"> <tr> <td><0</td> <td>Enable report if <code>iparm(19) < 0</code> on entry. This increases the reordering time.</td> </tr> <tr> <td>≥ 0</td> <td>Disable report.</td> </tr> </table>	<0	Enable report if <code>iparm(19) < 0</code> on entry. This increases the reordering time.	≥ 0	Disable report.
<0	Enable report if <code>iparm(19) < 0</code> on entry. This increases the reordering time.				
≥ 0	Disable report.				
<code>iparm(20)</code>	Report CG/CGS diagnostics.				
<code>output</code>	<table border="0"> <tr> <td>> 0</td> <td>CGS succeeded, reports the number of completed iterations.</td> </tr> <tr> <td>< 0</td> <td>CG/CGS failed (<code>error=-4</code> after the solution phase). If <code>phase= 23</code>, then the factors L and U are recomputed for the matrix A and the error flag <code>error=0</code> in case of a successful factorization. If <code>phase = 33</code>, then <code>error = -4</code> signals failure. <code>iparm(20)= - it_cgs*10 - cgs_error.</code> Possible values of <code>cgs_error</code>: 1 - fluctuations of the residuum are too large</td> </tr> </table>	> 0	CGS succeeded, reports the number of completed iterations.	< 0	CG/CGS failed (<code>error=-4</code> after the solution phase). If <code>phase= 23</code> , then the factors L and U are recomputed for the matrix A and the error flag <code>error=0</code> in case of a successful factorization. If <code>phase = 33</code> , then <code>error = -4</code> signals failure. <code>iparm(20)= - it_cgs*10 - cgs_error.</code> Possible values of <code>cgs_error</code> : 1 - fluctuations of the residuum are too large
> 0	CGS succeeded, reports the number of completed iterations.				
< 0	CG/CGS failed (<code>error=-4</code> after the solution phase). If <code>phase= 23</code> , then the factors L and U are recomputed for the matrix A and the error flag <code>error=0</code> in case of a successful factorization. If <code>phase = 33</code> , then <code>error = -4</code> signals failure. <code>iparm(20)= - it_cgs*10 - cgs_error.</code> Possible values of <code>cgs_error</code> : 1 - fluctuations of the residuum are too large				

Component	Description
	<p>2 - $\ \mathbf{dx}_{\text{max_it_cgs}/2} \$ is too large (slow convergence)</p> <p>3 - stopping criterion is not reached at max_it_cgs</p> <p>4 - perturbed pivots caused iterative refinement</p> <p>5 - factorization is too fast for this matrix. It is better to use the factorization method with <code>iparm(4) = 0</code></p>
<code>iparm(21)</code> input	Pivoting for symmetric indefinite matrices.
	<p>NOTE</p> <p>Use <code>iparm(11) = 1</code> (scaling) and <code>iparm(13) = 1</code> (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p>
0	Apply 1x1 diagonal pivoting during the factorization process.
1*	Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of $mtype=-2$, $mtype=-4$, or $mtype=6$.
2	Apply 1x1 diagonal pivoting during the factorization process. Using this value is the same as using <code>iparm(21) = 0</code> except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <code>iparm(8)</code> (0 by default).
3	Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of $mtype=-2$, $mtype=-4$, or $mtype=6$. Using this value is the same as using <code>iparm(21) = 1</code> except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <code>iparm(8)</code> (0 by default).
<code>iparm(22)</code> output	Inertia: number of positive eigenvalues. Intel MKL PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.
<code>iparm(23)</code> output	Inertia: number of negative eigenvalues. Intel MKL PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.
<code>iparm(24)</code> input	Parallel factorization control.
	<p>NOTE</p> <p>The two-level factorization algorithm does not improve performance in OOC mode.</p>
0*	Intel MKL PARDISO uses the classic algorithm for factorization.
1	Intel MKL PARDISO uses a two-level factorization algorithm. This algorithm generally improves scalability in case of parallel factorization on many threads (more than eight).
<code>iparm(25)</code> input	Parallel forward/backward solve control.
	0* Intel MKL PARDISO uses a parallel algorithm for the solve step.

Component	Description
1	Intel MKL PARDISO uses the sequential forward and backward solve. This feature is available only for in-core Intel MKL PARDISO (see iparm(60)).
<i>iparm</i> (26)	Reserved. Set to zero.
<i>iparm</i> (27)	Matrix checker.
input	<p>0* Intel MKL PARDISO does not check the sparse matrix representation for errors.</p> <p>1 Intel MKL PARDISO checks integer arrays <i>ia</i> and <i>ja</i>. In particular, Intel MKL PARDISO checks whether column indices are sorted in increasing order within each row.</p>
<i>iparm</i> (28)	Single or double precision Intel MKL PARDISO.
input	See iparm(8) for information on controlling the precision of the refinement steps.
Important	
The <i>iparm</i> (28) value is stored in the Intel MKL PARDISO handle between Intel MKL PARDISO calls, so the precision mode can be changed only during phase 1.	
0*	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.
1	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.
<i>iparm</i> (29)	Reserved. Set to zero.
<i>iparm</i> (30)	Number of zero or negative pivots.
output	If Intel MKL PARDISO detects zero or negative pivot for <i>mtype</i> =2 or <i>mtype</i> =4 matrix types, the factorization is stopped, Intel MKL PARDISO returns immediately with an <i>error</i> = -4, and <i>iparm</i> (30) reports the number of the equation where the first zero or negative pivot is detected.
<i>iparm</i> (31)	Partial solve and computing selected components of the solution vectors.
input	This parameter controls the solve step of Intel MKL PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define <i>perm</i> so that when <i>perm</i> (<i>i</i>) = 1 it means that either the <i>i</i> -th component in the right-hand sides is nonzero, or the <i>i</i> -th component in the solution vectors is computed, or both, depending on the value of <i>iparm</i> (31). The permutation vector <i>perm</i> must be present in all phases of Intel MKL PARDISO software. At the reordering step, the software overwrites the input vector <i>perm</i> by a permutation vector used by the software at the factorization and solver step. If <i>m</i> is the number of components such that <i>perm</i> (<i>i</i>) = 1, then the last <i>m</i> components of the output vector <i>perm</i> are a set of the indices <i>i</i> satisfying the condition <i>perm</i> (<i>i</i>) = 1 on input.
NOTE	
Turning on this option often increases the time used by Intel MKL PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.	

Component	Description
	<p>Important This feature is only available for in-core Intel MKL PARDISO, so to use it you must set <code>iparm(60) = 0</code>. Set the parameters <code>iparm(8)</code> (iterative refinement steps), <code>iparm(4)</code> (preconditioned CGS), <code>iparm(5)</code> (user permutation), and <code>iparm(36)</code> (Schur complement) to 0 as well.</p>
0*	Disables this option.
1	<p>it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <code>perm</code> is defined so that <code>perm(i) = 1</code> means that the (i)-th component in the right-hand sides is nonzero. In this case Intel MKL PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the i-th component in the solution vectors is only computed if <code>perm(i) = 1</code>.</p>
2	<p>It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <code>perm</code> is defined so that <code>perm(i) = 1</code> means that the i-th component in the right-hand sides is nonzero.</p> <p>Unlike for <code>iparm(31)=1</code>, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for <code>iparm(31)=2</code> you must set the i-th component of the right-hand sides to zero explicitly if <code>perm(i)</code> is not equal to 1.</p>
3	Selected components of the solution vectors are computed. The <code>perm</code> array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case <code>perm(i) = 1</code> means that the i -th component in the solution vectors is computed.
<code>iparm(32)</code>	Reserved. Set to zero.
<code>iparm(33)</code>	
<code>iparm(34)</code>	Optimal number of threads for conditional numerical reproducibility (CNR) mode.
input	<p>Intel MKL PARDISO reads the value of <code>iparm(34)</code> during the analysis phase (phase 1), so you cannot change it later.</p> <p>Because Intel MKL PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results:</p> <ul style="list-style-type: none"> • Do not alter the states of the random number generators. • Do not run multiple instances of Intel MKL PARDISO in parallel in the analysis phase (phase 1).
NOTE	
<p>CNR is only available for the in-core version of Intel MKL PARDISO, so you must also set <code>iparm(60)</code> to 0 in order to use the in-core version. Otherwise Intel MKL PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel MKL using the functionality described in Support Functions for CNR.</p>	
0*	CNR mode for Intel MKL PARDISO is enabled only if it is enabled for Intel MKL using the functionality described in Support Functions for CNR and the in-core version is used. Intel MKL PARDISO determines the optimal number of threads automatically, and produces numerically reproducible results regardless of the number of threads.

Component	Description				
	>0 CNR mode is enabled for Intel MKL PARDISO if in-core version is used and the optimal number of threads for Intel MKL PARDISO to rely on is defined by the value of <i>iparm(34)</i> . You can use <i>iparm(34)</i> to enable CNR mode independent from other Intel MKL domains. To get the best performance, set <i>iparm(34)</i> to the actual number of hardware threads dedicated for Intel MKL PARDISO. Setting <i>iparm(34)</i> to fewer threads than the maximum number of threads in use reduces the scalability of the problem being solved. Setting <i>iparm(34)</i> to more threads than are available can reduce the performance of Intel MKL PARDISO.				
<i>iparm(35)</i>	One- or zero-based indexing of columns and rows.				
input	<table border="0"> <tr> <td>0*</td> <td>One-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 1 (Fortran-style indexing).</td> </tr> <tr> <td>1</td> <td>Zero-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 0 (C-style indexing).</td> </tr> </table>	0*	One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).	1	Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).
0*	One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).				
1	Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).				
<i>iparm(36)</i>	Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <i>perm</i> to a set of indexes such that when <i>perm(i) = 1</i> , the <i>i</i> -th element of the initial matrix is an element of the Schur matrix.				
	CAUTION You can only set one of <i>iparm(5)</i> , <i>iparm(31)</i> , and <i>iparm(36)</i> , so be sure that the <i>iparm(5)</i> (user permutation) and the <i>iparm(31)</i> (partial solution) parameters are 0 if you set <i>iparm(36)</i> .				
	<table border="0"> <tr> <td>0*</td> <td>Do not compute Schur complement.</td> </tr> <tr> <td>1</td> <td>Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector.</td> </tr> </table>	0*	Do not compute Schur complement.	1	Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector.
0*	Do not compute Schur complement.				
1	Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector.				
	NOTE This option only computes the Schur complement matrix, and does not calculate factorization arrays.				
	<table border="0"> <tr> <td>2</td> <td>Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.</td> </tr> </table>	2	Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.		
2	Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.				
<i>iparm(37)</i>	Reserved. Set to zero.				
<i>iparm(55)</i>					
<i>iparm(56)</i>	Diagonal and pivoting control.				
	<table border="0"> <tr> <td>0*</td> <td>Internal function used to work with pivot and calculation of diagonal arrays turned off.</td> </tr> <tr> <td>1</td> <td>You can use the <i>mkl_pardiso_pivot</i> callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <i>pardiso</i> factorization step diagonal using the <i>pardiso_getdiag</i> routine. This parameter can be turned on only in the in-core version of Intel MKL PARDISO.</td> </tr> </table>	0*	Internal function used to work with pivot and calculation of diagonal arrays turned off.	1	You can use the <i>mkl_pardiso_pivot</i> callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <i>pardiso</i> factorization step diagonal using the <i>pardiso_getdiag</i> routine. This parameter can be turned on only in the in-core version of Intel MKL PARDISO.
0*	Internal function used to work with pivot and calculation of diagonal arrays turned off.				
1	You can use the <i>mkl_pardiso_pivot</i> callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <i>pardiso</i> factorization step diagonal using the <i>pardiso_getdiag</i> routine. This parameter can be turned on only in the in-core version of Intel MKL PARDISO.				
<i>iparm(57)</i>	Reserved. Set to zero.				
<i>iparm(59)</i>					

Component	Description
<i>iparm</i> (60)	Intel MKL PARDISO mode.
input	<p><i>iparm</i>(60) switches between in-core (IC) and out-of-core (OOC) Intel MKL PARDISO. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC.</p> <p>Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better Intel MKL PARDISO performance by setting <i>iparm</i>(60) before the reordering phase.</p>
NOTE	
The amount of memory used in OOC mode depends on the number of threads.	
WARNING	
Do not increase the number of threads used for Intel MKL PARDISO between the first call to <code>pardiso</code> and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of threads, increasing it after the initial call can cause incorrect results.	
0*	IC mode.
1	<p>IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> (default value 2000 MB) and <code>MKL_PARDISO_OOC_MAX_SWAP_SIZE</code> (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>.</p> <p>If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible.</p>
2	<p>OOC mode.</p> <p>The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode.</p> <p>If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible.</p> <p>To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.</p>
<i>iparm</i> (61)	Reserved. Set to zero.
-	
<i>iparm</i> (62)	
<i>iparm</i> (63)	Size of the minimum OOC memory for numerical factorization and solution.
output	<p>This parameter provides the size in kilobytes of the minimum memory required by OOC Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1.</p> <p>Total peak memory consumption of OOC Intel MKL PARDISO can be estimated as $\max(\text{iparm}(15), \text{iparm}(16) + \text{iparm}(63))$.</p>
<i>iparm</i> (64)	Reserved. Set to zero.

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

PARDISO_DATA_TYPE

The following table lists the values of `PARDISO_DATA_TYPE` depending on the matrix types and values of the parameter `iparm(28)`.

Data type value	Matrix type <i>mtype</i>	<i>iparm(28)</i>	comments
DOUBLE PRECISION	1, 2, -2, 11	0	Real matrices, double precision
REAL		1	Real matrices, single precision
DOUBLE COMPLEX	3, 6, 13, 4, -4	0	Complex matrices, double precision
COMPLEX		1	Complex matrices, single precision

Parallel Direct Sparse Solver for Clusters Interface

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Parallel Direct Sparse Solver for Clusters Interface provides a Fortran interface, but can be called from C programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems. Code examples are available in the Intel MKL installation examples directory.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Supported Configuration

Parallel Direct Sparse Solver for Clusters Interface supports Intel® 64 architecture and compatible architectures with 64-bit Linux* and an ILP64/LP64 interface.

Parallel Direct Sparse Solver for Clusters Interface supports these MPI implementations:

- Intel® MPI Library 3.0 or later
- MPICH2 1.2.1
- Open MPI 1.2.6
- MVAPICH2 1.2

Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$$A^*X = B$$

with multiple right-hand sides using a distributed LU , LL^T , LDL^T or LDL^* factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation P based on the nested dissection algorithm from the METIS package [Karypis98] (included with Intel MKL), followed by the Cholesky or other type of factorization (depending on matrix type) [Schenk00-2] of PAP^T . The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of X by forward and backward substitution and iterative refinement.

The initial matrix A is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix A that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the [Sparse Matrix Storage Formats](#) section using the variable *ja* for *columns*, *ia* for *rowIndex*, and *a* for *values*. Column indices *ja* must be in increasing order per row and each diagonal element to be present in the matrix structure (even if it is zero).

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

Algorithm Parallelization and Data Distribution

Intel® MKL Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix A as computational tree. Then matrix A is divided among all MPI processes in a one-dimensional manner. The same distribution is used for *L-factor* (the lower triangular matrix in Cholesky decomposition). Matrix A and all required internal data are broadcast to slave MPI processes. Each MPI process fills in its own parts of *L-factor* with initial values of the matrix A .

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of *L-factor* completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO* software. Level 3 BLAS operations from Intel MKL ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband* technology. Another advantage of the approach is the effective distribution of *L-factor* among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix A and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP* threads per node equal to the number of physical cores on the node.

NOTE

Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in `<install_dir>/examples`.

cluster_sparse_solver

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

Fortran:

```
call cluster_sparse_solver (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs,
iparm, msglvl, b, x, comm, error)
```

C:

```
void cluster_sparse_solver (_MKL_DSS_HANDLE_t pt, MKL_INT *maxfct, MKL_INT *mnum,
MKL_INT *mtype, MKL_INT *phase, MKL_INT *n, void *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*perm, MKL_INT *nrhs, MKL_INT *iparm, MKL_INT *msglvl, void *b, void *x, MKL_INT
*comm, MKL_INT *error);
```

Include Files

- Fortran: `mkl_cluster_sparse_solver.f77`
- Fortran 90: `mkl_cluster_sparse_solver.f90`

- C: mkl_cluster_sparse_solver.h

Description

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

$$A^*X = B$$

with single or multiple right-hand sides, using a parallel LU , LDL , or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ vectors or matrices.

Input Parameters

NOTE

Most of the input parameters (except for the `pt`, `phase`, and `comm` parameters and, for the distributed format, the `a`, `ia`, and `ja` arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, `comm`.

NOTE

The types given for parameters in this section are specified in FORTRAN 77 notation.

`pt` INTEGER*8 for 64-bit architectures
 Array of size 64.
 Handle to internal data structure. The entries must be set to zero before the first call to `cluster_sparse_solver`.

CAUTION

After the first call to `cluster_sparse_solver` do not modify `pt`, as that could cause a serious memory leak.

`maxfct` INTEGER
 Ignored; assumed equal to 1.

`mnum` INTEGER
 Ignored; assumed equal to 1.

`mtype` INTEGER
 Defines the matrix type, which influences the pivoting method. The Parallel Direct Sparse Solver for Clusters solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite

-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase INTEGER

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Parallel Direct Sparse Solver for Clusters has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement
- Memory release (*phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
-1	Release all internal memory for all matrices

n INTEGER

Number of equations in the sparse linear systems of equations $A \cdot X = B$.
Constraint: $n > 0$.

a DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28)=0)
REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28)=1)
DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28)=1)

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The size of *a* is the same as that of *ja* and the coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) format with increasing values of *ja* for each row. Refer to *values* array description in [Storage Formats for the Direct Sparse Solvers](#) for more details.

NOTE

For centralized input (*iparm*(40)=0), provide the *a* array for the master MPI process only. For distributed assembled input (*iparm*(40)=1 or *iparm*(40)=2), provide it for all MPI processes.

Important

The column indices of non-zero elements of each row of the matrix *A* must be stored in increasing order, and the diagonal elements must be available and stored in the array, even if they are zero.

ia

INTEGER

Array, dimension $(n+1)$. For $i \leq n$, *ia*(*i*) points to the first column index of row *i* in the array *ja* in compressed sparse row format. That is, *ia*(*i*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*($n+1$) is taken to be equal to the number of non-zero elements in *A*, plus one (for one-based indexing). Refer to *rowIndex* array description in [Storage Formats for the Direct Sparse Solvers](#) for more details. The array *ia* is also accessed in all phases of the solution process.

Indexing of *ia* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35). For zero-based indexing, the last element *ia*($n+1$) is assumed to be equal to the number of non-zero elements in matrix *A*.

NOTE

For centralized input (*iparm*(40)=0), provide the *ia* array at the master MPI process only. For distributed assembled input (*iparm*(40)=1 or *iparm*(40)=2), provide it at all MPI processes.

ja

INTEGER

Array *ja*(*) contains column indices of the sparse matrix *A* stored in compressed sparse row format. The indices must be stored in increasing order per row. The array *ja* is also accessed in all phases of the solution process. All diagonal elements are stored (even if they are zeros) in the list of non-zero elements in *a* and *ja*. The solver only requires the upper triangular part of the system as is shown for the *columns* array in [Storage Formats for the Direct Sparse Solvers](#).

Indexing of ja is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [iparm\(35\)](#).

NOTE

For centralized input ([iparm\(40\)=0](#)), provide the ja array at the master MPI process only. For distributed assembled input ([iparm\(40\)=1](#) or [iparm\(40\)=2](#)), provide it at all MPI processes.

perm

INTEGER

Ignored.

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, dimension (64). This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.

See [cluster_sparse_solver iparm Parameter](#) for more details about the *iparm* parameters.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then [cluster_sparse_solver](#) generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

Statistics include information such as the number of non-zero elements in *L-factor* and the timing for each phase.

Set *msglvl* = 1 if you report a problem with the solver, since the additional information provided can facilitate a solution.

b

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters ([iparm\(28\)=0](#))

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters ([iparm\(28\)=1](#))

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters ([iparm\(28\)=0](#))

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters ([iparm\(28\)=1](#))

Array, dimension (*n*, *nrhs*). On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b*(*i*+(*k*-1)×*nrhs*) must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.

comm

INTEGER

MPI communicator. The solver uses the Fortran MPI communicator internally. For C, convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples`

Output Parameters

<i>pt</i>	Handle to internal data structure.												
<i>iparm</i>	On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors. See cluster_sparse_solver iparm Parameter for more details about the <i>iparm</i> parameters.												
<i>b</i>	On output, the array is replaced with the solution if <code>iparm(6) = 1</code> .												
<i>x</i>	DOUBLE PRECISION - for real types of matrices (<i>mtype</i> =1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters (<code>iparm(28)=0</code>) REAL - for real types of matrices (<i>mtype</i> =1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters (<code>iparm(28)=1</code>) DOUBLE COMPLEX - for complex types of matrices (<i>mtype</i> =3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters (<code>iparm(28)=0</code>) COMPLEX - for complex types of matrices (<i>mtype</i> =3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters (<code>iparm(28)=1</code>) Array, dimension (<i>n,nrhs</i>). If <code>iparm(6)=0</code> it contains solution vector/matrix <i>X</i> , which is placed contiguously in memory. The $x(i + (k-1) \times n)$ element must hold the <i>i</i> -th component of the <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.												
<i>error</i>	INTEGER The error indicator according to the below table:												
	<table border="0"> <thead> <tr> <th><i>error</i></th> <th>Information</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>no error</td> </tr> <tr> <td>-1</td> <td>input inconsistent</td> </tr> <tr> <td>-2</td> <td>not enough memory</td> </tr> <tr> <td>-3</td> <td>reordering problem</td> </tr> <tr> <td>-5</td> <td>unclassified (internal) error</td> </tr> </tbody> </table>	<i>error</i>	Information	0	no error	-1	input inconsistent	-2	not enough memory	-3	reordering problem	-5	unclassified (internal) error
<i>error</i>	Information												
0	no error												
-1	input inconsistent												
-2	not enough memory												
-3	reordering problem												
-5	unclassified (internal) error												

cluster_sparse_solver iparm Parameter

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface `iparm()` parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description
<i>iparm</i> (1)	Use default values.
input	0 <i>iparm</i> (2) - <i>iparm</i> (64) are filled with default values. !=0 You must supply all values in components <i>iparm</i> (2) - <i>iparm</i> (64).
<i>iparm</i> (2)	Fill-in reducing ordering for the input matrix.
input	2* The nested dissection algorithm from the METIS package [Karypis98]. 3 The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time.
<i>iparm</i> (3) - <i>iparm</i> (5)	Reserved. Set to zero.
<i>iparm</i> (6)	Write solution on <i>x</i> .
input	<p>NOTE The array <i>x</i> is always used.</p> <hr/> <p>0* The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.</p> <p>1 The solver stores the solution on the right-hand side <i>b</i>.</p>
<i>iparm</i> (7)	Number of iterative refinement steps performed.
output	Reports the number of iterative refinement steps that were actually performed during the solve step.
<i>iparm</i> (8)	Iterative refinement step.
input	On entry to the solve and iterative refinement step, <i>iparm</i> (8) must be set to the maximum number of iterative refinement steps that the solver performs.
0*	The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
>0	Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i> (8) steps of iterative refinement. The solver might stop the process before the maximum number of steps if <ul style="list-style-type: none"> • a satisfactory level of accuracy of the solution in terms of backward error is achieved, • or if it determines that the required accuracy cannot be reached. In this case Parallel Direct Sparse Solver for Clusters Interface returns -4 in the <i>error</i> parameter. The number of executed iterations is reported in <i>iparm</i> (7).
<0	Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of <i>iparm</i> (8)=0) and the number of executed iterations is reported in <i>iparm</i> (7).
<i>iparm</i> (9)	Reserved. Set to zero.
<i>iparm</i> (10)	Pivoting perturbation.
input	This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver

Component	Description
	<p>uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].</p> <p>Small pivots are perturbed with $\text{eps} = 10^{-\text{iparm}(10)}$.</p> <p>The magnitude of the potential pivot is tested against a constant threshold of $\text{alpha} = \text{eps} * \ A_2\ _{\infty}$, where $\text{eps} = 10^{(-\text{iparm}(10))}$, $A_2 = P^* P_{MPS}^* D_r^* A^* D_c^* P$, and $\ A_2\ _{\infty}$ is the infinity norm of the scaled and permuted matrix A. Any tiny pivots encountered during elimination are set to the sign $(\text{L}_1)^* \text{eps} * \ A_2\ _{\infty}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-\text{iparm}(10))}$.</p>
$\text{iparm}(11)$	<p>Scaling vectors.</p> <p>input</p> <p>Parallel Direct Sparse Solver for Clusters Interface uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale.</p> <p>Use $\text{iparm}(11) = 1$ (scaling) and $\text{iparm}(13) = 1$ (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase ($\text{phase}=11$) you must provide the numerical values of the matrix A in array a in case of scaling and symmetric weighted matching.</p>
	<p>0* Disable scaling. Default for symmetric indefinite matrices.</p> <p>1* Enable scaling. Default for nonsymmetric matrices.</p> <p>Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices ($\text{mtype} = 11, \text{mtype} = 13$). The scaling can also be used for symmetric indefinite matrices ($\text{mtype} = -2, \text{mtype} = -4, \text{mtype} = 6$) when the symmetric weighted matchings are applied ($\text{iparm}(13) = 1$).</p> <p>Note that in the analysis phase ($\text{phase}=11$) you must provide the numerical values of the matrix A in case of scaling.</p>
$\text{iparm}(12)$	Reserved. Set to zero.
$\text{iparm}(13)$	Improved accuracy using (non-) symmetric weighted matching.
input	<p>Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.</p>
	<p>0* Disable matching. Default for symmetric indefinite matrices.</p> <p>1* Enable matching. Default for nonsymmetric matrices.</p> <p>Maximum weighted matching algorithm to permute large elements close to the diagonal.</p> <p>It is recommended to use $\text{iparm}(11) = 1$ (scaling) and $\text{iparm}(13) = 1$ (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p>

Component	Description				
	Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix <i>A</i> in case of symmetric weighted matching.				
<i>iparm</i> (14)	Reserved. Set to zero.				
-					
<i>iparm</i> (20)					
<i>iparm</i> (21)	Pivoting for symmetric indefinite matrices.				
input	<table> <tr> <td>0</td><td>Apply 1x1 diagonal pivoting during the factorization process.</td></tr> <tr> <td>1*</td><td>Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i>=-2, <i>mtype</i>=-4, or <i>mtype</i>=6.</td></tr> </table>	0	Apply 1x1 diagonal pivoting during the factorization process.	1*	Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6.
0	Apply 1x1 diagonal pivoting during the factorization process.				
1*	Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6.				
<i>iparm</i> (22)	Reserved. Set to zero.				
-					
<i>iparm</i> (26)					
<i>iparm</i> (27)	Matrix checker.				
input	<table> <tr> <td>0*</td><td>Do not check the sparse matrix representation for errors.</td></tr> <tr> <td>1</td><td>Check integer arrays <i>ia</i> and <i>ja</i>. In particular, check whether the column indices are sorted in increasing order within each row.</td></tr> </table>	0*	Do not check the sparse matrix representation for errors.	1	Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row.
0*	Do not check the sparse matrix representation for errors.				
1	Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row.				
<i>iparm</i> (28)	Single or double precision Parallel Direct Sparse Solver for Clusters Interface.				
input	<p>See iparm(8) for information on controlling the precision of the refinement steps.</p> <table> <tr> <td>0*</td><td>Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.</td></tr> <tr> <td>1</td><td>Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.</td></tr> </table>	0*	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.	1	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.
0*	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.				
1	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.				
<i>iparm</i> (29)	Reserved. Set to zero.				
-					
<i>iparm</i> (34)					
<i>iparm</i> (35)	One- or zero-based indexing of columns and rows.				
input	<table> <tr> <td>0*</td><td>One-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 1 (Fortran-style indexing).</td></tr> <tr> <td>1</td><td>Zero-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 0 (C-style indexing).</td></tr> </table>	0*	One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).	1	Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).
0*	One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).				
1	Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).				
<i>iparm</i> (36)	Reserved. Set to zero.				
-					
<i>iparm</i> (39)					
<i>iparm</i> (40)	Matrix input format.				
input	<p>NOTE</p> <p>Performance of the reordering step of the Parallel Direct Sparse Solver for Clusters Interface is slightly better for assembled format (CSR, <i>iparm</i>(40) = 0) than for distributed format (DCSR, <i>iparm</i>(40) > 0) for the same matrices, so if the matrix is assembled on one node do not distribute it before calling <code>cluster_sparse_solver</code>.</p>				
0*	Provide the matrix in usual centralized input format: the master MPI process stores all data from matrix <i>A</i> , with rank=0.				

Component	Description
1	Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix A data. Set the bounds of the domain using <code>iparm(41)</code> and <code>iparm(42)</code> . The solution vector is placed on the master process.
2	Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix A data. Set the bounds of the domain using <code>iparm(41)</code> and <code>iparm(42)</code> . The solution vector, A , and RHS elements are distributed between processes in same manner.
<code>iparm(41)</code>	Beginning of input domain.
input	The number of the matrix A row, RHS element, and, for $\text{iparm}(40)=2$, solution vector that begins the input domain belonging to this MPI process. Only applicable to the distributed assembled matrix input format ($\text{iparm}(40)=1$ or $\text{iparm}(40)=2$). See Sparse Matrix Storage Formats for more details.
<code>iparm(42)</code>	End of input domain.
input	The number of the matrix A row, RHS element, and, for $\text{iparm}(40)=2$, solution vector that ends the input domain belonging to this MPI process. Only applicable to the distributed assembled matrix input format ($\text{iparm}(40)=1$ or $\text{iparm}(40)=2$). See Sparse Matrix Storage Formats for more details.
<code>iparm(43)</code>	Reserved. Set to zero.
-	
<code>iparm(64)</code>	
input	

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports the DSS interface, an alternative to the Intel MKL PARDISO interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in [Appendix A Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The DSS interface also supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

DSS Interface Routines

Routine	Description
<code>dss_create</code>	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.

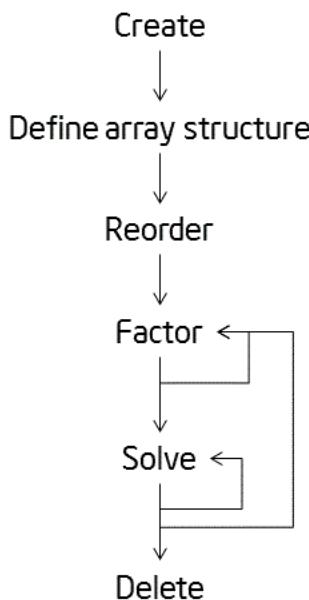

Routine	Description
<code>dss_define_structure</code>	Informs the solver of the locations of the non-zero elements of the matrix.
<code>dss_reorder</code>	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.
<code>dss_factor_real, dss_factor_complex</code>	Computes the LU , LDL^T or LL^T factorization of a real or complex matrix.
<code>dss_solve_real, dss_solve_complex</code>	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
<code>dss_delete</code>	Deletes all data structures created during the solving process.
<code>dss_statistics</code>	Returns statistics about various phases of the solving process.
<code>mkl_cvt_to_null_terminated_str</code>	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right-hand side, invoke the Intel MKL DSS interface routines in this order:

1. `dss_create`
2. `dss_define_structure`
3. `dss_reorder`
4. `dss_factor_real, dss_factor_complex`
5. `dss_solve_real, dss_solve_complex`
6. `dss_delete`

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel MKL sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. [Figure "Typical order for invoking DSS interface routines"](#) indicates the typical order in which the DSS interface routines can be invoked.

[Typical order for invoking DSS interface routines](#)

See the code examples that use the DSS interface routines to solve systems of linear equations in the Intel MKL installation directory (`dss_*.f` and `dss_*.c`).

- Fortran examples: `examples/solverf/source`
- C examples: `examples/solverc/source`

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

C and C++ programmers should refer to [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table "Symbolic Names for the Message and Termination Levels Options"](#). Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
<code>MKL_DSS_MSG_LVL_SUCCESS</code>	<code>MKL_DSS_TERM_LVL_SUCCESS</code>
<code>MKL_DSS_MSG_LVL_INFO</code>	<code>MKL_DSS_TERM_LVL_INFO</code>
<code>MKL_DSS_MSG_LVL_WARNING</code>	<code>MKL_DSS_TERM_LVL_WARNING</code>
<code>MKL_DSS_MSG_LVL_ERROR</code>	<code>MKL_DSS_TERM_LVL_ERROR</code>
<code>MKL_DSS_MSG_LVL_FATAL</code>	<code>MKL_DSS_TERM_LVL_FATAL</code>

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix.

CAUTION

Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Implementation Details

To promote portability across platforms and ease of use across different languages, one of the following Intel MKL DSS language-specific header files can be included:

- `mkl_dss.f77` for F77 programs
- `mkl_dss.f90` for F90 programs
- `mkl_dss.h` for C programs

These header files define symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE

Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

You do not need to allocate any temporary working storage in order to use the Intel MKL DSS routines, because the solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a *handle* data object.

Each of the Intel MKL DSS routines creates, uses, or deletes a handle. Consequently, any program calling an Intel MKL DSS routine must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in your code.

- C and C++:

```
#include "mkl_dss.h"
_MKL_DSS_HANDLE_t handle;
```

- Fortran 90:

```
INCLUDE "mkl_dss.f90"
TYPE(MKL_DSS_HANDLE) handle
```

- FORTRAN 77 (compilers that support eight byte integers):

```
INCLUDE "mkl_dss.f77"
INTEGER*8 handle
```

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

DSS Routines

dss_create

Initializes the solver.

Syntax

Fortran:

```
call dss_create(handle, opt)
```

C:

```
MKL_INT dss_create(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of the handle returned by `dss_create`.

WARNING

Do not write the value of handle directly.

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the `opt` parameter:

```
MKL_DSS_SINGLE_PRECISION.
```

Input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style indexing for input arrays of integer types (the first value is referenced as array element 1), regardless of whether the Fortran or the C interface is used. To set indexing to C style (the first value is referenced as array element 0), add the following value to the `opt` parameter:

```
MKL_DSS_ZERO_BASED_INDEXING.
```

The `opt` parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

`MKL_DSS_REFINEMENT_OFF` - maximum number of refinement steps is set to zero;

`MKL_DSS_REFINEMENT_ON` (default value) - maximum number of refinement steps is set to 2.

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC DSS uses the in-core kernels of Intel MKL PARDISO, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the description of the [pardiso](#) routine).

WARNING

Other than message and termination level options, do not change the OOC DSS settings after they are specified in the routine `dss_create`.

Input Parameters

opt

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Parameter to pass the DSS options. The default value is
`MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle

FORTRAN 77: INTEGER*8

Fortran 90: TYPE (`MKL_DSS_HANDLE`), INTENT (OUT)

Pointer to the data structure storing internal DSS results
`(MKL_DSS_HANDLE)`.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

[dss_define_structure](#)

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

Fortran:

```
call dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

C:

```
MKL_INT dss_define_structure(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
MKL_INT const *rowIndex, MKL_INT const *nRows, MKL_INT const *nCols,
MKL_INT const *columns, MKL_INT const *nNonZeros);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The routine `dss_define_structure` communicates the locations of the `nNonZeros` number of non-zero elements in a matrix of `nRows * nCols` size to the solver.

NOTE

The Intel MKL DSS software operates only on square matrices, so `nRows` must be equal to `nCols`.

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument `opt`. You can set the following values for real matrices:
 - `MKL_DSS_SYMMETRIC_STRUCTURE`
 - `MKL_DSS_SYMMETRIC`
 - `MKL_DSS_NON_SYMMETRIC`
 and for complex matrices:
 - `MKL_DSS_SYMMETRIC_STRUCTURE_COMPLEX`
 - `MKL_DSS_SYMMETRIC_COMPLEX`
 - `MKL_DSS_NON_SYMMETRIC_COMPLEX`
 The information about the matrix type must be defined in `dss_define_structure`.
2. Provide the actual locations of the non-zeros by means of the arrays `rowIndex` and `columns` (see [Sparse Matrix Storage Format](#)).

Input Parameters

`opt`

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Parameter to pass the DSS options. The default value for the matrix structure is `MKL_DSS_SYMMETRIC`.

`rowIndex`

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Array of size `nRows+1`. Defines the location of non-zero entries in the matrix.

`nRows`

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Number of rows in the matrix.

<i>nCols</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)
Number of columns in the matrix; must be equal to <i>nRows</i> .	
<i>columns</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)
Array of size <i>nNonZeros</i> . Defines the column location of non-zero entries in the matrix.	
<i>nNonZeros</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)
Number of non-zero elements in the matrix.	

Output Parameters

<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT (INOUT)
Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).	

Return Values

MKL_DSS_SUCCESS
MKL_DSS_STATE_ERR
MKL_DSS_INVALID_OPTION
MKL_DSS_STRUCTURE_ERR
MKL_DSS_ROW_ERR
MKL_DSS_COL_ERR
MKL_DSS_NOT_SQUARE

dss_reordered

Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.

Syntax

Fortran:

```
call dss_reordered(handle, opt, perm)
```

C:

```
MKL_INT dss_reordered(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *perm)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine dss_reorder computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_METIS_OPENMP_ORDER, then the routine dss_reorder computes permutation vector using the parallel nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of dss_reorder call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_MY_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to [dss_define_structure](#).

If *opt* contains the option MKL_DSS_GET_ORDER, then the permutation vector computed during the dss_reorder call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option MKL_DSS_AUTO_ORDER is set.

Input Parameters

<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)
Parameter to pass the DSS options. The default value for the permutation type is MKL_DSS_AUTO_ORDER.	
<i>perm</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)
Array of length <i>nRows</i> . Contains a user-defined permutation vector (accessed only if <i>opt</i> contains MKL_DSS_MY_ORDER or MKL_DSS_GET_ORDER).	

Output Parameters

<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT(INOUT)
Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).	

Return Values

MKL_DSS_SUCCESS
MKL_DSS_STATE_ERR
MKL_DSS_INVALID_OPTION
MKL_DSS_REORDER_ERR
MKL_DSS_REORDER1_ERR
MKL_DSS_I32BIT_ERR

```
MKL_DSS_FAILURE
MKL_DSS_OUT_OF_MEMORY
MKL_DSS_MSG_LVL_ERR
MKL_DSS_TERM_LVL_ERR
```

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

Syntax

FORTRAN 77:

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
```

Fortran 90:

```
call dss_factor(handle, opt, Values)
```

C:

```
MKL_INT dss_factor_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
void const *rValues)

MKL_INT dss_factor_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
void const *cValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss_define_structure](#) and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to *dss_define_structure*.

NOTE

The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine *dss_create*.

The *opt* argument can contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE
- MKL_DSS_INDEFINITE
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE
- MKL_DSS_HERMITIAN_INDEFINITE

depending on your matrix's type.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT(INOUT)
	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)
	Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE.
<i>rValues</i>	FORTRAN 77: REAL*4 or REAL*8 Fortran 90: REAL(KIND=4), INTENT(IN) or REAL(KIND=8), INTENT(IN)
	Array of elements of the matrix <i>A</i> . Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cValues</i>	FORTRAN 77: COMPLEX*8 or COMPLEX*16 Fortran 90: COMPLEX(KIND=4), INTENT(IN) or COMPLEX(KIND=8), INTENT(IN)
	Array of elements of the matrix <i>A</i> . Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>Values</i>	 Fortran 90: REAL(KIND=4), INTENT(OUT), or REAL(KIND=8), INTENT(OUT), or COMPLEX(KIND=4), INTENT(OUT), or COMPLEX(KIND=8), INTENT(OUT)
	Array of elements of the matrix <i>A</i> . Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OPTION_CONFLICT

MKL_DSS_VALUES_ERR

MKL_DSS_OUT_OF_MEMORY

```
MKL_DSS_ZERO_PIVOT
MKL_DSS_FAILURE
MKL_DSS_MSG_LVL_ERR
MKL_DSS_TERM_LVL_ERR
MKL_DSS_OOC_MEM_ERR
MKL_DSS_OOC_OC_ERR
MKL_DSS_OOC_RW_ERR
```

[dss_solve_real, dss_solve_complex](#)

Compute the corresponding solution vector and place it in the output array.

Syntax

FORTRAN 77:

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Fortran 90:

```
call dss_solve(handle, opt, RhsValues, nRhs, SolValues)
```

C:

```
MKL_INT dss_solve_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
void const *rRhsValues, MKL_INT const *nRhs, void *rSolValues)

MKL_INT dss_solve_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
void const *cRhsValues, MKL_INT const *nRhs, void *cSolValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

For each right-hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

NOTE

The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine *dss_create*.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, must be defined in a previous call to [dss_define_structure](#).

By default, both routines perform the full solution step (it corresponds to *phase* = 33 in Intel MKL PARDISO). The parameter *opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to *MKL_DSS_FORWARD_SOLVE*, the forward substitution (corresponding to *phase* = 331 in Intel MKL PARDISO) is performed;

if it is set to `MKL_DSS_DIAGONAL_SOLVE`, the diagonal substitution (corresponding to `phase = 332` in Intel MKL PARDISO) is performed, if possible;

if it is set to `MKL_DSS_BACKWARD_SOLVE`, the backward substitution (corresponding to `phase = 333` in Intel MKL PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see [Separate Forward and Backward Substitution](#) in the Intel MKL PARDISO solver description.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

`MKL_DSS_CONJUGATE_SOLVE` option added to the parameter `opt` enables solving a conjugate transposed system $A^H X = B$ based on the factorization of the matrix A . This option is equivalent to the parameter `iparm(12) = 1` in Intel MKL PARDISO.

`MKL_DSS_TRANSPOSE_SOLVE` option added to the parameter `opt` enables solving a transposed system $A^T X = B$ based on the factorization of the matrix A . This option is equivalent to the parameter `iparm(12) = 2` in Intel MKL PARDISO.

Input Parameters

`handle`

FORTRAN 77: INTEGER*8

Fortran 90: TYPE (`MKL_DSS_HANDLE`), INTENT (INOUT)

Pointer to the data structure storing internal DSS results (`MKL_DSS_HANDLE`).

`opt`

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Parameter to pass the DSS options.

`nRhs`

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT (IN)

Number of the right-hand sides in the system of linear equations.

`rRhsValues`

FORTRAN 77: REAL*4 or

REAL*8

Fortran 90: REAL (KIND=4), INTENT (IN) or

REAL (KIND=8), INTENT (IN)

Array of size `nRows * nRhs`. Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter `opt` in the routine `dss_create`.

`cRhsValues`

FORTRAN 77: COMPLEX*8 or

COMPLEX*16

Fortran 90: COMPLEX (KIND=4), INTENT (IN) or

COMPLEX (KIND=8), INTENT (IN)

Array of size `nRows * nRhs`. Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter `opt` in the routine `dss_create`.

RhsValues

Fortran 90: REAL (KIND=4), INTENT (IN), or
 REAL (KIND=8), INTENT (IN), or
 COMPLEX (KIND=4), INTENT (IN), or
 COMPLEX (KIND=8), INTENT (IN)
 Array of size $nRows * nRhs$. Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter opt in the routine `dss_create`.

Output Parameters

rSolValues

FORTRAN 77: REAL*4 or
 REAL*8
Fortran 90: REAL (KIND=4), INTENT (OUT) or
 REAL (KIND=8), INTENT (OUT)
 Array of size $nCols * nRhs$. Contains real solution vectors. Real data, single or double precision as it is specified by the parameter opt in the routine `dss_create`.

cSolValues

FORTRAN 77: COMPLEX*8 or
 COMPLEX*16
Fortran 90: COMPLEX (KIND=4), INTENT (OUT) or
 COMPLEX (KIND=8), INTENT (OUT)
 Array of size $nCols * nRhs$. Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter opt in the routine `dss_create`.

SolValues

Fortran 90: REAL (KIND=4), INTENT (OUT), or
 REAL (KIND=8), INTENT (OUT), or
 COMPLEX (KIND=4), INTENT (OUT), or
 COMPLEX (KIND=8), INTENT (OUT)
 Array of size $nCols * nRhs$. Contains solution vectors. Real or complex data, single or double precision as it is specified by the parameter opt in the routine `dss_create`.

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_DIAG_ERR
 MKL_DSS_FAILURE
 MKL_DSS_MSG_LVL_ERR

```
MKL_DSS_TERM_LVL_ERR  
MKL_DSS_OOC_MEM_ERR  
MKL_DSS_OOC_OC_ERR  
MKL_DSS_OOC_RW_ERR
```

dss_delete

Deletes all of the data structures created during the solutions process.

Syntax

Fortran:

```
call dss_delete(handle, opt)
```

C:

```
MKL_INT dss_delete(_MKL_DSS_HANDLE_t const *handle, MKL_INT const *opt)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

opt

FORTRAN 77: INTEGER

Fortran 90: INTEGER, INTENT(IN)

Parameter to pass the DSS options. The default value is
`MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.`

Output Parameters

handle

FORTRAN 77: INTEGER*8

Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT(INOUT)

Pointer to the data structure storing internal DSS results
(`MKL_DSS_HANDLE`).

Return Values

```
MKL_DSS_SUCCESS  
MKL_DSS_STATE_ERR  
MKL_DSS_INVALID_OPTION  
MKL_DSS_OUT_OF_MEMORY  
MKL_DSS_MSG_LVL_ERR  
MKL_DSS_TERM_LVL_ERR
```

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

Fortran:

```
call dss_statistics(handle, opt, statArr, retValues)
```

C:

```
MKL_INT dss_statistics(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt,
_CHARACTER_STR_t const *statArr, _DOUBLE_PRECISION_t *retValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The dss_statistics routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the symmetric indefinite input matrix,
- inertia of the symmetric indefinite input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting FactorTime before a matrix is factored leads to an error.

The following table shows the point at which each individual statistics item can be requested:

Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After dss_reorder is completed successfully.
FactorTime	After dss_factor_real or dss_factor_complex is completed successfully.
SolveTime	After dss_solve_real or dss_solve_complex is completed successfully.
Determinant	After dss_factor_real or dss_factor_complex is completed successfully.
Inertia	After dss_factor_real is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After dss_factor_real or dss_factor_complex is completed successfully.
Peakmem	After dss_reorder is completed successfully.

Type of Statistics	When to Call
Factormem	After <code>dss_reordered</code> is completed successfully.
Solvemem	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.

Input Parameters

<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT(IN) Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).										
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) Parameter to pass the DSS options.										
<i>statArr</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table> <tbody> <tr> <td>ReorderTime</td><td>Amount of time taken to do the reordering.</td></tr> <tr> <td>FactorTime</td><td>Amount of time taken to do the factorization.</td></tr> <tr> <td>SolveTime</td><td>Amount of time taken to solve the problem after factorization.</td></tr> <tr> <td>Determinant</td><td> Determinant of the matrix A. For real matrices: the determinant is returned as <code>det_pow</code>, <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and <code>determinant = det_base * 10^(det_pow)</code>. For complex matrices: the determinant is returned as <code>det_pow</code>, <code>det_re</code>, <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_re}) + \text{abs}(\text{det_im}) < 10.0$ and <code>determinant = (det_re, det_im) * 10^(det_pow)</code>. </td></tr> <tr> <td>Inertia</td><td> Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z), where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z. Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0. </td></tr> </tbody> </table>	ReorderTime	Amount of time taken to do the reordering.	FactorTime	Amount of time taken to do the factorization.	SolveTime	Amount of time taken to solve the problem after factorization.	Determinant	Determinant of the matrix A . For real matrices: the determinant is returned as <code>det_pow</code> , <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and <code>determinant = det_base * 10^(det_pow)</code> . For complex matrices: the determinant is returned as <code>det_pow</code> , <code>det_re</code> , <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_re}) + \text{abs}(\text{det_im}) < 10.0$ and <code>determinant = (det_re, det_im) * 10^(det_pow)</code> .	Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z) , where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z . Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.
ReorderTime	Amount of time taken to do the reordering.										
FactorTime	Amount of time taken to do the factorization.										
SolveTime	Amount of time taken to solve the problem after factorization.										
Determinant	Determinant of the matrix A . For real matrices: the determinant is returned as <code>det_pow</code> , <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and <code>determinant = det_base * 10^(det_pow)</code> . For complex matrices: the determinant is returned as <code>det_pow</code> , <code>det_re</code> , <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_re}) + \text{abs}(\text{det_im}) < 10.0$ and <code>determinant = (det_re, det_im) * 10^(det_pow)</code> .										
Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z) , where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z . Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.										

Inertia of a k -by- k real symmetric positive definite matrix is always $(k, 0, 0)$. Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.

Flops	Number of floating point operations performed during the factorization.
Peakmem	Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.
Factormem	Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
Solvemem	Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

NOTE

To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of `mkl_cvt_to_null_terminated_str` for details.

Output Parameters

`retValues`

FORTRAN 77: REAL*8

Fortran 90: REAL (KIND=8), INTENT (OUT)

Value of the statistics returned.

Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValue)`, where `staArr` is "ReorderTime,Inertia"

In this example, `retValue` has the following values:

<code>retValue[0]</code>	Time to reorder.
<code>retValue[1]</code>	Positive Eigenvalues.
<code>retValue[2]</code>	Negative Eigenvalues.
<code>retValue[3]</code>	Zero Eigenvalues.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_STATISTICS_INVALID_MATRIX`

MKL_DSS_STATISTICS_INVALID_STATE
MKL_DSS_STATISTICS_INVALID_STRING
MKL_DSS_MSG_LVL_ERR
MKL_DSS_TERM_LVL_ERR

mkl_cvt_to_null_terminated_str

Passes character strings from Fortran routines to C routines.

Syntax

```
mkl_cvt_to_null_terminated_str (destStr, destLen, srcStr)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90

Description

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

<code>destLen</code>	INTEGER. Length of the output array <code>destStr</code> .
<code>srcStr</code>	STRING. Input string.

Output Parameters

<code>destStr</code>	INTEGER. One-dimensional array of integers.
----------------------	---

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as the RCI ISS interface. The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the [Appendix A Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

The term *RCI* indicates that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user performs them and passes the result to the solver. This makes the solver more universal as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines described in [Sparse BLAS Level 2 and Level 3 Routines](#).

NOTE

The RCI CG solver is implemented in two versions: for system of equations with a single right-hand side, and for systems of equations with multiple right-hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and not positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

RCI ISS Interface Routines

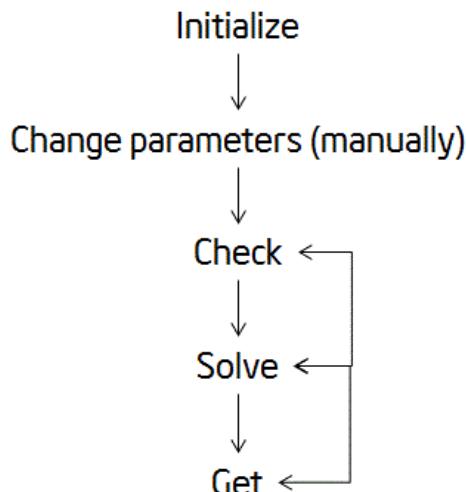

Routine	Description
<code>dcg_init</code> , <code>dcmgrhs_init</code> , <code>dfgmres_init</code>	Initializes the solver.
<code>dcg_check</code> , <code>dcmgrhs_check</code> , <code>dfgmres_check</code>	Checks the consistency and correctness of the user defined data.
<code>dcg</code> , <code>dcmgrhs</code> , <code>dfgmres</code>	Computes the approximate solution vector.
<code>dcg_get</code> , <code>dcmgrhs_get</code> , <code>dfgmres_get</code>	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in this order:

1. `<system_type>_init`
2. `<system_type>_check`
3. `<system_type>`
4. `<system_type>_get`

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram indicates the typical order in which the RCI ISS interface routines are invoked.

Typical Order for Invoking RCI ISS interface Routines

See the code examples that use the RCI ISS interface routines to solve systems of linear equations in the Intel MKL installation directory.

- Fortran examples: `examples/solverf/source`
- C examples: `examples/solverc/source`

CG Interface Description

All types in this documentation refer to the common Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right-hand side (SRHS), and for a system of equations with multiple right-hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see [CG Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `d cg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE

The default and initial values listed below are assigned to the parameters by calling the `d cg_init/`
`d cgmrhs_init` routine.

<i>n</i>	INTEGER, this parameter sets the size of the problem in the <code>d cg_init/</code> <code>d cgmrhs_init</code> routine. All the other routines uses the <code>i par(1)</code> parameter instead. Note that the coefficient matrix A is a square matrix of size $n \times n$.
<i>x</i>	DOUBLE PRECISION array of size n for SRHS, or matrix of size $(n \times nrhs)$ for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>d cg/d cgmrhs</code> routine, it contains the initial approximation to the solution.
<i>nrhs</i>	INTEGER, this parameter sets the number of right-hand sides for MRHS routines.
<i>b</i>	DOUBLE PRECISION array containing a single right-hand side vector, or matrix of size $n \times nrhs$ containing right-hand side vectors.
<i>RCI_request</i>	INTEGER, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <code>RCI_request = 1</code> multiply the matrix by $tmp(1:n, 1)$, put the result in $tmp(1:n, 2)$, and return the control to the <code>d cg/</code> <code>d cgmrhs</code> routine;

RCI_request= 2 to perform the stopping tests. If they fail, return the control to the `dchg/dcgmrhs` routine. If the stopping tests succeed, it indicates that the solution is found and stored in the `x` array;

RCI_request= 3 for SRHS: apply the preconditioner to `tmp(1:n, 3)`, put the result in `tmp(1:n, 4)`, and return the control to the `dchg` routine;

for MRHS: apply the preconditioner to `tmp(:, 3+ipar(3))`, put the result in `tmp(:, 3)`, and return the control to the `dcgmrhs` routine.

Note that the `dchg_get/dcgmrhs_get` routine does not change the parameter *RCI_request*. This enables use of this routine inside the *reverse communication* computations.

ipar INTEGER array, of size 128 for SRHS, and of size $(128+2*nrhs)$ for MRHS. This parameter specifies the integer set of data for the RCI CG computations:

ipar(1) specifies the size of the problem. The `dchg_init/dcgmrhs_init` routine assigns *ipar(1)=n*. All the other routines use this parameter instead of *n*. There is no default value for this parameter.

ipar(2) specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files `dchg_errors.txt` and `dchg_check_warnings.txt`, respectively. Note that if *ipar(6)* and *ipar(7)* parameters are set to 0, error and warning messages are not generated at all.

ipar(3) for SRHS: contains the current stage of the RCI CG computations. The initial value is 1;
for MRHS: contains the number of the right-hand side for which the calculations are currently performed.

WARNING

Avoid altering this variable during computations.

ipar(4) contains the current iteration number. The initial value is 0.

ipar(5) specifies the maximum number of iterations. The default value is `min(150, n)`.

ipar(6)

if the value is not equal to 0, the routines output error messages in accordance with the parameter *ipar(2)*. Otherwise, the routines do not output error messages at all, but return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(7)

if the value is not equal to 0, the routines output warning messages in accordance with the parameter *ipar(2)*. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(8)

if the value is not equal to 0, the *d_cg/d_cgmrhs* routine performs the stopping test for the maximum number of iterations: $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 1.

ipar(9)

if the value is not equal to 0, the *d_cg/d_cgmrhs* routine performs the residual stopping test:
 $dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$. Otherwise, the method is stopped and corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 0.

ipar(10)

if the value is not equal to 0, the *d_cg/d_cgmrhs* routine requests a user-defined stopping test by setting the output parameter *RCI_request*=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE

At least one of the parameters *ipar(8)*-
ipar(10) must be set to 1.

ipar(11)

if the value is equal to 0, the *d_cg/d_cgmrhs* routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

ipar(11:128)

are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *ipar* with length 128 for a single right-hand side.

ipar
(11:128+2**nrhs*)

are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *ipar* with length 128+2**nrhs* for multiple right-hand sides.

dpar

DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size (128+2**nrhs*) ; this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

<i>dpar</i> (1)	specifies the relative tolerance. The default value is 1.0X10 ⁻⁶ .
<i>dpar</i> (2)	specifies the absolute tolerance. The default value is 0.0.
<i>dpar</i> (3)	specifies the square norm of the initial residual (if it is computed in the <i>drg/dcgmrhs</i> routine). The initial value is 0.0.
<i>dpar</i> (4)	service variable equal to <i>dpar</i> (1) * <i>dpar</i> (3) + <i>dpar</i> (2) (if it is computed in the <i>drg/dcgmrhs</i> routine). The initial value is 0.0.
<i>dpar</i> (5)	specifies the square norm of the current residual. The initial value is 0.0.
<i>dpar</i> (6)	specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
<i>dpar</i> (7)	contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.
<i>dpar</i> (8)	contains the <i>beta</i> parameter of the CG method, it is equal to <i>dpar</i> (5) / <i>dpar</i> (6) The initial value is 0.0.
<i>dpar</i> (9:128)	are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *dpar* with length 128 for a single right-hand side.

dpar(9:128+2**nrhs*) are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *dpar* with length 128+2**nrhs* for multiple right-hand sides.

tmp

DOUBLE PRECISION array of size (*n*, 4) for SRHS, and (*n*, 3+*nrhs*) for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

<i>tmp</i> (:, 1)	specifies the current search direction. The initial value is 0.0.
<i>tmp</i> (:, 2)	contains the matrix multiplied by the current search direction. The initial value is 0.0.
<i>tmp</i> (:, 3)	contains the current residual. The initial value is 0.0.
<i>tmp</i> (:, 4)	contains the inverse of the preconditioner applied to the current residual for the SRHS version of CG. There is no initial value for this parameter.
<i>tmp</i> (:, 4:3+ <i>nrhs</i>)	contains the inverse of the preconditioner applied to the current residual for the MRHS version of CG. There is no initial value for this parameter.

NOTE

You can define this array in the code using RCI CG SRHS as DOUBLE PRECISION *tmp*(*n*, 3) if you run only non-preconditioned CG iterations.

Schemes of Using the RCI CG Routines

The following pseudocode shows the general schemes of using the RCI CG routines for the SRHS case. The MRHS is similar (see the example code for more details).

```
...
generate matrix A
generate preconditioner C (optional)
call dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
change parameters in ipar, dpar if necessary
call dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

```

1 call dcg(n, x, b, RCI_request, ipar, dpar, tmp)
  if (RCI_request.eq.1) then
    multiply the matrix A by tmp(1:n,1) and put the result in tmp(1:n,2)
    It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation
  c proceed with CG iterations
    goto 1
  endif
  if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
  c proceed with CG iterations
    go to 1
  else
  c stop CG iterations
    goto 2
  endif
  endif
  if (RCI_request.eq.3) then (optional)
    apply the preconditioner C inverse to tmp(1:n,3) and put the result in tmp(1:n,4)
  c proceed with CG iterations
    goto 1
  end
2 call dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
  current iteration number is in itercount
  the computed approximation is in the array x

```

FGMRES Interface Description

All types in this documentation refer to the common Fortran types: INTEGER and DOUBLE PRECISION.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see [FGMRES Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE

The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

<i>n</i>	INTEGER, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines uses <code>ipar(1)</code> parameter instead. Note that the coefficient matrix A is a square matrix of size $n \times n$.								
<i>x</i>	DOUBLE PRECISION array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.								
<i>b</i>	DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter <code>ipar(13)</code>), it might contain the approximate solution after execution.								
<i>RCI_request</i>	INTEGER, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <table border="0"> <tbody> <tr> <td><i>RCI_request</i>= 1</td><td>multiply the matrix by <code>tmp(ipar(22))</code>, put the result in <code>tmp(ipar(23))</code>, and return the control to the <code>dfgmres</code> routine;</td></tr> <tr> <td><i>RCI_request</i>= 2</td><td>perform the stopping tests. If they fail, return the control to the <code>dfgues</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;</td></tr> <tr> <td><i>RCI_request</i>= 3</td><td>apply the preconditioner to <code>tmp(ipar(22))</code>, put the result in <code>tmp(ipar(23))</code>, and return the control to the <code>dfgmres</code> routine.</td></tr> <tr> <td><i>RCI_request</i>= 4</td><td>check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.</td></tr> </tbody> </table>	<i>RCI_request</i> = 1	multiply the matrix by <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine;	<i>RCI_request</i> = 2	perform the stopping tests. If they fail, return the control to the <code>dfgues</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;	<i>RCI_request</i> = 3	apply the preconditioner to <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine.	<i>RCI_request</i> = 4	check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.
<i>RCI_request</i> = 1	multiply the matrix by <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine;								
<i>RCI_request</i> = 2	perform the stopping tests. If they fail, return the control to the <code>dfgues</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;								
<i>RCI_request</i> = 3	apply the preconditioner to <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine.								
<i>RCI_request</i> = 4	check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.								
<i>ipar(128)</i>	INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:								
<i>ipar(1)</i>	specifies the size of the problem. The <code>dfgmres_init</code> routine assigns <code>ipar(1)=n</code> . All the other routines uses this parameter instead of <i>n</i> . There is no default value for this parameter.								

ipar(2)

specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file `MKL_RCI_FGMRES_Log.txt`. Note that if *ipar(6)* and *ipar(7)* parameters are set to 0, error and warning messages are not generated at all.

ipar(3)

contains the current stage of the RCI FGMRES computations., The initial value is 1.

WARNING

Avoid altering this variable during computations.

ipar(4)

contains the current iteration number. The initial value is 0.

ipar(5)

specifies the maximum number of iterations. The default value is *min* (150,*n*).

ipar(6)

if the value is not 0, the routines output error messages in accordance with the parameter *ipar(2)*. If it is 0, the routines do not output error messages at all, but return a negative value of the parameter `RCI_request`. The default value is 1.

ipar(7)

if the value is not 0, the routines output warning messages in accordance with the parameter *ipar(2)*. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter `RCI_request`. The default value is 1.

ipar(8)

if the value is not equal to 0, the `dfgmres` routine performs the stopping test for the maximum number of iterations: $ipar(4) \leq ipar(5)$. If the value is 0, the `dfgmres` routine does not perform this stopping test. The default value is 1.

ipar(9)

if the value is not 0, the `dfgmres` routine performs the residual stopping test: $dpar(5) \leq dpar(4)$.If the value is 0, the `dfgmres` routine does not perform this stopping test. The default value is 0.

ipar(10)

if the value is not 0, the `dfgmres` routine indicates that the user-defined stopping test should be performed by setting `RCI_request=2`. If the value is 0, the `dfgmres` routine does not perform the user-defined stopping test. The default value is 1.

NOTE

At least one of the parameters $ipar(8)$ - $ipar(10)$ must be set to 1.

$ipar(11)$

if the value is 0, the `dfgmres` routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter `RCI_request=3`. The default value is 0.

$ipar(12)$

if the value is not equal to 0, the `dfgmres` routine performs the automatic test for zero norm of the currently generated vector: $dpar(7) \leq dpar(8)$, where $dpar(8)$ contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter `RCI_request=4`. The default value is 0.

$ipar(13)$

if the value is equal to 0, the `dfgmres_get` routine updates the solution to the vector x according to the computations done by the `dfgmres` routine. If the value is positive, the routine writes the solution to the right-hand side vector b . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

NOTE

It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter $ipar(13)$. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter $ipar(13)$ is not equal to zero. If $ipar(13)$ is positive, then the updated solution overwrites the right-hand side in the vector b . If you want to run the restarted version of FGMRES with the same right-hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive $ipar(13)$.

$ipar(14)$

contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING

Do not alter this variable during computations.

ipar(15)

specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of iterations to *ipar*(15) before the restart. The default value is $\min(150, n)$, which means that by default the non-restarted version of FGMRES method is used.

ipar(16)

service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the *tmp* array.

ipar(17)

service variable specifying the location of the rotation cosines from which the vector of cosines is started in the *tmp* array.

ipar(18)

service variable specifying the location of the rotation sines from which the vector of sines is started in the *tmp* array.

ipar(19)

service variable specifying the location of the rotated residual vector from which the vector is started in the *tmp* array.

ipar(20)

service variable, specifies the location of the least squares solution vector from which the vector is started in the *tmp* array.

ipar(21)

service variable specifying the location of the set of preconditioned vectors from which the set is started in the *tmp* array. The memory locations in the *tmp* array starting from *ipar*(21) are used only for the preconditioned FGMRES method.

ipar(22)

specifies the memory location from which the first vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(23)

specifies the memory location from which the second vector (output) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(24:128)

are reserved and not used in the current RCI FGMRES routines.

NOTE

You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(23) works, there is no guarantee of future compatibility with Intel MKL.

dpar(128)

DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

dpar(1)

specifies the relative tolerance. The default value is 1.0D-6.

dpar(2)

specifies the absolute tolerance. The default value is 0.0D-0.

dpar(3)

specifies the Euclidean norm of the initial residual (if it is computed in the *dfgmres* routine). The initial value is 0.0.

dpar(4)

service variable equal to *dpar*(1) **dpar*(3) +*dpar*(2) (if it is computed in the *dfgmres* routine). The initial value is 0.0.

dpar(5)

specifies the Euclidean norm of the current residual. The initial value is 0.0.

dpar(6)

specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.

dpar(7)

contains the norm of the generated vector. The initial value is 0.0.

dpar(8)

contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0D-12.

dpar(9:128)

are reserved and not used in the current RCI FGMRES routines.

NOTE

You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *dpar*(8) works, there is no guarantee of future compatibility with Intel MKL.

<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1)$ used to supply the double precision temporary space for the RCI FGMRES computations, specifically:
<i>tmp</i> $(1:ipar(16)-1)$	contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.
<i>tmp</i> $(ipar(16):ipar(17))$	contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of <i>tmp</i> array.
<i>tmp</i> $(ipar(17):ipar(18))$	contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp</i> $(ipar(18):ipar(19))$	contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp</i> $(ipar(19):ipar(20))$	contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp</i> $(ipar(20):ipar(21))$	contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp</i> $(ipar(21):)$	contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of <i>tmp</i> array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of <i>tmp</i> array.

NOTE

You can define this array in the code as
 DOUBLE PRECISION $tmp((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1)$ if you run only non-preconditioned FGMRES iterations.

Scheme of Using the RCI FGMRES Routines

The following pseudocode shows the general scheme of using the RCI FGMRES routines.

```

...
generate matrix A
generate preconditioner C (optional)
call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
  change parameters in ipar, dpar if necessary
call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1 call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
  if (RCI_request.eq.1) then

```

multiply the matrix A by $\text{tmp}(ipar(22))$ and put the result in $\text{tmp}(ipar(23))$

It is possible to use [MKL Sparse BLAS Level 2](#) subroutines for this operation

c proceed with FGMRES iterations

 goto 1

 endif

 if (RCI_request.eq.2) then

 do the stopping test

 if (test not passed) then

c proceed with FGMRES iterations

 go to 1

 else

c stop FGMRES iterations

 goto 2

 endif

 endif

 if (RCI_request.eq.3) then (optional)

 apply the preconditioner C inverse to $\text{tmp}(ipar(22))$ and put the result in $\text{tmp}(ipar(23))$

c proceed with FGMRES iterations

 goto 1

 endif

 if (RCI_request.eq.4) then

 check the norm of the next orthogonal vector, it is contained in $dpar(7)$

 if (the norm is not zero up to rounding/computational errors) then

c proceed with FGMRES iterations

 goto 1

 else

c stop FGMRES iterations

 goto 2

 endif

 endif

2 call dfgmres_get(n , x , b , RCI_request, ipar, dpar, tmp, itercount)

current iteration number is in $itercount$

the computed approximation is in the array x

NOTE

For the FGMRES method, the array *x* initially contains the current approximation to the solution. It can be updated only by calling the routine `dfgmres_get`, which updates the solution in accordance with the computations performed by the routine `dfgmres`.

The above pseudocode demonstrates two main differences in the use of RCI FGMRES interface comparing with the [CG Interface Description](#). The first difference relates to *RCI_request*=3: it uses different locations in the *tmp* array, which is two-dimensional for CG and one-dimensional for FGMRES. The second difference relates to *RCI_request*=4: the RCI CG interface never produces *RCI_request*=4.

RCI ISS Routines

`dcg_init`

Initializes the solver.

Syntax

Fortran:

```
dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dcg_init (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar,
double *dpar, double *tmp);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

CAUTION

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n INTEGER. Sets the size of the problem.

x DOUBLE PRECISION. Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.

b DOUBLE PRECISION. Array of size *n*. Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about the result of the routine.
<i>ipar</i>	INTEGER . Array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION . Array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -10000	Indicates failure to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

Fortran:

```
dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dcg_check (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar,  
double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about result of the routine.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size (<i>n</i> , 4). Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -1100	Indicates that the task is interrupted and the errors occur.
<i>RCI_request</i> = -1001	Indicates that there are some warning messages.
<i>RCI_request</i> = -1010	Indicates that the routine changed some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcg

Computes the approximate solution vector.

Syntax

Fortran:

```
dcg(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dcg (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar,
double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The `dcg` routine computes the approximate solution vector using the CG method [[Young71](#)]. The routine `dcg` uses the vector in the array *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
----------	--

<i>x</i>	DOUBLE PRECISION . Array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION . Array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	DOUBLE PRECISION . Array of size (<i>n</i> , 4) . Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about result of work of the routine.
<i>x</i>	DOUBLE PRECISION . Array of size <i>n</i> . Contains the updated approximation to the solution vector.
<i>ipar</i>	INTEGER . Array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION . Array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION . Array of size (<i>n</i> , 4) . Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<i>RCI_request</i> =-2	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<i>RCI_request</i> =- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <i>dpar</i> (6) was altered outside of the routine, or the <i>drg_check</i> routine was not called.
<i>RCI_request</i> =-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <i>ipar</i> (8), <i>ipar</i> (9), <i>ipar</i> (10) were altered outside of the routine, or the <i>drg_check</i> routine was not called.
<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by <i>tmp</i> (1: <i>n</i> , 1), put the result in the <i>tmp</i> (1: <i>n</i> , 2), and return the control back to the routine <i>drg</i> .

<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control back to the <code>dcg</code> routine. Otherwise, the solution is found and stored in the vector <i>x</i> .
<i>RCI_request</i> = 3	Indicates that you must apply the preconditioner to <i>tmp</i> (:, 3), put the result in the <i>tmp</i> (:, 4), and return the control back to the routine <code>dcg</code> .

dcg_get

Retrieves the number of the current iteration.

Syntax

Fortran:

```
dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
```

C:

```
void dcg_get (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar,  
double *dpar, double *tmp, MKL_INT *itercount);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the approximation vector to the solution.
<i>b</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the right-hand side vector.
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size (<i>n</i> , 4). Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER. Returns the current iteration number.
------------------	--

Return Values

The routine `dcg_get` has no return values.

dchgmrhs_init

Initializes the RCI CG solver with MRHS.

Syntax

Fortran:

```
dchgmrhs_init(n, x, nrhs, b, method, RCI_request, ipar, dpar, tmp)
```

C:

```
void dchgmrhs_init (MKL_INT *n, double *x, MKL_INT *nrhs, double *b, MKL_INT *method,  
MKL_INT *RCI_request, MKL_INT *ipar, double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dchgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right-hand sides (MRHS) routines use the values of all parameters that are returned by `dchgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dchgmrhs_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size $n \times nrhs$. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <i>b</i> .
<i>nrhs</i>	INTEGER. Sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION. Array of size $n \times nrhs$. Contains the right-hand side vectors.
<i>method</i>	INTEGER. Specifies the method of solution: A value of 1 indicates CG with multiple right-hand sides (default value)

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about the result of the routine.
<i>ipar</i>	INTEGER. Array of size $(128 + 2 \times nrhs)$. Refer to the CG Common Parameters .

<i>dpar</i>	DOUBLE PRECISION. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -10000	Indicates failure to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

Fortran:

```
dcgmrhs_check(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dcgmrhs_check (MKL_INT *n, double *x, MKL_INT *nrhs, double *b, MKL_INT  
*RCI_request, MKL_INT *ipar, double *dpar, double *tmp);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine `dcgmrhs_check` checks the consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the `dcgmrhs_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size $n*nrhs$. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <i>b</i> .
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION. Array of size $n*nrhs$. Contains the right-hand side vectors.

Output Parameters

<i>RCI_request</i>	INTEGER. Returns information about the results of the routine.
<i>ipar</i>	INTEGER. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -1100	Indicates that the task is interrupted and the errors occur.
<i>RCI_request</i> = -1001	Indicates that there are some warning messages.
<i>RCI_request</i> = -1010	Indicates that the routine changed some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dgmrhs

Computes the approximate solution vectors.

Syntax

Fortran:

```
dgmrhs(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dgmrhs (MKL_INT *n, double *x, MKL_INT *nrhs, double *b, MKL_INT *RCI_request,
MKL_INT *ipar, double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dgmrhs` computes approximate solution vectors using the CG with multiple right-hand sides (MRHS) method [Young71]. The routine `dgmrhs` uses the value that was in the `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dgmrhs_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION. Array of size $n \times nrhs$. Contains the initial approximation to the solution vectors.
<i>nrhs</i>	INTEGER. Sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION. Array of size $n \times nrhs$. Contains the right-hand side vectors.
<i>tmp</i>	DOUBLE PRECISION. Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about result of work of the routine.
<i>x</i>	DOUBLE PRECISION. Array of size n -by- $nrhs$. Contains the updated approximation to the solution vectors.
<i>ipar</i>	INTEGER. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request=0</i>	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request= 2</i> .
<i>RCI_request=-1</i>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
<i>RCI_request=-2</i>	The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<i>RCI_request=-10</i>	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <i>dpar(6)</i> was altered outside of the routine, or the <i>dgc_check</i> routine was not called.

RCI_request=-11

Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values $ipar(8)$, $ipar(9)$, $ipar(10)$ were altered outside of the routine, or the `drg_check` routine was not called.

RCI_request= 1

Indicates that you must multiply the matrix by $tmp(1:n, 1)$, put the result in the $tmp(1:n, 2)$, and return the control back to the routine `drg`.

RCI_request= 2

Indicates that you must perform the stopping tests. If they fail, return control back to the `drg` routine. Otherwise, the solution is found and stored in the vector x .

RCI_request= 3

Indicates that you must apply the preconditioner to $tmp(:, 3)$, put the result in the $tmp(:, 4)$, and return the control back to the routine `drg`.

drgmrhs_get

Retrieves the number of the current iteration.

Syntax

Fortran:

```
drgmrhs_get(n, x, nrhs, b, RCI_request, ipar, dpar, tmp, itercount)
```

C:

```
void drgmrhs_get (MKL_INT *n, double *x, MKL_INT *nrhs, double *b, MKL_INT
*RCI_request, MKL_INT *ipar, double *dpar, double *tmp, MKL_INT *itercount);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine `drgmrhs_get` retrieves the current iteration number of the solving process.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size $n*nrhs$. Contains the initial approximation to the solution vectors.
<i>nrhs</i>	INTEGER. Sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION. Array of size $n*nrhs$. Contains the right-hand side .
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .

<i>dpar</i>	DOUBLE PRECISION. Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER. Array of size $nrhs$. Returns the current iteration number for each right-hand side.
------------------	--

Return Values

The routine `dgmres_get` has no return values.

dfgmres_init

Initializes the solver.

Syntax

Fortran:

```
dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dfgmres_init (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT  
*ipar, double *dpar, double *tmp);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users can skip this step and set the values in the `ipar` and `dpar` arrays directly.

WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
<i>b</i>	DOUBLE PRECISION. Array of size n . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about the result of the routine.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $((2*ipar(15) + 1)*n + ipar(15)*(ipar(15) + 9)/2 + 1)$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -10000	Indicates failure to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

Fortran:

```
dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dfgmres_check (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar, double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Gives information about result of the routine.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $((2*ipar(15)+1)*n + ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -1100	Indicates that the task is interrupted and the errors occur.
<i>RCI_request</i> = -1001	Indicates that there are some warning messages.
<i>RCI_request</i> = -1010	Indicates that the routine changed some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

Fortran:

```
dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
```

C:

```
void dfgmres (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar,
double *dpar, double *tmp);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array *x* before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter *ipar*(13) is not equal to 0 (default value). Note that the updated solution overwrites the right-hand side in the vector *b* if the parameter *ipar*(13) is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right-hand side, you must save it in a different memory location before the first call to the `dfgmres_get` routine with a positive *ipar*(13).

The parameter *RCI_request* gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the `dfgmres_init` routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION. Array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	DOUBLE PRECISION. Array of size $((2*ipar(15)+1)*n + ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size $((2*ipar(15)+1)*n + ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2 or 4.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<i>RCI_request</i> = -10	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter <i>dpar</i> is altered, or if the method is not stopped when the solution is found.
<i>RCI_request</i> = -11	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values <i>ipar</i> (8), <i>ipar</i> (9), <i>ipar</i> (10) were altered outside of the routine, or the <code>dfgmres_check</code> routine was not called.

<i>RCI_request</i> = -12	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters <i>ipar</i> and <i>dpar</i> were altered by mistake outside the routine.
<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by <i>tmp(ipar(22))</i> , put the result in the <i>tmp(ipar(23))</i> , and return the control back to the routine <i>dfgmres</i> .
<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control to the <i>dfgmres</i> routine. Otherwise, the FGMRES solution is found, and you can run the <i>fgmres_get</i> routine to update the computed solution in the vector <i>x</i> .
<i>RCI_request</i> = 3	Indicates that you must apply the inverse preconditioner to <i>ipar(22)</i> , put the result in the <i>ipar(23)</i> , and return the control back to the routine <i>dfgmres</i> .
<i>RCI_request</i> = 4	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, return control to the <i>dfgmres</i> routine. Otherwise, the FGMRES solution is found, and you can run the <i>dfgmres_get</i> routine to update the computed solution in the vector <i>x</i> .

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

Fortran:

```
dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
```

C:

```
void dfgmres_get (MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT *ipar, double *dpar, double *tmp, MKL_INT *itercount);
```

Include Files

- Fortran: *mkl_rci.fi*
- Fortran 90: *mkl_rci.f90*
- C: *mkl_rci.h*

Description

The routine *dfgmres_get* retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the *dfgmres* routine. To retrieve the current iteration number only, set the parameter *ipar(13) = -1* beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see [FGMRES Common Parameters](#) and the Iterative Sparse Solver code examples in the Intel MKL installation directory:

- Fortran examples: *examples/solverf/source*

- C examples: examples/solverc/source

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>ipar</i>	INTEGER. Array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION. Array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION. Array of size ((2* <i>ipar</i> (15)+1)* <i>n</i> + <i>ipar</i> (15)* <i>ipar</i> (15)+9)/2 + 1). Refer to the FGMRES Common Parameters .

Output Parameters

<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . If <i>ipar</i> (13) = 0, it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>b</i>	DOUBLE PRECISION. Array of size <i>n</i> . If <i>ipar</i> (13) > 0, it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>RCI_request</i>	INTEGER. Gives information about result of the routine.
<i>itercount</i>	INTEGER. Contains the value of the current iteration number.

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -12	Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters <i>ipar</i> and <i>dpar</i> were altered by mistake outside of the routine.
<i>RCI_request</i> = -10000	Indicates that the routine failed to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files.

The C-language header file defines these function prototypes:

```
void dcg_init(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg_check(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar, double
*tmp);

void dcg_get(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp, int *itercount);
```

```

void dcgmrhs_init(int *n, double *x, int *nRhs, double *b, int *method, int
*rcl_request, int *ipar, double dpar, double *tmp);
void dcgmrhs_check(int *n, double *x, int *nRhs, double *b, int *rcl_request, int
*ipar, double dpar, double *tmp);
void dcgmrhs(int *n, double *x, int *nRhs, double *b, int *rcl_request, int *ipar,
double dpar, double *tmp);
void dcgmrhs_get(int *n, double *x, int *nRhs, double *b, int *rcl_request, int *ipar,
double dpar, double *tmp, int *itercount);

void dfgmres_init(int *n, double *x, double *b, int *rcl_request, int *ipar, double
dpar, double *tmp);
void dfgmres_check(int *n, double *x, double *b, int *rcl_request, int *ipar, double
dpar, double *tmp);
void dfgmres(int *n, double *x, double *b, int *rcl_request, int *ipar, double dpar,
double *tmp);
void dfgmres_get(int *n, double *x, double *b, int *rcl_request, int *ipar, double
dpar, double *tmp, int *itercount);

```

NOTE

Intel MKL does not support the RCI ISS interface unless you include the language-specific header file.

Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel MKL provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format described in [Sparse Matrix Storage Format](#)). The algorithms used are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

NOTE

Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the code examples for both preconditioners (`dcsrilu*.f` and `dcsrilu*.c`) in the examples folder of the Intel MKL installation directory:

- Fortran examples: `examples/solverf/source`
- C examples: `examples/solverc/source`

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

...

generate matrix `A`

generate preconditioner `C` (optional)

```

call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
    change parameters in ipar, dpar if necessary
    call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
    call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1   call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
    if (RCI_request.eq.1) then
        multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c    proceed with FGMRES iterations
        goto 1
    endif
    if (RCI_request.eq.2) then
        do the stopping test
        if (test not passed) then
            c proceed with FGMRES iterations
                go to 1
            else
                c stop FGMRES iterations.
                    goto 2
            endif
            if (RCI_request.eq.3) then
                c Below, trvec is an intermediate vector of length at least n
                c Here is the recommended use of the result produced by the ILUT routine.
                c via standard Intel MKL Sparse Blas solver routine mkl_dcsrtrsv.
            endif
        endif
    endif

```

```

call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut, tmp(ipar(22)),trvec)
call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec, tmp(ipar(23)))
c proceed with FGMRES iterations

    goto 1
endif
if (RCI_request.eq.4) then
    check the norm of the next orthogonal vector, it is contained in dpar(7)
    if (the norm is not zero up to rounding/computational errors) then
c proceed with FGMRES iterations

    goto 1
else
c stop FGMRES iterations

    goto 2
endif
endif
2 call dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
current iteration number is in itercount
the computed approximation is in the array x

```

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Appendix A Linear Solvers Basics](#).

In this section the FORTRAN style notations are used. All types refer to the standard Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers must refer to the section [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

Some parameters of the preconditioners are common with the [FGMRES Common Parameters](#). The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

`ipar(2)` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar(6)` is set to 0, then error messages are not generated at all.

ipar(6) - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter *ipar(2)*. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

For the ILUT preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called MKL_PREC_log.txt and writes error messages to it. Note if the parameter *ipar(6)* is set to 0, then error messages are not generated at all.

ipar(6) - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter *ipar(2)*. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

ipar(7) - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter *ipar(2)* and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter *ierr*. If its value is less than 0, the routine generates a warning message as specified by the parameter *ipar(2)* and returns a positive value of the parameter *ierr*. The default value is 1.

dcsrilo0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.

Syntax

Fortran:

```
call dcsrilo0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

C:

```
void dcsrilo0 (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , double *bilu0 ,
MKL_INT *ipar , double *dpar , MKL_INT *ierr );
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine dcsrilo0 computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L^* U$, where L is a lower triangular matrix with a unit diagonal, U is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix A is used to store the incomplete factors L and U .

CAUTION

This routine supports only one-based indexing of the array parameters, regardless of whether the Fortran or C interface is used.

Input Parameters

<i>n</i>	INTEGER. Size (number of rows or columns) of the original square <i>n</i> -by- <i>n</i> matrix <i>A</i> .
----------	---

<i>a</i>	DOUBLE PRECISION. Array containing the set of elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to the <i>values</i> array description in the Sparse Matrix Storage Format for more details.
<i>ia</i>	INTEGER. Array of size $(n+1)$ containing begin indices of rows of the matrix <i>A</i> such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> (<i>n</i> +1) is equal to the number of non-zero elements in the matrix <i>A</i> , plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . It is important that the indices are in increasing order per row. The matrix size is equal to the size of the array <i>a</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.

CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

<i>ipar</i>	INTEGER. Array of size 128. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the <i>ipar</i> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.
<i>ipar</i> (31)	specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine dfgmres_init), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of <i>dpar</i> (32) and the calculations continue.

NOTE

You can declare the *ipar* array with a size of 32. However, for future compatibility you must declare the array *ipar* with length 128.

<i>dpar</i>	DOUBLE PRECISION. Array of size 128. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the <i>dpar</i> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.
<i>dpar</i> (31)	specifies a small value, which is compared with the computed diagonal elements. When <i>ipar</i> (31) is not 0, then diagonal elements less than <i>dpar</i> (31) are set to <i>dpar</i> (32). The default value is 1.0D-16.

NOTE

This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

dpar(32)

specifies the value that is assigned to the diagonal element if its value is less than *dpar*(31) (see above). The default value is 1.0D-10.

NOTE

You can declare the *dpar* array with a size of 32. However, for future compatibility you must declare the array *dpar* with length 128.

Output Parameters

bilu0

DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

ierr

INTEGER. Error flag, gives information about the routine completion.

NOTE

To present the resulting preconditioning matrix in the CSR3 format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Return Values

ierr=0

Indicates that the task completed normally.

ierr=-101

Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR3 format (see [Sparse Matrix Storage Format](#)).

ierr=-102

Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.

ierr=-103

Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.

ierr=-104

Indicates that the routine was interrupted because the memory is insufficient for the internal work array.

ierr=-105

Indicates that the routine was interrupted because the input matrix size *n* is less than or equal to 0.

ierr=-106

Indicates that the routine was interrupted because the column indices *ja* are not in the ascending order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilu0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
INTEGER n, ierr, ipar(128)
INTEGER ia(*), ja(*)
DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

C:

```
void dcsrilu0 (int *n, double *a, int *ia, int *ja, double *bilu0, int *ipar, double *dpar, int *ierr);
```

dcsrilut

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

Fortran:

```
call dcsrilut(n, a, ia, ja, bilut, ibilut, jibilut, tol, maxfil, ipar, dpar, ierr)
```

C:

```
void dcsrilut (MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, double *bilut, MKL_INT
*ibilut, MKL_INT *jibilut, double *tol, MKL_INT *maxfil, MKL_INT *ipar, double *dpar,
MKL_INT *ierr);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine `dcsrilut` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L^* U$, where L is a lower triangular matrix with unit diagonal and U is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors L and U :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting L and U factors must not be greater than the value of the parameter `maxfil`.

CAUTION

This routine supports only one-based indexing of the array parameters, regardless of whether the Fortran or C interface is used.

Input Parameters

<i>n</i>	INTEGER. Size (number of rows or columns) of the original square <i>n</i> -by- <i>n</i> matrix <i>A</i> .
<i>a</i>	DOUBLE PRECISION. Array containing all non-zero elements of the matrix <i>A</i> . The length of the array is equal to their number. Refer to <i>values</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ia</i>	INTEGER. Array of size (<i>n</i> +1) containing indices of non-zero elements in the array <i>a</i> . <i>ia</i> (<i>i</i>) is the index of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> (<i>n</i> +1) is equal to the number of non-zeros in the matrix <i>A</i> , plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format for more details.
<i>ja</i>	INTEGER. Array of size equal to the size of the array <i>a</i> . This array contains the column numbers for each non-zero element of the matrix <i>A</i> . It is important that the indices are in increasing order per row. Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.

CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

<i>tol</i>	DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.
<i>maxfil</i>	INTEGER. Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner can not exceed (2* <i>maxfil</i> +1).
<i>ipar</i>	INTEGER array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the <i>ipar</i> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar(31)

specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*(31) = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by *dpar*(31) (see its description below), and the calculations continue.

NOTE

There is no default value for *ipar*(31) even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE

You must declare the array `ipar` with length 128. While defining the array in the code as `INTEGER ipar(31)` works, there is no guarantee of future compatibility with Intel MKL.

dpar

DOUBLE PRECISION array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the `dpar` array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar(31)

used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by `tol` are replaced with the value of `dpar(31)` multiplied by the matrix row norm.

NOTE

There is no default value for `dpar(31)` entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE

You must declare the array `dpar` with length 128. While defining the array in the code as DOUBLE PRECISION `ipar(31)` works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

bilut

DOUBLE PRECISION. Array containing non-zero elements of the resulting preconditioning matrix B , stored in the format accepted in the direct sparse solvers. Refer to the `values` array description in the [Sparse Matrix Storage Format](#) for more details. The size of the array is equal to $(2*maxfil+1)*n-maxfil*(maxfil+1)+1$.

NOTE

Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

ibilut

INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array `bilut`. `ibilut(i)` is the index of the first non-zero element from the row i . The value of the last element `ibilut(n+1)` is equal to the number of non-zeros in the matrix B , plus one. Refer to the `rowIndex` array description in the [Sparse Matrix Storage Format](#) for more details.

<i>jbilut</i>	INTEGER. Array, its size is equal to the size of the array <i>bilut</i> . This array contains the column numbers for each non-zero element of the matrix <i>B</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.
<i>ierr</i>	INTEGER. Error flag, informs about the routine completion.

Return Values

<i>ierr</i> =0	Indicates that the task completed normally.
<i>ierr</i> =-101	Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<i>ierr</i> =-102	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <i>dpar</i> (31)=0.
<i>ierr</i> =-103	Indicates that the routine was interrupted because the element <i>ia</i> (<i>i</i> +1) is less than or equal to the element <i>ia</i> (<i>i</i>) (see Sparse Matrix Storage Format).
<i>ierr</i> =-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
<i>ierr</i> =-105	Indicates that the routine was interrupted because the input value of <i>maxfil</i> is less than 0.
<i>ierr</i> =-106	Indicates that the routine was interrupted because the size <i>n</i> of the input matrix is less than 0.
<i>ierr</i> =-107	Indicates that the routine was interrupted because an element of the array <i>ja</i> is less than 1, or greater than <i>n</i> (see Sparse Matrix Storage Format).
<i>ierr</i> =101	The value of <i>maxfil</i> is greater than or equal to <i>n</i> . The calculation is performed with the value of <i>maxfil</i> set to (<i>n</i> -1).
<i>ierr</i> =102	The value of <i>tol</i> is less than 0. The calculation is performed with the value of the parameter set to (- <i>tol</i>).
<i>ierr</i> =103	The absolute value of <i>tol</i> is greater than value of <i>dpar</i> (31); it can result in instability of the calculation.
<i>ierr</i> =104	The value of <i>dpar</i> (31) is equal to 0. It can cause calculations to fail.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
INTEGER n, ierr, ipar(*), maxfil
INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

C:

```
void dcsrilut (int *n, double *a, int *ia, int *ja, double *bilut, int *ibilut, int *jbilut, double
*tol, int *maxfil, int *ipar, double *dpar, int *ierr);
```

Sparse Matrix Checker Routines

Intel MKL provides a sparse matrix checker so that you can find errors in the storage of sparse matrices before calling Intel MKL PARDISO, DSS, or Sparse BLAS routines.

[sparse_matrix_checker](#)

Checks correctness of sparse matrix.

Syntax

Fortran:

```
error = sparse_matrix_checker (handle)
```

C:

```
MKL_INT sparse_matrix_checker (sparse_struct* handle);
```

Include Files

- Fortran: `mkl_sparse_handle.fi`
- Fortran 90: `mkl_sparse_handle.f90`
- C: `mkl_sparse_handle.h`

Description

The `sparse_matrix_checker` routine checks a user-defined array used to store a sparse matrix in order to detect issues which could cause problems in routines that require sparse input matrices, such as Intel MKL PARDISO, DSS, or Sparse BLAS.

Input Parameters

`handle`

FORTRAN 77: INTEGER*8

Fortran 90: TYPE (SPARSE_STRUCT), INTENT(INOUT)

Pointer to the data structure describing the sparse array to check.

Return Values

The routine returns a value `error`. Additionally, the `check_result` parameter returns information about where the error occurred, which can be used when `message_level` is `MKL_NO_PRINT`.

Sparse Matrix Checker Error Values

error value	Meaning	Location
MKL_SPARSE_CHECKER_SUCCESS	The input array successfully passed all checks.	
MKL_SPARSE_CHECKER_NON_MONOTONIC	The input array is not 0 or 1 based (Fortran: <code>ia(1)</code> , C: <code>ia[0]</code>) or elements of <code>ia</code> are not in non-decreasing order as required.	Fortran:
		<code>ia(i + 1)</code> and <code>ia(i + 2)</code> are incompatible. <code>check_result(1) = i</code> <code>check_result(2) = ia(i + 1)</code> <code>check_result(3) = ia(i + 2)</code>
MKL_SPARSE_CHECKER_OUT_OF_BOUNDS	The value of the <code>ja</code> array is lower than the number of the first column or greater than the number of the last column.	C:
		<code>ia[i]</code> and <code>ia[i + 1]</code> are incompatible. <code>check_result[0] = i</code> <code>check_result[1] = ia[i]</code> <code>check_result[2] = ia[i + 1]</code>
MKL_SPARSE_CHECKER_NONTRIANGULAR	The <code>matrix_structure</code> parameter is <code>MKL_UPPER_TRIANGULAR</code> and both <code>ia</code> and <code>ja</code> are not upper triangular, or the <code>matrix_structure</code> parameter is <code>MKL_LOWER_TRIANGULAR</code> and both <code>ia</code> and <code>ja</code> are not lower triangular	Fortran:
		<code>ia(i + 1)</code> and <code>ja(j + 1)</code> are incompatible. <code>check_result(1) = i</code> <code>check_result(2) = ia(i + 1) = j</code> <code>check_result(3) = ja(j + 1)</code>
		C:
		<code>ia[i]</code> and <code>ja[j]</code> are incompatible. <code>check_result[0] = i</code> <code>check_result[1] = ia[i] = j</code> <code>check_result[2] = ja[j]</code>

error value	Meaning	Location
MKL_SPARSE_CHECKER_NONORD	The elements of the ja array are not in non-decreasing order in each row as required.	<p>Fortran:</p> <p><i>ja(j + 1)</i> and <i>ja(j + 2)</i> are incompatible.</p> <pre>check_result(1) = j check_result(2) = ja(j + 1) check_result(3) = ja(j + 2)</pre> <p>C:</p> <p><i>ia[i]</i> and <i>ia[i + 1]</i> are incompatible.</p> <pre>check_result[0] = j check_result[1] = ja[j] check_result[2] = ja[j + 1]</pre>

[sparse_matrix_init](#)

Initializes handle for sparse matrix checker.

Syntax

Fortran:

```
call sparse_matrix_init (handle)
```

C:

```
void sparse_matrix_init (sparse_struct* handle);
```

Include Files

- Fortran: `mkl_sparse_handle.fi`
- Fortran 90: `mkl_sparse_handle.f90`
- C: `mkl_sparse_handle.h`

Description

The `sparse_matrix_init` routine initializes the handle for the `sparse_matrix_checker` routine. The `handle` variable contains this data:

Description of `sparse_matrix_checker` handle Data

Field	Type	Possible Values	Meaning
n	Fortran: INTEGER C: MKL_INT		Order of the matrix stored in sparse array.

Field	Type	Possible Values	Meaning
csr_ia	Fortran: INTEGER (C_INTPTR_T) C: MKL_INT*	Pointer to <i>ia</i> array for matrix_format = MKL_CSR	
csr_ja	Fortran: INTEGER (C_INTPTR_T) C: MKL_INT*	Pointer to <i>ja</i> array for matrix_format = MKL_CSR	
check_result(3)	Fortran: INTEGER (KIND=4) C: MKL_INT	See Sparse Matrix Checker Error Values for a description of the values returned in <i>check_result</i> .	Indicates location of problem in array when message_level = MKL_NO_PRINT.
indexing	Fortran: INTEGER (KIND=4) C: sparse_matrix_indexing	MKL_ZERO_BASED MKL_ONE_BASED	Indexing style used in array.
matrix_structure	Fortran: INTEGER (KIND=4) C: sparse_matrix_structures	MKL_GENERAL_STRUCTURE MKL_UPPER_TRIANGULAR MKL_LOWER_TRIANGULAR MKL_STRUCTURAL_SYMMETRIC	Type of sparse matrix stored in array.
matrix_format	Fortran: INTEGER (KIND=4) C: sparse_matrix_formats	MKL_CSR	Format of array used for sparse matrix storage.
message_level	Fortran: INTEGER (KIND=4) C: sparse_matrix_message_levels	MKL_NO_PRINT MKL_PRINT	Determines whether or not feedback is provided on the screen.
print_style	Fortran: INTEGER (KIND=4) C: sparse_matrix_print_styles	MKL_C_STYLE MKL_FORTRAN_STYLE	Determines style of messages when message_level = MKL_PRINT.

Input Parameters

<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (SPARSE_STRUCT), INTENT(INOUT)
	Pointer to the data structure describing the sparse array to check.

Output Parameters

<i>handle</i>	Pointer to the initialized data structure.

Calling Sparse Solver and Preconditioner Routines from C and C++

All of the Intel MKL sparse solver and preconditioner routines are designed to be called easily from FORTRAN 77 or Fortran 90. However, any of these routines can be invoked directly from C or C++ if you are familiar with the inter-language calling conventions of your platforms. These conventions include, but are not limited to, the argument passing mechanisms for the language and the platform-specific method of decoration for Fortran external names.

To promote portability, the C header files provide a set of macros intended to hide the inter-language calling conventions and provide an interface to the Intel MKL sparse solver routines that appears natural for C and C++.

For example, consider a hypothetical library routine `foo` that takes a real vector of length `n`, and returns an integer status. Fortran users would access such a function using code such as:

```
INTEGER n, status, foo
REAL x(*)
status = foo(x, n)
```

As noted above, to invoke `foo`, C users need to know what argument passing mechanism the Fortran compiler uses and what, if any, name decoration the Fortran compiler performs when generating the external symbol `foo`.

However, by using the C specific header file, for example `mkl_solver.h`, the invocation of `foo`, within a C program would look like the following:

```
#include "mkl_solver.h"
MKL_INT i, status;
float x[];
status = foo( x, i );
```

Passing Constants as Parameters

One of the key differences between C/C++ and Fortran is the argument passing mechanisms for the languages: Fortran programs pass arguments by reference and C/C++ programs pass arguments by value. In the above example, the header file `mkl_solver.h` attempts to hide this difference by defining a macro `foo`, which takes the address of the appropriate arguments. For example, on the Tru64 UNIX* operating system `mkl_solver.h` defines the macro as follows:

```
#define foo(a,b) foo_((a), &(b))
```

Note how constants are treated when using the macro form of `foo`. `foo(x, 10)` is converted into `foo_(x, &10)`. In a strictly ANSI compliant C compiler, taking the address of a constant is not permitted, so a strictly conforming program would look like:

```
MKL_INT iTen = 10;
float * x;
status = foo( x, iTen );
```

However, some C compilers in a non-ANSI compliant mode enable taking the address of a constant for ease of use with Fortran programs. The form `foo(x, 10)` is acceptable for such compilers.

Extended Eigensolver Routines

The Extended Eigensolver functionality in Intel Math Kernel Library (Intel MKL) is based on the FEAST Eigenvalue Solver 2.0 (<http://www ecs umass edu/~polizzi/feast>) in compliance with a BSD license agreement.

Extended Eigensolver uses the same naming convention as the original FEAST package.

NOTE

Intel MKL only supports the shared memory programming (SMP) version of the eigenvalue solver.

- [The FEAST Algorithm](#) gives a brief description of the algorithm underlying the Extended Eigensolver.
- [Extended Eigensolver Functionality](#) describes the problems that can and cannot be solved with the Extended Eigensolver and how to get the best results from the routines.
- [Extended Eigensolver Interfaces](#) gives a reference for calling Extended Eigensolver routines.

The FEAST Algorithm

The Extended Eigensolver functionality is a set of high-performance numerical routines for solving symmetric standard eigenvalue problems, $Ax = \lambda x$, or generalized symmetric-definite eigenvalue problems, $Ax = \lambda Bx$. It yields all the eigenvalues (λ) and eigenvectors (x) within a given search interval $[\lambda_{\min}, \lambda_{\max}]$. It is based on the FEAST algorithm, an innovative fast and stable numerical algorithm presented in [Polizzi09], which fundamentally differs from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [Bai00]) or other Davidson-Jacobi techniques [Sleijpen96]. The FEAST algorithm is inspired by the density-matrix representation and contour integration techniques in quantum mechanics.

The FEAST numerical algorithm obtains eigenpair solutions using a numerically efficient contour integration technique. The main computational tasks in the FEAST algorithm consist of solving a few independent linear systems along the contour and solving a reduced eigenvalue problem. Consider a circle centered in the middle of the search interval $[\lambda_{\min}, \lambda_{\max}]$. The numerical integration over the circle in the current version of FEAST is performed using N_e -point Gauss-Legendre quadrature with x_e the e -th Gauss node associated with the weight ω_e . For example, for the case $N_e = 8$:

$$\begin{aligned} (x_1, \omega_1) &= (0.183434642495649, 0.362683783378361), \\ (x_2, \omega_2) &= (-0.183434642495649, 0.362683783378361), \\ (x_3, \omega_3) &= (0.525532409916328, 0.313706645877887), \\ (x_4, \omega_4) &= (-0.525532409916328, 0.313706645877887), \\ (x_5, \omega_5) &= (0.796666477413626, 0.222381034453374), \\ (x_6, \omega_6) &= (-0.796666477413626, 0.222381034453374), \\ (x_7, \omega_7) &= (0.960289856497536, 0.101228536290376), \text{ and} \\ (x_8, \omega_8) &= (-0.960289856497536, 0.101228536290376). \end{aligned}$$

The figure [FEAST Pseudocode](#) shows the basic pseudocode for the FEAST algorithm for the case of real symmetric (left pane) and complex Hermitian (right pane) generalized eigenvalue problems, using N for the size of the system and M for the number of eigenvalues in the search interval (see [Polizzi09]).

NOTE

The pseudocode presents a simplified version of the actual algorithm. Refer to <http://arxiv.org/abs/1302.0432> for an in-depth presentation and mathematical proof of convergence of FEAST.

FEAST Pseudocode

<p><i>A</i>: real symmetric <i>B</i>: symmetric positive definite (SPD) $\Re\{x\}$: real part of <i>x</i></p> <ol style="list-style-type: none"> Select $M_0 > M$ random vectors $Y_{N \times M_0} \in \mathbb{R}^{N \times M_0}$. If iterative refinement is needed, compute $Y = BX$ and go back to step 2.
---	---

Extended Eigensolver Functionality

Use Extended Eigensolver to compute all the eigenvalues and eigenvectors within a given search interval.

The eigenvalue problems covered are as follows:

- standard, $Ax = \lambda x$
 - *A* complex Hermitian
 - *A* real symmetric
- generalized, $Ax = \lambda Bx$
 - *A* complex Hermitian, *B* Hermitian positive definite (hpd)
 - *A* real symmetric and *B* real symmetric positive definite (spd)

The Extended Eigensolver functionality offers:

- Real/Complex and Single/Double precisions: double precision is recommended to provide better accuracy of eigenpairs.
- All Extended Eigensolver interfaces are compatible with FORTRAN 77, Fortran 90, and C.
- Reverse communication interfaces (RCI) provide maximum flexibility for specific applications. RCI are independent of matrix format and inner system solvers, so you must provide your own linear system solvers (direct or iterative) and matrix-matrix multiply routines.
- Predefined driver interfaces for dense, LAPACK banded, and sparse (CSR) formats are less flexible but are optimized and easy to use:

- The Extended Eigensolver interfaces for dense matrices are likely to be slower than the comparable LAPACK routines because the FEAST algorithm has a higher computational cost.
- The Extended Eigensolver interfaces for banded matrices support banded LAPACK-type storage.
- The Extended Eigensolver sparse interfaces support compressed sparse row format and use the Intel MKL PARDISO solver.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Parallelism in Extended Eigensolver Routines

How you achieve parallelism in Extended Eigensolver routines depends on which interface you use. Parallelism (via shared memory programming) is not *explicitly* implemented in Extended Eigensolver routines within one node: the inner linear systems are currently solved one after another.

- Using the Extended Eigensolver RCI interfaces, you can achieve parallelism by providing a threaded inner system solver and a matrix-matrix multiplication routine. When using the RCI interfaces, you are responsible for activating the threaded capabilities of your BLAS and LAPACK libraries most likely using the shell variable `OMP_NUM_THREADS`.
- Using the predefined Extended Eigensolver interfaces, parallelism can be implicitly obtained within the shared memory version of BLAS, LAPACK or Intel MKL PARDISO. The shell variable `MKL_NUM_THREADS` can be used for automatically setting the number of threads (cores) for BLAS, LAPACK, and Intel MKL PARDISO.

Achieving Performance With Extended Eigensolver Routines

In order to use the Extended Eigensolver Routines, you need to provide

- the search interval and the size of the subspace M_0 (overestimation of the number of eigenvalues M within a given search interval);
- the system matrix in dense, banded, or sparse CSR format if the Extended Eigensolver predefined interfaces are used, or a high-performance complex direct or iterative system solver and matrix-vector multiplication routine if RCI interfaces are used.

In return, you can expect

- fast convergence with very high accuracy when seeking up to 1000 eigenpairs (in two to four iterations using $M_0 = 1.5M$, and $N_e = 8$ or at most using $N_e = 16$ contour points);
- an extremely robust approach.

The performance of the basic FEAST algorithm depends on a trade-off between the choices of the number of Gauss quadrature points N_e , the size of the subspace M_0 , and the number of outer refinement loops to reach the desired accuracy. In practice you should use $M_0 > 1.5 M$, $N_e = 8$, and at most two refinement loops.

For better performance:

- M_0 should be much smaller than the size of the eigenvalue problem, so that the arithmetic complexity depends mainly on the inner system solver ($O(NM)$ for narrow-banded or sparse systems).
- Parallel scalability performance depends on the shared memory capabilities of the inner system solver (via the shell variable `MKL_NUM_THREADS`).
- For very large sparse and challenging systems, application users should make use of the Extended Eigensolver RCI interfaces with customized highly-efficient iterative systems solvers and preconditioners.

- For the Extended Eigensolver interfaces for banded matrices, the parallel performance scalability is limited.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Extended Eigensolver Interfaces

Extended Eigensolver Naming Conventions

There are two different types of interfaces available in the Extended Eigensolver routines:

- The reverse communication interfaces (RCI):

```
?feast_<matrix type>_rci
```

These interfaces are matrix free format (the interfaces are independent of the matrix data formats). You must provide matrix-vector multiply and direct/iterative linear system solvers for your own explicit or implicit data format.

- The predefined interfaces:

```
?feast_<matrix type><type of eigenvalue problem>
```

are predefined drivers for ?feast reverse communication interface that act on commonly used matrix data storage (dense, banded and compressed sparse row representation), using internal matrix-vector routines and selected inner linear system solvers.

For these interfaces:

- ? indicates the data type of matrix A (and matrix B if any) defined as follows:

s	real, single precision
d	real, double precision
c	complex, single precision
z	complex , double precision

- <matrix type> defined as follows:

Value of <matrix type>	Matrix format	Inner linear system solver used by Extended Eigensolver
sy	(symmetric real)	
he	(Hermitian complex)	Dense LAPACK dense solvers
sb	(symmetric banded real)	Banded-LAPACK Internal banded solver

Value of <matrix type>	Matrix format	Inner linear system solver used by Extended Eigensolver	
hb	(Hermitian banded complex)		
scsr	(symmetric real)		
hcsr	(Hermitian complex)	Compressed sparse row	PARDISO solver
s	(symmetric real)	Reverse communications	
h	(Hermitian complex)	interfaces	User defined

- <type of eigenvalue problem> is:

gv	generalized eigenvalue problem
ev	standard eigenvalue problem

For example, `sfeast_scsrev` is a single-precision routine with a symmetric real matrix stored in sparse compressed-row format for a standard eigenvalue problem, and `zfeast_hrci` is a complex double-precision routine with a Hermitian matrix using the reverse communication interface.

Note that:

- ? can be s or d if a matrix is real symmetric: <matrix type> is sy, sb, or scsr.
- ? can be c or z if a matrix is complex Hermitian: <matrix type> is he, hb, or hcsr.
- ? can be c or z if the Extended Eigensolver RCI interface is used for solving a complex Hermitian problem.
- ? can be s or d if the Extended Eigensolver RCI interface is used for solving a real symmetric problem.

feastinit

Initialize Extended Eigensolver input parameters with default values.

Syntax

Fortran:

```
call feastinit (fpm)
```

C:

```
feastinit (MKL_INT* fpm);
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Description

This routine sets all Extended Eigensolver parameters to their default values.

Output Parameters

<code>fpm</code>	INTEGER
------------------	---------

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

Extended Eigensolver Input Parameters

The input parameters for Extended Eigensolver routines are contained in an integer array named fpm . To call the Extended Eigensolver interfaces, this array should be initialized using the routine [feastinit](#).

Param	Default	Description
$fpm(1)$	0	Specifies whether Extended Eigensolver routines print runtime status. $fpm(1)=0$ Extended Eigensolver routines do not generate runtime messages at all. $fpm(1)=1$ Extended Eigensolver routines print runtime status to the screen.
$fpm(2)$	8	The number of contour points $N_e = 8$ (see the description of FEAST algorithm). Must be one of {3,4,5,6,8,10,12,16,20,24,32,40,48}.
$fpm(3)$	12	Error trace double precision stopping criteria ε ($\varepsilon = 10^{-fpm(3)}$) .
$fpm(4)$	20	Maximum number of Extended Eigensolver refinement loops allowed. If no convergence is reached within $fpm(4)$ refinement loops, Extended Eigensolver routines return $info=2$.
$fpm(5)$	0	User initial subspace. If $fpm(5)=0$ then Extended Eigensolver routines generate initial subspace, if $fpm(5)=1$ the user supplied initial subspace is used.
$fpm(6)$	0	Extended Eigensolver stopping test. $fpm(6)=0$ Extended Eigensolvers are stopped if this residual stopping test is satisfied: <ul style="list-style-type: none"> • generalized eigenvalue problem: $\max_{i=1:mode} \frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max(E_{\min} , E_{\max}) \ Bx_i\ _1} < \varepsilon$ • standard eigenvalue problem: $\max_{i=1:mode} \frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{\min} , E_{\max}) \ x_i\ _1} < \varepsilon$ where $mode$ is the total number of eigenvalues found in the search interval and $\varepsilon = 10^{-fpm(7)}$ for real and complex or $\varepsilon = 10^{-fpm(3)}$ for double precision and double complex.
$fpm(6)=1$		Extended Eigensolvers are stopped if this trace stopping test is satisfied: $\frac{ trace_j - trace_{j-1} }{\max(E_{\min} , E_{\max})} < \varepsilon,$ where $trace_j$ denotes the sum of all eigenvalues found in the search interval $[e_{\min}, e_{\max}]$ at the j -th Extended Eigensolver iteration:

Param	Default	Description
		$\text{trace}_j = \sum_{i=1}^M \lambda_i^{(j)}$.
$fpm(7)$	5	Error trace single precision stopping criteria ($10^{-fpm(7)}$).
$fpm(14)$	0	$fpm(14)=0$ Standard use for Extended Eigensolver routines. $fpm(14)=1$ Non-standard use for Extended Eigensolver routines: return the computed eigenvectors subspace after one single contour integration.
$fpm(30)$ to $fpm(63)$	-	Reserved for future use.
$fpm(64)$	0	Use the Intel MKL PARDISO solver with the user-defined PARDISO <i>iparm</i> array settings.

NOTE

This option can only be used by Extended Eigensolver Predefined Interfaces for Sparse Matrices.

$fpm(64)=0$	Extended Eigensolver routines use the Intel MKL PARDISO default <i>iparm</i> settings defined by calling the <i>pardisoinit</i> subroutine.
$fpm(64)=1$	The values from $fpm(65)$ to $fpm(128)$ correspond to <i>iparm(1)</i> to <i>iparm(64)</i> respectively according to the formula $fpm(64+i) = iparm(i)$ for $i = 1, 2, \dots, 64$.

NOTE

Using the C language, the components of the fpm array start at 0 and stop at 127. Therefore, the components $fpm[j]$ in C (for $j=0, 1, \dots, 127$) must correspond to the components $fpm(i)$ in Fortran (for $i=1, 2, \dots, 128$) specified above (i.e. $fpm[i-1]=fpm(i)$).

Extended Eigensolver Output Details

Errors and warnings encountered during a run of the Extended Eigensolver routines are stored in an integer variable, *info*. If the value of the output *info* parameter is not 0, either an error or warning was encountered. The possible return values for the *info* parameter along with the error code descriptions are given in the following table.

Return Codes for info Parameter

<i>info</i>	Classification	Description
202	Error	Problem with size of the system n ($n \leq 0$)
201	Error	Problem with size of initial subspace m_0 ($m_0 \leq 0$ or $m_0 > n$)
200	Error	Problem with emin, emax ($\text{emin} \geq \text{emax}$)

info	Classification	Description
(100+ <i>i</i>)	Error	Problem with <i>i</i> -th value of the input Extended Eigensolver parameter ($fpm(i)$). Only the parameters in use are checked.
4	Warning	Successful return of only the computed subspace after call with $fpm(14) = 1$
3	Warning	Size of the subspace $m0$ is too small ($m0 < m$)
2	Warning	No Convergence (number of iteration loops $> fpm(4)$)
1	Warning	No eigenvalue found in the search interval. See remark below for further details.
0	Successful exit	
-1	Error	Internal error for allocation memory.
-2	Error	Internal error of the inner system solver. Possible reasons: not enough memory for inner linear system solver or inconsistent input.
-3	Error	Internal error of the reduced eigenvalue solver Possible cause: matrix B may not be positive definite. It can be checked with LAPACK routines, if necessary.
-(100+ <i>i</i>)	Error	Problem with the <i>i</i> -th argument of the Extended Eigensolver interface.

In some extreme cases the return value $info=1$ may indicate that the Extended Eigensolver routine has failed to find the eigenvalues in the search interval. This situation could arise if a very large search interval is used to locate a small and isolated cluster of eigenvalues (i.e. the dimension of the search interval is many orders of magnitude larger than the number of contour points. It is then either recommended to increase the number of contour points $fpm(2)$ or simply rescale more appropriately the search interval. Rescaling means the initial problem of finding all eigenvalues the search interval $[\lambda_{\min}, \lambda_{\max}]$ for the standard eigenvalue problem $A x = \lambda x$ is replaced with the problem of finding all eigenvalues in the search interval $[\lambda_{\min}/t, \lambda_{\max}/t]$ for the standard eigenvalue problem $(A/t) x = (\lambda/t)x$ where t is a scaling factor.

Extended Eigensolver RCI Routines

If you do not require specific linear system solvers or matrix storage schemes, you can skip this section and go directly to [Extended Eigensolver Predefined Interfaces](#).

Extended Eigensolver RCI Interface Description

The Extended Eigensolver RCI interfaces can be used to solve standard or generalized eigenvalue problems, and are independent of the format of the matrices. As mentioned earlier, the Extended Eigensolver algorithm is based on the contour integration techniques of the matrix resolvent $G(\sigma) = (\sigma B - A)^{-1}$ over a circle. For solving a generalized eigenvalue problem, Extended Eigensolver has to perform one or more of the following operations at each contour point denoted below by Z_e :

- Factorize the matrix $(Z_e * B - A)$
- Solve the linear system $(Z_e * B - A)X = Y$ or $(Z_e * B - A)^H X = Y$ with multiple right hand sides, where H means transpose conjugate
- Matrix-matrix multiply $B X = Y$ or $A X = Y$

For solving a standard eigenvalue problem, replace the matrix B with the identity matrix I .

The primary aim of RCI interfaces is to isolate these operations: the linear system solver, factorization of the matrix resolvent at each contour point, and matrix-matrix multiplication. This gives universality to RCI interfaces as they are independent of data structures and the specific implementation of the operations like

matrix-vector multiplication or inner system solvers. However, this approach requires some additional effort when calling the interface. In particular, operations listed above are performed by routines that you supply on data structures that you find most appropriate for the problem at hand.

To initialize an Extended Eigensolver RCI routine, set the job indicator (*ijob*) parameter to the value -1. When the routine requires the results of an operation, it generates a special value of *ijob* to indicate the operation that needs to be performed. The routine also returns *ze*, the coordinate along the complex contour, the values of array *work* or *workc*, and the number of columns to be used. Your subroutine then must perform the operation at the given contour point *ze*, store the results in prescribed array, and return control to the Extended Eigensolver RCI routine.

The following pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a real symmetric problem:

NOTE

The `? option` in `?feast` in the pseudocode given above should be replaced by either `s` or `d`, depending on the matrix data type of the eigenvalue system.

The next pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a complex Hermitian problem:

NOTE

The `? option in ?feast in the pseudocode given above should be replaced by either c or z, depending on the matrix data type of the eigenvalue system.`

If case (20) can be avoided, performance could be up to twice as fast, and Extended Eigensolver functionality would use half of the memory.

If an iterative solver is used along with a preconditioner, the factorization of the preconditioner could be performed with $ijob = 10$ (and $ijob = 20$ if applicable) for a given value of Z_e , and the associated iterative solve would then be performed with $ijob = 11$ (and $ijob = 21$ if applicable).

Optimization Notice

- C: mkl.h

Description

Compute eigenvalues as described in [Extended Eigensolver RCI Interface Description](#).

Input Parameters

<i>ijob</i>	INTEGER	Job indicator variable. On entry, a call to ?feast_srci/?feast_hrci with <i>ijob</i> =-1 initializes the eigensolver.
<i>n</i>	INTEGER	Sets the size of the problem.
<i>work</i>	REAL for sfeast_srci DOUBLE PRECISION for dfeast_srci COMPLEX for cfeast_hrci COMPLEX*16 for zfeast_hrci	Workspace array of dimension <i>n</i> by <i>m0</i> .
<i>workc</i>	COMPLEX for sfeast_srci and cfeast_hrci COMPLEX*16 for dfeast_srci and zfeast_hrci	Workspace array of dimension <i>n</i> by <i>m0</i> .
<i>aq</i> , <i>sq</i>	REAL for sfeast_srci DOUBLE PRECISION for dfeast_srci COMPLEX for cfeast_hrci COMPLEX*16 for zfeast_hrci	Workspace arrays of dimension <i>m0</i> by <i>m0</i> .
<i>fpm</i>	INTEGER	

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

emin, emax

REAL for `sfeast_srci` and `cfeast_hrci`

DOUBLE PRECISION for `dfeast_srci` and `zfeast_hrci`

The lower and upper bounds of the interval to be searched for eigenvalues; $\text{emin} \leq \text{emax}$.

m0

INTEGER

On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[\text{emin}, \text{emax}]$. If the initial guess is wrong, Extended Eigensolver routines return $\text{info}=3$.

q

REAL for `sfeast_srci`

DOUBLE PRECISION for `dfeast_srci`

COMPLEX for `cfeast_hrci`

COMPLEX*16 for `zfeast_hrci`

On entry, if $fpm(5)=1$, the array $q(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

ijob

On exit, the parameter carries the status flag that indicates the condition of the return. The status information is divided into three categories:

1. A zero value indicates successful completion of the task.
2. A positive value indicates that the solver requires a matrix-vector multiplication or solving a specific system with a complex coefficient.
3. A negative value indicates successful initiation.

A non-zero value of *ijob* specifically means the following:

- $ijob = 10$ - factorize the complex matrix $Z_e^*B - A$ at a given contour point Z_e and return the control to the `?feast_srci/?feast_hrci` routine where Z_e is a complex number meaning contour point and its value is defined internally in `?feast_srci/?feast_hrci`.
- $ijob = 11$ - solve the complex linear system $(Z_e^*B - A)*y = workc(n, m0)$, put the solution in $workc(n, m0)$ and return the control to the `?feast_srci/?feast_hrci` routine.
- $ijob = 20$ - factorize the complex matrix $(Z_e^*B - A)^H$ at a given contour point Z_e and return the control to the `?feast_srci/?feast_hrci` routine where Z_e is a complex number meaning contour point and its value is defined internally in `?feast_srci/?feast_hrci`.

The symbol X^H means transpose conjugate of matrix X .

- $ijob = 21$ - solve the complex linear system $(Z_e^*B - A)^H*y = workc(n, m0)$, put the solution in $workc(n, m0)$ and return the control to the `?feast_srci/?feast_hrci` routine. The case $ijob=20$ becomes obsolete if the solve can be performed using the factorization computed for $ijob=10$.

The symbol X^H mean transpose conjugate of matrix X .

- $i_{job} = 30$ - multiply matrix A by $q(n, i:j)$, put the result in $work(n, i:j)$, and return the control to the `?feast_srci/?feast_hrci` routine.
 i is $fpm(24)$, and j is $fpm(24) + fpm(25) - 1$.
- $i_{job} = 40$ - multiply matrix B by $q(n, i:j)$, put the result in $work(n, i:j)$ and return the control to the `?feast_srci/?feast_hrci` routine. If a standard eigenvalue problem is solved, just return $work = q$.
 i is $fpm(24)$, and j is $fpm(24) + fpm(25) - 1$.
- $i_{job} = -2$ - rerun the `?feast_srci/?feast_hrci` task with the same parameters.

ze

COMPLEX for `sfeast_srci` and `cfeast_hrci`

COMPLEX*16 for `dfeast_srci` and `zfeast_hrci`

Defines the coordinate along the complex contour. All values of ze are generated by `?feast_srci/?feast_hrci` internally.

fpm

On output, contains coordinates of columns of work array needed for iterative refinement. (See [Extended Eigensolver RCI Interface Description](#).)

$epsout$

REAL for `sfeast_srci` and `cfeast_hrci`

DOUBLE PRECISION for `dfeast_srci` and `zfeast_hrci`

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

$loop$

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

$lambda$

REAL for `sfeast_srci` and `cfeast_hrci`

DOUBLE PRECISION for `dfeast_srci` and `zfeast_hrci`

Array of length m_0 . On output, the first m entries of $lambda$ are eigenvalues found in the interval.

q

On output, q contains all eigenvectors corresponding to $lambda$.

m

INTEGER

The total number of eigenvalues found in the interval $[emin, emax]$: $0 \leq m \leq m_0$.

res

REAL for `sfeast_srci` and `cfeast_hrci`

DOUBLE PRECISION for `dfeast_srci` and `zfeast_hrci`

Array of length m_0 . On exit, the first m components contain the relative residual vector:

- generalized eigenvalue problem:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

- standard eigenvalue problem:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|x_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

info

INTEGER

If *info*=0, the execution is successful. If *info* ≠ 0, see [Output Eigensolver info Details](#).

Extended Eigensolver Predefined Interfaces

The predefined interfaces include routines for standard and generalized eigenvalue problems, and for dense, banded, and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Dense	?feast_syev ?feast_heev	?feast_sygv ?feast_hegv
Banded	?feast_sbev ?feast_hbev	?feast_sbqv ?feast_hbqv
Sparse	?feast_scsrev ?feast_hcsrev	?feast_scsvqv ?feast_hcqv

Matrix Storage

The symmetric and Hermitian matrices used in Extended Eigensolvers predefined interfaces can be stored in full, band, and sparse formats.

- In the full storage format (described in [Full Storage](#) in additional detail) you store all elements, all of the elements in the upper triangle of the matrix, or all of the elements in the lower triangle of the matrix.
- In the band storage format (described in [Band storage](#) in additional detail), you store only the elements along a diagonal band of the matrix.
- In the sparse format (described in [Storage Arrays for a Matrix in CSR Format \(3-Array Variation\)](#)), you store only the non-zero elements of the matrix.

In generalized eigenvalue systems you must use the same family of storage format for both matrices *A* and *B*. The bandwidth can be different for the banded format (*k1b* can be different from *k1a*), and the position of the non-zero elements can also be different for the sparse format (CSR coordinates *ib* and *jb* can be different from *ia* and *ja*).

?feast_syev/?feast_heev

Extended Eigensolver interface for standard eigenvalue problem with dense matrices.

Syntax

Fortran:

```

call sfeast_syev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res,
info)

call dfeast_syev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res,
info)

call cfeast_heev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res,
info)

call zfeast_heev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res,
info)

```

C:

```

void sfeast_syev (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

<i>uplo</i>	CHARACTER*1
	Must be 'U' or 'L' or 'F' .
	If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> .
	If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> .
	If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	INTEGER
	Sets the size of the problem. $n \geq 0$.
<i>a</i>	REAL for sfeast_syev
	DOUBLE PRECISION for dfeast_syev

COMPLEX for `cfeast_heev`

COMPLEX*16 for `zfeast_heev`

Array of dimension `lda` by `n`, contains either full matrix A or upper or lower triangular part of the matrix A , as specified by `uplo`

`lda` INTEGER

The first dimension of the array `a`. Must be at least $\max(1, n)$.

`fpm` INTEGER

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

`emin, emax` REAL for `sfeast_syev` and `cfeast_heev`

DOUBLE PRECISION for `dfeast_syev` and `zfeast_heev`

The lower and upper bounds of the interval to be searched for eigenvalues; $\text{emin} \leq \text{emax}$.

`m0` INTEGER

On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where `m` is the total number of eigenvalues located in the interval $[\text{emin}, \text{emax}]$. If the initial guess is wrong, Extended Eigensolver routines return `info=3`.

`x` REAL for `sfeast_syev`

DOUBLE PRECISION for `dfeast_syev`

COMPLEX for `cfeast_heev`

COMPLEX*16 for `zfeast_heev`

On entry, if `fpm(5)=1`, the array `x(n, m)` contains a basis of guess subspace where `n` is the order of the input matrix.

Output Parameters

`epsout` REAL for `sfeast_syev` and `cfeast_heev`

DOUBLE PRECISION for `dfeast_syev` and `zfeast_heev`

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|\text{emin}|, |\text{emax}|)$

`loop` INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

`e` REAL for `sfeast_syev` and `cfeast_heev`

DOUBLE PRECISION for `dfeast_syev` and `zfeast_heev`

Array of length `m0`. On output, the first `m` entries of `e` are eigenvalues found in the interval.

<i>x</i>	On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e(i)</i> .
<i>m</i>	INTEGER The total number of eigenvalues found in the interval [<i>emin</i> , <i>emax</i>]: $0 \leq m \leq m_0$.
<i>res</i>	REAL for sfeast_syev and cfeast_heev DOUBLE PRECISION for dfeast_syev and zfeast_heev Array of length <i>m</i> . On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{\min} , E_{\max}) \ x_i\ _1}$ for $i=1, 2, \dots, m$, and where <i>m</i> is the total number of eigenvalues found in the search interval.
<i>info</i>	INTEGER If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see Output Eigensolver info Details .

?feast_sygv/?feast_hegv

Extended Eigensolver interface for generalized eigenvalue problem with dense matrices.

Syntax

Fortran:

```
call sfeast_sygv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call dfeast_sygv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call cfeast_hegv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call zfeast_hegv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)
```

C:

```
void sfeast_sygv (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT *
* lda, const float * b, const MKL_INT * ldb, MKL_INT * fpm, float * epsout, MKL_INT *
loop, const float * emin, const float * emax, MKL_INT * m0, float * e, float * x,
MKL_INT * m, float * res, MKL_INT * info);

void dfeast_sygv (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT *
* lda, const double * b, const MKL_INT * ldb, MKL_INT * fpm, double * epsout, MKL_INT *
loop, const double * emin, const double * emax, MKL_INT * m0, double * e, double *
x, MKL_INT * m, double * res, MKL_INT * info);
```

```
void cfeast_hegv (const char * uplo, const MKL_INT * n, const MKL_Complex8 * a, const
MKL_INT * lda, const MKL_Complex8 * b, const MKL_INT * ldb, MKL_INT * fpm, float *
epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float *
e, MKL_Complex8 * x, MKL_INT * m, float * res, MKL_INT * info);

void zfeast_hegv (const char * uplo, const MKL_INT * n, const MKL_Complex16 * a, const

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

Input Parameters

<i>uplo</i>	CHARACTER*1
	Must be 'U' or 'L' or 'F' .
	If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively.
	If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively.
	If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively.
<i>n</i>	INTEGER
	Sets the size of the problem. $n \geq 0$.
<i>a</i>	REAL for sfeast_sygv DOUBLE PRECISION for dfeast_sygv COMPLEX for cfeast_hegv COMPLEX*16 for zfeast_hegv
	Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	INTEGER
	The first dimension of the array <i>a</i> . Must be at least max(1, <i>n</i>).
<i>b</i>	REAL for sfeast_sygv DOUBLE PRECISION for dfeast_sygv COMPLEX for cfeast_hegv COMPLEX*16 for zfeast_hegv
	Array of dimension <i>ldb</i> by <i>n</i> , contains either full matrix <i>B</i> or upper or lower triangular part of the matrix <i>B</i> , as specified by <i>uplo</i>

<i>ldb</i>	INTEGER, the first dimension of the array <i>B</i> . Must be at least $\max(1, n)$.
<i>fpm</i>	INTEGER Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	REAL for <code>sfeast_sygv</code> and <code>cfeast_hegv</code> DOUBLE PRECISION for <code>dfeast_sygv</code> and <code>zfeast_hegv</code> The lower and upper bounds of the interval to be searched for eigenvalues; $\text{emin} \leq \text{emax}$.
<i>m0</i>	INTEGER On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[\text{emin}, \text{emax}]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>x</i>	REAL for <code>sfeast_sygv</code> DOUBLE PRECISION for <code>dfeast_sygv</code> COMPLEX for <code>cfeast_hegv</code> COMPLEX*16 for <code>zfeast_hegv</code> On entry, if $fpm(5)=1$, the array $x(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

<i>epsout</i>	REAL for <code>sfeast_sygv</code> and <code>cfeast_hegv</code> DOUBLE PRECISION for <code>dfeast_sygv</code> and <code>zfeast_hegv</code> On output, contains the relative error on the trace: $ trace_i - trace_{i-1} / \max(\text{emin} , \text{emax})$
<i>loop</i>	INTEGER On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	REAL for <code>sfeast_sygv</code> and <code>cfeast_hegv</code> DOUBLE PRECISION for <code>dfeast_sygv</code> and <code>zfeast_hegv</code> Array of length $m0$. On output, the first m entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first m columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the i -th column of <i>x</i> holding the eigenvector associated with <i>e</i> (<i>i</i>).
<i>m</i>	INTEGER

The total number of eigenvalues found in the interval [emin , emax]: $0 \leq m \leq m_0$.

res

REAL for `sfeast_sygv` and `cfeast_hegv`

DOUBLE PRECISION for `dfeast_sygv` and `zfeast_hegv`

Array of length m_0 . On exit, the first m components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

info

INTEGER

If $\text{info}=0$, the execution is successful. If $\text{info} \neq 0$, see [Output Eigensolver info Details](#).

?feast_sbev/?feast_hbev

Extended Eigensolver interface for standard eigenvalue problem with banded matrices.

Syntax

Fortran:

```
call sfeast_sbev(uplo, n, kla, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)
call dfeast_sbev(uplo, n, kla, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m,

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

<i>uplo</i>	CHARACTER*1
	Must be 'U' or 'L' or 'F' .
	If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> .
	If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> .
	If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	INTEGER
	Sets the size of the problem. <i>n</i> ≥ 0 .
<i>kla</i>	INTEGER, the number of super- or sub-diagonals within the band in <i>A</i> (<i>kla</i> ≥ 0).
<i>a</i>	REAL for sfeast_sbev DOUBLE PRECISION for dfeast_sbev COMPLEX for cfeast_hbev COMPLEX*16 for zfeast_hbev Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	INTEGER The first dimension of the array <i>a</i> . Must be at least max(1, <i>n</i>).
<i>fpm</i>	INTEGER Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin</i> , <i>emax</i>	REAL for sfeast_sbev and cfeast_hbev DOUBLE PRECISION for dfeast_sbev and zfeast_hbev The lower and upper bounds of the interval to be searched for eigenvalues; <i>emin</i> \leq <i>emax</i> .
<i>m0</i>	INTEGER

On entry, specifies the initial guess for subspace dimension to be used, $0 < m_0 \leq n$. Set $m_0 \geq m$ where m is the total number of eigenvalues located in the interval $[e_{\min}, e_{\max}]$. If the initial guess is wrong, Extended Eigensolver routines return $info=3$.

x REAL for sfeast_sbev

DOUBLE PRECISION for dfeast_sbev

COMPLEX for cfeast_hbev

COMPLEX*16 for zfeast_hbev

On entry, if $fpm(5)=1$, the array $x(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

epsout

REAL for sfeast_sbev and cfeast_hbev

DOUBLE PRECISION for dfeast_sbev and zfeast_hbev

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|e_{\min}|, |e_{\max}|)$

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

REAL for sfeast_sbev and cfeast_hbev

DOUBLE PRECISION for dfeast_sbev and zfeast_hbev

Array of length m_0 . On output, the first m entries of *e* are eigenvalues found in the interval.

x

On output, the first m columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the i -th column of *x* holding the eigenvector associated with *e(i)*.

m

INTEGER

The total number of eigenvalues found in the interval $[e_{\min}, e_{\max}]$: $0 \leq m \leq m_0$.

res

REAL for sfeast_sbev and cfeast_hbev

DOUBLE PRECISION for dfeast_sbev and zfeast_hbev

Array of length m_0 . On exit, the first m components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|x_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

info

INTEGER

If $info=0$, the execution is successful. If $info \neq 0$, see [Output Eigensolver info Details](#).

?feast_sbgv/?feast_hbgv

Extended Eigensolver interface for generalized eigenvalue problem with banded matrices.

Syntax

Fortran:

```
call sfeast_sbgv(uplo, n, kla, a, lda, klb, b, ldb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)

call dfeast_sbgv(uplo, n, kla, a, lda, klb, b, ldb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)

call cfeast_hbgv(uplo, n, kla, a, lda, klb, b, ldb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)

call zfeast_hbgv(uplo, n, kla, a, lda, klb, b, ldb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)
```

C:

```
void sfeast_sbgv (const char * uplo, const MKL_INT * n, const MKL_INT * kla, const
float * a, const MKL_INT * lda, const MKL_INT * klb, const float * b, const MKL_INT *
ldb, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float *

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

NOTE

Both matrices A and B must use the same family of storage format. The bandwidth, however, can be different (k_{lb} can be different from k_{la}).

Input Parameters

<i>uplo</i>	CHARACTER*1	
		Must be 'U' or 'L' or 'F' .
		If $UPLO = 'U'$, a and b store the upper triangular parts of A and B respectively.
		If $UPLO = 'L'$, a and b store the lower triangular parts of A and B respectively.
		If $UPLO= 'F'$, a and b store the full matrices A and B respectively.
<i>n</i>	INTEGER	
		Sets the size of the problem. $n \geq 0$.
<i>kla</i>	INTEGER	
		The number of super- or sub-diagonals within the band in A ($k_{la} \geq 0$).
<i>a</i>	REAL for sfeast_sbgv DOUBLE PRECISION for dfeast_sbgv COMPLEX for cfeast_hbgv COMPLEX*16 for zfeast_hbgv	
		Array of dimension lda by n , contains either full matrix A or upper or lower triangular part of the matrix A , as specified by <i>uplo</i>
<i>lda</i>	INTEGER	
		The first dimension of the array a . Must be at least $\max(1, n)$.
<i>klb</i>	INTEGER	
		The number of super- or sub-diagonals within the band in B ($k_{lb} \geq 0$).
<i>b</i>	REAL for sfeast_sbgv DOUBLE PRECISION for dfeast_sbgv COMPLEX for cfeast_hbgv COMPLEX*16 for zfeast_hbgv	
		Array of dimension ldb by n , contains either full matrix B or upper or lower triangular part of the matrix B , as specified by <i>uplo</i>
<i>ldb</i>	INTEGER, the first dimension of the array B . Must be at least $\max(1, n)$.	
<i>fpm</i>	INTEGER	

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

emin, emax

REAL for sfeast_sbgv and cfeast_hbgv

DOUBLE PRECISION for dfeast_sbgv and zfeast_hbgv

The lower and upper bounds of the interval to be searched for eigenvalues; $\text{emin} \leq \text{emax}$.

m0

INTEGER

On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[\text{emin}, \text{emax}]$. If the initial guess is wrong, Extended Eigensolver routines return $\text{info}=3$.

x

REAL for sfeast_sbgv

DOUBLE PRECISION for dfeast_sbgv

COMPLEX for cfeast_hbgv

COMPLEX*16 for zfeast_hbgv

On entry, if $fpm(5)=1$, the array $x(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

epsout

REAL for sfeast_sbgv and cfeast_hbgv

DOUBLE PRECISION for dfeast_sbgv and zfeast_hbgv

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|\text{emin}|, |\text{emax}|)$

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

REAL for sfeast_sbgv and cfeast_hbgv

DOUBLE PRECISION for dfeast_sbgv and zfeast_hbgv

Array of length $m0$. On output, the first m entries of *e* are eigenvalues found in the interval.

x

On output, the first m columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the i -th column of *x* holding the eigenvector associated with *e(i)*.

m

INTEGER

The total number of eigenvalues found in the interval $[\text{emin}, \text{emax}]$: $0 \leq m \leq m0$.

res

REAL for sfeast_sbgv and cfeast_hbgv

DOUBLE PRECISION for dfeast_sbgv and zfeast_hbgv

Array of length m_0 . On exit, the first m components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

info INTEGER

If $info=0$, the execution is successful. If $info \neq 0$, see [Output Eigensolver info Details](#).

?feast_scsrev/?feast_hcsrev

Extended Eigensolver interface for standard eigenvalue problem with sparse matrices.

Syntax

Fortran:

```
call sfeast_scsrev(uplo, n, a, ia, ja, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call dfeast_scsrev(uplo, n, a, ia, ja, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call cfeast_hcsrev(uplo, n, a, ia, ja, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)

call zfeast_hcsrev(uplo, n, a, ia, ja, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)
```

C:

```
void sfeast_scsrev (const char * uplo, const MKL_INT * n, const float * a, const
MKL_INT * ia, const MKL_INT * ja, MKL_INT * fpm, float * epsout, MKL_INT * loop, const
float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m,
float * res, MKL_INT * info);

void dfeast_scsrev (const char * uplo, const MKL_INT * n, const double * a, const
MKL_INT * ia, const MKL_INT * ja, MKL_INT * fpm, double * epsout, MKL_INT * loop,
const double * emin, const double * emax, MKL_INT * m0, double * e, double * x,
MKL_INT * m, double * res, MKL_INT * info);

void cfeast_hcsrev (const char * uplo, const MKL_INT * n, const MKL_Complex8 * a, const
MKL_INT * ia, const MKL_INT * ja, MKL_INT * fpm, float * epsout, MKL_INT * loop, const
float * emin, const float * emax, MKL_INT * m0, float * e, MKL_Complex8 * x, MKL_INT * m,

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

<i>uplo</i>	CHARACTER*1	
		Must be 'U' or 'L' or 'F' .
		If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> .
		If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> .
		If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	INTEGER	
		Sets the size of the problem. <i>n</i> ≥ 0 .
<i>a</i>	REAL for sfeast_scsrev DOUBLE PRECISION for dfeast_scsrev COMPLEX for cfeast_hcsrev COMPLEX*16 for zfeast_hcsrev	Array containing the nonzero elements of either the full matrix <i>A</i> or the upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> .
<i>ia</i>	INTEGER	Array of length <i>n</i> + 1, containing indices of elements in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> (<i>n</i> + 1) is equal to the number of non-zeros plus one.
<i>ja</i>	INTEGER	Array containing the column indices for each non-zero element of the matrix <i>A</i> being represented in the array <i>a</i> . Its length is equal to the length of the array <i>a</i> .
<i>fpm</i>	INTEGER	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin</i> , <i>emax</i>	REAL for sfeast_scsrev and cfeast_hcsrev DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev	The lower and upper bounds of the interval to be searched for eigenvalues; <i>emin</i> \leq <i>emax</i> .
<i>m0</i>	INTEGER	

On entry, specifies the initial guess for subspace dimension to be used, $0 < m_0 \leq n$. Set $m_0 \geq m$ where m is the total number of eigenvalues located in the interval $[e_{\min}, e_{\max}]$. If the initial guess is wrong, Extended Eigensolver routines return $\text{info}=3$.

x

```
REAL for sfeast_scsrev
DOUBLE PRECISION for dfeast_scsrev
COMPLEX for cfeast_hcsrev
COMPLEX*16 for zfeast_hcsrev
```

On entry, if $fpm(5)=1$, the array $x(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

fpm

On output, the last 64 values correspond to Intel MKL PARDISO $iparm(1)$ to $iparm(64)$ (regardless of the value of $fpm(64)$ on input).

epsout

```
REAL for sfeast_scsrev and cfeast_hcsrev
DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev
```

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|e_{\min}|, |e_{\max}|)$

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

```
REAL for sfeast_scsrev and cfeast_hcsrev
DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev
```

Array of length m_0 . On output, the first m entries of *e* are eigenvalues found in the interval.

x

On output, the first m columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the i -th column of *x* holding the eigenvector associated with *e*(i).

m

INTEGER

The total number of eigenvalues found in the interval $[e_{\min}, e_{\max}]$: $0 \leq m \leq m_0$.

res

```
REAL for sfeast_scsrev and cfeast_hcsrev
DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev
```

Array of length m_0 . On exit, the first m components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|x_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

info INTEGER
 If $info=0$, the execution is successful. If $info \neq 0$, see [Output Eigensolver info Details](#).

?feast_scsrgv/?feast_hcsrgv

Extended Eigensolver interface for generalized eigenvalue problem with sparse matrices.

Syntax

Fortran:

```
call sfeast_scsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)

call dfeast_scsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0,
e, x, m, res, info)

call cfeast_hcsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0,

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

NOTE

Both matrices A and B must use the same family of storage format. The position of the non-zero elements can be different (CSR coordinates ib and jb can be different from ia and ja).

Input Parameters

<i>uplo</i>	CHARACTER*1	
	Must be 'U' or 'L' or 'F' .	
	If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively.	
	If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively.	
	If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively.	
<i>n</i>	INTEGER	
	Sets the size of the problem. $n \geq 0$.	
<i>a</i>	REAL for sfeast_scsrgv DOUBLE PRECISION for dfeast_scsrgv COMPLEX for cfeast_hcsrgv COMPLEX*16 for zfeast_hcsrgv	
	Array containing the nonzero elements of either the full matrix <i>A</i> or the upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> .	
<i>ia</i>	INTEGER	
	Array of length $n + 1$, containing indices of elements in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> ($n + 1$) is equal to the number of non-zeros plus one.	
<i>ja</i>	INTEGER	
	Array containing the column indices for each non-zero element of the matrix <i>A</i> being represented in the array <i>a</i> . Its length is equal to the length of the array <i>a</i> .	
<i>b</i>	REAL for sfeast_scsrgv DOUBLE PRECISION for dfeast_scsrgv COMPLEX for cfeast_hcsrgv COMPLEX*16 for zfeast_hcsrgv	
	Array of dimension <i>ldb</i> by *, contains either full matrix <i>B</i> or upper or lower triangular part of the matrix <i>B</i> , as specified by <i>uplo</i>	

<i>ib</i>	INTEGER	Array of length $n + 1$, containing indices of elements in the array b , such that $ib(i)$ is the index in the array b of the first non-zero element from the row i . The value of the last element $ib(n + 1)$ is equal to the number of non-zeros plus one.
<i>jb</i>	INTEGER	Array containing the column indices for each non-zero element of the matrix B being represented in the array b . Its length is equal to the length of the array b .
<i>fpm</i>	INTEGER	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin</i> , <i>emax</i>	REAL for <code>sfeast_scsrgv</code> and <code>cfeast_hcsrgv</code> DOUBLE PRECISION for <code>dfeast_scsrgv</code> and <code>zfeast_hcsrgv</code>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	INTEGER	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <code>info=3</code> .
<i>x</i>	REAL for <code>sfeast_scsrgv</code> DOUBLE PRECISION for <code>dfeast_scsrgv</code> COMPLEX for <code>cfeast_hcsrgv</code> COMPLEX*16 for <code>zfeast_hcsrgv</code>	On entry, if $fpm(5)=1$, the array $x(n, m)$ contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

<i>fpm</i>	On output, the last 64 values correspond to Intel MKL PARDISO <code>iparm(1)</code> to <code>iparm(64)</code> (regardless of the value of <code>fpm(64)</code> on input).
<i>epsout</i>	REAL for <code>sfeast_scsrgv</code> and <code>cfeast_hcsrgv</code> DOUBLE PRECISION for <code>dfeast_scsrgv</code> and <code>zfeast_hcsrgv</code> On output, contains the relative error on the trace: $ trace_i - trace_{i-1} / \max(emin , emax)$
<i>loop</i>	INTEGER On output, contains the number of refinement loop executed. Ignored on input.

<i>e</i>	REAL for sfeast_scsrgv and cfeast_hcsrgv DOUBLE PRECISION for dfeast_scsrgv and zfeast_hcsrgv Array of length m_0 . On output, the first m entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first m columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the i -th column of <i>x</i> holding the eigenvector associated with <i>e</i> (i).
<i>m</i>	INTEGER The total number of eigenvalues found in the interval [e_{\min} , e_{\max}]: $0 \leq m \leq m_0$.
<i>res</i>	REAL for sfeast_scsrgv and cfeast_hcsrgv DOUBLE PRECISION for dfeast_scsrgv and zfeast_hcsrgv Array of length m_0 . On exit, the first m components contain the relative residual vector:
	$\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max(E_{\min} , E_{\max}) \ Bx_i\ _1}$ for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.
<i>info</i>	INTEGER If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see Output Eigensolver info Details .

Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematical Functions Library (VML), which computes a mathematical function of each of the vector elements. VML includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VML include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VML functions fall into the following groups according to the operations they perform:

- [VML Mathematical Functions](#) compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- [VML Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- [VML Service Functions](#) set/get the accuracy modes and the error codes, and free memory.

The VML mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VML mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

The Intel MKL interfaces are given in the following include files:

- `mkl_vml.f77`, which declares the FORTRAN 77 interfaces
- `mkl_vml.f90`, which declares the Fortran 90 interfaces; the `mkl_vml.fi` include file available in the previous versions of Intel MKL is retained for backward compatibility
- `mkl_vml_functions.h`, which declares the C interfaces

Examples that demonstrate how to use the VML functions are located in:

```
 ${MKL}/examples/vmlc/source
```

```
 ${MKL}/examples/vmlf/source
```

See VML performance and accuracy data in the online VML Performance and Accuracy Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Data Types, Accuracy Modes, and Performance Tips

VML includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and complex types. The library provides Fortran- and C-interfaces for all functions, including the associated service functions. The Function Naming Conventions section below shows how to call these functions from different languages.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VML for vector lengths larger than 40 elements.
 - Use the Intel® Compiler for vector lengths less than 40 elements.

All VML vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
 - Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
 - Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VML handles special values in accordance with the C99 standard [C99].

Intel MKL offers both functions and environment variables to switch between modes for VML. See the *Intel MKL User's Guide* for details about the environment variables. Use the `vmlSetMode(mode)` function (see [Table "Values of the mode Parameter"](#)) to switch between the HA, LA, and EP modes. The `vmlGetMode()` function returns the current mode.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

See Also

Function Naming Conventions

Function Naming Conventions

The VML function names are lowercase for Fortran (`vsabs`) and of mixed (lower and upper) case for C (`vsAbs`).

The VML mathematical and pack/unpack function names have the following structure:

v[m]<?><name><mod>

where

- v is a prefix indicating vector operations.
 - $[m]$ is an optional prefix for mathematical functions that indicates additional argument to specify a VML mode for a given function call (see [vmlSetMode](#) for possible values and their description).
 - $<?>$ is a precision prefix that indicates one of the following the data types:

s REAL (KIND=4) for the Fortran interface, or float for the C interface.

d REAL (KIND=8 for the Fortran interface, or double for the C interface).

C COMPLEX (KIND=4) for the Fortran interface, or `MKL_Complex8` for the C interface.

z COMPLEX (KIND=8) for the Fortran interface, or MKL_Complex16 for the C interface.

- <name> indicates the function short name, with some of its letters in uppercase for the C interface. See examples in [Table "VML Mathematical Functions"](#).
- <mod> field (written in uppercase for the C interface) is present only in the pack/unpack functions and indicates the indexing method used:

<i>i</i>	indexing with a positive increment
<i>v</i>	indexing with an index vector
<i>m</i>	indexing with a mask vector.

The VML service function names have the following structure:

vm/*<name>*

where

<name> indicates the function short name, with some of its letters in uppercase for the C interface. See examples in [Table "VML Service Functions"](#).

To call VML functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

call vsexp (*n*, *a*, *y*) for the Fortran interface

call vmsexp (*n*, *a*, *y*, *mode*) for the Fortran interface with a specified mode

vsExp (*n*, *a*, *y*); for the C interface

Function Interfaces

VML interfaces include the function names and argument lists. The following sections describe the interfaces for the VML functions. Note that some of the functions have multiple input and output arguments

Some VML functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

VML Mathematical Functions

Fortran:

```
call v<?><name>( n, a, [scalar input arguments,] y )
call v<?><name>( n, a, b, [scalar input arguments,] y )
call v<?><name>( n, a, y, z )
call vm<?><name>( n, a, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, b, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, y, z, mode )
```

C:

```
v<?><name>( n, a, [scalar input arguments,] y );
v<?><name>( n, a, b, [scalar input arguments,] y );
v<?><name>( n, a, y, z );
vm<?><name>( n, a, [scalar input arguments,] y, mode );
vm<?><name>( n, a, b, [scalar input arguments,] y, mode );
vm<?><name>( n, a, y, z, mode );
```

Pack Functions

Fortran:

```
call v<?>packi( n, a, inca, y )
call v<?>packv( n, a, ia, y )
call v<?>packm( n, a, ma, y )
```

C:

```
v<?>PackI( n, a, inca, y );
v<?>PackV( n, a, ia, y );
v<?>PackM( n, a, ma, y );
```

Unpack Functions

Fortran:

```
call v<?>unpacki( n, a, y, incy )
call v<?>unpackv( n, a, y, iy )
call v<?>unpackm( n, a, y, my )
```

C:

```
v<?>UnpackI( n, a, y, incy );
v<?>UnpackV( n, a, y, iy );
v<?>UnpackM( n, a, y, my );
```

Service Functions

Fortran:

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlsetErrorCallBack( callback );
callback = vmlgetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Note that *oldmode*, *olderr*, and *oldcallback* refer to settings prior to the call.

Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector
<i>inca</i>	vector increment for the input vector <i>a</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VML mode
<i>callback</i>	address of the callback function

Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VML mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VML mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All the Intel MKL VML mathematical functions can perform in-place operations.

Vector Indexing Methods

VML mathematical functions work only with unit stride. To accommodate arrays with other increments, or more complicated indexing, you can gather the elements into a contiguous vector and then scatter them after the computation is complete.

VML uses the three following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the `<mod>` field in [Function Naming Conventions](#)). For more information on the indexing methods, see [Vector Arguments in VML](#) in Appendix B.

Error Diagnostics

The VML mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

<code>vmlGetErrStatus,</code> <code>vmlSetErrStatus,</code> <code>vmlClearErrStatus</code>	These functions operate with a global variable called VML Error Status. The VML Error Status flags an error, a warning, or a successful execution of a VML function.
<code>vmlGetErrCallBack,</code> <code>vmlSetErrCallBack,</code> <code>vmlClearErrCallBack</code>	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
<code>vmlSetMode, vmlGetMode</code>	These functions get and set a VML mode. If you set a new VML mode using the <code>vmlSetMode</code> function, you can store the previous VML mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VML Error Status variable keeps only the value of the error code. See [Table "Values of the VML Error Status"](#) for possible values. If a VML function does not encounter errors or warnings, it sets the VML Error Status to `VML_STATUS_OK`.

If you use incorrect input arguments to a VML function (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`), the function calls `xerbla` to report errors. See [Table "Values of the VML Error Status"](#) for details

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VML mode, the error handling behavior includes the following operations:

- setting the VML Error Status to a value corresponding to the observed error or warning
- setting the `errno` variable to one of the values described in [Table "Set Values of the `errno` Variable"](#)
- writing error text information to the `stderr` stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorCallBack`.

Set Values of the `errno` Variable

Value of <code>errno</code>	Description
<code>0</code>	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.
<code>EDOM</code>	At least one of array values is out of a range of definition.
<code>ERANGE</code>	At least one of array values caused a singularity, overflow or underflow.

See Also

[vmlGetErrStatus](#) Gets the VML Error Status.

[vmlSetErrStatus](#) Sets the new VML Error Status according to `err` and stores the previous VML Error Status to `olderr`.

[vmlClearErrStatus](#) Sets the VML Error Status to `VML_STATUS_OK` and stores the previous VML Error Status to `olderr`.

[vmlSetErrorCallBack](#) Sets the additional error handler callback function and gets the old callback function.

[vmlGetErrorCallBack](#) Gets the additional error handler callback function.

`vmlClearColorCallBack` Deletes the additional error handler callback function and retrieves the former callback function.

`vmlGetMode` Gets the VML mode.

`vmlSetMode` Sets a new mode for VML functions according to the *mode* parameter and stores the previous VML mode to *oldmode*.

VML Mathematical Functions

This section describes VML functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- `FLOAT_MAX` denotes the maximum number representable in single precision real data type
- `DBL_MAX` denotes the maximum number representable in double precision real data type

Table "VML Mathematical Functions" lists available mathematical functions and associated data types.

VML Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
<code>v?Add</code>	<i>s, d, c, z</i>	Addition of vector elements
<code>v?Sub</code>	<i>s, d, c, z</i>	Subtraction of vector elements
<code>v?Sqr</code>	<i>s, d</i>	Squaring of vector elements
<code>v?Mul</code>	<i>s, d, c, z</i>	Multiplication of vector elements
<code>v?MulByConj</code>	<i>c, z</i>	Multiplication of elements of one vector by conjugated elements of the second vector
<code>v?Conj</code>	<i>c, z</i>	Conjugation of vector elements
<code>v?Abs</code>	<i>s, d, c, z</i>	Computation of the absolute value of vector elements
<code>v?Arg</code>	<i>c, z</i>	Computation of the argument of vector elements
<code>v?LinearFrac</code>	<i>s, d</i>	Linear fraction transformation of vectors
Power and Root Functions		
<code>v?Inv</code>	<i>s, d</i>	Inversion of vector elements
<code>v?Div</code>	<i>s, d, c, z</i>	Division of elements of one vector by elements of the second vector
<code>v?Sqrt</code>	<i>s, d, c, z</i>	Computation of the square root of vector elements
<code>v?InvSqrt</code>	<i>s, d</i>	Computation of the inverse square root of vector elements
<code>v?Cbrt</code>	<i>s, d</i>	Computation of the cube root of vector elements
<code>v?InvCbrt</code>	<i>s, d</i>	Computation of the inverse cube root of vector elements
<code>v?Pow2o3</code>	<i>s, d</i>	Raising each vector element to the power of 2/3
<code>v?Pow3o2</code>	<i>s, d</i>	Raising each vector element to the power of 3/2
<code>v?Pow</code>	<i>s, d, c, z</i>	Raising each vector element to the specified power
<code>v?Powx</code>	<i>s, d, c, z</i>	Raising each vector element to the constant power
<code>v?Hypot</code>	<i>s, d</i>	Computation of the square root of sum of squares
Exponential and Logarithmic Functions		
<code>v?Exp</code>	<i>s, d, c, z</i>	Computation of the exponential of vector elements
<code>v?Expm1</code>	<i>s, d</i>	Computation of the exponential of vector elements decreased by 1
<code>v?Ln</code>	<i>s, d, c, z</i>	Computation of the natural logarithm of vector elements
<code>v?Log10</code>	<i>s, d, c, z</i>	Computation of the denary logarithm of vector elements
<code>v?Log1p</code>	<i>s, d</i>	Computation of the natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
<code>v?Cos</code>	<i>s, d, c, z</i>	Computation of the cosine of vector elements

Function	Data Types	Description
v?Sin	s, d, c, z	Computation of the sine of vector elements
v?SinCos	s, d	Computation of the sine and cosine of vector elements
v?CIS	c, z	Computation of the complex exponent of vector elements (cosine and sine combined to complex value)
v?Tan	s, d, c, z	Computation of the tangent of vector elements
v?Acos	s, d, c, z	Computation of the inverse cosine of vector elements
v?Asin	s, d, c, z	Computation of the inverse sine of vector elements
v?Atan	s, d, c, z	Computation of the inverse tangent of vector elements
v?Atan2	s, d	Computation of the four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
v?Cosh	s, d, c, z	Computation of the hyperbolic cosine of vector elements
v?Sinh	s, d, c, z	Computation of the hyperbolic sine of vector elements
v?Tanh	s, d, c, z	Computation of the hyperbolic tangent of vector elements
v?Acosh	s, d, c, z	Computation of the inverse hyperbolic cosine of vector elements
v?Asinh	s, d, c, z	Computation of the inverse hyperbolic sine of vector elements
v?Atanh	s, d, c, z	Computation of the inverse hyperbolic tangent of vector elements.
Special Functions		
v?Erf	s, d	Computation of the error function value of vector elements
v?Erfc	s, d	Computation of the complementary error function value of vector elements
v?CdfNorm	s, d	Computation of the cumulative normal distribution function value of vector elements
v?ErfInv	s, d	Computation of the inverse error function value of vector elements
v?ErfcInv	s, d	Computation of the inverse complementary error function value of vector elements
v?CdfNormInv	s, d	Computation of the inverse cumulative normal distribution function value of vector elements
v?LGamma	s, d	Computation of the natural logarithm for the absolute value of the gamma function of vector elements
v?TGamma	s, d	Computation of the gamma function of vector elements
Rounding Functions		
v?Floor	s, d	Rounding towards minus infinity
v?Ceil	s, d	Rounding towards plus infinity
v?Trunc	s, d	Rounding towards zero infinity
v?Round	s, d	Rounding to nearest integer
v?NearbyInt	s, d	Rounding according to current mode
v?Rint	s, d	Rounding according to current mode and raising inexact result exception
v?Modf	s, d	Computation of the integer and fractional parts
v?Frac	s, d	Computation of the fractional part

Special Value Notations

This section defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- z, z_1, z_2 , etc. denote complex numbers.
- $i, i^2=-1$ is the imaginary unit.
- x, X, x_1, x_2 , etc. denote real imaginary parts.
- y, Y, y_1, y_2 , etc. denote imaginary parts.
- x and Y represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet NaN and signaling NaN are denoted with QNAN and SNAN, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a + sign before X, Y , etc.

- The IEEE-754 negative infinities or floating-point numbers are denoted with a - sign before X, Y, etc.

`CONJ(z)` and `CIS(z)` are defined as follows:

$$\text{CONJ}(x+i\cdot y) = x - i \cdot y$$

$$\text{CIS}(y) = \cos(y) + i \cdot \sin(y).$$

The special value tables show the result of the function for the `z` argument at the intersection of the `RE(z)` column and the `i*IM(z)` row. If the function raises an exception on the argument `z`, the lower part of this cell shows the raised exception and the VML Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

v?Add

Performs element by element addition of vector `a` and vector `b`.

Syntax

Fortran:

```
call vsadd( n, a, b, y )
call vmsadd( n, a, b, y, mode )
call vdadd( n, a, b, y )
call vmdadd( n, a, b, y, mode )
call vcadd( n, a, b, y )
call vmcadd( n, a, b, y, mode )
call vzadd( n, a, b, y )
call vmzadd( n, a, b, y, mode )
```

C:

```
vsAdd( n, a, b, y );
vmsAdd( n, a, b, y, mode );
vdAdd( n, a, b, y );
vmdAdd( n, a, b, y, mode );
vcAdd( n, a, b, y );
vmcAdd( n, a, b, y, mode );
vzAdd( n, a, b, y );
vmzAdd( n, a, b, y, mode );
```

Include Files

- Fortran: `mkl_vml.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsAdd, vmsAdd DOUBLE PRECISION for vdadd, vmdadd COMPLEX for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd Fortran 90: REAL, INTENT(IN) for vsAdd, vmsAdd DOUBLE PRECISION, INTENT(IN) for vdadd, vmdadd COMPLEX, INTENT(IN) for vcadd, vmcadd DOUBLE COMPLEX, INTENT(IN) for vzadd, vmzadd C: const float* for vsAdd, vmsAdd const double* for vdAdd, vmdAdd const MKL_Complex8* for vcAdd, vmcAdd const MKL_Complex16* for vzAdd, vmzAdd	Fortran: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsAdd, vmsAdd DOUBLE PRECISION for vdadd, vmdadd COMPLEX, for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd Fortran 90: REAL, INTENT(OUT) for vsAdd, vmsAdd	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (OUT) for vdadd, vmdadd	
	COMPLEX, INTENT (OUT) for vcadd, vmcadd	
	DOUBLE COMPLEX, INTENT (OUT) for vzadd, vmzadd	
C:	float* for vsAdd, vmsAdd double* for vdAdd, vmdAdd	
	MKL_Complex8* for vcAdd, vmcAdd	
	MKL_Complex16* for vzAdd, vmzAdd	

Description

The v?Add function performs element by element addition of vector *a* and vector *b*.

Special values for Real Function v?Add(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	+∞	
+∞	-∞	QNAN	INVALID
-∞	+∞	QNAN	INVALID
-∞	-∞	-∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Add}(x_1 + i \cdot y_1, x_2 + i \cdot y_2) = (x_1 + x_2) + i \cdot (y_1 + y_2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x*₁, *x*₂, *y*₁, *y*₂ are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?Sub

Performs element by element subtraction of vector *b* from vector *a*.

Syntax

Fortran:

```
call vssub( n, a, b, y )
call vmssub( n, a, b, y, mode )
call vdsub( n, a, b, y )
```

```
call vmdsub( n, a, b, y, mode )
call vcsub( n, a, b, y )
call vmcsub( n, a, b, y, mode )
call vzsub( n, a, b, y )
call vmzsub( n, a, b, y, mode )
```

C:

```
vsSub( n, a, b, y );
vmsSub( n, a, b, y, mode );
vdSub( n, a, b, y );
vmdSub( n, a, b, y, mode );
vcSub( n, a, b, y );
vmcSub( n, a, b, y, mode );
vzSub( n, a, b, y );
vmzSub( n, a, b, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	<small>FORTRAN 77:</small> INTEGER <small>Fortran 90:</small> INTEGER, INTENT(IN) <small>C:</small> const MKL_INT	Specifies the number of elements to be calculated.

Name	Type	Description
	const MKL_Complex8* for vcSub, vmcSub	
	const MKL_Complex16* for vzSub, vmzSub	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vssub, vmssub DOUBLE PRECISION for vdsub, vmdsub COMPLEX for vcsub, vmcsu DOUBLE COMPLEX for vzsub, vmzsub Fortran 90: REALINTENT(OUT) for vssub, vmssub DOUBLE PRECISION, INTENT(OUT) for vdsub, vmdsub COMPLEX, INTENT(OUT) for vcsub, vmcsu DOUBLE COMPLEX, INTENT(OUT) for vzsub, vmzsub C: float* for vsSub, vmsSub double* for vdSub, vmdSub MKL_Complex8* for vcSub, vmcSub MKL_Complex16* for vzSub, vmzSub	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Sub function performs element by element subtraction of vector *b* from vector *a*.

Special values for Real Function v?Sub(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	-0	
-0	-0	+0	
+∞	+∞	QNAN	INVALID
+∞	-∞	+∞	
-∞	+∞	-∞	

Argument 1	Argument 2	Result	Exception
-∞	-∞	QNAN	INVALID
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sub}(x_1+i*y_1, x_2+i*y_2) = (x_1-x_2) + i*(y_1-y_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?Sqr

Performs element by element squaring of the vector.

Syntax

Fortran:

```
call vssqr( n, a, y )
call vmssqr( n, a, y, mode )
call vdsqr( n, a, y )
call vmdsqr( n, a, y, mode )
```

C:

```
vsSqr( n, a, y );
vmsSqr( n, a, y, mode );
vdSqr( n, a, y );
vmdSqr( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77 : INTEGER Fortran 90 : INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	FORTRAN 77 : REAL for vssqr, vmssqr	Fortran : Array that specifies the input vector <i>a</i> . C : Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION for vdsqr, vmdsqr Fortran 90: REAL, INTENT(IN) for vssqr, vmssqr	
	DOUBLE PRECISION, INTENT(IN) for vdsqr, vmdsqr	
	C: const float* for vsSqr, vmsSqr const double* for vdSqr, vmdSqr	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vssqr, vmssqr DOUBLE PRECISION for vdsqr, vmdsqr Fortran 90: REAL, INTENT(OUT) for vssqr, vmssqr DOUBLE PRECISION, INTENT(OUT) for vdsqr, vmdsqr C: float* for vsSqr, vmsSqr double* for vdSqr, vmdSqr	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The `v?Sqr` function performs element by element squaring of the vector.

Special Values for Real Function `v?Sqr(x)`

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Mul

Performs element by element multiplication of vector *a* and vector *b*.

Syntax

Fortran:

```
call vsmul( n, a, b, y )
call vmsmul( n, a, b, y, mode )
call vdmul( n, a, b, y )
call vmdmul( n, a, b, y, mode )
call vcmul( n, a, b, y )
call vmcmul( n, a, b, y, mode )
call vzmul( n, a, b, y )
call vmzmul( n, a, b, y, mode )
```

C:

```
vsMul( n, a, b, y );
vmsMul( n, a, b, y, mode );
vdMul( n, a, b, y );
vmdMul( n, a, b, y, mode );
vcMul( n, a, b, y );
vmcMul( n, a, b, y, mode );
vzMul( n, a, b, y );
vmzMul( n, a, b, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsmul, vmsmul DOUBLE PRECISION for vdmul, vmdmul COMPLEX for vcmul, vmcmul DOUBLE COMPLEX for vzmul, vmzmul Fortran 90: REAL, INTENT(IN) for vsmul, vmsmul DOUBLE PRECISION, INTENT(IN) for vdmul, vmdmul	Fortran: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
	COMPLEX, INTENT(IN) for vcmul, vmcmul DOUBLE COMPLEX, INTENT(IN) for vzmul, vmzmul C: const float* for vsMul, vmsMul const double* for vdMul, vmdMul const MKL_Complex8* for vcMul, vmcMul const MKL_Complex16* for vzMul, vmzMul	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsmul, vmsmul DOUBLE PRECISION for vdmul, vmdmul COMPLEX, for vcmul, vmcmul DOUBLE COMPLEX for vzmul, vmzmul Fortran 90: REAL, INTENT(OUT) for vsmul, vmsmul DOUBLE PRECISION, INTENT(OUT) for vdmul, vmdmul COMPLEX, INTENT(OUT) for vcmul, vmcmul DOUBLE COMPLEX, INTENT(OUT) for vzmul, vmzmul C: float* for vsMul, vmsMul double* for vdMul, vmdMul MKL_Complex8* for vcMul, vmcMul MKL_Complex16* for vzMul, vmzMul	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Mul` function performs element by element multiplication of vector *a* and vector *b*.

Special values for Real Function v?Mul(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	-0	
-0	+0	-0	
-0	-0	+0	
+0	+∞	QNAN	INVALID
+0	-∞	QNAN	INVALID
-0	+∞	QNAN	INVALID
-0	-∞	QNAN	INVALID
+∞	+0	QNAN	INVALID

-∞	-∞	+∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Mul}(x_1 + i \cdot y_1, x_2 + i \cdot y_2) = (x_1 \cdot x_2 - y_1 \cdot y_2) + i \cdot (x_1 \cdot y_2 + y_1 \cdot x_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?MulByConj

Performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Syntax**Fortran:**

```
call vcmulbyconj( n, a, b, y )
call vmcmulbyconj( n, a, b, y, mode )
call vzmulbyconj( n, a, b, y )
call vmzmulbyconj( n, a, b, y, mode )
```

C:

```
vcMulByConj( n, a, b, y );
vmcMulByConj( n, a, b, y, mode );
vzMulByConj( n, a, b, y );
vmzMulByConj( n, a, b, y, mode );
```

Output Parameters

Name	Type	Description
<i>y</i>	<p>FORTRAN 77: COMPLEX for vcmulbyconj, vmcmulbyconj</p> <p>DOUBLE COMPLEX for vzmulbyconj, vmzmulbyconj</p> <p>Fortran 90: COMPLEX, INTENT(OUT) for vcmulbyconj, vmcmulbyconj</p> <p>DOUBLE COMPLEX, INTENT(OUT) for vzmulbyconj, vmzmulbyconj</p> <p>C: MKL_Complex8* for vcMulByConj, vmcMulByConj</p> <p>MKL_Complex16* for vzMulByConj, vmzMulByConj</p>	<p>Fortran: Array that specifies the output vector <i>y</i>.</p> <p>C: Pointer to an array that contains the output vector <i>y</i>.</p>

Description

The `v?MulByConj` function performs element by element multiplication of vector `a` element and conjugated vector `b` element.

Specifications for special values of the functions are found according to the formula

$$\text{MulByConj}(x_1+i*y_1, x_2+i*y_2) = \text{Mul}(x_1+i*y_1, x_2-i*y_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VML Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

`v?Conj`

Performs element by element conjugation of the vector.

Syntax

Fortran:

```
call vcconj( n, a, y )
call vmcconj( n, a, y, mode )
call vzconj( n, a, y )
call vmzconj( n, a, y, mode )
```

C:

```
vcConj( n, a, y );
vmcConj( n, a, y, mode );
vzConj( n, a, y );
vmzConj( n, a, y, mode );
```

Include Files

- Fortran: `mkl_vml.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>n</code>	<code>FORTRAN 77: INTEGER</code> <code>Fortran 90: INTEGER, INTENT(IN)</code> <code>C: const MKL_INT</code>	Specifies the number of elements to be calculated.

mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: COMPLEX, for vcconj, vmcconj DOUBLE COMPLEX for vzconj, vmzconj Fortran 90: COMPLEX, INTENT(OUT) for vcconj, vmcconj DOUBLE COMPLEX, INTENT(OUT) for vzconj, vmzconj C: MKL_Complex8* for vcConj, vmcConj MKL_Complex16* for vzConj, vmzConj	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Conj function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

v?Abs

Computes absolute value of vector elements.

Syntax

Fortran:

```
call vsabs( n, a, y )
call vmsabs( n, a, y, mode )
call vdabs( n, a, y )
call vmdabs( n, a, y, mode )
call vcabs( n, a, y )
call vmcabs( n, a, y, mode )
```

```
call vzabs( n, a, y )
call vmzabs( n, a, y, mode )
```

C:

```
vsAbs( n, a, y );
vmsAbs( n, a, y, mode );
vdAbs( n, a, y );
vmdAbs( n, a, y, mode );
vcAbs( n, a, y );
vmcAbs( n, a, y, mode );
vzAbs( n, a, y );
vmzAbs( n, a, y, mode );
```

Include Files

mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsabs, vmsabs, vcabs, vmcabs DOUBLE PRECISION for vdabs, vmdabs, vzabs, vmzabs Fortran 90: REAL, INTENT(OUT) for vsabs, vmsabs, vcabs, vmcabs DOUBLE PRECISION, INTENT(OUT) for vdabs, vmdabs, vzabs, vmzabs C: float* for vsAbs, vmsAbs, vcAbs, vmcAbs double* for vdAbs, vmdAbs, vzAbs, vmzAbs	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Abs` function computes an absolute value of vector elements.

Special Values for Real Function `v?Abs(x)`

Argument	Result	Exception
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Abs}(z) = \text{Hypot}(\text{RE}(z), \text{IM}(z)).$$

v?Arg

Computes argument of vector elements.

Syntax

Fortran:

```
call vcarg( n, a, y )
call vmcarg( n, a, y, mode )
```

```
call vzarg( n, a, y )
call vmzarg( n, a, y, mode )
```

C:

```
vcArg( n, a, y );
vmcArg( n, a, y, mode );
vzArg( n, a, y );
vmzArg( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN77: COMPLEX for vcarg, vmcarg DOUBLE COMPLEX for vzarg, vmzarg Fortran 90: COMPLEX, INTENT(IN) for vcarg, vmcarg DOUBLE COMPLEX , INTENT(IN) for vzarg, vmzarg C: const MKL_Complex8* for vcArg, vmcArg const MKL_Complex16* for vzArg, vmcArg	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vcarg, vmcarg DOUBLE PRECISION for vzarg, vmzarg Fortran 90: REAL, INTENT(OUT) for vcarg, vmcarg	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
		DOUBLE PRECISION, INTENT(OUT) for vzarg, vmzarg C: float* for vcArg, vmcArg double* for vzArg, vmcArg

Description

The v?Arg function computes argument of vector elements.

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Arg(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+3·π/4	+π/2	+π/2	+π/2	+π/2	+π/4	NAN
+i·Y	+π		+π/2	+π/2		+0	NAN
+i·0	+π	+π	+π	+0	+0	+0	NAN
-i·0	-π	-π	-π	-0	-0	-0	NAN
-i·Y	-π		-π/2	-π/2		-0	NAN
-i·∞	-3·π/4	-π/2	-π/2	-π/2	-π/2	-π/4	NAN
+i·NAN	NAN						

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $\text{Arg}(z) = \text{Atan2}(\text{IM}(z), \text{RE}(z))$.

v?LinearFrac

Performs linear fraction transformation of vectors *a* and *b* with scalar parameters.

Syntax

Fortran:

```
call vslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
call vdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
```

C:

```
vsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y );
vmsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
vmdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
```

Include Files

Name	Type	Description
	const double* for vdLinearFrac, vmdLinearFrac	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vslinearfrac, vmslinearfrac DOUBLE PRECISION for vdlinearfrac, vmdlinearfrac Fortran 90: REAL, INTENT(OUT) for vslinearfrac, vmslinearfrac DOUBLE PRECISION, INTENT(OUT) for vdlinearfrac, vmdlinearfrac C: float* for vsLinearFrac, vmsLinearFrac double* for vdLinearFrac, vmdLinearFrac	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The `v?LinearFrac` function performs linear fraction transformation of vectors a by vector b with scalar parameters: scaling multipliers $scalea$, $scaleb$ and shifting addends $shifta$, $shiftb$:

$$y[i] = (scalea \cdot a[i] + shifta) / (scaleb \cdot b[i] + shiftb), i=1,2 \dots n$$

The `v?LinearFrac` function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, `v?LinearFrac` sets the VML Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VML Status](#) table). Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters

$2^{E_{\text{MIN}}/2} \leq scalea \leq 2^{(E_{\text{MAX}}-2)/2}$
$2^{E_{\text{MIN}}/2} \leq scaleb \leq 2^{(E_{\text{MAX}}-2)/2}$
$ shifta \leq 2^{E_{\text{MAX}}-2}$
$ shiftb \leq 2^{E_{\text{MAX}}-2}$
$2^{E_{\text{MIN}}/2} \leq a[i] \leq 2^{(E_{\text{MAX}}-2)/2}$
$2^{E_{\text{MIN}}/2} \leq b[i] \leq 2^{(E_{\text{MAX}}-2)/2}$
$a[i] \neq - (shifta/scalea) * (1-\delta_1), \delta_1 \leq 2^{1-(p-1)/2}$
$b[i] \neq - (shiftb/scaleb) * (1-\delta_2), \delta_2 \leq 2^{1-(p-1)/2}$

E_{MIN} and E_{MAX} are the maximum and minimum exponents and p is the number of significant bits (precision) for corresponding data type according to the ANSI/IEEE Std 754-2008 standard ([[IEEE754](#)]):

- for single precision $E_{\text{MIN}} = -126$, $E_{\text{MAX}} = 127$, $p = 24$
- for double precision $E_{\text{MIN}} = -1022$, $E_{\text{MAX}} = 1023$, $p = 53$

The thresholds become less strict for common cases with $\text{scalea}=0$ and/or $\text{scaleb}=0$:

- if $\text{scalea}=0$, there are no limitations for the values of $a[i]$ and shifta
- if $\text{scaleb}=0$, there are no limitations for the values of $b[i]$ and shiftb

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax

Fortran:

```
call vsinv( n, a, y )
call vmsinv( n, a, y, mode )
call vdinv( n, a, y )
call vmdinv( n, a, y, mode )
```

C:

```
vsInv( n, a, y );
vmsInv( n, a, y, mode );
vdInv( n, a, y );
vmdInv( n, a, y, mode );
```

Include Files

- Fortran: `mkl_vml.f90`
- C: `mkl.h`

Description

The `v?Inv` function performs element by element inversion of the vector.

Special Values for Real Function `v?Inv(x)`

Argument	Result	VML Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Div

Performs element by element division of vector *a* by vector *b*

Syntax

Fortran:

```
call vsdiv( n, a, b, y )
```

```
call vmsdiv( n, a, b, y, mode )
call vddiv( n, a, b, y )
call vmddiv( n, a, b, y, mode )

Name	Type	Description
	C: const float* for vsDiv, vmsDiv const double* for vdDiv, vmdDiv const MKL_Complex8* for vcDiv, vmcDiv const MKL_Complex16* for vzDiv, vmzDiv	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL_MAX}$

Precision overflow thresholds for the complex v?Div function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsdiv, vmsdiv DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcdiv DOUBLE COMPLEX for vzdiv, vmzdiv Fortran 90: REAL, INTENT(OUT) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT(OUT) for vddiv, vmddiv COMPLEX, INTENT(OUT) for vcdiv, vmcdiv DOUBLE COMPLEX, INTENT(OUT) for vzdiv, vmzdiv C: float* for vsDiv, vmsDiv double* for vdDiv, vmdDiv MKL_Complex8* for vcDiv, vmcDiv MKL_Complex16* for vzDiv, vmzDiv	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Div function performs element by element division of vector *a* by vector *b*.

Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VML Error Status	Exception
X > +0	+0	+∞	VML_STATUS_SING	ZERODIVIDE
X > +0	-0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	+0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	-0	+∞	VML_STATUS_SING	ZERODIVIDE
+0	+0	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
X > +0	+∞	+0		
X > +0	-∞	-0		
+∞	+∞	QNAN		
-∞	-∞	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x_1+i*y_1, x_2+i*y_2) = (x_1+i*y_1)*(x_2-i*y_2) / (x_2*x_2+y_2*y_2).$$

Overflow in a complex function occurs when x_2+i*y_2 is not zero, x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sqrt

Computes a square root of vector elements.

Syntax**Fortran:**

```
call vssqrt( n, a, y )
call vmssqrt( n, a, y, mode )
call vdsqrt( n, a, y )
call vmdsqrt( n, a, y, mode )
call vc_sqrt( n, a, y )
call vmc_sqrt( n, a, y, mode )
call vzsqrt( n, a, y )
call vmzsqrt( n, a, y, mode )
```

C:

```
vs_sqrt( n, a, y );
vms_sqrt( n, a, y, mode );
vd_sqrt( n, a, y );
vmd_sqrt( n, a, y, mode );
vc_sqrt( n, a, y );
vmc_sqrt( n, a, y, mode );
vz_sqrt( n, a, y );
vmz_sqrt( n, a, y, mode );
```

Name	Type	Description
	COMPLEX for vcsqrt, vmcsqrt	
	DOUBLE COMPLEX for vzsqrt, vmzsqrt	C: Pointer to an array that contains the output vector y .
	Fortran 90: REAL, INTENT(OUT) for vssqrt, vmssqrt	
	DOUBLE PRECISION, INTENT(OUT) for vdsqrt, vmdsqrt	
	COMPLEX, INTENT(OUT) for vcsqrt, vmcsqrt	
	DOUBLE COMPLEX, INTENT(OUT) for vzsqrt, vmzsqrt	
	C: float* for vsqrt, vmsqrt	
	double* for vd_sqrt, vmd_sqrt	
	MKL_Complex8* for vc_sqrt, vmc_sqrt	
	MKL_Complex16* for vz_sqrt, vmz_sqrt	

Description

The $v?Sqrt$ function computes a square root of vector elements.

Special Values for Real Function $v?Sqrt(x)$

Argument	Result	VML Error Status	Exception
$X < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Sqrt(z)$

RE(z) i·IM(z)	$-\infty$	$-x$	-0	$+0$	$+x$	$+\infty$	NAN
$+i\cdot\infty$	$+\infty+i\cdot\infty$						
$+i\cdot Y$	$+0+i\cdot\infty$					$+0+i\cdot 0$	QNAN+i·QNAN
$+i\cdot 0$	$+0+i\cdot\infty$		$+0+i\cdot 0$	$+0+i\cdot 0$		$+0+i\cdot 0$	QNAN+i·QNAN
$-i\cdot 0$	$+0-i\cdot\infty$		$+0-i\cdot 0$	$+0-i\cdot 0$		$+0-i\cdot 0$	QNAN+i·QNAN
$-i\cdot Y$	$+0-i\cdot\infty$					$+0-i\cdot 0$	QNAN+i·QNAN
$-i\cdot\infty$	$+\infty-i\cdot\infty$						
$+i\cdot NAN$	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	$+0+i\cdot NAN$	QNAN+i·QNAN

Notes:

- raises INVALID exception when the real or imaginary part of the argument is SNAN
- $\text{Sqrt}(\text{CONJ}(z)) = \text{CONJ}(\text{Sqrt}(z))$.

v?InvSqrt

Computes an inverse square root of vector elements.

Syntax

Fortran:

```
call vsinvsqrt( n, a, y )
call vmsinvsqrt( n, a, y, mode )
call vdinvsqrt( n, a, y )
call vmdinvsqrt( n, a, y, mode )
```

C:

```
vsInvSqrt( n, a, y );
vmsInvSqrt( n, a, y, mode );
vdInvSqrt( n, a, y );
vmdInvSqrt( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION for vdinvsqrt, vmdinvsqrt Fortran 90: REAL, INTENT(IN) for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION, INTENT(IN) for vdinvsqrt, vmdinvsqrt C: const float* for vsInvSqrt, vmsInvSqrt const double* for vdInvSqrt, vmdInvSqrt	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTTRAN 77: INTEGER*8	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Name	Type	Description

	C: const MKL_INT64	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION for vdinvsqrt, vmdinvsqrt Fortran 90: REAL, INTENT(OUT) for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION, INTENT(OUT) for vdinvsqrt, vmdinvsqrt C: float* for vsInvSqrt, vmsInvSqrt double* for vdInvSqrt, vmdInvSqrt	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?InvSqrt* function computes an inverse square root of vector elements.

Special Values for Real Function *v?InvSqrt(x)*

Argument	Result	VML Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Cbrt

Computes a cube root of vector elements.

Syntax

Fortran:

```
call vscbrt( n, a, y )
call vmscbrt( n, a, y, mode )
call vdcbrt( n, a, y )
call vmdcbrt( n, a, y, mode )
```

C:

```
vsCbrt( n, a, y );
vmsCbrt( n, a, y, mode );
```

```
vdCbrt( n, a, y );
vmdCbrt( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.

Description

The `v?Pow` function computes a to the power b for elements of two vectors.

The real function `v(s/d) Pow` has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then $b[i]$ may be arbitrary. For negative $a[i]$, the value of $b[i]$ must be an integer (either positive or negative).

The complex function `v(c/z) Pow` has no input range limitations.

SNAN	SNAN	QNAN		INVALID

The complex double precision versions of this function, `vzPow` and `vmzPow`, are implemented in the EP accuracy mode only. If used in HA or LA mode, `vzPow` and `vmzPow` set the VML Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VML Status](#) table).

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VML Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?Powx

Raises each element of a vector to the constant power.

Syntax

Fortran:

```
call vspowx( n, a, b, y )
call vmspowl( n, a, b, y, mode )
call vdpoew( n, a, b, y )
call vmdpoew( n, a, b, y, mode )
call vcpoew( n, a, b, y )
call vmcpoew( n, a, b, y, mode )
call vzpoew( n, a, b, y )
call vmzpoew( n, a, b, y, mode )
```

C:

```
vsPowx( n, a, b, y );
vmsPowx( n, a, b, y, mode );
vdPowx( n, a, b, y );
vmdPowx( n, a, b, y, mode );
vcPowx( n, a, b, y );
vmcPowx( n, a, b, y, mode );
vzPowx( n, a, b, y );
vmzPowx( n, a, b, y, mode );
```

Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(a[i]) < (FLT_MAX) ^{1/b}
double precision	abs(a[i]) < (DBL_MAX) ^{1/b}

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vspowx, vmspowx DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx Fortran 90: REAL, INTENT(OUT) for vspowx, vmspowx DOUBLE PRECISION, INTENT(OUT) for vdpowx, vmdpowx COMPLEX, INTENT(OUT) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(OUT) for vzpowx, vmzpowx C: float* for vsPowx, vmsPowx double* for vdPowx, vmdPowx MKL_Complex8* for vcPowx, vmcPowx MKL_Complex16* for vzPowx, vmzPowx	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Powx function raises each element of a vector to the constant power.

The real function v(s/d) Powx has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then b may be arbitrary. For negative $a[i]$, the value of b must be an integer (either positive or negative).

The complex function v(c/z) Powx has no input range limitations.

Special values and VML Error Status treatment are the same as for the v?Pow function.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

Fortran:

```
call vshypot( n, a, b, y )
call vmshypot( n, a, b, y, mode )
call vdhypot( n, a, b, y )
call vmdhypot( n, a, b, y, mode )
```

C:

```
vsHypot( n, a, b, y );
vmsHypot( n, a, b, y, mode );
vdHypot( n, a, b, y );
vmdHypot( n, a, b, y, mode );
```

Input Parameters

Name	Type	Description
<i>n</i>	<small>FORTRAN 77:</small> INTEGER <small>Fortran 90:</small> INTEGER, INTENT(IN) <small>C:</small> const MKL_INT	Number of elements to be calculated.
<i>a, b</i>	<small>FORTRAN 77:</small> REAL for vshypot, vmshypot <small>DOUBLE PRECISION for vdhypot, vmdhypot</small> <small>Fortran 90:</small> REAL, INTENT(IN) for vshypot, vmshypot <small>DOUBLE PRECISION, INTENT(IN) for vdhypot, vmdhypot</small> <small>C:</small> const float* for vsHypot, vmsHypot const double* for vdHypot, vmdHypot	<small>Fortran:</small> Arrays that specify the input vectors <i>a</i> and <i>b</i> <small>C:</small> Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	<small>FORTRAN 77:</small> INTEGER*8 <small>Fortran 90:</small> INTEGER(KIND=8), INTENT(IN) <small>C:</small> const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	<code>abs(a[i]) < sqrt(FLT_MAX)</code> <code>abs(b[i]) < sqrt(FLT_MAX)</code>
double precision	<code>abs(a[i]) < sqrt(DBL_MAX)</code> <code>abs(b[i]) < sqrt(DBL_MAX)</code>

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vshypot, vmshypot DOUBLE PRECISION for vdhypot, vmdhypot Fortran 90: REAL, INTENT(OUT) for vshypot, vmshypot DOUBLE PRECISION, INTENT(OUT) for vdhypot, vmdhypot C: float* for vsHypot, vmsHypot double* for vdHypot, vmdHypot	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The function v?Hypot computes a square root of sum of two squared elements.

Special values for Real Function v?Hypot(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
-0	-0	+0	
$+\infty$	any value	$+\infty$	
any value	$+\infty$	$+\infty$	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Exponential and Logarithmic Functions

v?Exp

Computes an exponential of vector elements.

Syntax

Fortran:

```
call vsexp( n, a, y )
call vmsexp( n, a, y, mode )
```

```
call vdexp( n, a, y )
call vmdexp( n, a, y, mode )
call vcexp( n, a, y )
call vmcexp( n, a, y, mode )
call vzexp( n, a, y )
call vmzexp( n, a, y, mode )
```

C:

```
vsExp( n, a, y );
vmsExp( n, a, y, mode );
vdExp( n, a, y );
vmdExp( n, a, y, mode );
vcExp( n, a, y );
vmcExp( n, a, y, mode );
vzExp( n, a, y );
vmzExp( n, a, y, mode );
```

Input Parameters

Name	Type	Description
n	<small>FORTRAN 77:</small> INTEGER <small>Fortran 90:</small> INTEGER, INTENT(IN) <small>C:</small> const MKL_INT	Specifies the number of elements to be calculated.
a	<small>FORTRAN 77:</small> REAL for vsexp, <small>vmsexp</small> <small>DOUBLE PRECISION for vdexp,</small> <small>vmdexp</small> <small>COMPLEX for vcexp, vmcexp</small> <small>DOUBLE COMPLEX for vzexp, vmzexp</small> <small>Fortran 90:</small> REAL, INTENT(IN) for <small>vsexp, vmsexp</small> <small>DOUBLE PRECISION, INTENT(IN) for</small> <small>vdexp, vmdexp</small> <small>COMPLEX, INTENT(IN) for vcexp,</small> <small>vmcexp</small> <small>DOUBLE COMPLEX, INTENT(IN) for</small> <small>vzexp, vmzexp</small> <small>C: const float* for vsExp, vmsExp</small>	<small>Fortran:</small> Array, specifies the input vector <i>a</i> . <small>C:</small> Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdExp, vmdExp const MKL_Complex8* for vcExp, vmcExp const MKL_Complex16* for vzExp, vmzExp	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Exp Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \ln(\text{FLT_MAX})$
double precision	$a[i] < \ln(\text{DBL_MAX})$

Precision overflow thresholds for the complex v?Exp function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsexp, vmsexp DOUBLE PRECISION for vdexp, vmdexp COMPLEX for vcexp, vmcexp DOUBLE COMPLEX for vzexp, vmzexp Fortran 90: REAL, INTENT(OUT) for vsexp, vmsexp DOUBLE PRECISION, INTENT(OUT) for vdexp, vmdexp COMPLEX, INTENT(OUT) for vcexp, vmcexp DOUBLE COMPLEX, INTENT(OUT) for vzexp, vmzexp C: float* for vsExp, vmsExp double* for vdExp, vmdExp MKL_Complex8* for vcExp, vmcExp MKL_Complex16* for vzExp, vmzExp	Fortran: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The v?Exp function computes an exponential of vector elements.

Special Values for Real Function v?Exp(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Exp(z)

RE(z)	-∞	-X	-0	+0	+X	+∞	NAN
i·IM(z)							
+i·∞	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID
+i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+0·CIS(0)		+1+i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+0·CIS(0)		+1-i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+0-i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is SNAN
- raises the `INVALID` exception on argument $z = -\infty + i \cdot \text{QNAN}$
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when $\text{RE}(z)$, $\text{IM}(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

v?Expm1

Computes an exponential of vector elements decreased by 1.

Syntax**Fortran:**

```
call vsexpml( n, a, y )
call vmsexpml( n, a, y, mode )
call vdexpml( n, a, y )
call vdexpml( n, a, y, mode )
```

C:

```
vsExpml( n, a, y );
```

```
vmsExpm1( n, a, y, mode );
vdExpm1( n, a, y );
vmdExpm1( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsexpm1, vmsexpm1 DOUBLE PRECISION for vdexpm1, vmdexpm1 Fortran 90: REAL, INTENT(IN) for vsexpm1, vmsexpm1 DOUBLE PRECISION, INTENT(IN) for vdexpm1, vmdexpm1 C: const float* for vsExpm1, vmsExpm1 const double* for vdExpm1, vmdExpm1	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Expm1 Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \ln(\text{FLT_MAX})$
double precision	$a[i] < \ln(\text{DBL_MAX})$

Output Parameters

Name	Type	Description
<i>y</i>	FORTAN 77: REAL for vsexpm1, vmsexpm1 DOUBLE PRECISION for vdexpm1, vmdexpm1	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
		Fortran 90: REAL, INTENT(OUT) for vsexpm1, vmsexpm1
		DOUBLE PRECISION, INTENT(OUT) for vdexpm1, vmdexpm1
		C: float* for vsExpm1, vmsExpm1 double* for vdExpm1, vmdExpm1

Description

The $v\text{?Expm1}$ function computes an exponential of vector elements decreased by 1.

Special Values for Real Function $v\text{?Expm1}(x)$

Argument	Result	VML Error Status	Exception
+0	+0		
-0	+0		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	-1		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Ln

Computes natural logarithm of vector elements.

Syntax

Fortran:

```
call vsln( n, a, y )
call vmsln( n, a, y, mode )
call vdln( n, a, y )
call vmdln( n, a, y, mode )
call vcln( n, a, y )
call vmcln( n, a, y, mode )
call vzln( n, a, y )
call vmzln( n, a, y, mode )
```

C:

```
vsLn( n, a, y );
vmsLn( n, a, y, mode );
vdLn( n, a, y );
vmdLn( n, a, y, mode );
vcLn( n, a, y );
vmcln( n, a, y, mode );
vzLn( n, a, y );
```

```
vmzLn( n, a, y, mode );
```

Include Files

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

v?Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vmslog10( n, a, y, mode )
call vdlog10( n, a, y )
call vmdlog10( n, a, y, mode )
call vclog10( n, a, y )
call vmclog10( n, a, y, mode )
call vzlog10( n, a, y )
call vmzlog10( n, a, y, mode )
```

C:

```
vsLog10( n, a, y );
vmsLog10( n, a, y, mode );
vdLog10( n, a, y );
vmdLog10( n, a, y, mode );
vcLog10( n, a, y );
vmcLog10( n, a, y, mode );
vzLog10( n, a, y );
vmzLog10( n, a, y, mode );
```

Include Files

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )
call vmslog1p( n, a, y, mode )
call vdlog1p( n, a, y )
call vmdlog1p( n, a, y, mode )
```

C:

```
vsLog1p( n, a, y );
vmsLog1p( n, a, y, mode );
vdLog1p( n, a, y );
vmdLog1p( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.

Name	Type	Description
a	<p>FORTRAN 77: REAL for vslog1p, vmslog1p</p> <p>DOUBLE PRECISION for vdlog1p, vmdlog1p</p> <p>Fortran 90: REAL, INTENT(IN) for vslog1p, vmslog1p</p> <p>DOUBLE PRECISION, INTENT(IN) for vdlog1p, vmdlog1p</p> <p>C: const float* for vsLog1p, vmsLog1p</p> <p>const double* for vdLog1p, vmdLog1p</p>	<p>Fortran: Array that specifies the input vector a.</p> <p>C: Pointer to an array that contains the input vector a.</p>

Output Parameters

Name	Type	Description
y	<p>FORTRAN 77: REAL for vslog1p, vmslog1p</p> <p>DOUBLE PRECISION for vdlog1p, vmdlog1p</p> <p>Fortran 90: REAL, INTENT(OUT) for vslog1p, vmslog1p</p> <p>DOUBLE PRECISION, INTENT(OUT) for vdlog1p, vmdlog1p</p> <p>C: float* for vsLog1p, vmsLog1p</p> <p>double* for vdLog1p, vmdLog1p</p>	<p>Fortran: Array that specifies the output vector y.</p> <p>C: Pointer to an array that contains the output vector y.</p>

Description

The `v?Log1p` function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function `v?Log1p(x)`

Argument	Result	VML Error Status	Exception
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < -1$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		

Argument	Result	VML Error Status	Exception
SNAN	QNAN		INVALID

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )
call vmscos( n, a, y, mode )
call vdcos( n, a, y )
call vmdcos( n, a, y, mode )
call vccos( n, a, y )
call vmccos( n, a, y, mode )
call vzcos( n, a, y )
call vmzcos( n, a, y, mode )
```

C:

```
vsCos( n, a, y );
vmsCos( n, a, y, mode );
vdCos( n, a, y );
vmdCos( n, a, y, mode );
vcCos( n, a, y );
vmcCos( n, a, y, mode );
vzCos( n, a, y );
vmzCos( n, a, y, mode );
```

Include Files

mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vscos, vmscos	Fortran: Array that specifies the output vector y .
	DOUBLE PRECISION for vdcos, vmdcos	C: Pointer to an array that contains the output vector y .
	COMPLEX for vccos, vmccos	
	DOUBLE PRECISION for vzcos, vmzcos	
	Fortran 90: REAL, INTENT (OUT) for vscos, vmscos	
	DOUBLE PRECISION, INTENT (OUT) for vdcos, vmdcos	
	COMPLEX, INTENT (OUT) for vccos, vmccos	

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vzcos, vmzcos C: float* for vsCos, vmsCos double* for vdCos, vmdCos MKL_Complex8* for vcCos, vmcCos MKL_Complex16* for vzCos, vmzCos	

Description

The v?Cos function computes cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Cos(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

v?Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
call vmssin( n, a, y, mode )
call vdsin( n, a, y )
call vmdsin( n, a, y, mode )
call vcsin( n, a, y )
call vmcsin( n, a, y, mode )
call vzsin( n, a, y )
call vmzsin( n, a, y, mode )
```

C:

```
vsSin( n, a, y );
vmsSin( n, a, y, mode );
```

```
vdSin( n, a, y );
vmdSin( n, a, y, mode );
vcSin( n, a, y );
vmcSin( n, a, y, mode );
vzSin( n, a, y );
vmzSin( n, a, y, mode );
```

<i>mode</i>	FORTAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssin, vmssin DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin Fortran 90: REAL, INTENT(OUT) for vssin, vmssin DOUBLE PRECISION, INTENT(OUT) for vdsin, vmdsin COMPLEX, INTENT(OUT) for vcsin, vmcsin DOUBLE PRECISION, INTENT(OUT) for vzsin, vmzsin C: float* for vsSin, vmsSin double* for vdSin, vmdSin MKL_Complex8* for vcSin, vmcSin MKL_Complex16* for vzSin, vmzSin	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Sin(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sin}(z) = -i * \text{Sinh}(i * z).$$

v?SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
call vmssincos( n, a, y, z, mode )
call vdsincos( n, a, y, z )
call vmdsincos( n, a, y, z, mode )
```

C:

```
vsSinCos( n, a, y, z );
vmsSinCos( n, a, y, z, mode );
vdSinCos( n, a, y, z );
vmdSinCos( n, a, y, z, mode );
```

Include Files

QNAN	QNAN	QNAN		
SNAN	QNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sin}(z) = -i * \text{Sinh}(i * z).$$

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Fortran:

```
call vccis( n, a, y )
call vmccis( n, a, y, mode )
call vzcis( n, a, y )
call vmzcis( n, a, y, mode )
```

C:

```
vcCIS( n, a, y );
```

```
vmcCIS( n, a, y, mode );
vzCIS( n, a, y );
vmzCIS( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vccis, vmccis DOUBLE PRECISION for vzcis, vmzcis Fortran 90: REAL, INTENT(IN) for vccis, vmccis DOUBLE PRECISION, INTENT(IN) for vzcis, vmzcis C: const float* for vcCIS, vmcCIS const double* for vzCIS, vmzCIS	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: COMPLEX for vccis, vmccis DOUBLE COMPLEX for vzcis, vmzcis Fortran 90: COMPLEX, INTENT(OUT) for vccis, vmccis DOUBLE COMPLEX, INTENT(OUT) for vzcis, vmzcis C: MKL_Complex8* for vcCIS, vmcCIS MKL_Complex16* for vzCIS, vmzCIS	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?CIS` function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function `v?CIS(x)`

x	CIS(x)
+ ∞	QNAN+i·QNAN INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VML Error Status to `VML_STATUS_ERRDOM` for $x=+\infty, x=-\infty$

`v?Tan`

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )
call vmstan( n, a, y, mode )
call vdtan( n, a, y )
call vmdtan( n, a, y, mode )
call vctan( n, a, y )
call vmctan( n, a, y, mode )
call vztan( n, a, y )
call vmztan( n, a, y, mode )
```

C:

```
vsTan( n, a, y );
vmsTan( n, a, y, mode );
vdTan( n, a, y );
vmdTan( n, a, y, mode );
vcTan( n, a, y );
vmcTan( n, a, y, mode );
vzTan( n, a, y );
```

```
vmzTan( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vstan, vmstan DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan Fortran 90: REAL, INTENT(IN) for vstan, vmstan DOUBLE PRECISION, INTENT(IN) for vdtan, vmdtan COMPLEX, INTENT(IN) for vctan, vmctan DOUBLE COMPLEX, INTENT(IN) for vztan, vmztan C: const float* for vsTan, vmsTan const double* for vdTan, vmdTan const MKL_Complex8* for vcTan, vmcTan const MKL_Complex16* for vzTan, vmzTan	Fortran: Array that specifies the input vector a. C: Pointer to an array that contains the input vector a.
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vstan, vmstan	Fortran: Array that specifies the output vector y.

Name	Type	Description
	DOUBLE PRECISION for vdTan, vmdTan	C: Pointer to an array that contains the output vector y .
	COMPLEX for vctan, vmctan	
	DOUBLE COMPLEX for vzTan, vmzTan	
	Fortran 90: REAL, INTENT(OUT) for vstan, vmstan	
	DOUBLE PRECISION, INTENT(OUT) for vdTan, vmdTan	
	COMPLEX, INTENT(OUT) for vctan, vmctan	
	DOUBLE COMPLEX, INTENT(OUT) for vzTan, vmzTan	
	C: float* for vsTan, vmsTan	
	double* for vdTan, vmdTan	
	MKL_Complex8* for vcTan, vmcTan	
	MKL_Complex16* for vzTan, vmzTan	

Description

The v?Tan function computes tangent of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Tan(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Tan}(z) = -i \cdot \text{Tanh}(i \cdot z).$$

v?Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
call vmsacos( n, a, y, mode )
call vdacos( n, a, y )
```

```

call vmdacos( n, a, y, mode )
call vcacos( n, a, y )
call vmcacos( n, a, y, mode )
call vzacos( n, a, y )
call vmzacos( n, a, y, mode )

```

C:

```

vsAcos( n, a, y );
vmsAcos( n, a, y, mode );
vdAcos( n, a, y );
vmdAcos( n, a, y, mode );
vcAcos( n, a, y );
vmcAcos( n, a, y, mode );
vzAcos( n, a, y );
vmzAcos( n, a, y, mode );

```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vsacos, vmsacos DOUBLE PRECISION for vdacos, vmdacos COMPLEX for vcacos, vmcacos DOUBLE COMPLEX for vzacos, vmzacos Fortran 90: REAL, INTENT(IN) for vsacos, vmsacos DOUBLE PRECISION, INTENT(IN) for vdacos, vmdacos COMPLEX, INTENT(IN) for vcacos, vmcacos DOUBLE COMPLEX, INTENT(IN) for vzacos, vmzacos	Fortran: Array that specifies the input vector a. C: Pointer to an array that contains the input vector a.

Name	Type	Description
	C: const float* for vsAcos, vmsAcos const double* for vdAcos, vmdAcos const MKL_Complex8* for vcAcos, vmcAcos const MKL_Complex16* for vzAcos, vmzAcos	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsacos, vmsacos DOUBLE PRECISION for vdacos, vmdacos COMPLEX for vcacos, vmcacos DOUBLE COMPLEX for vzacos, vmzacos Fortran 90: REAL, INTENT (OUT) for vsacos, vmsacos DOUBLE PRECISION, INTENT (OUT) for vdacos, vmdacos COMPLEX, INTENT (OUT) for vcacos, vmcacos DOUBLE COMPLEX, INTENT (OUT) for vzacos, vmzacos	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Acos` function computes inverse cosine of vector elements.

Special Values for Real Function `v?Acos(x)`

Argument	Result	VML Error Status	Exception
+0	$+\pi/2$		

Argument	Result	VML Error Status	Exception
-0	+π/2		
+1	+0		
-1	+π		
X > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Acos(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	$+\frac{3\pi}{4} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{4} - i \cdot \infty$	QNAN-i·∞
+i·Y	$+\pi - i \cdot \infty$					$+0 - i \cdot \infty$	QNAN+i·QNAN
+i·0	$+\pi - i \cdot \infty$		$+\frac{\pi}{2} - i \cdot 0$	$+\frac{\pi}{2} - i \cdot 0$		$+0 - i \cdot \infty$	QNAN+i·QNAN
-i·0	$+\pi + i \cdot \infty$		$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$		$+0 + i \cdot \infty$	QNAN+i·QNAN
-i·Y	$+\pi + i \cdot \infty$					$+0 + i \cdot \infty$	QNAN+i·QNAN
-i·∞	$+\frac{3\pi}{4} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{4} + i \cdot \infty$	QNAN+i·∞
+i·NAN	QNAN+i·∞	QNAN+i·QNAN	$+\frac{\pi}{2} + i \cdot \text{QNAN}$	$+\frac{\pi}{2} + i \cdot \text{QNAN}$	QNAN+i·QNAN	QNAN+i·∞	QNAN+i·QNAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $\text{Acos}(\text{CONJ}(z)) = \text{CONJ}(\text{Acos}(z))$.

v?Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vmsasin( n, a, y, mode )
call vdasin( n, a, y )
call vmdasin( n, a, y, mode )
call vcasin( n, a, y )
call vmcasin( n, a, y, mode )
call vzasin( n, a, y )
call vmzasin( n, a, y, mode )
```

C:

```
vsAsin( n, a, y );
vmsAsin( n, a, y, mode );
vdAsin( n, a, y );
vmdAsin( n, a, y, mode );
vcAsin( n, a, y );
vmcAsin( n, a, y, mode );
vzAsin( n, a, y );
vmzAsin( n, a, y, mode );
```

Include Files

SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Atan}(z) = -i \cdot \text{Atanh}(i \cdot z).$$

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vmsatan2( n, a, b, y, mode )
call vdatan2( n, a, b, y )
call vmdatn2( n, a, b, y, mode )
```

C:

```
vsAtan2( n, a, b, y );
vmsAtan2( n, a, b, y, mode );
vdAtan2( n, a, b, y );
vmdatn2( n, a, b, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsatan2, vmsatan2 DOUBLE PRECISION for vdatan2, vmdataan2 Fortran 90: REAL, INTENT(IN) for vsatan2, vmsatan2 DOUBLE PRECISION, INTENT(IN) for vdatan2, vmdataan2 C: const float* for vsAtan2, vmsAtan2 const double* for vdAtan2, vmdAtan2	Fortran: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsatan2, vmsatan2 DOUBLE PRECISION for vdatan2, vmdataan2 Fortran 90: REAL, INTENT(OUT) for vsatan2, vmsatan2 DOUBLE PRECISION, INTENT(OUT) for vdatan2, vmdataan2 C: float* for vsAtan2, vmsAtan2 double* for vdAtan2, vmdAtan2	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector *y* are computed as the four-quadrant arctangent of $a[i] / b[i]$.

Hyperbolic Functions

v?Cosh

Computes hyperbolic cosine of vector elements.

Syntax

Fortran:

```
call vscosh( n, a, y )
call vmscosh( n, a, y, mode )
call vdcosh( n, a, y )
call vmdcosh( n, a, y, mode )
call vccosh( n, a, y )
call vmccosh( n, a, y, mode )
call vzcosh( n, a, y )
call vmzcosh( n, a, y, mode )
```

C:

```
vsCosh( n, a, y );
vmsCosh( n, a, y, mode );
vdCosh( n, a, y );
vmdCosh( n, a, y, mode );
vcCosh( n, a, y );
vmcCosh( n, a, y, mode );
vzCosh( n, a, y );
vmzCosh( n, a, y, mode );
```

	const double* for vdCosh, vmdCosh	
	const MKL_Complex8* for vcCosh, vmCosh	
	const MKL_Complex16* for vzCosh, vmzCosh	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Cosh Function

Data Type	Threshold Limitations on Input Parameters
single precision	-Ln(FLT_MAX)-Ln2 < a[i] < Ln(FLT_MAX)+Ln2
double precision	-Ln(DBL_MAX)-Ln2 < a[i] < Ln(DBL_MAX)+Ln2

Precision overflow thresholds for the complex v?Cosh function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vscosh, vmscosh	Fortran: Array that specifies the output vector y.
	DOUBLE PRECISION for vdcoh, vmdcoh	C: Pointer to an array that contains the output vector y.
	COMPLEX for vcccoh, vmcccoh	
	DOUBLE COMPLEX for vzccoh, vmzcoh	
	Fortran 90: REAL, INTENT(OUT) for vscosh, vmscosh	
	DOUBLE PRECISION, INTENT(OUT) for vdcoh, vmdcoh	
	COMPLEX, INTENT(OUT) for vcccoh, vmcccoh	
	DOUBLE COMPLEX, INTENT(OUT) for vzccoh, vmzcoh	

Name	Type	Description
	C: float* for vsCosh, vmsCosh	
	double* for vdCosh, vmdCosh	
	MKL_Complex8* for vcCosh, vmCosh	
	MKL_Complex16* for vzCosh, vmzCosh	

Description

The $v?Cosh$ function computes hyperbolic cosine of vector elements.

Special Values for Real Function $v?Cosh(x)$

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Cosh(z)$

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+∞-i·0		+1-i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+∞+i·0		+1+i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·0 INVALID	QNAN-i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+∞+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN-i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the INVALID exception when the real or imaginary part of the argument is SNAN
- raises the OVERFLOW exception and sets the VML Error Status to VML_STATUS_OVERFLOW in the case of overflow, that is, when $RE(z)$, $IM(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Cosh}(\text{CONJ}(z)) = \text{CONJ}(\text{Cosh}(z))$
- $\text{Cosh}(-z) = \text{Cosh}(z)$.

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vmssinh( n, a, y, mode )
call vdsinh( n, a, y )
call vmdsinh( n, a, y, mode )
call vcsinh( n, a, y )
call vmcsinh( n, a, y, mode )
call vzsinh( n, a, y )
call vmzsinh( n, a, y, mode )
```

C:

```
vsSinh( n, a, y );
vmsSinh( n, a, y, mode );
vdSinh( n, a, y );
vmdSinh( n, a, y, mode );
vcSinh( n, a, y );
vmcSinh( n, a, y, mode );
vzSinh( n, a, y );
vmzSinh( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Sinh}(\text{CONJ}(z)) = \text{CONJ}(\text{Sinh}(z))$

- $\text{Sinh}(-z) = -\text{Sinh}(z)$.

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
call vmstanh( n, a, y, mode )
call vdtanh( n, a, y )
call vmdtanh( n, a, y, mode )
call vctanh( n, a, y )
call vmctanh( n, a, y, mode )
call vztanh( n, a, y )
call vmztanh( n, a, y, mode )
```

C:

```
vsTanh( n, a, y );
vmsTanh( n, a, y, mode );
vdTanh( n, a, y );
vmdTanh( n, a, y, mode );
vcTanh( n, a, y );
vmcTanh( n, a, y, mode );
vzTanh( n, a, y );
vmzTanh( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Description

The `Erf` function computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x) ,$

where erfc is the complementary error function.

$$2. \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

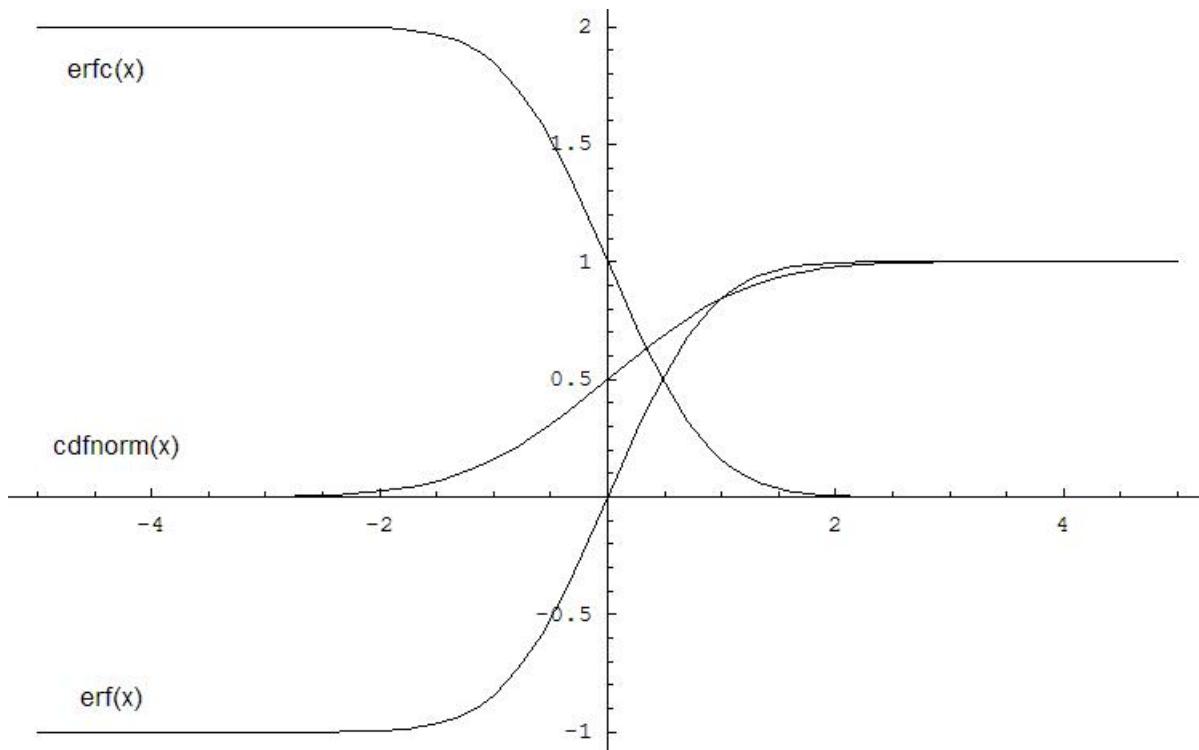

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

The following figure illustrates the relationships among `Erf`, `Erfc`, `CdfNorm`.

Erf Family Functions Relationship

Useful relations for these functions:

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf}\left(\frac{x}{\sqrt{2}}\right) \right) = 1 - \frac{1}{2} \text{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

C: Pointer to an array that contains the output vector y.

Description

The `Erfc` function computes the complementary error function values for elements of the input vector `a` and writes them to the output vector `y`.

The complementary error function is defined as follows:

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_0^{\infty} e^{-t^2} dt$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x)$.
2. $\Phi(x) = \frac{1}{2} \text{erf}\left(\frac{x}{\sqrt{2}}\right)$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

y	FORTRAN 77: REAL for vserfinv, vmserfinv DOUBLE PRECISION for vderfinv, vmderfinv Fortran 90: REAL, INTENT(OUT) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT(OUT) for vderfinv, vmderfinv C: float* for vsErfInv, vmsErfInv double* for vdErfInv, vmdErfInv	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The `ErfInv` function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \text{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$$

where erfc is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

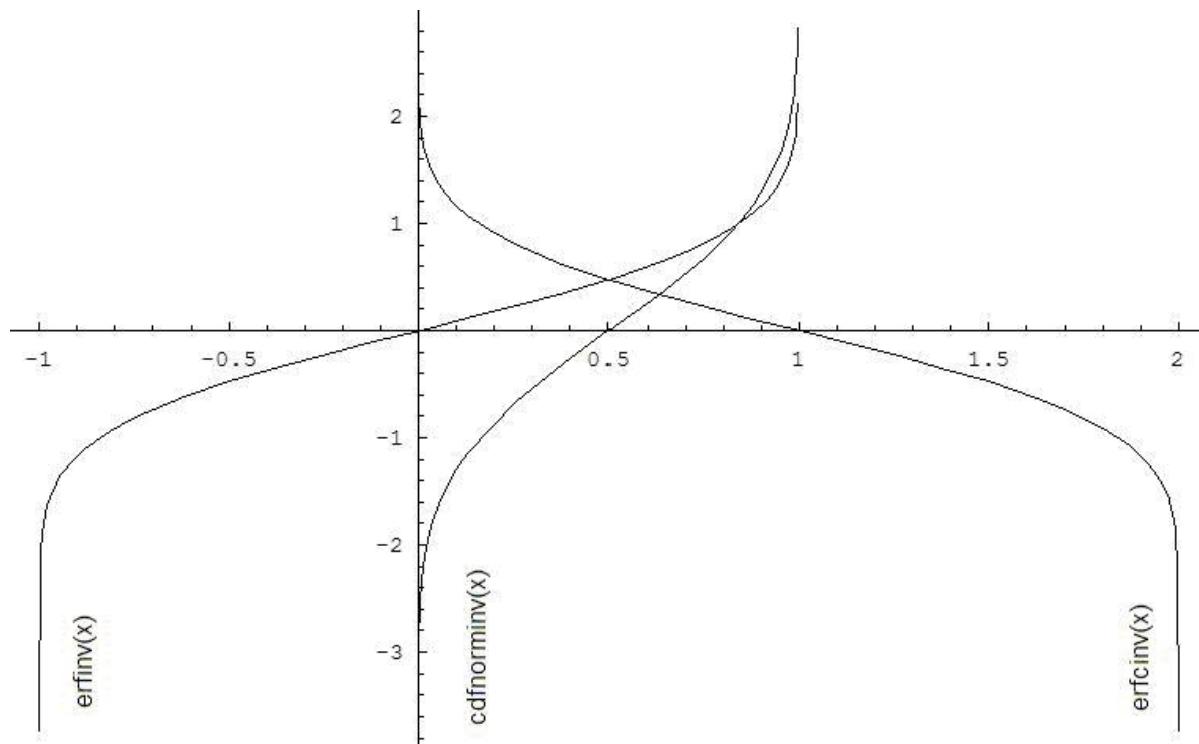

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

[Figure "ErfInv Family Functions Relationship"](#) illustrates the relationships among `ErfInv` family functions (`ErfInv`, `ErfcInv`, `CdfNormInv`).

[ErfInv Family Functions Relationship](#)

Useful relations for these functions:

erfcinv(x) = erfinv(1 - x)

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

Description

The `ErfcInv` function computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complementary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{erfinv}(x) = \text{erf}^{-1}(x)$$

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where $\text{erf}(x)$ denotes the error function and $\text{erfinv}(x)$ denotes the inverse error function.

See also [Figure "ErfInv Family Functions Relationship"](#) in [ErfInv](#) function description for [ErfcInv](#) function relationship with the other functions of [ErfInv](#) family.

v?CdfNormInv

Computes the inverse cumulative normal distribution function values of vector elements.

Syntax

Fortran:

```
call vscdfnorminv( n, a, y )
call vmscdfnorminv( n, a, y, mode )
call vdcdfnorminv( n, a, y )
call vmdcdfnorminv( n, a, y, mode )
```

C:

```
vsCdfNormInv( n, a, y );
vmsCdfNormInv( n, a, y, mode );
vdCdfNormInv( n, a, y );
vmdCdfNormInv( n, a, y, mode );
```

Include Files

<i>mode</i>	<small>FORTRAN 77:</small> INTEGER*8 <small>Fortran 90:</small> INTEGER(KIND=8), INTENT(IN) <small>C:</small> const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<small>FORTRAN 77:</small> REAL for vscdfnorminv, vmscdfnorminv <small>DOUBLE PRECISION for</small> vdcdfnorminv, vmdcdfnorminv <small>Fortran 90:</small> REAL, INTENT(OUT) for vscdfnorminv, vmscdfnorminv <small>DOUBLE PRECISION, INTENT(OUT) for</small> vdcdfnorminv, vmdcdfnorminv <small>C:</small> float* for vsCdfNormInv, vmsCdfNormInv <small>double* for</small> vdCdfNormInv, vmdCdfNormInv	<small>Fortran:</small> Array that specifies the output vector <i>y</i> . <small>C:</small> Pointer to an array that contains the output vector <i>y</i> .

Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector a and writes them to the output vector y .

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

See also [Figure "ErfInv Family Functions Relationship"](#) in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

<i>mode</i>	<small>FORTRAN 77:</small> INTEGER*8 <small>Fortran 90:</small> INTEGER(KIND=8), INTENT(IN) <small>C:</small> const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<small>FORTRAN 77:</small> REAL for vslgamma, vmslgamma <small>DOUBLE PRECISION</small> for vdlgamma, vmdlgamma <small>Fortran 90:</small> REAL, INTENT(OUT) for vs lgamma, vms lgamma <small>DOUBLE PRECISION, INTENT(OUT)</small> for vd lgamma, vmd lgamma	<small>Fortran:</small> Array that specifies the output vector <i>y</i> . <small>C:</small> Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
C:	float* for vsLGamma, vmsLGamma double* for vdLGamma, vmdLGamma	

Description

The `v?LGamma` function computes the natural logarithm of the absolute value of gamma function for elements of the input vector a and writes them to the output vector y . Precision overflow thresholds for the `v?LGamma` function are beyond the scope of this document. If the result does not meet the target precision, the function raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW`.

+?	+?		
X > overflow	+?	VML_STATUS_OVERFLOW	OVERFLOW
QNAN	QNAN		
SNAN	QNAN		INVALID

`v?TGamma`

Computes the gamma function of vector elements.

Syntax

Fortran:

```
call vstgamma( n, a, y )
call vmstgamma( n, a, y, mode )
call vdtgamma( n, a, y )
call vmdtgamma( n, a, y, mode )
```

C:

```
vstGamma( n, a, y );
vmstGamma( n, a, y, mode );
vdtGamma( n, a, y );
vmdtGamma( n, a, y, mode );
```

Include Files

- Fortran: `mkl_vml.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.

SNAN	QNAN		INVALID

Rounding Functions

v?Floor

Computes an integer value rounded towards minus infinity for each vector element.

Syntax

Fortran:

```
call vsfloor( n, a, y )
call vmsfloor( n, a, y, mode )
call vdfloor( n, a, y )
call vmdfloor( n, a, y, mode )
```

C:

```
vsFloor( n, a, y );
vmsFloor( n, a, y, mode );
vdFloor( n, a, y );

v?Rint

Computes a rounded integer value in the current rounding mode.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vmsrint( n, a, y, mode )
call vdrint( n, a, y )
call vmdrint( n, a, y, mode )
```

C:

```
vsRint( n, a, y );
vmsRint( n, a, y, mode );
vdRint( n, a, y );
vmdRint( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint Fortran 90: REAL, INTENT(IN) for vsrint, vmsrint DOUBLE PRECISION, INTENT(IN) for vdrint, vmdrint C: const float* for vsRint, vmsRint const double* for vdRint, vmdRint	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint Fortran 90: REAL, INTENT(OUT) for vsrint, vmsrint DOUBLE PRECISION, INTENT(OUT) for vdrint, vmdrint C: float* for vsRint, vmsRint double* for vdRint, vmdRint	Fortran: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Rint` function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- $f(0.5) = 0$, for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$, for rounding modes set to plus infinity.
- $f(-1.5) = -2$, for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function v?Rint(x)

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Modf

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vmsmodf( n, a, y, z, mode )
call vdmodf( n, a, y, z )
call vmdmodf( n, a, y, z, mode )
```

C:

```
vsModf( n, a, y, z );
vmsModf( n, a, y, z, mode );
vdModf( n, a, y, z );
vmdModf( n, a, y, z, mode );
```

Output Parameters

Name	Type	Description
y, z	FORTRAN 77: REAL for vsmodf, vmsmodf	Fortran: Array, specifies the output vector y and z .
	DOUBLE PRECISION for vdmodf, vmdmodf	C: Pointer to an array that contains the output vector y and z .
	Fortran 90: REAL, INTENT(OUT) for vsmodf, vmsmodf	
	DOUBLE PRECISION, INTENT(OUT) for vdmodf, vmdmodf	
	C: float* for vsModf, vmsModf	
	double* for vdModf, vmdModf	

Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

Special Values for Real Function v?Modf(x)

Argument	Result: $y(i)$	Result: $z(i)$	Exception
+0	+0	+0	

Argument	Result: $y(i)$	Result: $z(i)$	Exception
-0	-0	-0	
$+\infty$	$+\infty$	$+0$	
$-\infty$	$-\infty$	-0	
SNAN	QNAN	QNAN	INVALID
QNAN	QNAN	QNAN	

v?Frac

Computes a signed fractional part for each vector element.

Syntax

Fortran:

```
call vsfrac( n, a, y )
call vmsfrac( n, a, y, mode )
call vdfrac( n, a, y )
call vmdfrac( n, a, y, mode )
```

C:

```
vsFrac( n, a, y );
vmsFrac( n, a, y, mode );
vdFrac( n, a, y );
vmdFrac( n, a, y, mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsfrac, vmsfrac DOUBLE PRECISION for vdfrac, vmdfrac Fortran 90: REAL, INTENT(IN) for vsfrac, vmsfrac DOUBLE PRECISION, INTENT(IN) for vdfrac, vmdfrac C: const float* for vsFrac, vmsFrac	Fortran: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdFrac, vmdFrac	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsfrac, vmsfrac DOUBLE PRECISION for vdfrac, vmdfrac Fortran 90: REAL, INTENT(OUT) for vsfrac, vmsfrac DOUBLE PRECISION, INTENT(OUT) for vdfrac, vmdfrac C: float* for vsFrac, vmsFrac double* for vdFrac, vmdFrac	Fortran: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, & a_i \geq 0 \\ a_i - \lceil a_i \rceil, & a_i < 0 \end{cases}$$

Special Values for Real Function v?Frac(x)

QNAN	QNAN	

VML Pack/Unpack Functions

This section describes VML functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).

The table below lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

VML Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?Pack	s, d, c, z	I,V,M	Gathers elements of arrays, indexed by different methods.
v?Unpack	s, d, c, z	I,V,M	Scatters vector elements to arrays with different indexing.

See Also

[Vector Arguments in VML](#)

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax**Fortran:**

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
call vcpacki( n, a, inca, y )
call vcpackv( n, a, ia, y )
call vcpackm( n, a, ma, y )
call vzpacki( n, a, inca, y )
call vzpackv( n, a, ia, y )
call vzpackm( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
vcPackI( n, a, inca, y );
vcPackV( n, a, ia, y );
vcPackM( n, a, ma, y );
vzPackI( n, a, inca, y );
vzPackV( n, a, ia, y );
vzPackM( n, a, ma, y );
```

Name	Type	Description
	const MKL_Complex16* for vzPackI, vzPackV, vzPackM	

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
call vcunpacki( n, a, y, incy )
call vcunpackv( n, a, y, iy )
call vcunpackm( n, a, y, my )
call vzunpacki( n, a, y, incy )
call vzunpackv( n, a, y, iy )
call vzunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
vcUnpackI( n, a, y, incy );
vcUnpackV( n, a, y, iy );
vcUnpackM( n, a, y, my );
vzUnpackI( n, a, y, incy );
vzUnpackV( n, a, y, iy );
vzUnpackM( n, a, y, my );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	<p>FORTRAN 77: INTEGER</p> <p>Fortran 90: INTEGER, INTENT(IN)</p> <p>C: const MKL_INT</p>	Specifies the number of elements to be calculated.

VML Service Functions

The VML Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VML Service functions and their short description.

VML Service Functions

Function Short Name	Description
vmlSetMode	Sets the VML mode
vmlGetMode	Gets the VML mode
MKLFreeTls	Frees allocated VML/VSL thread local storage memory from within DllMain routine (Windows* OS only)
vmlSetErrStatus	Sets the VML Error Status
vmlGetErrStatus	Gets the VML Error Status
vmlClearErrStatus	Clears the VML Error Status
vmlSetErrorHandler	Sets the additional error handler callback function
vmlGetErrorHandler	Gets the additional error handler callback function
vmlClearErrorHandler	Deletes the additional error handler callback function

vmlSetMode

Sets a new mode for VML functions according to the mode parameter and stores the previous VML mode to oldmode.

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_UINT	Specifies the VML mode to be set.

Output Parameters

Name	Type	Description
oldmode	Fortran: INTEGER*8 Fortran 90: INTEGER(KIND=8) C: unsigned int	Specifies the former VML mode.

Description

The `vmlSetMode` function sets a new mode for VML functions according to the *mode* parameter and stores the previous VML mode to *oldmode*. The mode change has a global effect on all the VML functions within a thread.

NOTE

You can override the global mode setting and change the mode for a given VML function call by using a respective `vm[s,d]<Func>` variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter values by using bitwise OR (|) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the *mode* parameter is `VML_HA | VML_FTZDAZ_OFF | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (`DAZ` = denormals-are-zero) and denormalized results are flushed to zero (`FTZ` = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

Values of the *mode* Parameter

Value of <i>mode</i>	Description
Accuracy Control	
<code>VML_HA</code>	high accuracy versions of VML functions
<code>VML_LA</code>	low accuracy versions of VML functions
<code>VML_EP</code>	enhanced performance accuracy versions of VML functions
Denormalized Numbers Handling Control	
<code>VML_FTZDAZ_ON</code>	Faster processing of denormalized inputs is enabled.
<code>VML_FTZDAZ_OFF</code>	Faster processing of denormalized inputs is disabled.
Error Mode Control	
<code>VML_ERRMODE_IGNORE</code>	No action is set for computation errors.
<code>VML_ERRMODE_ERRNO</code>	On error, the <code>errno</code> variable is set.
<code>VML_ERRMODE_STDERR</code>	On error, the error text information is written to <code>stderr</code> .
<code>VML_ERRMODE_EXCEPT</code>	On error, an exception is raised.
<code>VML_ERRMODE_CALLBACK</code>	On error, an additional error handler function is called.
<code>VML_ERRMODE_DEFAULT</code>	On error, the <code>errno</code> variable is set, an exception is raised, and an additional error handler function is called.

Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and `stderr` error mode:

```
oldmode = vmlsetmode( VML_LA )
call vmlsetmode( IOR(VML_LA, VML_FTZDAZ_ON, VML_ERRMODE_STDERR) )

vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_STDERR );
```

vmlGetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
mod	Fortran: INTEGER C: unsigned int	Specifies the packed <i>mode</i> parameter.

Description

The function `vmlGetMode()` returns the VML *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "[Values of the *mode* Parameter](#)". You can obtain these values using the respective mask from the table "[Values of Mask for the *mode* Parameter](#)".

Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FTZDAZ_MASK	Specifies mask for FTZDAZ <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

Examples

```
mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
denm = IAND(mod, VML_FTZDAZ_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)

accm = vmlGetMode(void ) & VML_ACCURACY_MASK;
denm = vmlGetMode(void ) & VML_FTZDAZ_MASK;
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;
```

MKLFreeTls

Frees allocated VML/VSL thread local storage memory from within DllMain routine. Use on Windows OS only.*

Syntax

C:

```
void MKLFreeTls( const MKL_UINT fdwReason );
```

Include Files

- C: mkl_vml_functions_win.h

Description

The MKLFreeTls routine frees thread local storage (TLS) memory which has been allocated when using MKL static libraries to link into a DLL on the Windows* OS. The routine should only be used within DllMain.

NOTE

It is only necessary to use MKLFreeTls for TLS data in the VML and VSL domains.

Input Parameters

Name	Type	Description
fdwReason	const MKL_UINT	Reason code from the DllMain call.

Example

```
BOOL WINAPI DllMain(HINSTANCE hInst, DWORD fdwReason, LPVOID lpvReserved)
{
    /*customer code*/
    MKLFreeTls(fdwReason);
    /*customer code*/
}
```

vmlSetErrStatus

Sets the new VML Error Status according to err and stores the previous VML Error Status to olderr.

Syntax

Fortran:

```
olderr = vmlseterrstatus( status )
```

C:

```
olderr = vmlSetErrStatus( status );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	Fortran: INTEGER C: int	Specifies the former VML error status.

Description

Table "Values of the VML Status" lists possible values of the *err* parameter.

Values of the VML Status

Status	Description
Successful Execution	
VML_STATUS_OK	The execution was completed successfully.
Warnings	
VML_STATUS_ACCURACYWARNING	The execution was completed successfully in a different accuracy mode.
Errors	
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

vmlGetErrStatus

Gets the VML Error Status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
err	Fortran: INTEGER C: int	Specifies the VML error status.

vmlClearErrStatus

Sets the VML Error Status to VML_STATUS_OK and stores the previous VML Error Status to olderr.

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
olderr	Fortran: INTEGER C: int	Specifies the former VML error status.

vmlSetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Input Parameters

Name

Fortran: *callback* Address of the callback function.

Description

The callback function has the following format:

```
INTEGER FUNCTION ERRFUNC(par)
  TYPE (ERROR_STRUCTURE) par
  ! ...
  ! user error processing
  ! ...
  ! if ERRFUNC= 0 - standard VML error handler
  ! is called after the callback
  ! if ERRFUNC != 0 - standard VML error handler
  ! is not called
END
```

The passed error structure is defined as follows:

```
TYPE ERROR_STRUCTURE SEQUENCE
  INTEGER*4 ICODE
  INTEGER*4 IINDEX
  REAL*8 DBA1
  REAL*8 DBA2
  REAL*8 DBR1
  REAL*8 DBR2
  CHARACTER(64) CFUNCNAME
  INTEGER*4 IFUNCNAMELEN
  REAL*8 DBA1IM
  REAL*8 DBA2IM
  REAL*8 DBR1IM
  REAL*8 DBR2IM
END TYPE ERROR_STRUCTURE
```

C: *callback* Pointer to the callback function.

The callback function has the following format:

```
static int __stdcall
MyHandler(DefVmlErrorHandler*
pContext)
{
    /* Handler body */
}
```

Name**Description**

The passed error structure is defined as follows:

```
typedef struct _DefVmlErrorContext
{
    int iCode; /* Error status value */
    int iIndex; /* Index for bad array
                  element, or bad array
                  dimension, or bad
                  array pointer */

    double dbA1; /* Error argument 1 */
    double dbA2; /* Error argument 2 */
    double dbR1; /* Error result 1 */
    double dbR2; /* Error result 2 */
    char cFuncName[64]; /* Function name */
    int iFuncNameLen; /* Length of functionname*/
    double dbA1Im; /* Error argument 1, imag part*/
    double dbA2Im; /* Error argument 2, imag part*/
    double dbR1Im; /* Error result 1, imag part*/
    double dbR2Im; /* Error result 2, imag part*/
} DefVmlErrorContext;
```

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	Fortran: Address of the former callback function. C: Pointer to the former callback function.

NOTE

This function does not have a FORTRAN 77 interface due to the use of internal structures.

Description

The callback function is called on each VML mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "[Values of the mode Parameter](#)").

Use the `vmlSetErrorHandler()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value

- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

vmlGetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vmlgeterrorcallback( )
```

C:

```
callback = vmlGetErrorCallBack( void );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Description
<i>callback</i>	<p>Fortran 90: Address of the callback function C: Pointer to the callback function</p>

vmlClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

```
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldcallback = vmlClearErrorCallBack( void );
```

Include Files

- Fortran: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER	Fortran: Address of the former callback function

Name	Type	Description
C:	int	C: Pointer to the former callback function

Statistical Functions

Statistical functions in Intel® MKL are known as the Vector Statistical Library (VSL). It is designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and non-deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective [Random Number Generators](#), [Convolution and Correlation](#), and [Summary Statistics](#) sections.

See VSL performance data in the online VSL Performance Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

The basic notion in VSL is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VSL task parameters using the respective service functionality of the library.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Number Generators

Intel MKL VSL provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see [Chapter 9, "Vector Mathematical Functions"](#)).

VSL provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.f90` header file is provided. The `mkl_vsl.fi` header file available in the previous versions of Intel MKL is retained for backward compatibility. For users of the FORTRAN 77 language the `mkl_vsl.f77` header file is provided. All header files are found in the following directory:

```
 ${MKL}/include
```

The `mkl_vsl.f90` header is intended for use with the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources - the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.f90'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VSL interface:

```
use mkl_vsl_type
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.f90` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

The `mkl_vsl.f77` header is intended for use with the Fortran `include` clause as follows:

```
include 'mkl_vsl.f77'
```

NOTE

For Fortran 90 interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Function-style interface, unlike subroutine-style interface, allows the user to get error status of each routine. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.f90` by changing the line `include 'mkl_vsl.f90'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

For the FORTRAN 77 interface, VSL provides only function-style interface.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

Optimization Notice
<p>Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Notice revision #20110804

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the '*Random Numbers*' section in [VSL Notes](#) document provided at the Intel® MKL web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed

pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VSL Notes](#) for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VSL generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of [VSL Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
\oplus or xor	Bitwise exclusive OR.
C_{α}^{κ} or $\binom{\alpha}{\kappa}$	Binomial coefficient or combination ($\alpha \in R$, $\alpha \geq 0$; $\kappa \in N \cup \{0\}$).
$C_{\alpha}^0 = 1$	
	For $\alpha \geq k$ binomial coefficient is defined as
	$C_{\alpha}^{\kappa} = \frac{\alpha(\alpha - 1) \dots (\alpha - \kappa + 1)}{\kappa!}$
	If $\alpha < k$, then
	$C_{\alpha}^{\kappa} = 0$
$\Phi(x)$	Cumulative Gaussian distribution function
	$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$
	defined over $-\infty < x < +\infty$.
	$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.
$\Gamma(\alpha)$	The complete gamma function

$$\Gamma(\alpha) = \int_0^\infty t^{\alpha-1} e^{-t} dt$$

where $\alpha > 0$.

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where $p > 0$ and $q > 0$.

$\text{LCG}(a, c, m)$

Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the *multiplier*, c is called the *increment*, and m is called the *modulus* of the generator.

$\text{MCG}(a, m)$

Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.

$\text{GFSR}(p, q)$

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}.$$

Naming Conventions

The names of the Fortran routines in VSL random number generators are lowercase (`virnguniform`). The names are not case-sensitive.

The names of the C routines, types, and constants in VSL random number generators are case-sensitive and can contain lowercase and uppercase characters (`viRngUniform`).

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for the Fortran interface

`v<type of result>Rng<distribution>` for the C interface,

where

- `v` is the prefix of a VSL vector function.
- `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

`s` REAL for the Fortran interface

 float for the C interface

`d` DOUBLE PRECISION for the Fortran interface

 double for the C interface

`i` INTEGER for the Fortran interface

 int for the C interface

Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case.

- `rng` indicates that the routine is a random generator.
- `<distribution>` specifies the type of statistical distribution.

Names of service routines follow the template below:

```
vsl<name>
```

where

- `vsl` is the prefix of a VSL service function.
- `<name>` contains a short function name.

For a more detailed description of service routines, refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

The prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] )
```

where

- `method` defines the method of generation. A detailed description of this parameter can be found in table "[Values of <method> in method parameter](#)". See the next page, where the structure of the `method` parameter name is explained.
- `stream` defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- `n` defines the number of random values to be generated. If `n` is less than or equal to zero, no values are generated. Furthermore, if `n` is negative, an error condition is set.
- `r` defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least `n` random numbers.
- `status` defines the error status of a VSL routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into `<distribution parameters>` field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector `r`, composed of `n` independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value `a` and standard deviation `sigma`, write the following:

for the Fortran interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for the C interface

```
status = vsRngGaussian( method, stream, n, r, a, sigma )
```

The name of a `method` parameter has the following structure:

```
VSL_RNG_METHOD_<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- `<distribution>` is the probability distribution.
- `<method>` is the method name.

Type of the name structure for the `method` parameter corresponds to fast and accurate modes of random number generation (see "[Distribution Generators](#)" section and [VSL Notes](#) for details).

Method names `VSL_RNG_METHOD_<distribution>_<method>`

and

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

should be used with

`v<precision>Rng<distribution>`

function only, where

- `<precision>` is
 - `s` for single precision continuous distribution
 - `d` for double precision continuous distribution
 - `i` for discrete distribution
- `<distribution>` is the probability distribution.

is the probability distribution. [Table "Values of <method> in method parameter"](#) provides specific predefined values of the `method` name. The third column contains names of the functions that use the given method.

[Values of <method> in method parameter](#)

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous) , Uniform (discrete) , UniformBits , UniformBits32 , UniformBits64
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula:	Gaussian , GaussianMV
	$x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas:	Gaussian , GaussianMV , Lognormal
	$x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	
	$x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	
ICDF	Inverse cumulative distribution function method.	Exponential , Laplace , Weibull , Cauchy , Rayleigh , Gumbel , Bernoulli , Geometric , Gaussian , GaussianMV , Lognormal
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using	Gamma

Method	Short Description	Functions
	rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Johnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852\dots$, $C=-0.956\dots$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Johnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $n_{trial} \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: <ul style="list-style-type: none">- 2 parallelograms- triangle- left exponential tail- right exponential tail	Binomial
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: <ul style="list-style-type: none">- rectangular- left exponential tail- right exponential tail	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: <ul style="list-style-type: none">- 2 parallelograms- triangle- left exponential tail- right exponential tail; otherwise, table lookup method is used.	Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	Poisson, PoissonV
NBAR	Acceptance/rejection method for , $\frac{(\alpha - 1) \cdot (1 - p)}{p} \geq 100$ with decomposition into 5 regions: <ul style="list-style-type: none">- rectangular- 2 trapezoid- left exponential tail	NegBinomial

with decomposition into 5 regions:

- rectangular
- 2 trapezoid
- left exponential tail

Method	Short Description	Functions
	- right exponential tail	

NOTE

In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

Basic Generators

VSL provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator $MCG(1132489760, 2^{31}-1)$ [[L'Ecuyer99](#)]
- the 32-bit generalized feedback shift register pseudorandom number generator $GFSR(250, 103)$ [[Kirkpatrick81](#)]
- the combined multiple recursive pseudorandom number generator $MRG32k3a$ [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator $MCG(13^{13}, 2^{59})$ from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator $MT19937$ [[Matsumoto98](#)] with period length $2^{19937}-1$ of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators $MT2203$ [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator $SFMT19937$ [[Saito08](#)] with a period length equal to $2^{19937}-1$ of the produced sequence.
- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Non-deterministic random number generator (RDRAND-based generators only) [[AVX](#)], [[IntelSWMan](#)].

NOTE

You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, *Chapter 8: Post-32nm Processor Instructions* in [[AVX](#)] or *Chapter 4: RdRand Instruction Usage* in [[BMT](#)].

NOTE

The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VSL limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the `vslNewStreamEx` function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [IntelSWMan] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

See some testing results for the generators in [VSL Notes](#) and comparative performance data at http://software.intel.com/sites/products/documentation/hpc/mkl/vsl/vsl_data/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a, b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a, b) interval.

Such basic generators are called the abstract basic random number generators.

See [VSL Notes](#) for a more detailed description of the generator properties.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MR32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.

Value	Short Description
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOl	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.
VSL_BRNG_NONDETERM	A non-deterministic random number generator.

See [VSL Notes](#) for detailed description.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VSL Notes](#) for details.

NOTE

Random streams associated with abstract basic random number generator are called the abstract random streams. See [VSL Notes](#) for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VSL [Service Routines](#) like `NewStream` and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine `DeleteStream`.

VSL provides service functions `SaveStreamF` and `LoadStreamF` to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VSL Notes](#) for detailed description.

Data Types

FORTRAN 77:

```
INTEGER*4 vslstreamstate(2)
```

Fortran 90:

```
TYPE
    VSL_STREAM_STATE
INTEGER*4 descriptor1
INTEGER*4 descriptor2
END
    TYPE VSL_STREAM_STATE
```

C:

```
typedef (void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VSL RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

`VSL_ERROR_<ERROR_NAME>` - indicates VSL errors common for all VSL domains.

`VSL_RNG_ERROR_<ERROR_NAME>` - indicates VSL RNG errors.

VSL RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: `VSL_ERROR_OK` (or synonymous `VSL_STATUS_OK`).

Status Codes

Status Code	Description
Common VSL	
<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	No error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Input argument value is not valid.
<code>VSL_ERROR_CPU_NOT_SUPPORTED</code>	CPU version is not supported.
<code>VSL_ERROR_FEATURE_NOT_IMPLEMENTED</code>	Feature invoked is not implemented.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory.
<code>VSL_ERROR_NULL_PTR</code>	Input pointer argument is NULL.
<code>VSL_ERROR_UNKNOWN</code>	Unknown error.

VSL RNG Specific

<code>VSL_RNG_ERROR_BAD_FILE_FORMAT</code>	File format is unknown.
<code>VSL_RNG_ERROR_BAD_MEM_FORMAT</code>	Descriptive random stream format is unknown.
<code>VSL_RNG_ERROR_BAD_NBITS</code>	The value in NBits field is bad.

Status Code	Description
VSL_RNG_ERROR_BAD_NSEEDS	The value in NSeeds field is bad.
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in StreamStateSize field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in WordSize field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED	Non-deterministic random number generator is not supported on the CPU running the application.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 <i>Non-deterministic</i> in [VSL Notes] for more details)

VSL RNG Usage Model

A typical algorithm for VSL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.

-
- 2.** Call one or more RNGs.
 - 3.** Process the output.
 - 4.** Delete the streamstreams. Function `vslDeleteStream`.

NOTE

You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters $a = 5$ and $\sigma = 2$. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

C Example of VSL RNG Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;

    /* Initializing */
    s = 0.0;
    vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

    /* Generating */
    for ( i=0; i<10; i++ ) {
        vdRngGaussian( VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
        for ( j=0; j<1000; j++ ) {
            s += r[j];
        }
    }
    s /= 10000.0;

    /* Deleting the stream */
    vslDeleteStream( &stream );

    /* Printing results */
    printf( "Sample mean of normal distribution = %f\n", s );
}

return 0;
}
```

Fortran Example of VSL RNG Usage

```
include 'mkl_vsl.f90'

program MKL_VSL_GAUSSIAN

USE MKL_VSL_TYPE
USE MKL_VSL

real(kind=8) r(1000) ! buffer for random numbers
real(kind=8) s         ! average
real(kind=8) a, sigma ! parameters of normal distribution
```

```

TYPE (VSL_STREAM_STATE) :: stream

integer(kind=4) errcode
integer(kind=4) i,j
integer brng,method,seed,n

n = 1000
s = 0.0
a = 5.0
sigma = 2.0
brng=VSL_BRNG_MT19937
method=VSL RNG METHOD GAUSSIAN_ICDF
seed=777

! ***** Initializing *****
errcode=vslnewstream( stream, brng, seed )

! ***** Generating *****
do i = 1,10
    errcode=vdrnggaussian( method, stream, n, r, a, sigma )
    do j = 1, 1000
        s = s + r(j)
    end do
end do

s = s / 10000.0

! ***** Deinitialize *****
errcode=vsldeletestream( stream )

! ***** Printing results *****
print *, "Sample mean of normal distribution = ", s

end

```

Additionally, examples that demonstrate usage of VSL random number generators are available in:

`$(MKL)/examples/vslc/source`
`$(MKL)/examples/vslf/source`

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table "Service Routines"](#) lists all available service routines

Service Routines

Routine	Short Description
<code>vslNewStream</code>	Creates and initializes a random stream.
<code>vslNewStreamEx</code>	Creates and initializes a random stream for the generators with multiple initial conditions.
<code>vslI NewAbstractStream</code>	Creates and initializes an abstract random stream for integer arrays.
<code>vslD NewAbstractStream</code>	Creates and initializes an abstract random stream for double precision floating-point arrays.

Routine	Short Description
<code>vslsNewAbstractStream</code>	Creates and initializes an abstract random stream for single precision floating-point arrays.
<code>vslDeleteStream</code>	Deletes previously created stream.
<code>vslCopyStream</code>	Copies a stream to another stream.
<code>vslCopyStreamState</code>	Creates a copy of a random stream state.
<code>vslSaveStreamF</code>	Writes a stream to a binary file.
<code>vslLoadStreamF</code>	Reads a stream from a binary file.
<code>vslSaveStreamM</code>	Writes a random stream descriptive data, including state, to a memory buffer.
<code>vslLoadStreamM</code>	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
<code>vslGetStreamSize</code>	Computes size of memory necessary to hold the random stream.
<code>vslLeapfrogStream</code>	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
<code>vslSkipAheadStream</code>	Initializes the stream by the skip-ahead method.
<code>vslGetStreamStateBrng</code>	Obtains the index of the basic generator responsible for the generation of a given random stream.
<code>vslGetNumRegBrngs</code>	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (`vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream (`vslDeleteStream`).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the `vslDeleteStream` function to delete all the streams afterwards.

vslNewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Index of the basic generator to initialize the stream. See Table Values of <i>brng</i> parameter for specific value.
<i>seed</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_UINT	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Stream state descriptor

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. Use this function to create and initialize a new stream with a 32-bit seed only. If you need to provide multiple initial conditions such as several 32-bit or wider seeds, use the function [vslNewStreamEx](#). See [VSL Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE

This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Note: deterministic random number generator is not supported.

vslNewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Index of the basic generator to initialize the stream. See Table "Values of <i>brng</i> parameter" for specific value.
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of initial conditions contained in <i>params</i>
<i>params</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Stream state descriptor

Description

The `vslNewStreamEx` function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use `vslNewStream`, which is analogous

to `vs1NewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vs1NewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VSL Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VSL Notes](#) for the format for their passing and registration in VSL.

NOTE

This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vs1sNewAbstractStream` or `vs1dNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_INVALID_BRNG_INDEX</code>	BRNG index is invalid.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED</code>	Note Non-deterministic random number generator is not supported.

vsliNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslineabSTRACTSTREAM( stream, n, ibuf, icallback )
```

C:

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>FORTRAN 77: INTEGER</code> <code>Fortran 90: INTEGER,</code> INTENT(IN)	Size of the array <i>ibuf</i>
	<code>C: const MKL_INT</code>	
<i>ibuf</i>	<code>FORTRAN 77: INTEGER</code> <code>Fortran 90:</code> INTEGER(KIND=4), INTENT(IN)	Array of <i>n</i> 32-bit integers

Name	Type	Description
	C: const unsigned int	
<i>icallback</i>	See Note below	<p>Fortran: Address of the callback function used for <i>ibuf</i> update</p> <p>C: Pointer to the callback function used for <i>ibuf</i> update</p>

NOTE

Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
INTEGER*4 ibuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION IUPDATEFUNC[C]( stream, n, ibuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)    :: n[reference]
INTEGER(KIND=4),INTENT(OUT)   :: ibuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)    :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)    :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)    :: idx[reference]
```

Format of the callback function in C:

```
int iUpdateFunc( VSLStreamStatePtr stream, int* n, unsigned int ibuf[], int* nmin, int* nmax,
int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table icallback Callback Function Parameters](#) gives the description of the callback function parameters.

icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Descriptor of the stream state structure

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(OUT)

C: VSLStreamStatePtr*

Description

The `vsliNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vsldNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Size of the array <i>dbuf</i>

C: const MKL_INT

Name	Type	Description
<i>dbuf</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Array of n double precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Left boundary a
<i>b</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Right boundary b
<i>dcallback</i>	See Note below	Fortran: Address of the callback function used for update of the array <i>dbuf</i> C: Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE

Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
DOUBLE PRECISION dbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN) :: n[reference]
REAL(KIND=8),INTENT(OUT) :: dbuf[reference] (0:n-1)
```

```
INTEGER(KIND=4), INTENT(IN)      :: nmin[reference]
INTEGER(KIND=4), INTENT(IN)      :: nmax[reference]
INTEGER(KIND=4), INTENT(IN)      :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax, int*
idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table dcallback Callback Function Parameters](#) gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Description

The `vslsNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

vslsNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Size of the array <i>sbuf</i>
<i>sbuf</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (<i>a,b</i>)
<i>a</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Left boundary <i>a</i>
<i>b</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Right boundary <i>b</i>
<i>callback</i>	See Note below	Fortran: Address of the callback function used for update of the array <i>sbuf</i> C: Pointer to the callback function used for update of the array <i>sbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE

Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
REAL sbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC[C]( stream, n, sbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)    :: n[reference]
REAL(KIND=4),   INTENT(OUT)   :: sbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)    :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)    :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)    :: idx[reference]
```

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table callback Callback Function Parameters](#) gives the description of the callback function parameters.

callback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a single precision array *sbuf* and your callback function *callback* that is intended for updating of *sbuf* content.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

vslDeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input/Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	<p>Fortran: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid.</p> <p>C: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL.</p>

Description

The function deletes the random stream created by one of the initialization functions.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

vslCopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90

- C: mkl.h

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTRAN 77: INTEGER*4 srcstream(2)	Fortran: Descriptor of the stream to be copied C: Pointer to the stream state structure to be copied

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(IN)

C: const VSLStreamStatePtr

Output Parameters

Name	Type	Description
<i>newstream</i>	FORTRAN 77: INTEGER*4 newstream(2)	Copied random stream descriptor

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(OUT)

C: VSLStreamStatePtr*

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

vslCopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTRAN 77: INTEGER*4 srcstream(2)	Fortran: Descriptor of the destination stream where the state of <i>scrstream</i> stream is copied

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(IN)

C: const VSLStreamStatePtr

Output Parameters

Name	Type	Description
<i>deststream</i>	FORTRAN 77: INTEGER*4 deststream(2)	Fortran: Descriptor of the stream with the state to be copied

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(OUT)

C: VSLStreamStatePtr

Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Random stream to be written to the file
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	
	C: const VSLStreamStatePtr	
<i>fname</i>	FORTRAN 77: CHARACTER(*) Fortran 90: CHARACTER(*), INTENT(IN)	Fortran: File name specified as a C-style null-terminated string C: File name specified as a null-terminated string
	C: const char*	

Output Parameters

Name	Type	Description
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>fname</i>	FORTRAN 77: CHARACTER(*) Fortran 90: CHARACTER(*), INTENT(IN) C: const char*	Fortran: File name specified as a C-style null-terminated string C: File name specified as a null-terminated string

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Fortran: Descriptor of a new random stream C: Pointer to a new random stream
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslLoadStreamF` function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use `vslSaveStreamF` function.

CAUTION

Calling `vslLoadStreamF` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamF`, you should call the `vslDeleteStream` function first to deallocate the resources.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>fname</i> is a NULL pointer.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Note: Non-deterministic random number generator is not supported.

vslSaveStreamM

Writes random stream descriptive data, including stream state, to a memory buffer.

Syntax

Fortran:

```
errstatus = vslsavestreamm( stream, memptr )
```

C:

```
errstatus = vslSaveStreamM( stream, memptr );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2)	Random stream to be written to the memory
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	
	C: const VSLStreamStatePtr	
<i>memptr</i>	FORTRAN 77: INTEGER*1 Fortran 90: INTEGER(KIND=1), DIMENSION(*), INTENT(IN)	Fortran: Memory buffer to save random stream descriptive data to C: Memory buffer to save random stream descriptive data to

Name	Type	Description
	C: char*	

Output Parameters

Name	Type	Description
errstatus	Fortran: INTEGER	Error status of the operation
	C: int	

Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at `memptr`. Random stream `stream` must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The `memptr` parameter must be a valid pointer to the memory of size sufficient to hold the random stream `stream`. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, `errstatus` has a non-zero value. The random stream can be read from the memory pointed by `memptr` using the `vslLoadStreamM` function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <code>memptr</code> or <code>stream</code> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<code>stream</code> is a NULL pointer.

vslLoadStreamM

Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.

Syntax

Fortran:

```
errstatus = vslloadstreamm( stream, memptr )
```

C:

```
errstatus = vslLoadStreamM( &stream, memptr );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<code>memptr</code>	FORTRAN 77: INTEGER*1	Fortran: Memory buffer to load random stream descriptive data from

Name	Type	Description
	<pre>Fortran 90: INTEGER(KIND=1), DIMENSION(*), INTENT(IN) C: const char*</pre>	C: Memory buffer to load random stream descriptive data from

Output Parameters

Name	Type	Description
<i>stream</i>	<pre>FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*</pre>	Fortran: Descriptor of a new random stream C: Pointer to a new random stream
<i>errstatus</i>	<pre>Fortran: INTEGER C: int</pre>	Error status of the operation

Description

The `vslLoadStreamM` function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by `memptr`. If the stream cannot be read (for example, `memptr` is invalid), `errstatus` has a non-zero value. To save random stream to the memory, use `vslSaveStreamM` function. Use the service routine `vslGetStreamSize` to determine the amount of memory sufficient to hold the random stream.

CAUTION

Calling `LoadStreamM` with a previously initialized `stream` pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamM`, you should call the `vslDeleteStream` function first to deallocate the resources.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>memptr</code> is a NULL pointer.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.
<code>VSL_RNG_ERROR_BAD_MEM_FORMAT</code>	Descriptive random stream format is unknown.
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED</code>	Non-deterministic random number generator is not supported.

`vslGetSize`

Computes size of memory necessary to hold the random stream.

Syntax

Fortran:

```
memsize = vslgetstreamsize( stream )
```

C:

```
memsize = vslGetStreamSize( stream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Random stream

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 INTENT(IN)

C: const VSLStreamStatePtr

Output Parameters

Name	Type	Description
<i>memsize</i>	Fortran: INTEGER C: int	Amount of memory in bytes necessary to hold descriptive data of random stream <i>stream</i>

Description

The `vslGetStreamSize` function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the `vslSaveStreamM` function.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is a NULL pointer.

`vslLeapfrogStream`

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

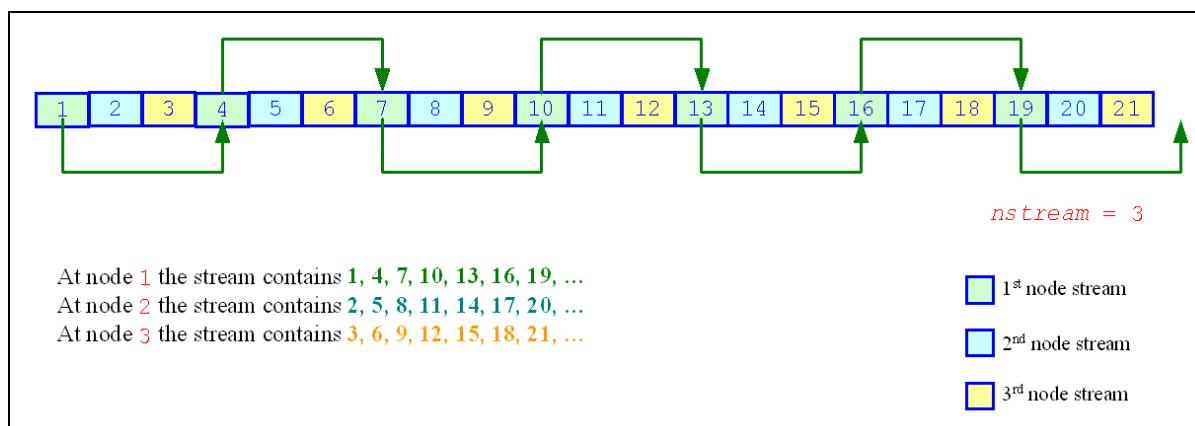

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Fortran: Descriptor of the stream to which leapfrog method is applied
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	C: Pointer to the stream state structure to which leapfrog method is applied
	C: VSLStreamStatePtr	
<i>k</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Index of the computational node, or stream number
	C: const MKL_INT	
<i>nstreams</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Largest number of computational nodes, or stride
	C: const MKL_INT	

Description

The `vslLeapfrogStream` function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the *nstreams* buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The function initializes the original random stream (see [Figure "Leapfrog Method"](#)) to generate random numbers for the computational node *k*, $0 \leq k < nstreams$, where *nstreams* is the largest number of computational nodes used.

Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VSL Notes](#) for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code illustrates the initialization of three independent streams using the leapfrog method:

Fortran 90 Code for Leapfrog Method

```
...
TYPE(VSL_STREAM_STATE)    ::stream1
TYPE(VSL_STREAM_STATE)    ::stream2
TYPE(VSL_STREAM_STATE)    ::stream3

! Creating 3 identical streams
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
status = vslcopystream(stream2, stream1)
status = vslcopystream(stream3, stream1)

! Leapfrogging the streams
status = vslleapfrogstream(stream1, 0, 3)
status = vslleapfrogstream(stream2, 1, 3)
status = vslleapfrogstream(stream3, 2, 3)

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vsllLeapfrogStream(stream1, 0, 3);
status = vsllLeapfrogStream(stream2, 1, 3);
status = vsllLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
```

```
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

vslSkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

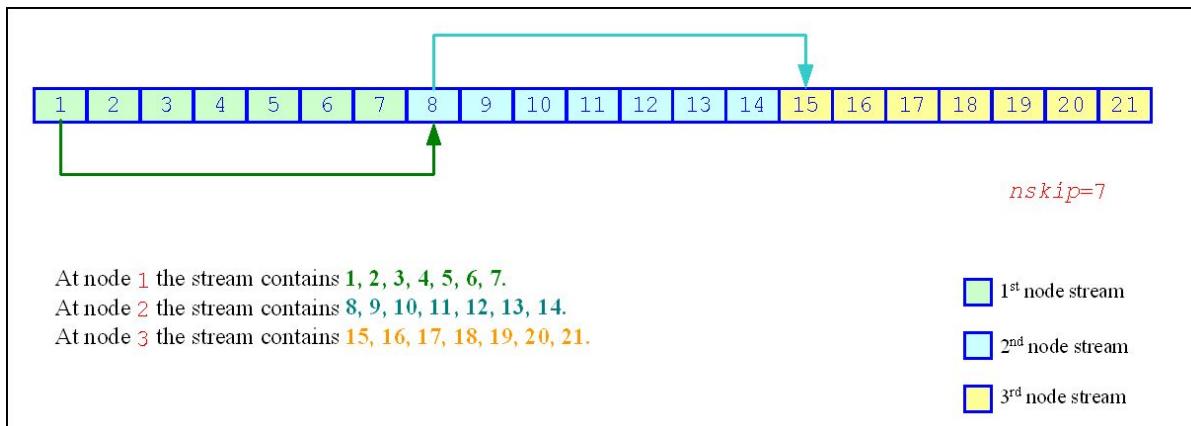

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Fortran: Descriptor of the stream to which block-splitting method is applied
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	C: Pointer to the stream state structure to which block-splitting method is applied
	C: VSLStreamStatePtr	
<i>nskip</i>	FORTRAN 77: INTEGER*4 nskip(2)	Number of skipped elements
	Fortran 90: INTEGER(KIND=8), INTENT(IN)	
	C: const long long int	

Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of

nskip size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see Figure "Block-Splitting Method").

Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VSL Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip *NS* quasi-random vectors, set the *nskip* parameter equal to the *NS*DIMEN*, where *DIMEN* is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is $2^{32}-1$, the library returns the `VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED` error code.

The following code illustrates how to initialize three independent streams using the `vslSkipAheadStream` function:

Fortran 90 Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE) ::stream1
type(VSL_STREAM_STATE) ::stream2
type(VSL_STREAM_STATE) ::stream3

! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)

! Skipping ahead by 7 elements the 2nd stream
status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);

! Skipping ahead by 7 elements the 3rd stream
status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);

! Generating random numbers
...
! Deleting the streams
status = vsdeletestream(stream1)
```

```
status = vslDeleteStream(stream2)
status = vslDeleteStream(stream3)
...
```

C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating the 1st stream
 */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
 */
...
/* Deleting the streams
 */
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the Skip-Ahead method.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the quasi-random number generator is exceeded.

vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Include Files

- Fortran: mkl.fi

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Fortran: Descriptor of the stream state C: Pointer to the stream state structure

Fortran 90:
 TYPE(VSL_STREAM_STATE),
 TINTENT(IN)
C: const VSLStreamStatePtr

Output Parameters

Name	Type	Description
<i>brng</i>	Fortran: INTEGER C: int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Description

The vslGetStreamStateBrng function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Output Parameters

Name	Type	Description
<code>nregbrngs</code>	Fortran: INTEGER C: int	Number of basic generators registered at the moment of the function call

Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

Intel MKL VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both Fortran and C-interface and the explanation of input and output parameters. [Table "Continuous Distribution Generators"](#) and [Table "Discrete Distribution Generators"](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	s, d	s, d	Uniform continuous distribution on the interval $[a,b)$
<code>vRngGaussian</code>	s, d	s, d	Normal (Gaussian) distribution
<code>vRngGaussianMV</code>	s, d	s, d	Multivariate normal (Gaussian) distribution
<code>vRngExponential</code>	s, d	s, d	Exponential distribution
<code>vRngLaplace</code>	s, d	s, d	Laplace distribution (double exponential distribution)
<code>vRngWeibull</code>	s, d	s, d	Weibull distribution
<code>vRngCauchy</code>	s, d	s, d	Cauchy distribution
<code>vRngRayleigh</code>	s, d	s, d	Rayleigh distribution
<code>vRngLognormal</code>	s, d	s, d	Lognormal distribution
<code>vRngGumbel</code>	s, d	s, d	Gumbel (extreme value) distribution
<code>vRngGamma</code>	s, d	s, d	Gamma distribution
<code>vRngBeta</code>	s, d	s, d	Beta distribution

Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	i	d	Uniform discrete distribution on the interval $[a,b)$

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniformBits	i	i	Underlying BRNG integer recurrence
vRngUniformBits32	i	i	Uniformly distributed bits in 32-bit chunks
vRngUniformBits64	i	i	Uniformly distributed bits in 64-bit chunks
vRngBernoulli	i	s	Bernoulli distribution
vRngGeometric	i	s	Geometric distribution
vRngBinomial	i	d	Binomial distribution
vRngHypergeometric	i	d	Hypergeometric distribution
vRngPoisson	i	s (for VSL_RNG_METHOD_POISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_RNG_METHOD_POISSON_PTPE)	Poisson distribution
vRngPoissonV	i	s	Poisson distribution with varying mean
vRngNegBinomial	i	d	Negative binomial distribution, or Pascal distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
vRngUniform	s, d
vRngExponential	s, d
vRngWeibull	s, d
vRngRayleigh	s, d
vRngLognormal	s, d
vRngGamma	s, d
vRngBeta	s, d

See additional details about accurate and fast mode of random number generation in [VSL Notes](#).

New method names

The current version of Intel MKL has a modified structure of VSL RNG method names. (See [RNG Naming Conventions](#) for details.) The old names are kept for backward compatibility. The set correspondence between the new and legacy method names for VSL random number generators.

Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
vRngGaussian	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
vRngGaussianMV	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER , VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2 , VSL_RNG_METHOD_GAUSSIANMV_ICDF
vRngExponential	VSL_METHOD_SEXPONENTIAL_ICDF, VSL_METHOD_DEXPOENTIAL_ICDF, VSL_METHOD_SEXPONENTIAL_ICDF_ACCURATE ,	VSL_RNG_METHOD_EXPONENTIAL_ICDF, VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE
vRngLaplace	VSL_METHOD_SLAPLACE_ICDF, VSL_METHOD_DLAPLACE_ICDF	VSL_RNG_METHOD_LAPLACE_ICDF
vRngWeibull	VSL_METHOD_SWEIFULL_ICDF, VSL_METHOD_DWEIBULL_ICDF, VSL_METHOD_SWEIFULL_ICDF_ACCURATE, VSL_METHOD_DWEIBULL_ICDF_ACCURATE	VSL_RNG_METHOD_WEIBULL_ICDF, VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE
vRngCauchy	VSL_METHOD_SCAUCHY_ICDF, VSL_METHOD_DCAUCHY_ICDF	VSL_RNG_METHOD_CAUCHY_ICDF
vRngRayleigh	VSL_METHOD_SRAYLEIGH_ICDF, VSL_METHOD_DRAYLEIGH_ICDF, VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE, VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE	VSL_RNG_METHOD_RAYLEIGH_ICDF, VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE
vRngLognormal	VSL_METHOD_SLOGNORMAL_BOXMULLER2, VSL_METHOD_DLGNORMAL_BOXMULLER2, VSL_METHOD_SLOGNORMAL_BOXMULLER2_ACCURATE ,	VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2 ,
		VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2_ACCURATE
	VSL_METHOD_SLOGNORMAL_ICDF, VSL_METHOD_DLGNORMAL_ICDF, VSL_METHOD_SLOGNORMAL_ICDF_ACCURATE ,	VSL_RNG_METHOD_LOGNORMAL_ICDF, VSL_RNG_METHOD_LOGNORMAL_ICDF_ACCURATE
	VSL_METHOD_DLGNORMAL_ICDF_ACCURATE	

RNG	Legacy Method Name	New Method Name
vRngGumbel	VSL_METHOD_SGUMBEL_ICDF, VSL_METHOD_DGUMBEL_ICDF	VSL_RNG_METHOD_GUMBEL_ICDF
vRngGamma	VSL_METHOD_SGAMMA_GNORM, VSL_METHOD_DGAMMA_GNORM, VSL_METHOD_SGAMMA_GNORM_ACCURATE, VSL_METHOD_DGAMMA_GNORM_ACCURATE	VSL_RNG_METHOD_GAMMA_GNORM, VSL_RNG_METHOD_GAMMA_GNORM_ACCURATE
vRngBeta	VSL_METHOD_SBETA_CJA, VSL_METHOD_DBETA_CJA, VSL_METHOD_SBETA_CJA_ACCURATE, VSL_METHOD_DBETA_CJA_ACCURATE	VSL_RNG_METHOD_BETA_CJA, VSL_RNG_METHOD_BETA_CJA_ACCURATE

Method Names for Discrete Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_IUNIFORM_STD	VSL_RNG_METHOD_UNIFORM_STD
vRngUniformBits	VSL_METHOD_IUNIFORMBITS_STD	VSL_RNG_METHOD_UNIFORMBITS_STD
vRngBernoulli	VSL_METHOD_IBERNOULLI_ICDF	VSL_RNG_METHOD_BERNOULLI_ICDF
vRngGeometric	VSL_METHOD_IGEOMETRIC_ICDF	VSL_RNG_METHOD_GEOMETRIC_ICDF

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

vRngUniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
status = vdRngUniform( method, stream, n, r, a, b );
```

Include Files

Name	Type	Description
	const double for vdRngUniform	

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnguniform REAL(KIND=8), INTENT(OUT) for vdrnguniform C: float* for vsRngUniform double* for vdRngUniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b]$

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in R ; a < b$.

The probability density function is given by:

$$f(x) = \frac{1}{b-a} \quad a \leq x \leq b$$

The cumulative distribution function is as follows:

$$F(x) = \frac{x-a}{b-a} \quad a \leq x \leq b$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnggaussian REAL(KIND=8), INTENT(OUT) for vdrnggaussian C: float* for vsRngGaussian	Vector of <i>n</i> normally distributed random numbers

Name	Type	Description
	double* for vdRngGaussian	

Description

The vdRngGaussian function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ , where

$$a, \sigma \in \mathbb{R} ; \sigma > 0.$$

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y - a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a, \sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a, \sigma}(x) = \Phi((x - a)/\sigma)$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
status = vdrgngaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Description

The `vRngGaussianMV` function generates random numbers with d -variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C , where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a, C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x - a)^T C^{-1} (x - a)) ,$$

where $x \in R^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C .

Instead of variance-covariance matrix C the generation routines require Cholesky factor of C in input. To compute Cholesky factor of matrix C , the user may call Intel MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV/v?rnggaussianmv` routines (`? means either s or d for single and double precision respectively). See Application Notes for more details.`

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of Intel MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv dpotrf for vdrnggaussianmv	'U'	Upper triangle of T^T . Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv dpptrf for vdrnggaussianmv	'L'	Upper triangle of T^T packed by rows into a one-dimensional array.

Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Lower triangle of T . Upper triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L'	Lower triangle of T packed by columns into a one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngExponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Description

The `vRngExponential` function generates random numbers with exponential distribution that has displacement a and scalefactor β , where $a, \beta \in \mathbb{R} ; \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x - a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x - a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL RNG ERROR BAD STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL RNG ERROR BAD UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL RNG ERROR NO NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL RNG ERROR QRNG PERIOD ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL RNG ERROR NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

`vRngLaplace`

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
status = vdrglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Description

The `vRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) α and scalefactor β , where $\alpha, \beta \in \mathbb{R}$; $\beta > 0$. The scalefactor value determines the standard deviation as

.....

The probability density function is given by:

$$f_{\alpha, \beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x - \alpha|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{\alpha, \beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x - \alpha|}{\beta}\right), & x \geq \alpha \\ 1 - \frac{1}{2} \exp\left(-\frac{|x - \alpha|}{\beta}\right), & x < \alpha \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

Description

The `vRngWeibull` function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in R ; \alpha > 0, \beta > 0$.

The probability density function is given by:

$$f_{\alpha, \beta, a}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{\alpha, \beta, a}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a, -\infty < x < +\infty. \\ 0, & x < a \end{cases}$$

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngCauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Description

The function generates Cauchy distributed random numbers with displacement a and scalefactor β , where $a, \beta \in R$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x-a}{\beta}\right)^2\right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{x-a}{\beta}\right), -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngRayleigh

Generates Rayleigh distributed random values.

Syntax

Fortran:

```
status = vsrngrayleigh( method, stream, n, r, a, beta )
status = vdrngrayleigh( method, stream, n, r, a, beta )
```

C:

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

<i>r</i>	FORTRAN 77: REAL for vsrngrayleigh DOUBLE PRECISION for vdrngrayleigh Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrngrayleigh REAL(KIND=8), INTENT(OUT) for vdrngrayleigh C: float* for vsRngRayleigh double* for vdRngRayleigh	Vector of <i>n</i> Rayleigh distributed random numbers

Description

The `vRngRayleigh` function generates Rayleigh distributed random numbers with displacement a and scalefactor β , where $a, \beta \in R ; \beta > 0$.

The Rayleigh distribution is a special case of the [Weibull](#) distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x - a)}{\beta^2} \exp\left(-\frac{(x - a)^2}{\beta^2}\right), & x \geq a, -\infty < x < +\infty. \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x - a)^2}{\beta^2}\right), & x \geq a, -\infty < x < +\infty. \\ 0, & x < a \end{cases}$$

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngLognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Description

The `vRngLognormal` function generates lognormally distributed random numbers with average of distribution a and standard deviation σ of subject normal distribution, displacement b , and scalefactor β , where $a, \sigma, b, \beta \in \mathbb{R}$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x - b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x - b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi(\ln((x - b)/\beta) - a)/\sigma, & x > b \\ 0, & x \leq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrgngumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

<i>r</i>	FORTRAN 77: REAL for vsrnggumbel DOUBLE PRECISION for vdrnggumbel Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnggumbel REAL(KIND=8), INTENT(OUT) for vdrnggumbel C: float* for vsRngGumbel double* for vdRngGumbel	Vector of <i>n</i> random numbers with Gumbel distribution

Description

The `vRngGumbel` function generates Gumbel distributed random numbers with displacement α and scalefactor β , where $\alpha, \beta \in R ; \beta > 0$.

The probability density function is given by:

$$f_{\alpha, \beta}(x) = \frac{1}{\beta} \exp\left(\frac{x - \alpha}{\beta}\right) \exp(-\exp((x - \alpha) / \beta)), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{\alpha, \beta}(x) = 1 - \exp(-\exp((x - \alpha) / \beta)), -\infty < x < +\infty$$

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.

`VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED` Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGamma

Generates gamma distributed random values.

Syntax

Fortran:

```
status = vsrnggamma( method, stream, n, r, alpha, a, beta )
status = vdrnggamma( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Name	Type	Description
	C: float* for vsRngGamma double* for vdRngGamma	

Description

The `vRngGamma` function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in \mathbb{R}$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, \quad -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha,a,\beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, \quad -\infty < x < +\infty$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.

Description

The `vRngBeta` function generates random numbers with beta distribution that has shape parameters p and q , displacement a , and scale parameter β , where p, q, a , and $\beta \in \mathbb{R}$; $p > 0, q > 0, \beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p, q)\beta^{p+q-1}} (x - a)^{p-1}(\beta + a - x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, \quad -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p, q)\beta^{p+q-1}} (y - a)^{p-1}(\beta + a - y)^{q-1} dy, & a \leq x < a + \beta, -\infty < x < \infty. \\ 1, & x \geq a + \beta \end{cases}$$

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

`vRngUniform`

Generates random numbers uniformly distributed over the interval $[a, b]$.

Syntax

Fortran:

```
status = virnguniform( method, stream, n, r, a, b )
```

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
method	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Generation method; the specific value is as follows: VSL_RNG_METHOD_UNIFORM_STD Standard method. Currently there is only one method for this distribution generator.
stream	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of random values to be generated
a	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Left interval bound a
b	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Right interval bound b

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of n random numbers uniformly distributed over the interval [a, b)

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in \mathbb{R} \\ 1, & x \geq b \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

`vRngUniformBits`

Generates bits of underlying BRNG integer recurrence.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Include Files

- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS_STD
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: unsigned int*	Fortran: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>wordsize</i> of the structure VSL_BRNG_PROPERTIES . The total number of bits that are actually used to store the value are contained in the field <i>nbits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties . C: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure VSLBRngProperties . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties .

Description

The `vRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit LCG only 24 higher bits of an integer value can be considered random. See [VSL Notes](#) for details.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

`vRngUniformBits32`

Generates uniformly distributed bits in 32-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits32( method, stream, n, r )
```

C:

```
status = viRngUniformBits32( method, stream, n, r );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>method</code>	<code>FORTRAN 77:</code> INTEGER <code>Fortran 90:</code> INTEGER, INTENT (IN)	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS32_STD</code>

Name	Type	Description
	C: const MKL_INT	
stream	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
	C: VSLStreamStatePtr	
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: unsigned int*	Fortran: Vector of n 32-bit random integer numbers with uniform bit distribution. C: Vector of n 32-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits32` function generates uniformly distributed bits in 32-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits32` is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See [VSL Notes](#) for details.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<code>stream</code> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<code>stream</code> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngUniformBits64

Generates uniformly distributed bits in 64-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits64( method, stream, n, r )
```

C:

```
status = viRngUniformBits64( method, stream, n, r );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS64_STD
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT(OUT) C: unsigned MKL_INT64*	Fortran: Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution. C: Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution.

Description

The vRngUniformBits64 function generates uniformly distributed bits in 64-bit chunks. Unlike vRngUniformBits, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, vRngUniformBits64 is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See [VSL Notes](#) for details.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.

VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngBernoulli

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_BERNOULLI_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of random values to be generated
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Success probability <i>p</i> of a trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: int*	Vector of <i>n</i> Bernoulli distributed random values

Description

The vRngBernoulli function generates Bernoulli distributed random numbers with probability *p* of a single trial success, where

$$p \in R; 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success *p*, and to 0 with probability $1 - p$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R. \\ 1, & x \geq 1 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGeometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_GEOOMETRIC_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of random values to be generated
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Success probability <i>p</i> of a trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of <i>n</i> geometrically distributed random values

Description

The `vRngGeometric` function generates geometrically distributed random numbers with probability *p* of a single trial success, where $p \in R$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \end{cases} \quad x \in R.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngBinomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	<pre>FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT</pre>	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_BINOMIAL_BTPE</code>
<i>stream</i>	<pre>FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr</pre>	<code>Fortran</code> : Descriptor of the stream state structure. <code>C</code> : Pointer to the stream state structure
<i>n</i>	<pre>FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT</pre>	Number of random values to be generated
<i>ntrial</i>	<pre>FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int</pre>	Number of independent trials m
<i>p</i>	<pre>FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double</pre>	Success probability p of a single trial

Output Parameters

Name	Type	Description
<i>r</i>	<pre>FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*</pre>	Vector of n binomially distributed random values

Description

The `vRngBinomial` function generates binomially distributed random numbers with number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngHypergeometric

Generates hypergeometrically distributed random values.

Syntax

Fortran:

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90

- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	See brief description of the H2PE method in Table "Values of <method> in method parameter" Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT	Number of random values to be generated
<i>l</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Lot size l
<i>s</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Size of sampling without replacement s
<i>m</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Number of marked elements m

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of <i>n</i> hypergeometrically distributed random values

Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \cup \{0\}$; $l \geq \max(s, m)$.

Consider a lot of l elements comprising m "marked" and $l-m$ "unmarked" elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0,s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngPoisson

Generates Poisson distributed random values.

Syntax

Fortran:

```
status = virngpoisson( method, stream, n, r, lambda )
```

C:

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_POISSON_PTPE VSL_RNG_METHOD_POISSON_POISNORM
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	See brief description of the PTPE and POISNORM methods in Table "Values of <method> in method parameter" . Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Number of random values to be generated
<i>lambda</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT (IN) C: const double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT (OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Description

The vRngPoisson function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R$; $\lambda > 0$.

The probability distribution is given by:

...|::|::|::|::|::|::|...

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0, x \in R \\ 0, & x < 0 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngPoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	<pre>FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const MKL_INT</pre>	Generation method. The specific value is as follows: VSL_RNG_METHOD_POISSONV_POISNORM
<i>stream</i>	<pre>FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr</pre>	See brief description of the POISNORM method in Table "Values of <method> in <i>method</i> parameter" Fortran: Descriptor of the stream state structure. Output Parameters

Name	Type	Description
<i>r</i>	<pre>FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*</pre>	Vector of <i>n</i> Poisson distributed random values

Description

The vRngPoissonV function generates *n* Poisson distributed random numbers x_i ($i = 1, \dots, n$) with distribution parameter λ_i , where $\lambda_i \in R$; $\lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, \quad k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0, x \in R \\ 0, & x < 0 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngNegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
method	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Generation method. The specific value is: VSL_RNG_METHOD_NEGBINOMIAL_NBAR See brief description of the NBAR method in Table "Values of <method> in method parameter"

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: descriptor of the stream state structure. C: pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const MKL_INT	Number of random values to be generated
<i>a</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT (IN) C: const double	The first distribution parameter <i>a</i>
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT (IN) C: const double	The second distribution parameter <i>p</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of <i>n</i> random values with negative binomial distribution.

Description

The vRngNegBinomial function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where *p*, *a* ∈ ℝ; $0 < p < 1$; $a > 0$.

If the first distribution parameter *a* ∈ ℤ, this distribution is the same as Pascal distribution. If *a* ∈ ℝ, the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\alpha, p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{\alpha+k-1}^k p^\alpha (1-p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator (`vslRegisterBrng`) and for obtaining properties of the previously registered basic generators (`vslGetBrngProperties`). See [VSL Notes](#) ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

NOTE

The `vslRegisterBrng` function is provided in C for registering a user-defined basic generator, but it is not supported for Fortran. If you need to use a user-defined generator in Fortran, use an abstract basic random generator and abstract stream as described in the VSL Notes.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator.

This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbBits
    INTEGER reserved(8)
END TYPE VSL_BRNG_PROPERTIES
```

This structure is described in C as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
```

```

int IncludesZero;
int WordSize;
int NBits;
InitStreamPtr InitStream;
sBRngPtr sBRng;
dBRngPtr dBRng;
iBRngPtr iBRng;
} VSLBRngProperties;

```

The following table provides brief descriptions of the fields engaged in the above structure:

Field Descriptions

Field	Short Description
Fortran: streamstatesize C: StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
Fortran: nseeds C: NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
Fortran: includeszero C: IncludesZero	Flag value indicating whether the generator can produce a random 0.
Fortran: wordsize C: WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
Fortran: nbits C: NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
C: InitStream	Contains the pointer to the initialization routine of a given basic generator.
C: sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (a,b) (float).
C: dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (a,b) (double).
C: iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution (unsigned int).
Fortran: reserved(8)	Reserved for internal use.

NOTE

Using Advanced Service routines for defining generators is not supported for Fortran, but you can use the Fortran interface to get information about a previously-registered generator using [vslGetBrngProperties](#).

vslRegisterBrng

Registers user-defined basic generator.

¹ A specific generator that permits operations over single bits and bit groups of random numbers.

Syntax

C:

```
brng = vslRegisterBrng( &properties );
```

Include Files

- C: mkl.h

Input Parameters

Name	Type	Description
<i>properties</i> C:	const VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

NOTE

This function is not supported for Fortran. If you need to use a user-defined generator in Fortran, use an abstract basic random generator and abstract stream as described in the VSL Notes.

Output Parameters

Name	Type	Description
<i>brng</i>	C: int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

An example of a registration procedure can be found in the respective directory of the VSL examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.
VSL_RNG_ERROR_BAD_WORD_SIZE	Bad value in WordSize field.
VSL_RNG_ERROR_BAD_NSEEDS	Bad value in NSeeds field.
VSL_RNG_ERROR_BAD_NBITS	Bad value in NBits field.
VSL_ERROR_NULL_PTR	At least one of the fields iBrng, dBrng, sBrng or InitStream is a NULL pointer.

vslGetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>brng</i>	Fortran: INTEGER(KIND=4), INTENT(IN) C: const int	Number (index) of the registered basic generator; used for identification. See specific values in Table "Values of <i>brng</i> parameter" . Negative values indicate the registration error.

Output Parameters

Name	Type	Description
<i>properties</i>	Fortran: TYPE(VSL_BRNG_PROPERTIES), INTENT(OUT) C: VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See recommendations below on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

NOTE

This function is not supported for Fortran. If you need to use a user-defined generator in Fortran, use an abstract basic random generator and abstract stream as described in the VSL Notes.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] );
typedef int(*sBRngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );
typedef int(*dBRngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );
typedef int(*iBRngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] )
{
    /* Initialize the stream */
    ...
} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_RNG_ERROR_SKIPHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of `vslLeapfrogStream` and `vslSkipAheadStream`, respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;

- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in $LCG(a, c, m)$, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1)c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBRng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
     * store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE

When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector r correctly. For example, storing one 64-bit value requires two elements of r , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of r to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i; /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dB Rng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i; /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
```

```

    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */

```

Convolution and Correlation

Intel MKL VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

`SCONF, SCORF`

`SCOND, SCORD`

`SDCON, SDCOR`

`DDCON, DDCOR`

`SDDCON, SDDCOR.`

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for Fortran and C:

`$(MKL)/examples/vslc/essl/vsl_wrappers`

`$(MKL)/examples/vslf/essl/vsl_wrappers`

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers:

`$(MKL)/examples/vslc/essl`

`$(MKL)/examples/vslf/essl`

The convolution and correlation API provides interfaces for FORTRAN 77, Fortran 90 and C/89 languages. You can use the C89 interface with later versions of the C/C++. You can use the Fortran 90 interface with programs written in Fortran 95.

Intel MKL provides the `mkl_vsl.h` header file for C, and the `mkl_vsl.f90` and `mkl_vsl.f77` header files for Fortran. All header files are in the directory

`$(MKL)/include`

See more details about the Fortran header in [Random Number Generators](#) section of this chapter.

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel MKL VSL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of Fortran routines in the convolution and correlation API are written in lowercase (`vslsconvexec`), while the names of Fortran types and constants are written in uppercase. The names are not case-sensitive.

The names of C routines, types, and constants in the convolution and correlation API are case-sensitive and can contain both lowercase and uppercase characters (`vslsConvExec`).

The names of routines have the following structure:

`vsl[datatype] {Conv|Corr}<base name>` for the C interface

`vsl[datatype] {conv|corr}<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.
- `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTRAN 77: <code>INTEGER*4 task (2)</code>	Pointer to a task descriptor for convolution
Fortran 90: <code>TYPE(VSL_CONV_TASK)</code>	
C: <code>VSLConvTaskPtr</code>	
FORTRAN 77: <code>INTEGER*4 task (2)</code>	Pointer to a task descriptor for correlation
Fortran 90: <code>TYPE(VSL_CORR_TASK)</code>	
C: <code>VSLCorrTaskPtr</code>	
FORTRAN 77: <code>REAL*4</code>	Input/output user real data in single precision
Fortran 90: <code>REAL(KIND=4)</code>	

Type	Data Object
C: float	
FORTRAN 77: REAL*8	Input/output user real data in double precision
Fortran 90: REAL (KIND=8)	
C: double	
FORTRAN 77: COMPLEX*8	Input/output user complex data in single precision
Fortran 90: COMPLEX (KIND=4)	
C: MKL_Complex8	
FORTRAN 77: COMPLEX*16	Input/output user complex data in double precision
Fortran 90: COMPLEX (KIND=8)	
C: MKL_Complex16	
FORTRAN 77: INTEGER	All other data
Fortran 90: INTEGER	
C: int	

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE

The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x,y,z</i> .

Name	Category	Type	Default Value Label	Description
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape,</i> <i>yshape,</i> <i>zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x, y, z</i> . See Data Allocation for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The header files define symbolic names for the status codes. These names for the C/C++ interface are defined as macros via the `#define` statements. These names for the Fortran interface are defined as integer constants via the `PARAMETER` operators.

If there is no error, the `VSL_STATUS_OK` status is returned, which is defined as zero:

```
C/C++:      #define VSL_STATUS_OK 0
F90/F95:    INTEGER(KIND=4) VSL_STATUS_OK
            PARAMETER(VSL_STATUS_OK = 0)
F77:        INTEGER*4 VSL_STATUS_OK
            PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files.

Convolution/Correlation Status Codes

Status Code	Description
<code>VSL_CC_ERROR_NOT_IMPLEMENTED</code>	Requested functionality is not implemented.
<code>VSL_CC_ERROR_ALLOCATION_FAILURE</code>	Memory allocation failure.
<code>VSL_CC_ERROR_BAD_DESCRIPTOR</code>	Task descriptor is corrupted.
<code>VSL_CC_ERROR_SERVICE_FAILURE</code>	A service function has failed.
<code>VSL_CC_ERROR_EDIT_FAILURE</code>	Failure while editing the task.
<code>VSL_CC_ERROR_EDIT_PROHIBITED</code>	You cannot edit this parameter.
<code>VSL_CC_ERROR_COMMIT_FAILURE</code>	Task commitment has failed.
<code>VSL_CC_ERROR_COPY_FAILURE</code>	Failure while copying the task.
<code>VSL_CC_ERROR_DELETE_FAILURE</code>	Failure while deleting the task.
<code>VSL_CC_ERROR_BAD_ARGUMENT</code>	Bad argument or task parameter.
<code>VSL_CC_ERROR_JOB</code>	Bad parameter: <i>job</i> .
<code>SL_CC_ERROR_KIND</code>	Bad parameter: <i>kind</i> .
<code>VSL_CC_ERROR_MODE</code>	Bad parameter: <i>mode</i> .
<code>VSL_CC_ERROR_METHOD</code>	Bad parameter: <i>method</i> .

Status Code	Description
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .
VSL_CC_ERROR_ZSHAPE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > <i>nmax</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Another error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE

If the constructor fails to create a task descriptor, it returns the NULL task pointer.

The Table "Task Constructors" lists available task constructors:

Task Constructors

Routine	Description
<code>vslConvNewTask/vslCorrNewTask</code>	Creates a new convolution or correlation task descriptor for a multidimensional case.
<code>vslConvNewTask1D/vslCorrNewTask1D</code>	Creates a new convolution or correlation task descriptor for a one-dimensional case.
<code>vslConvNewTaskX/vslCorrNewTaskX</code>	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
<code>vslConvNewTaskX1D/vslCorrNewTaskX1D</code>	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

`vslConvNewTask/vslCorrNewTask`

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax**Fortran:**

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslccorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const MKL_INT	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
<i>dims</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const MKL_INT	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtask, vslldconvnewtask, vslccconvnewtask, vslzconvnewtask Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvnewtask, vslldconvnewtask, vslccconvnewtask, vslzconvnewtask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	TYPE(VSL_CORR_TASK) for vslscorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask	
	C: VSLConvTaskPtr* for vslsConvNewTask, vsldConvNewTask, vslcConvNewTask, vslzConvNewTask	
	VSLCorrTaskPtr* for vslsCorrNewTask, vsldCorrNewTask, vslcCorrNewTask, vslzCorrNewTask	
status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each vslConvNewTask/vslCorrNewTask constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

vslConvNewTask1D/vslCorrNewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslcconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslccorrnewtask1d(task, mode, xshape, yshape, zshape)
```

```
status = vslzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Description

Each `vslConvNewTask1D/vslCorrNewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)). Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter `dims` is 1. The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

vslConvNewTaskX/vslCorrNewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

```

status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)

<i>status</i>	<pre> FORTRAN 77: INTEGER Fortran 90: INTEGER C: int </pre>	Set to <code>VSL_STATUS_OK</code> if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTaskX/vslCorrNewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by

the `vslConvNewTaskX/vslCorrNewTaskX` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask/vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

The stride parameter `xstride` specifies the physical location of the input data in the array `x`. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every s^{th} element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

`vslConvNewTaskX1D/vslCorrNewTaskX1D`

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

Description

Each `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter `dims` is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [vslConvDeleteTask/vslCorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

The **stride parameters** `xstride` specifies the physical location of the input data in the array `x` and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every `s`th element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of Intel MKL are routines intended for setting up or changing the following task parameters (see [Table "Convolution and Correlation Task Parameters"](#)):

- `mode`
- `internal_precision`
- `start`
- `decimation`

For setting up or changing each of the above parameters, a separate routine exists.

NOTE

Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the [Introduction to Convolution and Correlation](#).

Table "Task Editors" lists available task editors.

Task Editors

Routine	Description
<code>vslConvSetMode/vslCorrSetMode</code>	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
<code>vslConvSetInternalPrecision/ vslCorrSetInternalPrecision</code>	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
<code>vslConvSetStart/vslCorrSetStart</code>	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
<code>vslConvSetDecimation/ vslCorrSetDecimation</code>	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslConvSetMode/vslCorrSetMode

Changes the value of the parameter mode in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>FORTTRAN 77:</code> <code>INTEGER*4 task(2) for vslconvsetmode</code>	Pointer to the task descriptor.

Name	Type	Description
	INTEGER*4 task(2) for vslcorrsetmode	
	Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetmode	
	TYPE(VSL_CORR_TASK) for vslcorrsetmode	
	C: VSLConvTaskPtr for vslConvSetMode	
	VSLCorrTaskPtr for vslCorrSetMode	
newmode	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const MKL_INT	New value of the parameter mode.

Output Parameters

Name	Type	Description
status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This function is declared in `mkl_vsl.f77` for the FORTRAN 77 interface, in `mkl_vsl.f90` for the Fortran 90 interface, and in `mkl_vsl_functions.h` for the C interface.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Values of `mode` parameter

Value	Purpose
<code>VSL_CONV_MODE_FFT</code>	Compute convolution by using fast Fourier transform.
<code>VSL_CORR_MODE_FFT</code>	Compute correlation by using fast Fourier transform.
<code>VSL_CONV_MODE_DIRECT</code>	Compute convolution directly.
<code>VSL_CORR_MODE_DIRECT</code>	Compute correlation directly.
<code>VSL_CONV_MODE_AUTO</code>	Automatically choose direct or Fourier mode for convolution.
<code>VSL_CORR_MODE_AUTO</code>	Automatically choose direct or Fourier mode for correlation.

vslConvSetInternalPrecision/vslCorrSetInternalPrecision

Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetinternalprecision INTEGER*4 task(2) for vslcorrsetinternalprecision Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetinternalprecision TYPE(VSL_CORR_TASK) for vslcorrsetinternalprecision C: VSLConvTaskPtr for vslConvSetInternalPrecision VSLCorrTaskPtr for vslCorrSetInternalPrecision	Pointer to the task descriptor.
<i>precision</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const MKL_INT	New value of the parameter <code>internal_precision</code> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

The `vslConvSetInternalPrecision/vslCorrSetInternalPrecision` routine changes the value of the parameter `internal_precision` for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for `internal_precision` is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the `internal_precision` can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the `internal_precision` input parameter are as follows:

Values of `internal_precision` Parameter

Value	Purpose
<code>VSL_CONV_PRECISION_SINGLE</code>	Compute convolution with single precision.
<code>VSL_CORR_PRECISION_SINGLE</code>	Compute correlation with single precision.
<code>VSL_CONV_PRECISION_DOUBLE</code>	Compute convolution with double precision.
<code>VSL_CORR_PRECISION_DOUBLE</code>	Compute correlation with double precision.

`vslConvSetStart/vslCorrSetStart`

Changes the value of the parameter `start` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
status = vslCorrSetStart(task, start);
```

	C: VSLConvTaskPtr for vslConvSetStart	
	VSLCorrTaskPtr for vslCorrSetStart	
<i>start</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <i>start</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

The `vslConvSetStart/vslCorrSetStart` routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `vslConvSetStart/vslCorrSetStart` routines.

vslConvSetDecimation/vslCorrSetDecimation

Changes the value of the parameter decimation in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Include Files

Input Parameters

Name	Type	Description
<code>task</code>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetdecimation INTEGER*4 task(2) for vslcorrsetdecimation Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetdecimation TYPE(VSL_CORR_TASK) for vslcorrsetdecimation C: VSLConvTaskPtr for vslConvSetDecimation VSLCorrTaskPtr for vslCorrSetDecimation	Pointer to the task descriptor.
<code>decimation</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <code>decimation</code> .

Output Parameters

Name	Type	Description
<code>status</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

The routine sets the value of the parameter `decimation` for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if `decimation` = $d > 1$, only every d -th element of the mathematical result is written to the output array z . In a multidimensional case, `decimation` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for `decimation` is undefined and this parameter is not used. Therefore the only way to set and use the `decimation` parameter is via assigning it some value by one of the `vslSetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays x and y on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array y on input because the first array x has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE

You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

NOTE

Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Task Execution Routines

Routine	Description
vslConvExec/vslCorrExec	Computes convolution or correlation for a multidimensional case.
vslConvExec1D/vslCorrExec1D	Computes convolution or correlation for a one-dimensional case.
vslConvExecX/vslCorrExecX	Computes convolution or correlation as X-form for a multidimensional case.
vslConvExecX1D/vslCorrExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

[vslConvExec/vslCorrExec](#)

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

Description

Each of the `vslConvExec/vslCorrExec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask/vslCorrNewTask` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every s^{th} element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

vslConvExec1D/vslCorrExec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec1d(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);

status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec1D/vslCorrExec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask1D/vslCorrNewTask1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

vslConvExecX/vslCorrExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```

status = vslsconvexecx(task, y, ystride, z, zstride)
status = vslldconvexecx(task, y, ystride, z, zstride)
status = vslcconvexecx(task, y, ystride, z, zstride)
status = vslzconvexecx(task, y, ystride, z, zstride)

status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the vslConvExecX/vslCorrExecX routines computes convolution or correlation of the data provided by the arrays x and y and then stores the results in the array z . These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array x .

Parameters of the operation are read from the task descriptor created previously by a corresponding [vslConvNewTaskX/vslCorrNewTaskX](#) constructor and pointed to by $task$. If $task$ is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array x against different vectors in array y . This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

vslConvExecX1D/vslCorrExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
status = vsldconvexecx1d(task, y, ystride, z, zstride)

status	<pre>FORTRAN 77: INTEGER Fortran 90: INTEGER C: int</pre>	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX1D/vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destroyors

Task destructors are routines designed for deleting task objects and deallocating memory.

vslConvDeleteTask/vslCorrDeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);
errcode = vslCorrDeleteTask(task);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslconvdeletetask</code> INTEGER*4 <code>task(2)</code> for <code>vslcorrdeletetask</code> Fortran 90: TYPE(VSL_CONV_TASK) for <code>vslconvdeletetask</code> TYPE(VSL_CORR_TASK) for <code>vslcorrdeletetask</code> C: <code>VSLConvTaskPtr*</code> for <code>vslConvDeleteTask</code> <code>VSLCorrTaskPtr*</code> for <code>vslCorrDeleteTask</code>	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
<code>errcode</code>	<code>FORTRAN 77:</code> INTEGER <code>Fortran 90:</code> INTEGER <code>C:</code> int	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

Description

The `vslConvDeleteTask/vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask/vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE

You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

`vslConvCopyTask/vslCorrCopyTask`

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
status = vslCorrCopyTask(newtask, srctask);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>srctask</code>	<code>FORTRAN 77:</code> INTEGER*4 <code>srctask(2)</code> for <code>vslconvcopytask</code>	Pointer to the source task descriptor.

Name	Type	Description
	<pre>INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask C: const VSLConvTaskPtr for vslConvCopyTask const VSLCorrTaskPtr for vslCorrCopyTask</pre>	

Output Parameters

Name	Type	Description
<i>newtask</i>	<pre>FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask C: VSLConvTaskPtr* for vslConvCopyTask VSLCorrTaskPtr* for vslCorrCopyTask</pre>	Pointer to the new task descriptor.
<i>status</i>	<pre>FORTRAN 77: INTEGER Fortran 90: INTEGER C: int</pre>	Current status of the source task.

Description

If a task object *srctask* already exists, you can use an appropriate `vslConvCopyTask/vslCorrCopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Introduction to Convolution and Correlation](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

Function `scond1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task,VSL_CONV_MODE_DIRECT,nh,nx,ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h,inch, x,incx, y,incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Function `sconf1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inc1h,
    float x[], int inc1x, int inc2x,
    float y[], int inc1y, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;
    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
            nh, nx, ny, h, inc1h);
    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);
        for (i=0; i<m; i++) {
            float* xi = &x[inc2x * i];
            float* yi = &y[inc2y * i];
            /* task is implicitly committed at i==0 */
            status = vslsConvExecX1D(*task, xi, inc1x, yi, inc1y);
        };
    };
    vslConvDeleteTask(task);
    return status;
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If $m>1$, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create m copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    ...
    vslConvSetStart(*task, &iy0);
    ...
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    ...
}
```

Then, m threads may be started to execute different copies of the task:

```
...
float* xi = &x[inc2x * i];
float* yi = &y[inc2y * i];
ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
...
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
...
for (i=0; i<m; i++) {
    status = ss[i];
    if (status != 0) /* 0 means "OK" */
        break;
}
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbb{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbb{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbb{Z}^N = \mathbb{Z} \times \dots \times \mathbb{Z}$	The set of N -dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbb{Z}^N$	N -dimensional series of integers.

$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from \mathbf{Z}^N and values from \mathbf{R} .
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument (p_1, \dots, p_N) .
$w = u * v$	Function w is the convolution of the functions u, v .
$w = u \cdot v$	Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defined as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $P^{\min}, P^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$P^{\min} \leq p \leq P^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $P^{\min}, P^{\max}, Q^{\min}, Q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } P^{\min} \leq p \leq P^{\max}.$$

$$v(q) \neq 0 \text{ implies } Q^{\min} \leq q \leq Q^{\max}.$$

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$$w(r) \neq 0 \text{ implies } R^{\min} \leq r \leq R^{\max},$$

where $R^{\min} = P^{\min} + Q^{\min}$ and $R^{\max} = P^{\max} + Q^{\max}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$$w(r) = \sum_u(t) \cdot v(r-t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } T^{\min} \leq t \leq T^{\max},$$

where $T^{\min} = \sup\{P^{\min}, r - Q^{\max}\}$ and $T^{\max} = \inf\{P^{\max}, r - Q^{\min}\}$.

Linear Correlation

If function $w = u \cdot v$ is the correlation of u and v , then:

$$w(r) \neq 0 \text{ implies } R^{\min} \leq r \leq R^{\max},$$

where $R^{\min} = Q^{\min} - P^{\max}$ and $R^{\max} = Q^{\max} - P^{\min}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$$w(r) = \sum_u(t) \cdot v(r+t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } T^{\min} \leq t \leq T^{\max},$$

where $T^{\min} = \sup\{P^{\min}, Q^{\min} - r\}$ and $T^{\max} = \inf\{P^{\max}, Q^{\max} - r\}$.

Representation of the functions u, v, w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u, v, w introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions u, v, w ;

- arrays u, v, w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x, y, z
- Shape arrays $xshape, yshape, zshape$
- Strides within arrays $xstride, ystride, zstride$
- Parameters $start, decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

```
inputu(i1, ..., idims) for u(p1, ..., pN)
inputv(j1, ..., jdims) for v(q1, ..., qN)
output(k1, ..., kdims) for w(r1, ..., rN).
```

Parameter $dims$ represents the number of dimensions and is equal to N.

The parameters $xshape$, $yshape$, and $zshape$ define the shapes of input/output vectors:

```
inputu(i1, ..., idims) is defined if 1 ≤ in ≤ xshape(n) for every n=1, ..., dims
inputv(j1, ..., jdims) is defined if 1 ≤ jn ≤ yshape(n) for every n=1, ..., dims
output(k1, ..., kdims) is defined if 1 ≤ kn ≤ zshape(n) for every n=1, ..., dims.
```

Relation between the input vectors and the functions u and v is defined by the following formulas:

```
inputu(i1, ..., idims) = u(p1, ..., pN), where pn = Pnmin + (in-1) for every n
inputv(j1, ..., jdims) = v(q1, ..., qN), where qn = Qnmin + (jn-1) for every n.
```

The relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters $start$ and $decimation$ are not defined):

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn = Rnmin + (kn-1) for every n.
```

If the parameter $start$ is defined, it must belong to the interval $R_n^{min} ≤ start(n) ≤ R_n^{max}$. If defined, the $start$ parameter replaces R^{min} in the formula:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn = start(n) + (kn-1)
```

If the parameter $decimation$ is defined, it changes the relation according to the following formula:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn = Rnmin + (kn-1) * decimation(n)
```

If both parameters $start$ and $decimation$ are defined, the formula is as follows:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn = start(n) + (kn-1) * decimation(n)
```

The convolution and correlation software checks the values of $zshape$, $start$, and $decimation$ during task commitment. If r_n exceeds R_n^{max} for some $k_n, n=1, ..., dims$, an error is raised.

Allocation of Data Vectors

Both parameter arrays x and y contain input data vectors in memory, while array z is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters x , y , and z , you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays x , y , and z is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

```
inputu( $i_1, \dots, i_{\text{dims}}$ ) is allocated at  $x(e)$   

inputv( $j_1, \dots, j_{\text{dims}}$ ) is allocated at  $y(f)$   

output( $k_1, \dots, k_{\text{dims}}$ ) is allocated at  $z(g)$ .
```

The indices e , f , and g are defined as follows:

$$\begin{aligned} e &= 1 + \sum x\text{stride}(n) \cdot dx(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \\ f &= 1 + \sum y\text{stride}(n) \cdot dy(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \\ g &= 1 + \sum z\text{stride}(n) \cdot dz(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \end{aligned}$$

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$$\begin{aligned} dx(n) &= i_n - 1 \text{ if } x\text{stride}(n) > 0, \text{ or } dx(n) = i_n - x\text{shape}(n) \text{ if } x\text{stride}(n) < 0 \\ dy(n) &= j_n - 1 \text{ if } y\text{stride}(n) > 0, \text{ or } dy(n) = j_n - y\text{shape}(n) \text{ if } y\text{stride}(n) < 0 \\ dz(n) &= k_n - 1 \text{ if } z\text{stride}(n) > 0, \text{ or } dz(n) = k_n - z\text{shape}(n) \text{ if } z\text{stride}(n) < 0 \end{aligned}$$

The definitions of indices e , f , and g assume that indexes for arrays x , y , and z are started from unity:

$x(e)$ is defined for $e=1, \dots, \text{length}(x)$
 $y(f)$ is defined for $f=1, \dots, \text{length}(y)$
 $z(g)$ is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array z for one-dimensional and two-dimensional cases.

One-dimensional case. If $\text{dims}=1$, then $z\text{shape}$ is the number of the output values to be stored in the array z . The actual length of array z may be greater than $z\text{shape}$ elements.

If $z\text{stride} > 1$, output values are stored with the stride: $\text{output}(1)$ is stored to $z(1)$, $\text{output}(2)$ is stored to $z(1+z\text{stride})$, and so on. Hence, the actual length of z must be at least $1+z\text{stride} \cdot (z\text{shape}-1)$ elements or more.

If $z\text{stride} < 0$, it still defines the stride between elements of array z . However, the order of the used elements is the opposite. For the k -th output value, $\text{output}(k)$ is stored in $z(1+|z\text{stride}| \cdot (z\text{shape}-k))$, where $|z\text{stride}|$ is the absolute value of $z\text{stride}$. The actual length of the array z must be at least $1+|z\text{stride}| \cdot (z\text{shape} - 1)$ elements.

Two-dimensional case. If $\text{dims}=2$, the output data is a two-dimensional matrix. The value $z\text{stride}(1)$ defines the stride inside matrix columns, that is, the stride between the $\text{output}(k_1, k_2)$ and $\text{output}(k_1+1, k_2)$ for every pair of indices k_1, k_2 . On the other hand, $z\text{stride}(2)$ defines the stride between columns, that is, the stride between $\text{output}(k_1, k_2)$ and $\text{output}(k_1, k_2+1)$.

If $z\text{stride}(2)$ is greater than $z\text{shape}(1)$, this causes sparse allocation of columns. If the value of $z\text{stride}(2)$ is smaller than $z\text{shape}(1)$, this may result in the transposition of the output matrix. For example, if $z\text{shape} = (2, 3)$, you can define $z\text{stride} = (3, 1)$ to allocate output values like transposed matrix of the shape 3×2 .

Whether $z\text{stride}$ assumes this kind of transformations or not, you need to ensure that different elements $\text{output}(k_1, \dots, k_{\text{dims}})$ will be stored in different locations $z(g)$.

Summary Statistics

The Summary Statistics domain comprises a set of routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

See the definition of the supported operations in the [Mathematical Notation and Definitions](#) section.

The Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers
- raw/central partial sums up to the fourth order (for brevity referred to as *raw/central sums*)
- matrix of cross-products and sums of squares (for brevity referred to as *cross-product matrix*)
- median absolute deviation, mean absolute deviation

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

You can access the Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can use the C89 interface with later versions of the C/C++. You can use the Fortran 90 interface with programs written in Fortran 95.

Intel MKL provides the `mkl_vsl.h` header file for C, and the `mkl_vsl.f90` and `mkl_vsl.f77` header files for Fortran. All header files are in the directory

```
 ${MKL}/include
```

See more details about the Fortran header in the [Random Number Generators](#) section of this chapter.

You can find examples that demonstrate calculation of the Summary Statistics estimates in the examples directories:

```
 ${MKL}/examples/vs1c
```

```
 ${MKL}/examples/vs1f
```

The Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The Summary Statistics functions fall into the following categories:

Task Constructors - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Computation Routine - a routine that computes specified statistical estimates.

Task Destructor - a routine that deletes the task object and frees the memory.

A Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® MKL Summary Statistics Library Application Notes* [[SSL Notes](#)].

Naming Conventions

The names of the Fortran routines in the Summary Statistics are in lowercase (`vslssreditquantiles`), while the names of types and constants are in uppercase. The names are not case-sensitive.

The names of the C Summary Statistics routines, types, and constants are case-sensitive and can contain lowercase and uppercase characters (`vslsSEditQuantiles`).

The names of routines have the following structure:

`vsl[datatype] SS<base name>` for the C interface

`vsl[datatype] ss<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to the Vector Statistical Library of Intel MKL.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS/ss` indicates that the routine is intended for calculations of the Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

NOTE

The Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

Data Types

The Summary Statistics routines use the following data types for the calculations:

Type	Data Object
<code>Fortran 90: TYPE(VSL_SS_TASK)</code>	Pointer to a Summary Statistics task
<code>C: VSLSSTaskPtr</code>	
<code>Fortran 90: REAL(KIND=4)</code>	Input/output user data in single precision
<code>C: float</code>	
<code>Fortran 90: REAL(KIND=8)</code>	Input/output user data in double precision
<code>C: double</code>	
<code>Fortran 90: INTEGER or INTEGER(KIND=8)</code>	Other data
<code>C: MKL_INT or long long</code>	

NOTE

The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The header files define symbolic names for the status codes. These names for the C/C++ interface are defined as macros via the `#define` statements. These names for the Fortran interface are defined as integer constants via the `PARAMETER` operators.

If no error is detected, the function returns the `VSL_STATUS_OK` code, which is defined as zero:

```
C/C++: #define VSL_STATUS_OK 0
F90/F95: INTEGER, PARAMETER::VSL_STATUS_OK = 0
```

In the case of an error, the function returns a non-zero error code that specifies the origin of the failure. The header files define the following status codes for the Summary Statistics error codes:

Summary Statistics Status Codes

Status Code	Description
<code>VSL_STATUS_OK</code>	Operation is successfully completed.
<code>VSL_SS_ERROR_ALLOCATION_FAILURE</code>	Memory allocation has failed.
<code>VSL_SS_ERROR_BAD_DIMEN</code>	Dimension value is invalid.
<code>VSL_SS_ERROR_BAD_OBSERV_N</code>	Invalid number (zero or negative) of observations was obtained.
<code>VSL_SS_ERROR_STORAGE_NOT_SUPPORTED</code>	Storage format is not supported.
<code>VSL_SS_ERROR_BAD_INDC_ADDR</code>	Array of indices is not defined.
<code>VSL_SS_ERROR_BAD_WEIGHTS</code>	Array of weights contains negative values.
<code>VSL_SS_ERROR_BAD_MEAN_ADDR</code>	Array of means is not defined.
<code>VSL_SS_ERROR_BAD_2R_MOM_ADDR</code>	Array of the second order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_3R_MOM_ADDR</code>	Array of the third order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_4R_MOM_ADDR</code>	Array of the fourth order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_2C_MOM_ADDR</code>	Array of the second order central moments is not defined.
<code>VSL_SS_ERROR_BAD_3C_MOM_ADDR</code>	Array of the third order central moments is not defined.
<code>VSL_SS_ERROR_BAD_4C_MOM_ADDR</code>	Array of the fourth order central moments is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_KURTOSIS_ADDR	Array of kurtosis values is not defined.
VSL_SS_ERROR_BAD_SKEWNESS_ADDR	Array of skewness values is not defined.
VSL_SS_ERROR_BAD_MIN_ADDR	Array of minimum values is not defined.
VSL_SS_ERROR_BAD_MAX_ADDR	Array of maximum values is not defined.
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.
VSL_SS_ERROR_BAD_SUM_ADDR	Array of sums is not defined.
VSL_SS_ERROR_BAD_2R_SUM_ADDR	Array of raw sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3R_SUM_ADDR	Array of raw sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4R_SUM_ADDR	Array of raw sums of 4th order is not defined.
VSL_SS_ERROR_BAD_2C_SUM_ADDR	Array of central sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3C_SUM_ADDR	Array of central sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4C_SUM_ADDR	Array of central sums of 4th order is not defined.
VSL_SS_ERROR_BAD_CP_SUM_ADDR	Cross-product matrix is not defined.
VSL_SS_ERROR_BAD_MDAD_ADDR	Array of median absolute deviations is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MNAD_ADDR	Array of mean absolute deviations is not defined.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel MKL routines other than the Summary Statistics routines.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

vslSSNewTask

Creates and initializes a new summary statistics task descriptor.

Syntax

Fortran:

```
status = vslsssnewtask(task, p, n, xstorage, x, w, indices)
status = vslldssnewtask(task, p, n, xstorage, x, w, indices)
```

C:

```
status = vslsSSNewTask(&task, p, n, xstorage, x, w, indices);
status = vsldSSNewTask(&task, p, n, xstorage, x, w, indices);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>p</code>	Fortran: INTEGER C: const MKL_INT	Dimension of the task, number of variables
<code>n</code>	Fortran: INTEGER C: const MKL_INT	Number of observations
<code>xstorage</code>	Fortran: INTEGER C: const MKL_INT	Storage format of matrix of observations
<code>x</code>	Fortran: REAL(KIND=4) DIMENSION(*) for <code>vslsssnewtask</code>	Matrix of observations

Name	Type	Description
w	<pre>REAL(KIND=8) DIMENSION(*) for vslDSSNewTask C: const float* for vslsSSNewTask const double* for vslDSSNewTask</pre>	Array of weights of size n . Elements of the arrays are non-negative numbers. If a NULL pointer is passed, each observation is assigned weight equal to 1.
indices	<pre>Fortran: REAL(KIND=4) DIMENSION(*) for vslSSNewTask REAL(KIND=8) DIMENSION(*) for vslDSSNewTask C: const float* for vslsSSNewTask const double* for vslDSSNewTask</pre>	Array of vector components that will be processed. Size of array is p . If a NULL pointer is passed, all components of random vector are processed.

Output Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr*	Descriptor of the task
status	Fortran: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully, otherwise a non-zero error code is returned.

Description

Each `vslSSNewTask` constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, which are n vectors of dimension p , are passed as a one-dimensional array x . The parameter `xstorage` defines the storage format of the observations and takes one of the possible values listed in [Table "Storage format of matrix of observations and order statistics"](#).

Storage format of matrix of observations and order statistics

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_ROWS</code>	The observations of random vector ξ are packed by rows: n data points for the vector component ξ_1 come first, n data points for the vector component ξ_2 come second, and so forth.
<code>VSL_SS_MATRIX_STORAGE_COLS</code>	The observations of random vector ξ are packed by columns: the first p -dimensional observation of the vector ξ comes first, the second p -dimensional observation of the vector comes second, and so forth.

NOTE

Since matrices in Fortran are stored by columns while in C they are stored by rows, initialization of the `xstorage` variable in Fortran is opposite to that in C. Set `xstorage` to `VSL_SS_MATRIX_STORAGE_COLS`, if the dataset is stored as a two-dimensional matrix that consists of p rows and n columns; otherwise, use the `VSL_SS_MATRIX_STORAGE_ROWS` constant.

A one-dimensional array `w` of size n contains non-negative weights assigned to the observations. You can pass a `NULL` array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size p contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

Task Editors

Task editors are intended to set up or change the task parameters listed in [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#). As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM    1
#define N     1000

int main()
{
    VSLSSTaskPtr task;
    double x[N];
    double mean;
    MKL_INT p, n, xstorage;
    int status;
    /* initialize variables used in the computations of sample mean */
    p = DIM;
    n = N;
    xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
    mean = 0.0;

    /* create task */
    status = vslsSsNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

    /* initialize task parameters */
    status = vslsSsEditTask( task, VSL_SS_ED_MEAN, &mean );

    /* compute mean using SS fast method */
    status = vslsSsCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

    /* deallocate task resources */
    status = vslsSsDeleteTask( &task );

    return 0;
}
```

Use the single (`vslsssedittask`) or double (`vslsSseditTask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vslsSseditTask`) to initialize parameters of the integer type.

Table "Summary Statistics Task Editors" lists the task editors for Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

Summary Statistics Task Editors

Editor	Description
<code>vslSSEditTask</code>	Changes a pointer in the task descriptor.
<code>vslSSEditMoments</code>	Changes pointers to arrays associated with raw and central moments.
<code>vslSSEditSums</code>	Modifies the pointers to arrays that hold sum estimates.
<code>vslSSEditCovCor</code>	Changes pointers to arrays associated with covariance and/or correlation matrices.
<code>vslSSEditCP</code>	Modifies the pointers to cross-product matrix parameters.
<code>vslSSEditPartialCovCor</code>	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
<code>vslSSEditQuantiles</code>	Changes pointers to arrays associated with quantile/order statistics calculations.
<code>vslSSEditStreamQuantiles</code>	Changes pointers to arrays for quantile related calculations for streaming data.
<code>vslSSEditPooledCovariance</code>	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.
<code>vslSSEditRobustCovariance</code>	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
<code>vslSSEditOutliersDetection</code>	Changes pointers to arrays for detection of outliers.
<code>vslSSEditMissingValues</code>	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
<code>vslSSEditCorParameterization</code>	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

`vslSSEditTask`

Modifies address of an input/output parameter in the task descriptor.

Syntax

Fortran:

```
status = vslsssedittask(task, parameter, par_addr)
status = vslssedittask(task, parameter, par_addr)
status = vslissedittask(task, parameter, par_addr)
```

C:

```
status = vslsSSEditTask(task, parameter, par_addr);
status = vsldSSEditTask(task, parameter, par_addr);
```

```
status = vslisSEditTask(task, parameter, par_addr);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
parameter	Fortran: INTEGER C: const MKL_INT	Parameter to change
par_addr	Fortran: REAL(KIND=4) DIMENSION(*) for vslsssedittask REAL(KIND=8) DIMENSION(*) for vsldssedittask INTEGER DIMENSION(*) for vslissedittask C: const float* for vslsSEditTask const double* for vsldSSEditTask const MKL_INT* for vslisSEditTask	Address of the new parameter

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The `vslsSEditTask` routine replaces the pointer to the parameter stored in the Summary Statistics task descriptor with the `par_addr` pointer. If you pass the NULL pointer to the editor, no changes take place in the task and a corresponding error code is returned. See [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#) for the predefined values of the parameter.

Use the single (`vslssedittask`) or double (`vsldssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vslissedittask`) to initialize parameters of the integer type.

Parameters of Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_DIMEN	i	Address of a variable that holds the task dimension	Required. Positive integer value.
VSL_SS_ED_OBSERV_N	i	Address of a variable that holds the number of observations	Required. Positive integer value.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_OBSERV	d, s	Address of the observation matrix	Required. Provide the matrix containing your observations.
VSL_SS_ED_OBSERV_STORAGE	i	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations. ¹
VSL_SS_ED_INDC	i	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry i of the array to one to include the i th coordinate in the analysis. Set entry i of the array to zero to exclude the i th coordinate from the analysis.
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix. ²
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix. ²
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_QUANT_QUANTILES	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry i to integer value k if the observation belongs to group k . Values of k take values in the range $[0, g-1]$, where g is the number of groups.
VSL_SS_ED_POOLED_COV_STORAGE		Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance. ²
VSL_SS_ED_POOLED_MEAN	d, s	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.
VSL_SS_ED_GROUP_COV_INDC	i	Address of an array of indices for which covariance/means should be computed	Optional. Set the k th entry of the array to 1 if you need group covariance and mean for group k ; otherwise set it to zero.
VSL_SS_ED_REQ_GROUP_INDC	i	Address of an array of indices for which group estimates such as covariance or means are requested	Optional. Set the k th entry of the array to 1 if you need an estimate for group k ; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.
VSL_SS_ED_GROUP_COV_STORAGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance. ²
VSL_SS_ED_GROUP_COV	d, s	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STORAGE	s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance ² .
VSL_SS_ED_ROBUST_COV_PARAMS_N		Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, <i>VSL_SS_TBS_PARAMS_N</i> .
VSL_SS_ED_ROBUST_COV_PARAMS	s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in vsISSEditRobustCovariance .

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAMS_N	i, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, <i>VSL_SS_BACON_PARAMS_N</i> .
VSL_SS_ED_OUTLIERS_PARAMS	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in vslSSEditOutliersDetection .
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_STORAGE	i	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics. ¹
VSL_SS_ED_PARTIAL_COV_IDX	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in vslSSEditPartialCovCor .
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance. ²
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation. ²
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, <i>VSL_SS_MI_PARAMS_SIZE</i> .
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in vslSSEditMissingValues .

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_MI_INIT_ESTIMATES_N		Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$, where p is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATES, s		Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document [SSL Notes].
VSL_SS_ED_MI_SIMUL_VALS_N i		Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS d, s		Address of an array of simulated values in the Multiple Imputation method	None.
VSL_SS_ED_MI_ESTIMATES_N i		Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document [SSL Notes].
VSL_SS_ED_MI_ESTIMATES d, s		Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N i		Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$, where p is the task dimension.
VSL_SS_ED_MI_PRIOR d, s		Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document [SSL Notes].

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_STORAGE		Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix. ²
VSL_SS_ED_STREAM_QUANT_PARAMS_N		Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, <i>VSL_SS_SQUANTS_ZW_PARAMS_N</i> .
VSL_SS_ED_STREAM_QUANT_PARAMS		Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document [SSL Notes].
VSL_SS_ED_STREAM_QUANT_ORDER_N		Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.
VSL_SS_ED_STREAM_QUANT_ORDER_S	s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_QUANTILES		Address of an array of quantiles for streaming data	None.
VSL_SS_ED_SUM	d, s	Address of array of sums	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_SUM	d, s	Address of array of raw sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_SUM	d, s	Address of array of raw sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_4R_SUM	d, s	Address of array of raw sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_SUM	d, s	Address of array of central sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3C_SUM	d, s	Address of array of central sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4C_SUM	d, s	Address of array of central sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_CP	d, s	Address of cross-product matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_MDAD	d, s	Address of array of median absolute deviations	None.
VSL_SS_ED_MNAD	d, s	Address of array of mean absolute deviations	None.

1. See [Table: "Storage format of matrix of observations and order statistics"](#) for storage formats.
2. See [Table: "Storage formats of a variance-covariance/correlation matrix"](#) for storage formats.

vslSSSEditMoments

Modifies the pointers to arrays that hold moment estimates.

Syntax

Fortran:

```
status = vslssreditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
status = vslssreditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
```

C:

```
status = vslsSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
status = vslsSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>mean</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vsldsseditmoments REAL (KIND=8) DIMENSION(*) for vsldsseditmoments C: const float* for vsldssEditMoments const double* for vsldSSEditMoments	Pointer to the array of means
<i>r2m</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vsldsseditmoments REAL (KIND=8) DIMENSION(*) for vsldsseditmoments C: const float* for vsldssEditMoments const double* for vsldSSEditMoments	Pointer to the array of raw moments of the 2 nd order
<i>r3m</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vsldsseditmoments REAL (KIND=8) DIMENSION(*) for vsldsseditmoments C: const float* for vsldssEditMoments const double* for vsldSSEditMoments	Pointer to the array of raw moments of the 3 rd order
<i>r4m</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vsldsseditmoments REAL (KIND=8) DIMENSION(*) for vsldsseditmoments C: const float* for vsldssEditMoments const double* for vsldSSEditMoments	Pointer to the array of raw moments of the 4 th order
<i>c2m</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vsldsseditmoments REAL (KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of central moments of the 2 nd order

Name	Type	Description
<i>c3m</i>	<pre>C: const float* for vslssSEEditMoments const double* for vslsSSEEditMoments</pre> <p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsSSEEditMoments C: const float* for vslsSSEEditMoments const double* for vslsSSEEditMoments</pre>	Pointer to the array of central moments of the 3 rd order
<i>c4m</i>	<pre>REAL(KIND=4) DIMENSION(*) for vslsseditmoments</pre> <p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsSSEEditMoments C: const float* for vslsSSEEditMoments const double* for vslsSSEEditMoments</pre>	Pointer to the array of central moments of the 4 th order

Output Parameters

Name	Type	Description
<i>status</i>	<p>Fortran: INTEGER</p> <p>C: int</p>	Current status of the task

Description

The `vslssSEEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

vslssSEEditSums

Modifies the pointers to arrays that hold sum estimates.

Syntax

Fortran:

```
status = vslssseditsums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s)
status = vslsSSEEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s)
```

C:

```
status = vslssSEEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
status = vslsSSEEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>sum</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditsums REAL (KIND=8) DIMENSION(*) for vsldsseditsums C: const float* for vslsSSEditSums const double* for vsldSSEditSums	Pointer to the array of sums
<i>r2s</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditsums REAL (KIND=8) DIMENSION(*) for vsldsseditsums C: const float* for vslsSSEditSums const double* for vsldSSEditSums	Pointer to the array of raw sums of the second order
<i>r3s</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditsums REAL (KIND=8) DIMENSION(*) for vsldsseditsums C: const float* for vslsSSEditSums const double* for vsldSSEditSums	Pointer to the array of raw sums of the third order
<i>r4s</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditsums REAL (KIND=8) DIMENSION(*) for vsldsseditsums C: const float* for vslsSSEditSums const double* for vsldSSEditSums	Pointer to the array of raw sums of the fourth order
<i>c2s</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditsums REAL (KIND=8) DIMENSION(*) for vsldsseditsums C: const float* for vslsSSEditSums const double* for vsldSSEditSums	Pointer to the array of central sums of the second order

Name	Type	Description
<i>c3s</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vs1ssseditsums C: const float* for vs1sSSEditSums const double* for vs1dSSEditSums	Pointer to the array of central sums of the third order
<i>c4s</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vs1ssseditsums C: const float* for vs1sSSEditSums const double* for vs1dSSEditSums	Pointer to the array of central sums of the fourth order

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditSums` routine replaces pointers to the arrays that hold estimates of raw and central sums with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

`vslSSEditCovCor`

Modifies the pointers to covariance/correlation/cross-product parameters.

Syntax

Fortran:

```
status = vslsseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
status = vsldsseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
```

C:

```
status = vs1sSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
status = vs1dSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>mean</i>	Fortran: REAL (KIND=4) DIMENSION (*) for vslsseditcovcor REAL (KIND=8) DIMENSION (*) for vsldsseditcovcor C: const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to the array of means
<i>cov</i>	Fortran: REAL (KIND=4) DIMENSION (*) for vslsseditcovcor REAL (KIND=8) DIMENSION (*) for vsldsseditcovcor C: const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to a covariance matrix
<i>cov_storage</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	Fortran: REAL (KIND=4) DIMENSION (*) for vslsseditcovcor REAL (KIND=8) DIMENSION (*) for vsldsseditcovcor C: const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to a correlation matrix
<i>cor_storage</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the `cov_storage` and `cor_storage` parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

[Storage formats of a variance-covariance/correlation/cross-product matrix](#)

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_FULL</code>	A symmetric variance-covariance/correlation/cross-product matrix is a one-dimensional array with elements $c(i, j)$ stored as $cp(i*p + j)$. The size of the array is $p*p$.
<code>VSL_SS_MATRIX_STORAGE_L_PACKED</code>	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + (2n - j)*(j - 1)/2)$ for $j \leq i$. The size of the array is $p*(p+1)/2$.
<code>VSL_SS_MATRIX_STORAGE_U_PACKED</code>	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + j*(j - 1)/2)$ for $i \leq j$. The size of the array is $p*(p+1)/2$.

`vslSSEditCP`

Modifies the pointers to cross-product matrix parameters.

Syntax

Fortran:

```
status = vslssseditcp(task, mean, sum, cp, cp_storage)
status = vslrsseditcp(task, mean, sum, cp, cp_storage)
```

C:

```
status = vslsSSEditCP(task, mean, sum, cp, cp_storage);
status = vslsSSEditCP(task, mean, sum, cp, cp_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: <code>TYPE(VSL_SS_TASK)</code> C: <code>VSLSSTaskPtr</code>	Descriptor of the task
<code>mean</code>	Fortran: <code>REAL(KIND=4) DIMENSION(*)</code> for <code>vslssseditcp</code>	Pointer to array of means

Name	Type	Description
	REAL(KIND=8) DIMENSION(*) for vslsseditcp C: const float* for vs1sSSEditCP const double* for vsldSSEditCP	
sum	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditcp REAL(KIND=8) DIMENSION(*) for vslsseditcp C: const float* for vs1sSSEditCP const double* for vsldSSEditCP	Pointer to array of sums
cp	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditcp REAL(KIND=8) DIMENSION(*) for vslsseditcp C: const float* for vs1sSSEditCP const double* for vsldSSEditCP	Pointer to a cross-product matrix
cp_storage	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the cross-product matrix

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The `vslsSEditCP` routine replaces pointers to the array of means, array of sums, cross-product matrix, and its storage format with values passed as corresponding parameters of the routine. See [Table: "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the `cp_storage` parameter. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

Storage formats of a variance-covariance/correlation/cross-product matrix

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_FULL</code>	A symmetric variance-covariance/correlation/cross-product matrix is a one-dimensional array with elements $c(i, j)$ stored as $cp(i*p + j)$. The size of the array is $p*p$.
<code>VSL_SS_MATRIX_STORAGE_L_PACKED</code>	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + (2n - j)*(j - 1)/2)$ for $j \leq i$. The size of the array is $p*(p+1)/2$.

Parameter	Description
VSL_SS_MATRIX_STORAGE_U_PACKED	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + j*(j - 1)/2)$ for $i \leq j$. The size of the array is $p*(p + 1)/2$.

vslSSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

Syntax

Fortran:

```
status = vslssreditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

```
status = vslrssreditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

C:

```
status = vslsSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

```
status = vslsSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSTaskPtr	Descriptor of the task
p_idx_array	Fortran: INTEGER C: const MKL_INT*	Pointer to the array that encodes indices of subcomponents Z and Y of the random vector as described in section Mathematical Notation and Definitions . $p_{idx_array}[i]$ equals to -1 if the i -th component of the random vector belongs to Z 1, if the i -th component of the random vector belongs to Y.
cov	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpartialcovcor REAL(KIND=8) DIMENSION(*) for vslrssreditpartialcovcor	Pointer to a covariance matrix

Name	Type	Description
	<pre>C: const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor</pre>	
<i>cov_storage</i>	Fortran: INTEGER <pre>C: const MKL_INT*</pre>	Pointer to the storage format of the covariance matrix
<i>cor</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor C: const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor	Pointer to a correlation matrix
<i>cor_storage</i>	Fortran: INTEGER <pre>C: const MKL_INT*</pre>	Pointer to the storage format of the correlation matrix
<i>p_cov</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor C: const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor	Pointer to a partial covariance matrix
<i>p_cov_storage</i>	Fortran: INTEGER <pre>C: const MKL_INT*</pre>	Pointer to the storage format of the partial covariance matrix
<i>p_cor</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor C: const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor	Pointer to a partial correlation matrix
<i>p_cor_storage</i>	Fortran: INTEGER <pre>C: const MKL_INT*</pre>	Pointer to the storage format of the partial correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cov_storage`, `cor_storage`, `p_cov_storage`, and `p_cor_storage` parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

vslSSEditQuantiles

Modifies the pointers to parameters related to quantile computations.

Syntax

Fortran:

```
status = vslsseditquantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage)

status = vslseditquantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage)
```

C:

```
status = vslSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);

status = vslsSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of quantile orders
<i>quant_order</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditquantiles REAL(KIND=8) DIMENSION(*) for vslseditquantiles	Pointer to the array of quantile orders

Name	Type	Description
	C: const float* for vslssSEditQuantiles const double* for vsldSSEditQuantiles	
quants	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles C: const float* for vslssSEditQuantiles const double* for vsldSSEditQuantiles	Pointer to the array of quantiles
order_stats	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles C: const float* for vslssSEditQuantiles const double* for vsldSSEditQuantiles	Pointer to the array of order statistics
order_stats_storage	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the order statistics array

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The `vslssSEditQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See [Table "Storage format of matrix of observations and order statistics"](#) for possible values of the `order_statistics_storage` parameter. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

`vslssSEditStreamQuantiles`

Modifies the pointers to parameters related to quantile computations for streaming data.

Syntax

Fortran:

```
status = vslsseditstreamquantiles(task, quant_order_n, quant_order, quants, nparams,  
params)
```

```
status = vslsSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params)
```

C:

```
status = vsldsseditstreamquantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

```
status = vsldSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of quantile orders
<i>quant_order</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles C: const float* for vslsSSEditStreamQuantiles const double* for vsldSSEditStreamQuantiles	Pointer to the array of quantile orders
<i>quants</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles C: const float* for vslsSSEditStreamQuantiles const double* for vsldSSEditStreamQuantiles	Pointer to the array of quantiles
<i>nparams</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of the algorithm parameters
<i>params</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles REAL(KIND=8) DIMENSION(*)	Pointer to the array of the algorithm parameters

Name	Type	Description
	<code>for vslsSSEditStreamQuantiles</code>	
	<code>C: const float*</code>	
	<code>for vslsSSEditStreamQuantiles</code>	
	<code>const double*</code>	
	<code>for vslsSSEditStreamQuantiles</code>	

Output Parameters

Name	Type	Description
<code>status</code>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslsSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

vslsSSEditPooledCovariance

Modifies pooled/group covariance matrix array pointers.

Syntax

Fortran:

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov)
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov)
```

C:

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(VSL_SS_TASK) C: VSLSTaskPtr	Descriptor of the task

Name	Type	Description
<i>grp_indices</i>	Fortran: INTEGER DIMENSION(*) C: const MKL_INT*	Pointer to an array of size n . The i -th element of the array contains the number of the group the observation belongs to.
<i>pld_mean</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: const float* for vslsSEditPooledCovariance const double* for vslsSEEditPooledCovariance	Pointer to the array of pooled means
<i>pld_cov</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: const float* for vslsSEEditPooledCovariance const double* for vslsSEEditPooledCovariance	Pointer to the array that holds a pooled covariance matrix
<i>req_grp_indices</i>	Fortran: INTEGER DIMENSION(*) C: const MKL_INT*	Pointer to the array that contains indices of groups for which estimates to return (such as covariance and mean)
<i>grp_means</i>	Fortran: REAL(KIND=4) DIMENSION(*) for product=Fortran vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: const float* for vslsSEEditPooledCovariance const double* for vslsSEEditPooledCovariance	Pointer to the array of group means
<i>grp_cov</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: const float* for vslsSEEditPooledCovariance const double* for vslsSEEditPooledCovariance	Pointer to the array that holds group covariance matrices

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged. Use the `vslSSEditTask` routine to replace the storage format for pooled and group covariance matrices.

`vslSSEditRobustCovariance`

Modifies pointers to arrays related to a robust covariance matrix.

Syntax

Fortran:

```
status = vslsseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
status = vslseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
```

C:

```
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>rcov_storage</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of a robust covariance matrix
<i>nparams</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of method parameters
<i>params</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditrobustcovariance REAL(KIND=8) DIMENSION(*) for	Pointer to the array of method parameters

Name	Type	Description
	<pre> vsldsseditrobustcovariance C: const float* for vslsSSEditRobustCovariance const double* for vslsSSEditRobustCovariance </pre>	
rmean	<p>Fortran: REAL(KIND=4) DIMENSION(*) for</p> <pre> vslsseditrobustcovariance REAL(KIND=8) DIMENSION(*) for vsldsseditrobustcovariance C: const float* for vslsSSEditRobustCovariance const double* for vslsSSEditRobustCovariance </pre>	Pointer to the array of robust means
rcov	<p>Fortran: REAL(KIND=4) DIMENSION(*) for</p> <pre> vslsseditrobustcovariance REAL(KIND=8) DIMENSION(*) for vsldsseditrobustcovariance C: const float* for vslsSSEditRobustCovariance const double* for vslsSSEditRobustCovariance </pre>	Pointer to a robust covariance matrix

Output Parameters

Name	Type	Description
status	<p>Fortran: INTEGER</p> <p>C: int</p>	Current status of the task

Description

The `vslSSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size `nparams`
- pointers to the arrays that hold robust means and covariance

See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `rcov_storage` parameter. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of TBS Parameters" describes the *params* structure.

Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	ϵ	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p) / (2n)$.
1	α	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	δ	Stopping criterion: the algorithm is terminated if weights are changed less than δ . By default, the value is 0.001.
3	max_iter	Maximum number of iterations. The algorithm terminates after max_iter iterations. By default, the value is 10. If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

The robust estimator of variance-covariance implementation in Intel MKL requires that the number of observations n be greater than twice the number of variables: $n > 2p$.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Library Application Notes* document [[SSL Notes](#)].

vsISSEditOutliersDetection

Modifies array pointers related to multivariate outliers detection.

Syntax

Fortran:

```
status = vslssreditoutliersdetection(task, nparams, params, w)
status = vsldssreditoutliersdetection(task, nparams, params, w)
```

C:

```
status = vslsSSEditOutliersDetection(task, nparams, params, w);
status = vsldSSEditOutliersDetection(task, nparams, params, w);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task

Name	Type	Description
<i>nparams</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of method parameters
<i>params</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection C: const float* for vslsSSEditOutliersDetection const double* for vsldSSEEditOutliersDetection	Pointer to the array of method parameters
<i>w</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection C: const float* for vslsSSEditOutliersDetection const double* for vsldSSEEditOutliersDetection	Pointer to an array of size <i>n</i> . The array holds the weights of observations to be marked as outliers.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- the pointer to the array that holds the calculated weights of the observations

If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the *params* structure.

Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values: <code>VSL_SS_METHOD_BACON_MEDIAN_INIT</code> , if the algorithm is started using the median estimate. This is the default value of the parameter.

Array Position	Algorithm Parameter	Description
		VSL_SS_METHOD_BACON_MAHALANOBIS_INIT, if the algorithm is started using the Mahalanobis distances.
1	α	One-tailed probability that defines the $(1 - \alpha)$ quantile of χ^2 distribution with p degrees of freedom. The recommended value is α / n , where n is the number of observations. By default, the value is 0.05.
2	δ	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than δ . By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i) = 0` if i -th observation is detected as an outlier. Otherwise `BaconWeights(i) = w(i)`, where `w` is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the i -th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel(R) MKL Summary Statistics Library Application Notes* document [[SSL Notes](#)].

vslSSEditMissingValues

Modifies pointers to arrays associated with the method of supporting missing values in a dataset.

Syntax

Fortran:

```
status = vslssreditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

```
status = vsldssreditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

C:

```
status = vslsSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsldSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

estimates_n	Fortran: INTEGER C: const MKL_INT*	Pointer to the number of estimates to be returned by the routine
estimates	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmissingvalues REAL(KIND=8) DIMENSION(*) for vslseditmissingvalues C: const float* for vslssSEditMissingValues const double* for vslsSEditMissingValues	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The `vslssSEditMissingValues` routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Before you call the Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel MKL provides the `VSL_SS_METHOD_MI` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

NOTE

The DA component of the MI procedure is simulation-based and uses the `VSL_BRNG_MCG59` basic random number generator with predefined `seed = 250` and the Gaussian distribution generator (`ICDF` method) available in Intel MKL [Gaussian].

Pack the parameters of the MI algorithm into the `params` array. [Table "Structure of the Array of MI Parameters"](#) describes the `params` structure.

Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	<code>em_iter_num</code>	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	<code>da_iter_num</code>	Maximal number of iterations for the DA algorithm. By default, this value is 30.
2	ε	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than ε . By default, this value is 0.001.
3	<code>m</code>	Number of sets to impute
4	<code>missing_vals_num</code>	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array `init_estimates`. The size of the array should be at least $p + p(p + 1)/2$. For $i=0, \dots, p-1$, the `init_estimates[i]` array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass `prior` parameters for μ and Σ into the library: μ_0 , τ , m , and Λ^{-1} . Pack these parameters as a one-dimensional array `prior` with a size of at least

$$(p^2 + 3p + 4)/2.$$

The storage format is as follows:

- `prior[0], \dots, prior[p-1]` contain the elements of the vector μ_0 .
- `prior[p]` contains the parameter τ .
- `prior[p+1]` contains the parameter m .
- The remaining positions are occupied by the upper-triangular part of the inverted matrix Λ^{-1} .

If you provide no `prior` parameters, the editor uses their default values:

- The array of p zeros is used as μ_0 .
- τ is set to 0.
- m is set to p .
- The zero matrix is used as an initial approximate of Λ^{-1} .

The `EditMissingValues` editor returns m sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the `simul_missing_vals` array. The size of the array should be sufficient to hold m sets each of the `missing_vals_num` size, that is, at least $m * missing_vals_num$ in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations n is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is $m=2$. Then, `simul_missing_vals[0]` and `simul_missing_vals[1]` contains the first and the second points for the second observation vector, and `simul_missing_vals[2]` holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

$$m \cdot da_iter_num \cdot (p + (p^2 + p) / 2)$$

where

- m is the number of sets of values to impute.
- `da_iter_num` is the number of DA iterations.
- The value $p + (p^2 + p) / 2$ determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first p positions and the remaining $(p^2 + p) / 2$ positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of m sets of imputed values, you can place them in cells of the data matrix with missing values and use the Summary Statistics routines to analyze and get estimates for each of the m complete datasets.

NOTE

Intel MKL implementation of the MI algorithm rewrites cells of the dataset that contain the `VSL_SS_SNAN`/`VSL_SS_DNAN` values. If you want to use the Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Library Application Notes* document [[SSL Notes](#)].

[vslSSEditCorParameterization](#)

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

Syntax

Fortran:

```
status = vslsseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
status = vslseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
```

C:

```
status = vslsSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
status = vslsSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>cor</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditcorparameterization REAL (KIND=8) DIMENSION(*) for vsldsseditcorparameterization C: const float* for vslsSSEditCorParameterization const double* for vsldSSEditCorParameterization	Pointer to the correlation matrix
<i>cor_storage</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the correlation matrix
<i>pcor</i>	Fortran: REAL (KIND=4) DIMENSION(*) for vslsseditcorparameterization REAL (KIND=8) DIMENSION(*) for vsldsseditcorparameterization C: const float* for vslsSSEditCorParameterization const double* for vsldSSEditCorParameterization	Pointer to the parameterized correlation matrix
<i>por_storage</i>	Fortran: INTEGER C: const MKL_INT*	Pointer to the storage format of the parameterized correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cor_storage` and `pcor_storage` parameters. If an input parameter is NULL, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. [Table "Summary Statistics Estimates Obtained with vsISSCompute Routine"](#) lists the statistical estimates that you can obtain using the `vsISSCompute` routine.

NOTE

The Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

Summary Statistics Estimates Obtained with vsISSCompute Routine

Estimate	Support of Observations Available in Blocks	Description
<code>VSL_SS_MEAN</code>	Yes	Computes the array of means.
<code>VSL_SS_SUM</code>	Yes	Computes the array of sums.
<code>VSL_SS_2R_MOM</code>	Yes	Computes the array of the 2 nd order raw moments.
<code>VSL_SS_2R_SUM</code>	Yes	Computes the array of raw sums of the 2 nd order.
<code>VSL_SS_3R_MOM</code>	Yes	Computes the array of the 3 rd order raw moments.
<code>VSL_SS_3R_SUM</code>	Yes	Computes the array of raw sums of the 3 rd order.
<code>VSL_SS_4R_MOM</code>	Yes	Computes the array of the 4 th order raw moments.
<code>VSL_SS_4R_SUM</code>	Yes	Computes the array of raw sums of the 4 th order.
<code>VSL_SS_2C_MOM</code>	Yes	Computes the array of the 2 nd order central moments.
<code>VSL_SS_2C_SUM</code>	Yes	Computes the array of central sums of the 2 nd order.
<code>VSL_SS_3C_MOM</code>	Yes	Computes the array of the 3 rd order central moments.
<code>VSL_SS_3C_SUM</code>	Yes	Computes the array of central sums of the 3 rd order.
<code>VSL_SS_4C_MOM</code>	Yes	Computes the array of the 4 th order central moments.
<code>VSL_SS_4C_SUM</code>	Yes	Computes the array of central sums of the 4 th order.
<code>VSL_SS_KURTOSIS</code>	Yes	Computes the array of kurtosis values.
<code>VSL_SS_SKEWNESS</code>	Yes	Computes the array of skewness values.
<code>VSL_SS_MIN</code>	Yes	Computes the array of minimum values.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_MAX	Yes	Computes the array of maximum values.
VSL_SS_VARIATION	Yes	Computes the array of variation coefficients.
VSL_SS_COV	Yes	Computes a covariance matrix.
VSL_SS_COR	Yes	Computes a correlation matrix. The main diagonal of the correlation matrix holds variances of the random vector components.
VSL_SS_CP	Yes	Computes a cross-product matrix.
VSL_SS_POOLED_COV	No	Computes a pooled covariance matrix.
VSL_SS_POOLED_MEAN	No	Computes an array of pooled means.
VSL_SS_GROUP_COV	No	Computes group covariance matrices.
VSL_SS_GROUP_MEAN	No	Computes group means.
VSL_SS_QUANTS	No	Computes quantiles.
VSL_SS_ORDER_STATS	No	Computes order statistics.
VSL_SS_ROBUST_COV	No	Computes a robust covariance matrix.
VSL_SS_OUTLIERS	No	Detects outliers in the dataset.
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.
VSL_SS_MDAD	No	Computes median absolute deviation.
VSL_SS_MNAD	No	Computes mean absolute deviation.

[Table "Summary Statistics Computation Method"](#) lists estimate calculation methods supported by Intel MKL. See the *Intel(R) MKL Summary Statistics Library Application Notes* document [[SSL Notes](#)] for a detailed description of the methods.

Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	<p>Fast method for calculation of the estimates:</p> <ul style="list-style-type: none"> • raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix • min/max/quantile/order statistics • partial variance-covariance • median/mean absolute deviation
VSL_SS_METHOD_FAST_USER_MEAN	Fast method for calculation of the estimates given user-defined mean:

Method	Description
	<ul style="list-style-type: none"> central moments/sums of 2-4 order, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix, mean absolute deviation
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates:
	<ul style="list-style-type: none"> raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix pooled/group covariance matrix
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the Compute routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
...
status = vsldSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate [Editors](#) to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See [Table "Summary Statistics Estimates Obtained with vs1SSCompute Routine"](#) for information on such observations supported by the Intel MKL Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslSSCompute

Computes Summary Statistics estimates.

Syntax**Fortran:**

```
status = vslssscompute(task, estimates, method)
status = vslldsscompute(task, estimates, method)
```

C:

```
status = vsllsSSCompute(task, estimates, method);
status = vsldSSCompute(task, estimates, method);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>estimates</i>	Fortran: INTEGER (KIND=8) C: const MKL_INT64	List of statistical estimates to compute
<i>method</i>	Fortran: INTEGER C: const MKL_INT	Method to be used in calculations

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSCompute` routine calculates statistical estimates passed as the `estimates` parameter using the algorithms passed as the `method` parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See [Table "Summary Statistics Estimates Obtained with Compute Routine"](#) for the list of the estimates that you can calculate with the `vslSSCompute` routine. See [Table "Summary Statistics Computation Methods"](#) for the list of possible values of the `method` parameter.

To initialize single or double precision version task parameters, use the single (`vslssscompute`) or double (`vslldsscompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslisscompute`).

NOTE

Requesting a combination of the `VSL_SS_MISSING_VALS` value and any other estimate parameter in the `Compute` function results in processing only the missing values.

Application Notes

Be aware that when computing a correlation matrix, the `vslSSCompute` routine allocates an additional array for each thread which is running the task. If you are running on a large number of threads `vslSSCompute` might consume large amounts of memory.

When calculating covariance, correlation, or cross product, the number of bytes of memory required is at least $(P*P*T + P*T)*b$, where P is the dimension of the task or number of variables, T is the number of threads, and b is the number of bytes required for each unit of data. If observation is weighted and the method is `VSL_SS_METHOD_FAST`, then the memory required is at least $(P*P*T + P*T + N*P)*b$, where N is the number of observations.

Task Destructor

Task destructor is the `vslSSDeleteTask` routine intended to delete task objects and release memory.

vslSSDeleteTask

Destroys the task object and releases the memory.

Syntax

Fortran:

```
status = vslssdeletetask(task)
```

C:

```
status = vslSSDeleteTask(&task);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: <code>TYPE(VSL_SS_TASK)</code> C: <code>VSLSSTaskPtr*</code>	Descriptor of the task to destroy

Output Parameters

Name	Type	Description
<code>status</code>	Fortran: <code>INTEGER</code> C: <code>int</code>	Sets to <code>VSL_STATUS_OK</code> if the task is deleted; otherwise a non-zero code is returned.

Description

The `vslSSDeleteTask` routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to `NULL`. If `vslSSDeleteTask` fails to delete the task successfully, it returns an error code.

NOTE

Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

Usage Examples

The following examples show various standard operations with Summary Statistics routines.

Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
...
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vsldSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );
```

You can process data arrays that come in blocks as follows:

```
for ( i = 0; i < num_of_blocks; i++ )
{
    status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
```

Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```

/* Set parameters for the task */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vslSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );

/* Initialize the task parameters */
status = vslSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vslSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vslSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */
status = vslSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vslSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vslSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
...
status = vslSSDeleteTask( &task );

```

Similarly, you can modify indices of the variables to be processed for the next data block.

Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel MKL Summary Statistics functions.

Matrix and Weights of Observations

For a random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, this manual denotes the following:

- $(X)_{i=(x_{ij})_{j=1..n}}$ is the result of n independent observations for the i -th component ξ_i of the vector ξ .
- The two-dimensional array $X=(x_{ij})_{p \times n}$ is the matrix of observations.
- The column $[X]_{j=(x_{ij})_{i=1..p}}$ of the matrix X is the j -th observation of the random vector ξ .

Each observation $[X]_j$ is assigned a non-negative weight w_j , where

- The vector $(w_j)_{j=1..n}$ is a vector of weights corresponding to n observations of the random vector ξ .
-

$$W = \sum_{i=1}^n w_i$$

is the accumulated weight corresponding to observations X .

Vector of sample means

$$M(X) = (M_1(X), \dots, M_p(X)) \text{ with } M_i(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}$$

for all $i = 1, \dots, p$.

Vector of sample partial sums

$$S(X) = (S_1(X), \dots, S_p(X)) \text{ with } S_i(X) = \sum_{j=1}^n w_j x_{ij}$$

for all $i = 1, \dots, p$.

Vector of sample variances

$$V(X) = (V_1(X), \dots, V_p(X)) \text{ with } V_i(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^2, B = W - \sum_{j=1}^n w_j^2 / W$$

for all $i = 1, \dots, p$.

Vector of sample raw/algebraic moments of k -th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \dots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}^k$$

for all $i = 1, \dots, p$.

Vector of sample raw/algebraic partial sums of k -th order, $k = 2, 3, 4$ (raw/algebraic partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j x_{ij}^k$$

for all $i = 1, \dots, p$.

Vector of sample central moments of the third and the fourth order

$$C^{(k)}(X) = (C_1^{(k)}(X), \dots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^k, B = \sum_{j=1}^n w_j$$

for all $i = 1, \dots, p$ and $k = 3, 4$.

Vector of sample central partial sums of k -th order, $k = 2, 3, 4$ (central partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j (x_{ij} - S_i(X))^k$$

for all $i = 1, \dots, p$.

Vector of sample excess kurtosis values

$$B(X) = (B_1(X), \dots, B_p(X)) \text{ with } B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all $i = 1, \dots, p$.

Vector of sample skewness values

$$\Gamma(X) = (\Gamma_1(X), \dots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all $i = 1, \dots, p$.

Vector of sample variation coefficients

$$VC(X) = (VC_1(X), \dots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all $i = 1, \dots, p$.

Matrix of order statistics

Matrix $Y = (Y_{ij})_{pxn}$, in which the i -th row $(Y)_i = (Y_{ij})_{j=1\dots n}$ is obtained as a result of sorting in the ascending order of row $(X)_i = (x_{ij})_{j=1\dots n}$ in the original matrix of observations.

Vector of sample minimum values

$$Min(X) = (Min_1(X), \dots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all $i = 1, \dots, p$.

Vector of sample maximum values

$$\text{Max}(X) = (\text{Max}_1(X), \dots, \text{Max}_p(X)), \text{ where } \text{Max}_i(X) = y_{i\text{m}}$$

for all $i = 1, \dots, p$.

Vector of sample median values

$$\text{Med}(X) = (\text{Med}_1(X), \dots, \text{Med}_p(X)), \text{ where } \text{Med}_i(X) = \begin{cases} y_{i,(n+1)/2}, & \text{if } n \text{ is odd} \\ (y_{i,n/2} + y_{i,n/2+1})/2, & \text{if } n \text{ is even} \end{cases}$$

for all $i = 1, \dots, p$.

Vector of sample median absolute deviations

$$MDAD(X) = (MDAD_1(X), \dots, MDAD_p(X)) \text{ where}$$

$$MDAD_i(X) = \text{Med}_i(Z) \text{ with } Z = (z_{ij})_{i=1 \dots p, j=1 \dots n}, z_{ij} = |x_{ij} - \text{Med}_i(X)|$$

for all $i = 1, \dots, p$.

Vector of sample mean absolute deviations

$$\dots, (|x_{11} - \bar{x}|, \dots, |x_{1n} - \bar{x}|), (|x_{21} - \bar{x}|, \dots, |x_{2n} - \bar{x}|), \dots, (|x_{p1} - \bar{x}|, \dots, |x_{pn} - \bar{x}|)$$

$$\dots, (|x_{11} - \bar{x}|, \dots, |x_{1n} - \bar{x}|), (|x_{21} - \bar{x}|, \dots, |x_{2n} - \bar{x}|), \dots, (|x_{p1} - \bar{x}|, \dots, |x_{pn} - \bar{x}|),$$

for all $i = 1, \dots, p$.

Vector of sample quantile values

For a positive integer number q and k belonging to the interval $[0, q-1]$, point z_i is the k -th q quantile of the random variable ξ_i if $P\{\xi_i \leq z_i\} \geq \beta$ and $P\{\xi_i \leq z_i\} \geq 1 - \beta$, where

- P is the probability measure.
- $\beta = k/n$ is the quantile order.

The calculation of quantiles is as follows:

$j = [(n-1)\beta]$ and $f = \{(n-1)\beta\}$ as integer and fractional parts of the number $(n-1)\beta$, respectively, and the vector of sample quantile values is

$$Q(X, \beta) = (Q_1(X, \beta), \dots, Q_p(X, \beta))$$

where

$$(Q_i(X, \beta)) = y_{i,j+1} + f(y_{i,j+2} - y_{i,j+1})$$

for all $i = 1, \dots, p$.

Variance-covariance matrix

$$C(X) = (c_{ij}(X))_{p \times p}$$

where

$$c_{ij}(X) = \frac{1}{B} \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), B = W - \sum_{j=1}^n w_j^2 / W$$

Cross-product matrix (matrix of cross-products and sums of squares)

$$CP(X) = (cp_{ij}(X))_{p \times p}$$

where

$$cp_{ij}(X) = \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X))$$

Pooled and group variance-covariance matrices

The set $N = \{1, \dots, n\}$ is partitioned into non-intersecting subsets

$$G_i, i = 1..g, N = \bigcup_{i=1}^g G_i$$

The observation $[X]_j = (x_{ij})_{i=1..p}$ belongs to the group r if $j \in G_r$. One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \dots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, W^{(r)} = \sum_{j \in G_r} w_j$$

for all $i = 1, \dots, p$,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \dots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \dots + W^{(g)}} \sum_{r=1}^g W^{(r)} M_i^{(r)}(X)$$

for all $i = 1, \dots, p$,

$$C^{pooled}(X) = (C_{ij}^{pooled}(X))_{p \times p}, C_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \dots + B^{(g)}} \sum_{r=1}^g B^{(r)} C_{ij}^{(r)}(X)$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{C_{ij}}{\sqrt{C_{ii} C_{jj}}}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Partial variance-covariance matrix

For a random vector ξ partitioned into two components Z and Y , a variance-covariance matrix C describes the structure of dependencies in the vector ξ :

$$C(X) = \begin{bmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{bmatrix}.$$

The partial covariance matrix $P(X) = (p_{ij}(X))_{k \times k}$ is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}(X)C_{ZY}(X).$$

where k is the dimension of Y .

Partial correlation matrix

The following is a partial correlation matrix for all $i = 1, \dots, k$ and $j = 1, \dots, k$:

$$RP(X) = (rp_{ij}(X))_{k \times k}, \text{ where } rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- k is the dimension of Y .
- $p_{ij}(X)$ are elements of the partial variance-covariance matrix.

Fourier Transform Functions

The general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_1 = 0, \dots, n_1-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the inverse (backward) transform. In the forward transform, the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® Math Kernel Library (Intel® MKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. Prefixes `Dfti` in function names and `DFTI` in the names of configuration parameters stand for Discrete Fourier Transform Interface.

This chapter describes the following implementations of the fast Fourier transform functions available in Intel MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#))
- [Cluster FFT functions](#) for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* operating systems only)

NOTE

Intel MKL also supports the FFTW3* interfaces to the fast Fourier transform functionality for shared memory paradigm (SMP) systems.

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.
3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward/DftiComputeBackward` or `DftiComputeForwardDM/DftiComputeBackwardDM` functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.

5. Deallocate the descriptor with a call to the [DftiFreeDescriptor](#) or [DftiFreeDescriptorDM](#) function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the [DftiErrorClass](#) or [DftiErrorMessage](#) function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel MKL User's Guide* for specific radices supported efficiently.

NOTE

The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see [Example "Conversion from Cartesian to polar representation of complex data"](#) and [Example "Conversion from polar to Cartesian representation of complex data"](#)).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

[Table "FFT Functions in Intel MKL"](#) lists FFT functions implemented in Intel MKL:

FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptor	Allocates the descriptor data structure and initializes it with default configuration values.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
DftiCopyDescriptor	Makes a copy of an existing descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.

Function Name	Operation
<code>DftiGetValue</code>	Gets the value of one particular configuration parameter.
Status Checking Functions	
<code>DftiErrorClass</code>	Checks if the status reflects an error of a predefined class.
<code>DftiErrorMessage</code>	Translates the numeric value of an error status into a message.

FFT Interface

The Intel MKL FFT functions are provided with the Fortran and C interfaces. Fortran 95 is required because it offers features that have no counterpart in FORTRAN 77.

NOTE

The Fortran interface of the FFT computation functions requires one-dimensional data arrays for any dimension of FFT problem. For multidimensional transforms, pass the address of the first column of the multidimensional data to the computation functions.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

To use the FFT functions, you need to access the module `MKL_DFTI` through the Fortran `use` statement or include `mkl_dfti.h` in your C code.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`, named constants representing various names of configuration parameters and their possible values, and overloaded functions through the generic functionality of Fortran 95.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

NOTE

The current version of the library may not support some of the FFT functions or functionality described in the subsequent sections of this chapter. You can find the complete list of the implementation-specific exceptions in the Intel MKL Release Notes.

For the main categories of Intel MKL FFT functions, see [FFT Functions](#).

Computing an FFT

You can find code examples that compute transforms in the [Fourier Transform Functions Code Examples](#) section in the Code Examples appendix.

Usually you can compute an FFT by five function calls (refer to the [usage model](#) for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function `DftiSetValue` as illustrated in [Example "Changing Default Settings \(Fortran\)"](#) and [Example "Changing Default Settings \(C\)"](#).

Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. In C, these named constants have the enumeration type `DFTI_CONFIG_PARAM`.

All the Intel MKL FFT configuration parameters are readable. Some of them are read-only, while others can be set using the `DftiCreateDescriptor` or `DftiSetValue` function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a single-precision number.
- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants. In C, the named constants for configuration values have the enumeration type `DFTI_CONFIG_VALUE`.

[Table "Configuration Parameters"](#) summarises the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

Configuration Parameters

Configuration Parameter	Type/Value	Comments
<i>Most common configuration parameters, no default, must be set explicitly by <code>DftiCreateDescriptor</code></i>		
<code>DFTI_PRECISION</code>	Named constant <code>DFTI_SINGLE</code> or <code>DFTI_DOUBLE</code>	Precision of the computation.
<code>DFTI_FORWARD_DOMAIN</code>	Named constant <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code>	Type of the transform.
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform.
<code>DFTI_LENGTH</code>	Integer scalar/array	Lengths of each dimension.
<i>Common configuration parameters, settable by <code>DftiSetValue</code></i>		
<code>DFTI_PLACEMENT</code>	Named constant <code>DFTI_INPLACE</code> or <code>DFTI_NOT_INPLACE</code>	Defines whether the result overwrites the input data. Default value: <code>DFTI_INPLACE</code> .
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_NUMBER_OF_USER_THREADS</code>	Integer scalar	This configuration parameter is no longer used and kept for compatibility with previous versions of Intel MKL.

Configuration Parameter	Type/Value	Comments
DFTI_THREAD_LIMIT	Integer scalar	Limits the number of threads for the DftiComputeForward and DftiComputeBackward functions to use. Default value: 0. In case of the default value, call mkl_domain_set_num_threads to limit the number of threads for the FFT computation functions.
DFTI_DESCRIPTOR_NAME	Character string	Assigns a name to a descriptor. Assumed length of the string is DFTI_MAX_NAME_LENGTH. Default value: empty string.
<i>Data layout configuration parameters for single and multiple transforms. Settable by DftiSetValue</i>		
DFTI_INPUT_STRIDES	Integer array	Defines the input data layout.
DFTI_OUTPUT_STRIDES	Integer array	Defines the output data layout.
DFTI_NUMBER_OF_TRANSFORMS	Integer scalar	Number of transforms. Default value: 1.
DFTI_INPUT_DISTANCE	Integer scalar	Defines the distance between input data sets for multiple transforms. Default value: 0.
DFTI_OUTPUT_DISTANCE	Integer scalar	Defines the distance between output data sets for multiple transforms. Default value: 0.
DFTI_COMPLEX_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_REAL_REAL	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays. Default value: DFTI_COMPLEX_COMPLEX.
DFTI_REAL_STORAGE	Named constant DFTI_REAL_REAL	Defines how real data for a real transform is stored. Only the DFTI_REAL_REAL value is supported.
DFTI_CONJUGATE_EVEN_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_COMPLEX_REAL	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements. For the default value, see the detailed description.
DFTI_PACKED_FORMAT	Named constant DFTI_CCE_FORMAT, DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT	Defines the layout of real elements in the backward domain of a one-dimensional or two-dimensional real transform.

Advanced configuration parameters, settable by [DftiSetValue](#)

Configuration Parameter	Type/Value	Comments
DFTI_WORKSPACE	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the library should prefer algorithms using additional memory. Default value: DFTI_ALLOW.
DFTI_ORDERING	Named constant DFTI_ORDERED or DFTI_BACKWARD_SCRAMBLE	Defines whether the result of a complex transform is ordered or permuted. Default value: DFTI_ORDERED.
<i>Read-Only configuration parameters</i>		
DFTI_COMMIT_STATUS	Named constant DFTI_UNCOMMITTED or DFTI_COMMITED	Readiness of the descriptor for computation.
DFTI_VERSION	String	Version of Intel MKL. Assumed length of the string is DFTI_VERSION_LENGTH.

DFTI_PRECISION

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

`DFTI_PRECISION` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

NOTE

Fortran module `MKL_DFTI` also defines named constants `DFTI_SINGLE_R` and `DFTI_DOUBLE_R`, with the same semantics as `DFTI_SINGLE` and `DFTI_DOUBLE`, respectively. Do not use these constants to set the `DFTI_PRECISION` configuration parameter. Use them only as described in section [DftiCreateDescriptor](#).

To better understand configuration of the precision of transforms, you can refer to these examples in your Intel MKL directory:

C:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
./examples/dftc/source/basic_dp_complex_dft_1d.c
```

Fortran:

```
./examples/dftf/source/basic_sp_complex_dft_1d.f90
./examples/dftf/source/basic_dp_complex_dft_1d.f90
```

[DFTI_FORWARD_DOMAIN](#)

[DFTI_DIMENSION, DFTI_LENGTHS](#)

[DftiCreateDescriptor](#)

DFTI_FORWARD_DOMAIN

The general form of a discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \cdots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the backward transform.

The Intel MKL implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the `DFTI_FORWARD_DOMAIN` configuration parameter: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table "Correspondence of Forward and Backward Domain"](#).

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \dots, k_d) = \text{conjugate}(x(n_1 - k_1, n_2 - k_2, \dots, n_d - k_d)),$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\dots, expr_s, \dots) \equiv x(\dots, \text{mod}(expr_s, n_s), \dots),$$

and therefore

$$x(\dots, n_s, \dots) \equiv x(\dots, 0, \dots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [DFTI_CONJUGATE_EVEN_STORAGE](#).

[Correspondence of Forward and Backward Domain](#)

Forward Domain	Implied Backward Domain
Complex (<code>DFTI_COMPLEX</code>)	Complex (<code>DFTI_COMPLEX</code>)
Real (<code>DFTI_REAL</code>)	Conjugate-even

`DFTI_FORWARD_DOMAIN` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand usage of the `DFTI_FORWARD_DOMAIN` configuration parameter, you can refer to these examples in your Intel MKL directory:

C:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
./examples/dftc/source/basic_sp_real_dft_1d.c
```

Fortran:

```
./examples/dftf/source/basic_sp_complex_dft_1d.f90
./examples/dftf/source/basic_sp_real_dft_1d.f90
```

[DFTI_PRECISION](#)

[DFTI_DIMENSION, DFTI_LENGTHS](#)

[DftiCreateDescriptor](#)

DFTI_DIMENSION, DFTI_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer array (of `Integer` data type in Fortran and `MKL_LONG` data type in C).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

To better understand usage of the `DFTI_DIMENSION` and `DFTI_LENGTHS` configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel MKL directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

C:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
./examples/dftc/source/basic_sp_complex_dft_2d.c
```

Fortran:

```
./examples/dftf/source/basic_sp_real_dft_2d.f90
./examples/dftf/source/basic_sp_complex_dft_2d.f90
```

See Also

[DFTI_FORWARD_DOMAIN](#)[DFTI_PRECISION](#)[DftiCreateDescriptor](#)[DftiSetValue](#)

DFTI_PLACEMENT

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. You can change that by setting it to `DFTI_NOT_INPLACE`.

NOTE

The data sets have no common elements.

To better understand usage of the `DFTI_PLACEMENT` configuration parameter, refer to the following examples in your Intel MKL directory:

C:

```
./examples/dftc/source/config_placement.c
```

Fortran:

```
./examples/dftf/source/config_placement.f90
```

[DftiSetValue](#)

DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE

The forward transform and backward transform are each associated with a scale factor σ of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be $1/n$, thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

NOTE

For inquiry of the scale factor with the `DftiGetValue` function in C, the `config_val` parameter must have the same floating-point precision as the descriptor.

DFTI_NUMBER_OF_USER_THREADS

The `DFTI_NUMBER_OF_USER_THREADS` configuration parameter is no longer used and kept for compatibility with previous versions of Intel MKL.

See Also

`DftiSetValue`

DFTI_THREAD_LIMIT

In some situations you may need to limit the number of threads that the `DftiComputeForward` and `DftiComputeBackward` functions use. For example, if more than one thread calls Intel MKL, it might be important that the thread calling these functions does not oversubscribe computing resources (CPU cores). Similarly, a known limit of the maximum number of threads to be used in computations might help the `DftiCommitDescriptor` function to select a more optimal computation method.

Set the parameter `DFTI_THREAD_LIMIT` as follows:

- To a positive number, to specify the maximum number of threads to be used by the compute functions.
- To zero (the default value), to use the maximum number of threads specified by threading control functions `mkl_set_num_threads_local`, `mkl_set_num_threads`, `mkl_domain_set_num_threads`, and/or `omp_set_num_threads`.

On an attempt to set a negative value, the `DftiSetValue` function returns an error and does not update the descriptor.

The value of the `DFTI_THREAD_LIMIT` configuration parameter returned by the `DftiGetValue` function is defined as follows:

- 1 if Intel MKL runs in the sequential mode
 - Depends of the commit status of the descriptor if Intel MKL runs in a threaded mode:
-

Commit Status	Value
Not committed	The value of <code>DFTI_THREAD_LIMIT</code> set in a previous call to the <code>DftiSetValue</code> function or the default value
Committed	The minimum of the value returned by the <code>mkl_domain_get_max_threads(MKL_DOMAIN_FFT)</code> function call and the optimal number of threads computed by the <code>DftiCommitDescriptor</code> function

To better understand usage of the `DFTI_THREAD_LIMIT` configuration parameter, refer to the following examples in your Intel MKL directory:

C:

```
./examples/dftc/source/config_thread_limit.c
```

Fortran:

```
./examples/dftf/source/config_thread_limit.f90
```

DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For d -dimensional data set X defined by dimensions $N_1 \times N_2 \times \dots \times N_d$, the layout describes where a particular element $X(k_1, k_2, \dots, k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2, \dots, k_d)$ is expressed by the formula

$$\begin{aligned} \text{address of } X(k_1, k_2, \dots, k_d) &= \text{address of } X(0, 0, \dots, 0) + \text{offset} \\ &= \text{address of } X(0, 0, \dots, 0) + s_0 + k_1*s_1 + k_2*s_2 + \dots + k_d*s_d, \end{aligned}$$

where s_0 is the displacement and s_1, \dots, s_d are generalized strides. The configuration parameters [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) enable you to get and set these values. The configuration value is an array of values (s_0, s_1, \dots, s_d) of [INTEGER](#) data type in Fortran and [MKL_LONG](#) data type in C.

The offset is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the

[DFTI_FORWARD_DOMAIN](#), [DFTI_COMPLEX_STORAGE](#), and [DFTI_CONJUGATE_EVEN_STORAGE](#) configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#):

Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX	Complex	Complex
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX	Real	Complex

The [DFTI_INPUT_STRIDES](#) configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the [DftiComputeForward](#) function and by the backward domain for the [DftiComputeBackward](#) function. The [DFTI_OUTPUT_STRIDES](#) configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the [DftiComputeForward](#) function and by the forward domain for [DftiComputeBackward](#) function.

NOTE

The [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^d (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
/* C/C++ */
MKL_LONG dims[] = { nd, ..., n2, n1 };
DftiCreateDescriptor( &hand, precision, domain, d, dims );
// The above call assumes data declaration: type X[nd]...[n2][n1]
// Default strides are { 0, nd*...*n2*n1, ..., n2*n1, n1, 1 }
```

```
! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
status = DftiCreateDescriptor( hand, precision, domain, d, dims )
! The above call assumes data declaration: type X(n1,n2,...,nd)
! Default strides are [ 0, 1, n1, n1*n2, ..., n1*n2*...*nd]
```

Note that in case of a real FFT (`DFTI_FORWARD_DOMAIN=DFTI_REAL`), where different data layouts in the backward domain are available (see [DFTI_PACKED_FORMAT](#)), the default value of the strides is not intuitive for the recommended CCE format (configuration setting

`DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
/* C/C++ */
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG rstrides[] = { 0, 2*nd*...*n2*(n1/2+1), ..., 2*n2*(n1/2+1), 2*(n1/2+1), 1 };
MKL_LONG cstrides[] = { 0, nd*...*n2*(n1/2+1), ..., n2*(n1/2+1), (n1/2+1), 1 };
DftiCreateDescriptor( &hand, precision, DFTI_REAL, d, dims );
DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform
```

```
! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
INTEGER :: rstrides(1+d) = [0, 1, 2*(n1/2+1), 2*(n1/2+1)*n2, ... ]
INTEGER :: cstrides(1+d) = [0, 1, (n1/2+1), (n1/2+1)*n2, ... ]
status = DftiCreateDescriptor( hand, precision, domain, d, dims )
status = DftiSetValue( hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
! Set the strides appropriately for forward/backward transform
```

To better understand configuration of strides, you can also refer to these examples in your Intel MKL directory:

C:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
./examples/dftc/source/basic_sp_real_dft_3d.c
./examples/dftc/source/basic_dp_real_dft_2d.c
./examples/dftc/source/basic_dp_real_dft_3d.c
```

Fortran:

```

DFTI_NUMBER_OF_TRANSFORMS

In some situations, you may need to perform a number of identical FFTs. You can do this with a single call to a `DftiCompute*` function if the value of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter is set to the actual number of the transforms. The default value of this parameter is one. You can set this parameter to a positive integer value using the `Integer` data type in Fortran and `MKL_LONG` data type in C. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input and output data sets using one of the `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` configuration parameters or both.

-
- The data sets to be transformed must not have common elements.
 - All the sets of data must be located within the same memory block.
-

To better understand usage of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter, refer to the following examples in your Intel MKL directory:

C:

```
./examples/dftc/source/config_number_of_transforms.c
```

Fortran:

```
./examples/dftf/source/config_number_of_transforms.f90
```

[FFT Computation Functions](#)
[DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE](#)
[DftiSetValue](#)

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE

The FFT interface in Intel MKL enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, `DFTI_INPUT_DISTANCE` for input data or `DFTI_OUTPUT_DISTANCE` for output data, specifies the distribution. The configuration setting is a value of `INTEGER` data type in Fortran and `MKL_LONG` data type in C.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see [DFTI_NUMBER_OF_TRANSFORMS](#)).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#).

NOTE

The configuration parameters `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_DISTANCE` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_DISTANCE` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

The following example in C and Fortran illustrates setting of the `DFTI_INPUT_DISTANCE` configuration parameter:

```
/* C/C++ */
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG distance = nd*...*n2*n1;
DftiCreateDescriptor( &hand, precision, DFTI_COMPLEX, d, dims );
DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, (MLK_LONG)howmany );
DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );

! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
INTEGER :: distance = n1*n2*...*nd
status = DftiCreateDescriptor( hand, precision, DFTI_COMPLEX, d, dims)
status = DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, howmany )
status = DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );
```

To better understand configuration of the distances, you can also refer to the following examples in your Intel MKL directory:

C:

```
./examples/dftc/source/config_number_of_transforms.c
```

Fortran:

```
./examples/dftf/source/config_number_of_transforms.f90
```

[DftiComputeForward](#)

[DftiComputeBackward](#)

DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE

Depending on the value of the `DFTI_FORWARD_DOMAIN` configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see `DFTI_INPUT_STRIDES`, `DFTI_OUTPUT_STRIDES`). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see `DFTI_NUMBER_OF_TRANSFORMS` and `DFTI_INPUT_DISTANCE`, `DFTI_OUTPUT_DISTANCE`).

TIP

In C/C++, avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

[FFT Examples](#) demonstrate the usage of storage formats in both C and Fortran.

DFTI_COMPLEX_STORAGE: storage schemes for a complex domain

For the DFTI_COMPLEX forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter DFTI_COMPLEX_STORAGE can have one of the two values: DFTI_COMPLEX_COMPLEX (default) or DFTI_REAL_REAL.

NOTE

In the Intel MKL FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With DFTI_COMPLEX_COMPLEX storage, complex-valued data sequences are referenced by a single complex parameter (array) AZ so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m-th d-dimensional sequence is located at $AZ[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$ as a structure consisting of the real and imaginary parts.

The following code illustrates usage of the DFTI_COMPLEX_COMPLEX storage:

```
! Fortran
complex :: AZ(N1,N2,N3,M) ! sizes and number of transforms
...
! on input: Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)
status = DftiComputeForward( desc, AZ(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)

// C/C++
complex *AZ = malloc( N1*N2*N3*M * sizeof(AZ[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AZ );
// on output: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

With the DFTI_REAL_REAL storage, complex-valued data sequences are referenced by two real parameters AR and AI so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m-th sequence is computed as $AR[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d] + \sqrt{-1} * AI[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$.

The following code illustrates usage of the DFTI_REAL_REAL storage:

```
! Fortran
real :: AR(N1,N2,N3,M), AI(N1,N2,N3,M)
...
! on input: Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))
status = DftiComputeForward( desc, AR(:,1,1,1), AI(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))

// C/C+
float *AR = malloc( N1*N2*N3*M * sizeof(AR[0]) );
float *AI = malloc( N1*N2*N3*M * sizeof(AI[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AR, AI );
```

```
// on output: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

DFTI_REAL_STORAGE: storage schemes for a real domain

The Intel MKL FFT interface supports only one configuration value for this storage scheme: DFTI_REAL_REAL. With the DFTI_REAL_REAL storage, real-valued data sequences in a real domain are referenced by one real parameter AR so that real-valued element of the m -th sequence is located as $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*strided]$.

DFTI_CONJUGATE_EVEN_STORAGE: storage scheme for a conjugate-even domain

The Intel MKL FFT interface supports two configuration values for this parameter: DFTI_COMPLEX_REAL (default) and DFTI_COMPLEX_COMPLEX. In both cases, the conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the DFTI_COMPLEX_REAL storage, the complex-valued data sequences in the conjugate-even domain can be reconstructed as described in section [DFTI_PACKED_FORMAT](#).

Important

Although DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL is the default setting for the DFTI_REAL forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms and will be deprecated in future.

With the DFTI_COMPLEX_COMPLEX storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter AZ so that a complex-valued element Z_{k_1, k_2, \dots, k_d} of the m -th sequence can be referenced or reconstructed as described below.

Important

Use the DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX configuration setting, which will become the default in future. This setting is supported for all transform ranks, provides a uniform pattern for reconstructing the entire conjugate-even sequence from the part of it that is actually stored, and is compatible with data layouts supported by other FFT libraries, such as FFTW. This storage scheme disregards the setting of DFTI_PACKED_FORMAT.

Consider a d-dimensional real-to-complex transform

$$Z_{k_1, k_2, \dots, k_d} \equiv \sum_{n_1=0}^{N_1-1} \cdots \sum_{n_d=0}^{N_d-1} R_{n_1, n_2, \dots, n_d} e^{\frac{-2\pi i}{N_1} k_1 \cdot n_1} \cdots e^{\frac{-2\pi i}{N_d} k_d \cdot n_d}$$

Because the input sequence R is real-valued, the mathematical result Z has conjugate-even symmetry:

$$Z_{k_1, k_2, \dots, k_d} = \text{conjugate}(Z_{N_1-k_1, N_2-k_2, \dots, N_d-k_d}),$$

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$$Z_{0, 0, \dots, 0} = \text{conjugate}(Z_{0, 0, \dots, 0}).$$

For dimensions with even lengths, the other elements are real-valued too. For example, if N_s is even,

$$Z_{0, 0, \dots, N_s/2, 0, \dots, 0} = \text{conjugate}(Z_{0, 0, \dots, N_s/2, 0, \dots, 0}).$$

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension h , it suffices to store elements $z_{k_1, \dots, k_h, \dots, k_d}$ for the following indices:

- $k_h = 0, \dots, [N_h / 2]$
- $k_i = 0, \dots, N_i - 1$, where $i = 1, \dots, d$ and $i \neq h$

The symmetry property enables reconstructing the remaining elements: for $k_h = [N_h / 2] + 1, \dots, N_h - 1$. In the Intel MKL FFT interface, the halved dimension is the first dimension in Fortran and the last dimension in C/C++.

The following code illustrates usage of the `DFTI_COMPLEX_COMPLEX` storage for a conjugate-even domain:

```

! Fortran
real :: AR(N1,N2,M)           ! Array containing values of R
complex :: AZ(N1/2+1,N2,M)    ! Array containing values of Z
...
! on input: R{k1,k2,m} = AR(k1,k2,m)
status = DftiComputeForward( desc, AR(:,1,1), AZ(:,1,1) )
! on output:
! for k1=1 ... N1/2+1: Z{k1,k2,m} = AZ(k1,k2,m)
! for k1=N1/2+2 ... N1: Z{k1,k2,m} = conj(AZ(mod(N1-k1+1,N1)+1,mod(N2-k2+1,N2)+1,m))
// C/C++
float *AR = malloc( N1*N2*M * sizeof(AR[0]) );
complex *AZ = malloc( N1*(N2/2+1)*M * sizeof(AZ[0]) );
MKL_LONG is[3], os[3], idist, odist; // input and output strides and distance
...
// on input: R{k1,k2,m}
// = AR[is[0] + k1*is[1] + k2*is[2] + m*idist]
status = DftiComputeForward( desc, R, C );
// on output:
// for k2=0..N2/2:      Z{k1,k2,m} = AZ[os[0]+k1*os[1]+k2*os[2]+m*odist]
// for k2=N2/2+1..N2-1: Z{k1,k2,m} = conj(AZ[os[0]+(N1-k1)%N1*os[1]
//                                         +(N2-k2)%N2*os[2]+m*odist])
// 
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```

...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, fwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeForward( desc, ... )
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, bwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeBackward( desc, ... )

```

Important

For in-place transforms, ensure the first element of the input data has the same address as the first element of the output data for each dimension.

[DftiSetValue](#)

[DFTI_PACKED_FORMAT](#)

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The `DFTI_PACKED_FORMAT` configuration parameter defines how the data is packed. Possible values of `DFTI_PACKED_FORMAT` depend on the values of the `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameter:

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`.

The only value of `DFTI_PACKED_FORMAT` can be `DFTI_CCE_FORMAT`. You can use this value with transforms of any dimension. For a description of the corresponding packed format, see `DFTI_CONJUGATE_EVEN_STORAGE`.

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL`.

`DFTI_PACKED_FORMAT` can be `DFTI_CCS_FORMAT`, `DFTI_PACK_FORMAT`, or `DFTI_PERM_FORMAT`. You can use these values with one- and two-dimensional transforms only. The corresponding packed formats are described below.

NOTE

Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms, is incompatible with storage schemes of other FFT libraries, and will be deprecated in future.

DFTI_CCS_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size- N conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size $N+2$, while the other formats require an array of size N . Zero-based indexing is used.

Storage of a 1D Size- N Conjugate-even Sequence in a Real Array

	$n=$	0	1	2	3	...	$2L-2$	$2L-1$	$2L$	$2L+1$	$2L+2$
CCS, $N=2L$		R_0	0	R_1	I_1	...	R_{L-1}	I_{L-1}	R_L	0	
PACK, $N=2L$		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L			
PERM, $N=2L$		R_0	R_L	R_1	I_1	...	R_{L-1}	I_{L-1}			
CCS, $N=2L+1$		R_0	0	R_1	I_1	...	R_{L-1}	I_{L-1}	R_L	I_L	not used
PACK, $N=2L+1$		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L	I_L		
PERM, $N=2L+1$		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L	I_L		

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in a real-valued array `AC` as illustrated by figure "Storage of a 1D Size- N Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```

! Fortran
real :: AR(N), AC(N+2)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT )
...
! on input: R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC ) ! real-to-complex FFT
! on output:
! for k=1 ... N/2+1: Z{k} = cmplx( AC(1 + (2*(k-1)+0)),
```

```
!           AC(1 + (2*(k-1)+1)) )
! for k=N/2+2 ... N: Z{k} = cmplx( AC(1 + (2*mod(N-k+1,N)+0)),
!                                -AC(1 + (2*mod(N-k+1,N)+1)) )
```

```
// C/C++
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*(N+2) )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output:
// for k=0..N/2:      Z{k} =      AC[2*k+0]          + I*AC[2*k+1]
// for k=N/2+1..N-1: Z{k} =      AC[2*(N-k)%N + 0] - I*AC[2*(N-k)%N + 1]
```

DFTI_CCS_FORMAT for Two-dimensional Transforms

The following figure illustrates the storage of a two-dimensional (2D) M -by- N conjugate-even sequence in a real array for the CCS packed format. This format requires an array of size $(M+2)$ -by- $(N+2)$. Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result. "n/u" means "not used".

DFTI_PERM_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in real-valued array `AC` as illustrated by figure "[Storage of a 1D Size- \$N\$ Conjugate-even Sequence in a Real Array](#)" and can be used to reconstruct the whole conjugate-even sequence as follows:

```

! Fortran
real :: AR(N), AC(N)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT )
...
! on input: R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC ) ! real-to-complex FFT
! on output: Z{k} = cmplx( re, im ), where
! if (k == 1) then
!   re = AC(1)
!   im = 0
! else if (k-1 == N-k+1) then
!   re = AC(2)
```

```
!     im = 0
! else if (k <= N/2+1) then
!   re = AC(1+2*(k-1)+0-mod(N,2))
!   im = AC(1+2*(k-1)+1-mod(N,2))
! else
!   re = AC(1+2*(N-k+1)+0-mod(N,2))
!   im = -AC(1+2*(N-k+1)+1-mod(N,2))
! end if
```

```
// C/C++
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*N )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output: Z{k} = re + I*im, where
// if (k == 0) {
//   re = AC[0];
//   im = 0;
// } else if (k == N-k) {
//   re = AC[1];
//   im = 0;
// } else if (k <= N/2) {
//   re = AC[2*k+0 - N%2];
//   im = AC[2*k+1 - N%2];
// } else {
//   re = AC[2*(N-k)+0 - N%2];
//   im = -AC[2*(N-k)+1 - N%2];
// }
```

DFTI_PERM_FORMAT for Two-dimensional Transforms

The following figure illustrates the storage of a 2D M -by- N conjugate-even sequence in a real array for the PERM packed format. This format requires an array of size M -by- N . Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result.

Storage of a 2D M -by- N Conjugate-Even Sequence in a Real Array for the PERM Format

DFTI_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel MKL enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

`DFTI_ALLOW` (default) Permits the use of the auxiliary storage.

`DFTI_AVOID` Instructs Intel MKL to avoid using the auxiliary storage if possible.

See Also

[DftiSetValue](#)

DFTI_COMMIT_STATUS

The `DFTI_COMMIT_STATUS` configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

`DFTI_UNCOMMITTED` Default value, set after a successful call of `DftiCreateDescriptor`.

`DFTI_COMMITTED` The value after a successful call to `DftiCommitDescriptor`.

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to `DftiSetValue`, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to `DFTI_UNCOMMITTED`.

DFTI_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLED`: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

Scrambled Order Transform

	<code>DftiComputeForward</code>	<code>DftiComputeBackward</code>
<code>DFTI_ORDERING</code>	Input → Output	Input → Output
<code>DFTI_ORDERED</code>	ordered → ordered	ordered → ordered
<code>DFTI_BACKWARD_SCRAMBLED</code>	ordered → scrambled	scrambled → ordered

NOTE

The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

DftiCreateDescriptor

Allocates the descriptor data structure and initializes it with default configuration values.

Syntax

Fortran:

```
status = DftiCreateDescriptor( desc_handle, precision, forward_domain, dimension,
length )
```

C:

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension,
length);
```

Include Files

- Fortran 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>precision</i>	FORTRAN: INTEGER C: enum	Precision of the transform: DFTI_SINGLE or DFTI_DOUBLE.
<i>forward_domain</i>	FORTRAN: INTEGER C: enum	Forward domain of the transform: DFTI_COMPLEX or DFTI_REAL.
<i>dimension</i>	FORTRAN: INTEGER C: MKL_LONG	Dimension of the transform.
<i>length</i>	FORTRAN: INTEGER if <i>dimension</i> = 1. Array INTEGER, DIMENSION(*) otherwise. C: MKL_LONG if <i>dimension</i> = 1. Array of type MKL_LONG otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all necessary parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```

! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.

INTERFACE DftiCreateDescriptor

  FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
    INTEGER :: some_actual_function_1d
    ...
    INTEGER, INTENT(IN) :: length
  END FUNCTION some_actual_function_1d

  FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
    INTEGER :: some_actual_function_md
    ...
    INTEGER, INTENT(IN), DIMENSION(*) :: lengths
  END FUNCTION some_actual_function_md

  ...

END INTERFACE DftiCreateDescriptor

```

Note that the function is overloaded: the actual parameter for the formal parameter *length* can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the *precision* parameter in order to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use specific functions, change the "USE MKL_DFTI" statement in your program unit to one of the following:

```
USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
```

```
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R
```

where the name "FORGET" can be replaced with any name that is not used in the program unit.

Prototype

```

/* C prototype.
 * Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
    enum DFTI_CONFIG_VALUE precision,
    enum DFTI_CONFIG_VALUE domain,
    MKL_LONG dimension, ... /* length/lengths */ );

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
  ((prec)==DFTI_SINGLE && (dim)==1) ? \

```

```
some_actual_function_s1d((desc),(domain),(MKL_LONG)(sizes)) : \
...
```

Variable *length/lengths* is interpreted as a scalar (`MKL_LONG`) or an array (`MKL_LONG*`), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```
#include "mkl_dfti.h"
#undef DftiCreateDescriptor
```

DftiCommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
status = DftiCommitDescriptor( desc_handle )
```

C:

```
status = DftiCommitDescriptor(desc_handle);
```

Include Files

- Fortran 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>FORTTRAN: DFTI_DESCRIPTOR</code> <code>C: DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.

Output Parameters

Name	Type	Description
<code>desc_handle</code>	<code>FORTTRAN: DFTI_DESCRIPTOR</code> <code>C: DFTI_DESCRIPTOR_HANDLE</code>	Updated FFT descriptor.
<code>status</code>	<code>FORTTRAN: INTEGER</code> <code>C: MKL_LONG</code>	Function completion status.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the `DftiSetValue` function to change configuration parameters of a committed descriptor (see [Descriptor Configuration Functions](#)), you must re-commit the descriptor before invoking a computation function. Typically, a committal function call is immediately followed by a computation function call (see [FFT Computation Functions](#)).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```

! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
  FUNCTION some_actual_function_1 ( Desc_Handle )
    INTEGER :: some_actual_function_1
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
  END FUNCTION some_actual_function_1
END INTERFACE DftiCommitDescriptor

```

Prototype

```

/* C prototype */
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );

```

DftiFreeDescriptor

Frees the memory allocated for a descriptor.

Syntax

Fortran:

```
status = DftiFreeDescriptor( desc_handle )
```

C:

```
status = DftiFreeDescriptor(&desc_handle);
```

Include Files

- Fortran 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>FORTTRAN: DESCRIPTOR_HANDLE</code>	FFT descriptor.

Name	Type	Description
	C: DFTI_DESCRIPTOR_HANDLE	

Output Parameters

Name	Type	Description
desc_handle	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	Memory for the FFT descriptor is released.
status	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function frees all memory allocated for a descriptor.

NOTE

Memory allocation/deallocation inside Intel MKL is managed by Intel MKL memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See [Example "mkl_free_buffers Usage with FFT Functions"](#) in the description of the service function `FreeBuffers` on how to use Intel MKL memory management software and release memory to the OS.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_3( Desc_Handle )
INTEGER :: some_actual_function_3
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

Prototype

```
/* C prototype */
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

DftiCopyDescriptor

Makes a copy of an existing descriptor.

Syntax

Fortran:

```
status = DftiCopyDescriptor( desc_handle_original, desc_handle_copy )
```

C:

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

Include Files

- Fortran 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
desc_handle_original	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	The FFT descriptor to copy.

Output Parameters

Name	Type	Description
desc_handle_copy	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	The copy of the FFT descriptor.
status	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function `DftiFreeDescriptor`.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```
! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
! argument list and types of dummy arguments. The interface
! does not guarantee what the actual function names are.
! Users can only rely on the function name following the
! keyword INTERFACE
FUNCTION some_actual_function_2( Desc_Handle_Original,
Desc_Handle_Copy )
INTEGER :: some_actual_function_2
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Original, Desc_Handle_Copy
```

```
END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor
```

Prototype

```
/* C prototype */
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

Descriptor Configuration Functions

This category contains the following functions: the value setting function `DftiSetValue` sets one particular configuration parameter to an appropriate value, and the value getting function `DftiGetValue` reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

DftiSetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
status = DftiSetValue( desc_handle, config_param, config_val )
```

C:

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

Include Files

- Fortran 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<code>config_param</code>	FORTRAN: INTEGER C: enum	Configuration parameter.
<code>config_val</code>	Depends on the configuration parameter.	Configuration value.

Output Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	Updated FFT descriptor.

Name	Type	Description
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- DFTI_PRECISION
- DFTI_FORWARD_DOMAIN
- DFTI_DIMENSION, DFTI_LENGTH
- DFTI_PLACEMENT
- DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE
- DFTI_THREAD_LIMIT
- DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES
- DFTI_NUMBER_OF_TRANSFORMS
- DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE
- DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE
- DFTI_PACKED_FORMAT
- DFTI_WORKSPACE
- DFTI_ORDERING

The `DftiSetValue` function cannot be used to change configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS`. Use the `DftiCreateDescriptor` function to set them.

Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in Fortran](#) and [Configuring and Computing an FFT in C/C++](#).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```

[DftiSetValue](#)

FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

DftiComputeForward

Computes the forward FFT.

Syntax

Fortran:

```

status = DftiComputeForward( desc_handle, x_inout )
status = DftiComputeForward( desc_handle, x_in, y_out )

```

```
status = DftiComputeForward( desc_handle, xre_inout, xim_inout )
status = DftiComputeForward( desc_handle, xre_in, xim_in, yre_out, yim_out )
```

C:

```
status = DftiComputeForward(desc_handle, x_inout);
status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);
```

Input Parameters

Name	Type	Description
desc_handle	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
x_inout, x_in	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform, specified in the DFTI_PRECISION configuration setting.	Data to be transformed in case of a real forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.
xre_inout, xim_in	FORTRAN: Array yim_in REAL(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
y_out	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	The transformed data in case of a real backward domain, determined by the DFTI_FORWARD_DOMAIN configuration setting.

Name	Type	Description
	<p>C: Array of type float or double depending on the precision of the transform.</p>	
xre_inout, xim_ino	FORTRAN: <code>REAL(KIND=WP), DIMENSION(*)</code> , where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Real and imaginary parts of the transformed data in the case of a complex backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
	<p>C: Array of type float or double depending on the precision of the transform.</p>	
status	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

Include Files

- Fortran 90: `mkl_dfti.f90`
- C: `mkl.h`

Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the `transform` with the minus sign in the exponent, $\delta = -1$.

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in Fortran](#) and [Configuring and Computing an FFT in C/C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation functions is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```

! Fortran interface
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function

```

```

! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

FUNCTION some_actual_function_1(desc,sSrcDst)
  INTEGER some_actual_function_1
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
  ...
END FUNCTION some_actual_function_1

FUNCTION some_actual_function_2(desc,cSrcDst)
  INTEGER some_actual_function_2
  COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
  ...
END FUNCTION some_actual_function_2

FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
  INTEGER some_actual_function_3
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
  ...
END FUNCTION some_actual_function_3
...
END INTERFACE DftiComputeForward

```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

Prototype

```

/* C prototype */
MKL_LONG DftiComputeForward( DFTI_DESCRIPTOR_HANDLE, void*, ... );

```

status = DftiComputeBackward(desc_handle, xre_inout, xim_inout);
status = DftiComputeBackward(desc_handle, yre_in, yim_in, xre_out, xim_out);

```

Input Parameters

Name	Type	Description
desc_handle	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
x_inout, y_in	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform, specified in the DFTI_PRECISION configuration setting.	Data to be transformed in case of a real backward domain, determined by the DFTI_FORWARD_DOMAIN configuration setting.
xre_inout, xim_inout, yim_in	FORTRAN: Array yim_in REAL(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex backward domain, determined by the DFTI_FORWARD_DOMAIN configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
x_out	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	The transformed data in case of a real forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.

Name	Type	Description
	C: Array of type float or double depending on the precision of the transform.	
xre_inout, xim_ino	FORTRAN: <code>REAL(KIND=WP), DIMENSION(*)</code> , where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Real and imaginary parts of the transformed data in the case of a complex forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.
	C: Array of type float or double depending on the precision of the transform.	
status	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter DFTI_PLACEMENT as follows:

- `_inout` to DFTI_INPLACE
- `_out` to DFTI_NOT_INPLACE

Include Files

- Fortran 90: `mkl_dfti.f90`
- C: `mkl.h`

Description

The function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, the `DftiComputeBackward` function computes the inverse FFT, that is, the `transform` with the plus sign in the exponent, $\delta = +1$.

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in Fortran](#) and [Configuring and Computing an FFT in C/C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation functions is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface

```
! Fortran interface
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
```

```

! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeBackward

  FUNCTION some_actual_function_1(desc,sSrcDst)
    INTEGER some_actual_function_1
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
    ...
  END FUNCTION some_actual_function_1

  FUNCTION some_actual_function_2(desc,cSrcDst)
    INTEGER some_actual_function_2
    COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
    ...
  END FUNCTION some_actual_function_2

  FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
    INTEGER some_actual_function_3
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
    ...
  END FUNCTION some_actual_function_3

  ...
END INTERFACE DftiComputeBackward

```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

Prototype

Real-to-complex, out-of-place, forward	Real numbers	Numbers in the CCE format	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_REAL, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, <real_strides>); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, </pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
Complex-to-real, in-place, backward	Numbers in the CCE format	Real numbers	<pre> <complex_strides>; status = DftiCommitDescriptor(hand); /* Compute an FFT */ status = DftiComputeForward(hand, X_in, Y_out); </pre>
Complex-to-real, out-of-place, backward	Numbers in the CCE format	Real numbers	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_REAL, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, <complex_strides>); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, <real_strides>); status = DftiCommitDescriptor(hand); /* Compute an FFT */ status = DftiComputeBackward(hand, X_inout); </pre>

You can find C programs that illustrate configuring and computing FFTs in the examples/dftc/ subdirectory of your Intel MKL directory.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

DftiErrorClass

Checks whether the status reflects an error of a predefined class.

Syntax

Fortran:

```
predicate = DftiErrorClass( status, error_class )
```

C:

```
predicate = DftiErrorClass(status, error_class);
```

Include Files

- Fortran 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
status	<small>FORTRAN:</small> INTEGER <small>C:</small> MKL_LONG	Completion status of an FFT function.
error_class	<small>FORTRAN:</small> INTEGER <small>C:</small> MKL_LONG	Predefined error class.

Output Parameters

Name	Type	Description
<i>predicate</i>	<small>FORTRAN:</small> LOGICAL <small>C:</small> MKL_LONG	Result of checking.

Description

The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table "Predefined Error Classes"](#). They are named constants and have the type INTEGER in Fortran and MKL_LONG in C.

Predefined Error Classes

Named Constants	Comments
DFTI_NO_ERROR	No error. The zero status belongs to this class.
DFTI_MEMORY_ERROR	Usually associated with memory allocation
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors

Named Constants	Comments
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent
DFTI_MKL_INTERNAL_ERROR	Internal library error
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

The `DftiErrorClass` function returns a non-zero value in C or the value of `.TRUE.` in Fortran if the status belongs to the predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example "Using Status Checking Functions"](#) for an illustration of correct use of the status checking functions.

NOTE

It is incorrect to directly compare a status with a predefined class.

Interface

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_8( Status, Error_Class )
LOGICAL some_actual_function_8
INTEGER, INTENT(IN) :: Status, Error_Class
END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

Prototype

```
/* C prototype */
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

DftiErrorMessage

Generates an error message.

Syntax

Fortran:

```
error_message = DftiErrorMessage( status )
```

C:

```
error_message = DftiErrorMessage(status);
```

Include Files

- Fortran 90: `mkl_dfti.f90`

- C: mkl.h

Input Parameters

Name	Type	Description
status	FORTRAN : INTEGER C : MKL_LONG	Completion status of a function.

Output Parameters

Name	Type	Description
error_message	FORTRAN : CHARACTER (LEN=DFTI_MAX_MESSAGE_LENGTH) C : Array of char	The character string with the error message.

Description

The error message function generates an error message character string. In Fortran, use a character string of length DFTI_MAX_MESSAGE_LENGTH as a target for the error message. In C, the function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

[Example "Using Status Checking Function"](#) shows how this function can be used.

Interface

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_9( Status )
CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
INTEGER, INTENT(IN) :: Status
END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage
```

Prototype

```
/* C prototype */
char *DftiErrorMessage( MKL_LONG );
```

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE

These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

Table "Cluster FFT Functions in Intel MKL" lists cluster FFT functions implemented in Intel MKL:

Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by [DftiComputeForwardDM](#) and [DftiComputeBackwardDM](#) functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates on the local part of the input data, that is, some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` in C/C++ or `MPI_INIT` in Fortran (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling [DftiCreateDescriptorDM](#).
3. Specify one of several values of configuration parameters by one or more calls to [DftiSetValueDM](#).

4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling [DftiGetValueDM](#).
5. Initialize the descriptor for the FFT computation by calling [DftiCommitDescriptorDM](#).
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling [DftiComputeForwardDM](#) or [DftiComputeBackwardDM](#).
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling [DftiFreeDescriptorDM](#).
10. Finalize communication through MPI by calling `MPI_Finalize` in C/C++ or `MPI_FINALIZE` in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the "[Examples for Cluster FFT Functions](#)" section in the Code Examples appendix illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix A of size (m,n) is stored in a vector B of size $m*n$ so that

$B[i*n+j]=A[i][j]$ in C/C++ ($i=0, \dots, m-1, j=0, \dots, n-1$)

and

$B((j-1)*m+i)=A(i,j)$ in Fortran ($i=1, \dots, m, j=1, \dots, n$) .

NOTE

Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with `Lengths=(m,n,l)` can be computed over an array `Ar[m][n][l]` in C/C++ or `AR(m,n,l)` in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last dimension in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term "rows" will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size $(11,15,12)$, the processes may store local arrays of sizes $(6,15,12)$ and $(5,15,12)$, respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m,n,l) , in C, each MPI process works with local data array of size (m_q, n, l) , where $\sum m_q=m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the [DftiGetValueDM](#) function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If `A` is a global array and `L` is the appropriate local array, then

`L[i][j][k]=A[i+cdft_local_start_x][j][k]`, where $i=0, \dots, m_q-1, j=0, \dots, n-1, k=0, \dots, l-1$, for C/C++

and

`L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where $i=1, \dots, m, j=1, \dots, n, k=1, \dots, l_q$, for Fortran.

[Example "2D Out-of-place Cluster FFT Computation" in the Code Examples appendix](#) shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in [Table "Data Distribution Configuration Parameters for 1D Transforms"](#):

Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	<code>CDFT_LOCAL_NX</code>	<code>CDFT_LOCAL_OUT_NX</code>
Elements shift in input array	<code>CDFT_LOCAL_START_X</code>	<code>CDFT_LOCAL_OUT_START_X</code>
Number of elements in output array	<code>CDFT_LOCAL_OUT_NX</code>	<code>CDFT_LOCAL_NX</code>
Elements shift in output array	<code>CDFT_LOCAL_OUT_START_X</code>	<code>CDFT_LOCAL_START_X</code>

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table "Settable configuration Parameters"](#)), it must have the same size as the local arrays. [Example "1D In-place Cluster FFT Computations" in the Code Examples appendix](#) illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation performed with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are

defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory: `examples/cdftc/source/cdft_example_support.c` for C/C++ and `examples/cdftf/source/cdft_example_support.f90` for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details).

To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "use" statement in Fortran; or access the header file `mkl_cdft.h` through "include" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

```
INCLUDE "mpif.h"
(for some MPI versions, "mpif90.h" header may be used instead).
```

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation.** There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
2. **FFT Computation.** There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
3. **Descriptor Configuration.** There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

DftiCreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size);
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes);
```

Include Files

- Fortran 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>comm</i>	MPI communicator, e.g. MPI_COMM_WORLD.
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be DFTI_COMPLEX for complex-to-complex transforms or DFTI_REAL for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.
---------------	---

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function [DftiCommitDescriptorDM](#) in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function [DftiSetValueDM](#).

The value of the parameter *v1* is specified through named constants DFTI_SINGLE and DFTI_DOUBLE. It corresponds to precision of input data, output data, and computation. A setting of DFTI_SINGLE indicates single-precision floating-point data type and a setting of DFTI_DOUBLE indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter *size* having type MKL_LONG; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type MKL_LONG. In Fortran, length is an integer or an array of integers.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in `handle`. If the function fails, it returns a value of another error class constant

Interface

```
! Fortran interface
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE
```

Prototype

```
/* C/C++ prototype */
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

DftiCommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C:

```
status = DftiCommitDescriptorDM(handle);
```

Include Files

- Fortran 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

<code>handle</code>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
---------------------	--

Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration Functions](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation Functions](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```
! Fortran interface
INTERFACE DftiCommitDescriptorDM
    INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE
```

Prototype

```
/* C/C++ prototype */
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

DftiFreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C:

```
status = DftiFreeDescriptorDM(&handle);
```

Include Files

- Fortran 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
---------------	--

Output Parameters

<i>handle</i>	The descriptor handle. Memory allocated for the handle is released on output.
---------------	---

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```
! Fortran interface
INTERFACE DftiFreeDescriptorDM
  INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
  END FUNCTION
END INTERFACE
```

Prototype

```
/* C/C++ prototype */
MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

DftiComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Include Files

- Fortran 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

<code>handle</code>	The descriptor handle.
<code>in_X, in_out_X</code>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

out_X, *in_out_X*

Local part of output data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate the array.

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data Among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION

Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFI_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```

! Fortran interface
INTERFACE DftiComputeForwardDM
  INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    COMPLEX(8), DIMENSION(*) :: in_X, out_X
  END FUNCTION DftiComputeForwardDM
END INTERFACE

```

```

END FUNCTION DftiComputeForwardDM
INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    COMPLEX(8), DIMENSION(*) :: in_out_X
END FUNCTION DftiComputeForwardDMi
INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    COMPLEX(4), DIMENSION(*) :: in_X, out_X
END FUNCTION DftiComputeForwardDMs
INTEGER(4) FUNCTION DftiComputeForwardDMIs(h, in_out_X)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    COMPLEX(4), DIMENSION(*) :: in_out_X
END FUNCTION DftiComputeForwardDMIs
END INTERFACE

```

Prototype

```

/* C/C++ prototype */
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

DftiComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```

Status = DftiComputeBackwardDM(handle, in_X, out_X)
Status = DftiComputeBackwardDM(handle, in_out_X)

```

C:

```

status = DftiComputeBackwardDM(handle, in_X, out_X);
status = DftiComputeBackwardDM(handle, in_out_X);

```

Include Files

- Fortran 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.
------------------------	--

Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION

Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```

INTERFACE DftiComputeBackwardDM
    INTEGER(4) FUNCTION DftiComputeBackwardDM(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_X, out_X
    END FUNCTION DftiComputeBackwardDM
    INTEGER(4) FUNCTION DftiComputeBackwardDMi(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeBackwardDMi
    INTEGER(4) FUNCTION DftiComputeBackwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_X, out_X
    END FUNCTION DftiComputeBackwardDMs
    INTEGER(4) FUNCTION DftiComputeBackwardDMis(h, in_out_X)

```

```

    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    COMPLEX(4), DIMENSION(*) :: in_out_X
  END FUNCTION DftiComputeBackwardDMIs
END INTERFACE

```

Prototype

```

/* C/C++ prototype */
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function [DftiSetValueDM](#) sets one particular configuration parameter to an appropriate value, the value getting function [DftiGetValueDM](#) reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the "FFT Functions" section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type MKL_LONG in C/C++ and INTEGER(4) in Fortran. The exact type of the configuration parameters being floating-point scalars is float or double in C/C++ and REAL(4) or REAL(8) in Fortran. The configuration parameters whose values are named constants have the enum type in C/C++ and INTEGER type in Fortran. They are defined in the mkl_cdft.h header file in C/C++ and MKL_CDFT module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix CDFT.

DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C:

```
status = DftiSetValueDM (handle, param, value);
```

Include Files

- Fortran 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table "Settable Configuration Parameters" for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
CDFT_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
DFTI_PACKED_FORMAT	Named constant	Packed format, real data.	<ul style="list-style-type: none"> • DFTI_PERM_FORMAT — default and the only available value for one-dimensional transforms • DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is DFTI_NONE, the data is located in a usual manner described in this manual. If the value is DFTI_ALLOW, the last (first) global transposition is not performed for a forward (backward) transform.	DFTI_NONE

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```
! Fortran interface
INTERFACE DftiSetValueDM
```

```

INTEGER(4) FUNCTION DftiSetValueDM(h, p, v)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    INTEGER(4) :: p, v

    INTEGER(4) :: p
    COMPLEX(4) :: v(*)
END FUNCTION
INTEGER(4) FUNCTION DftiSetValueDMdw(h, p, v)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
    INTEGER(4) :: p
    COMPLEX(8) :: v(*)
END FUNCTION
END INTERFACE

```

Prototype

```

/* C/C++ prototype */
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);

```

DftiGetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C:

```
status = DftiGetValueDM(handle, param, &value);
```

Include Files

- Fortran 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

handle

The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

param

Name of a parameter to be retrieved from the descriptor. See [Table "Retrievable Configuration Parameters"](#) for the list of available parameters.

Output Parameters

<code>value</code>	Value of the parameter.
--------------------	-------------------------

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table "Configuration Parameters"](#) and relevant subsections of the [Configuration Settings](#) section.

Retrievable Configuration Parameters

Parameter Name	Data Type	Description
<code>DFTI_PRECISION</code>	Named constant	Precision of computation, input data and output data.
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform
<code>DFTI_LENGTHS</code>	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor of forward transform.
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor of backward transform.
<code>DFTI_PLACEMENT</code>	Named constant	Placement of the computation result.
<code>DFTI_COMMIT_STATUS</code>	Named constant	Shows whether descriptor has been committed.
<code>DFTI_FORWARD_DOMAIN</code>	Named constant	Forward domain of transforms, has the value of <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code> .
<code>DFTI_ORDERING</code>	Named constant	Scrambling of data order.
<code>CDFT_MPI_COMM</code>	Type of MPI communicator	MPI communicator used for transforms.
<code>CDFT_LOCAL_SIZE</code>	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
<code>CDFT_LOCAL_X_START</code>	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .
<code>CDFT_LOCAL_NX</code>	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
<code>CDFT_LOCAL_OUT_X_START</code>	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Parameter Name	Data Type	Description
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface

```

! Fortran interface
INTERFACE DftiGetValueDM
    INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMar(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v(*)

        REAL(4) :: v
    END FUNCTION
END INTERFACE

```

Prototype

```

/* C/C++ prototype */
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);

```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table "Error Codes that Cluster FFT Functions Return"](#) lists error codes that the cluster FFT functions may return.

Error Codes that Cluster FFT Functions Return

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error.

Named Constants	Comments
DFTI_MEMORY_ERROR	Usually associated with memory allocation.
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
CDFT_SPREAD_ERROR	Data cannot be distributed (For more information, see Distributing Data among Processes .)
CDFT_MPI_ERROR	MPI error. Occurs when calling MPI.

PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

NOTE

PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see [Intel® MKL Release Notes](#) and [Intel® MKL User's Guide](#).

For full reference on PBLAS routines and related information, see http://www.netlib.org/scalapack/html/pblas_qref.html.

Optimization Notice

<p>Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.</p>

Notice revision #20110804

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. [Table "Content of the array descriptor for dense matrices"](#) gives an example of an array descriptor structure.

Content of Array Descriptor for Dense Matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <i>sub(A)</i>
<i>n</i>	The number of columns of <i>sub(A)</i>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <i>sub(A)</i> in the global array
<i>ja</i>	The column index of <i>sub(A)</i> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

The Intel MKL PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The *<character>* field indicates the Fortran data type:

<i>s</i>	real, single precision
<i>c</i>	complex, single precision
<i>d</i>	real, double precision
<i>z</i>	complex, double precision
<i>i</i>	integer

Some routines and functions can have combined character codes, such as *sc* or *dz*.

For example, the function *pscasum* uses a complex input array and returns a real value.

The *<name>* field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines p?dot, p?swap, p?copy compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, *<name>* reflects the matrix argument type:

ge	general matrix
sy	symmetric matrix
he	Hermitian matrix
tr	triangular matrix

In PBLAS level 3, the *<name>=tran* indicates the transposition of the matrix.

The *<mod>* field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the *<mod>* field:

c	conjugated vector
u	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the *<mod>* field:

mv	matrix-vector product
sv	solving a system of linear equations with matrix-vector operations
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the *<mod>* field:

mm	matrix-matrix product
sm	solving a system of linear equations with matrix-matrix operations
rk	rank- <i>k</i> update of a matrix
r2k	rank-2 <i>k</i> update of a matrix.

The examples below show how to interpret PBLAS routine names:

pddot	<p> <d> <dot>: double-precision real distributed vector-vector dot product
pcdotc	<p> <c> <dot> <c>: complex distributed vector-vector dot product, conjugated
pscasum	<p> <sc> <asum>: sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
pcdotu	<p> <c> <dot> <u>: distributed vector-vector dot product, unconjugated, complex
psgemv	<p> <s> <ge> <mv>: distributed matrix-vector product, general matrix, single precision
pztrmm	<p> <z> <tr> <mm>: distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. Table "PBLAS Level 1 Routine Groups and Their Data Types" lists the PBLAS Level 1 routine groups and the data types associated with them.

PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
p?amax	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
p?asum	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
p?axpy	s, d, c, z	Calculates distributed vector-scalar product
p?copy	s, d, c, z	Copies a distributed vector
p?dot	s, d	Calculates a dot product of two distributed real vectors
p?dotc	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated
p?dotu	c, z	Calculates a dot product of two distributed complex vectors
p?nrm2	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
p?scal	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
p?swap	s, d, c, z	Swaps two distributed vectors

p?amax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

Fortran:

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

C:

```
void psamax (MKL_INT *n , float *amax , MKL_INT *indx , float *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
void pdamax (MKL_INT *n , double *amax , MKL_INT *indx , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
void pcamax (MKL_INT *n , float *amax , MKL_INT *indx , float *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
void pzamax (MKL_INT *n , double *amax , MKL_INT *indx , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_pblas.h

Description

The functions p?amax compute global index of the maximum element in absolute value of a distributed vector sub(x),

where sub(x) denotes $x(ix, jx:jx+n-1)$ if $incx=m_x$, and $x(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vector sub(x), $n \geq 0$.
<i>x</i>	(local) REAL for psamax DOUBLE PRECISION for pdamax COMPLEX for pcamax DOUBLE COMPLEX for pzamax Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector sub(x).
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix sub(X), respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X.
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of sub(x). Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>amax</i>	(global) REAL for psamax . DOUBLE PRECISION for pdamax. COMPLEX for pcamax. DOUBLE COMPLEX for pzamax. Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.
<i>indx</i>	(global) INTEGER. The global index of the maximum element in absolute value of the distributed vector sub(x) only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

Fortran:

```
call psasum(n, asum, x, ix, jx, descx, incx)
```

```
call pscasum(n, asum, x, ix, jx, descx, incx)
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

C:

```
void psasum (MKL_INT *n , float *asum , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdasum (MKL_INT *n , double *asum , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pscasum (MKL_INT *n , float *asum , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdzasum (MKL_INT *n , double *asum , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_pblas.h

Description

The functions p?asum compute the sum of the magnitudes of elements of a distributed vector $\text{sub}(x)$, where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.
<i>x</i>	(local) REAL for psasum DOUBLE PRECISION for pdasum COMPLEX for pscasum DOUBLE COMPLEX for pdzasum Array, size $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix</i> , <i>jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

<i>asum</i>	(local) REAL for psasum and pscasum. DOUBLE PRECISION for pdasum and pdzasum
-------------	---

Contains the sum of magnitudes of elements of the distributed vector only in its scope.

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

Fortran:

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void psaxpy (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
void pdaxpy (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
void pcaxpy (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
void pzaxpy (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?axpy routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

a is a scalar;

sub(x) and *sub(y)* are *n*-element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n (global) INTEGER. The length of distributed vectors, $n \geq 0$.

a (local) REAL for psaxpy

DOUBLE PRECISION for pdaxpy

COMPLEX for pcaxpy

DOUBLE COMPLEX for pzaxpy

Specifies the scalar a .

x

(local) REAL for psaxpy

DOUBLE PRECISION for pdaxpy

COMPLEX for pcaxpy

DOUBLE COMPLEX for pzaxpy

Array, size $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$.

This array contains the entries of the distributed vector $\text{sub}(x)$.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

$descx$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

$incx$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

y

(local) REAL for psaxpy

DOUBLE PRECISION for pdaxpy

COMPLEX for pcaxpy

DOUBLE COMPLEX for pzaxpy

Array, size $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$.

This array contains the entries of the distributed vector $\text{sub}(y)$.

iy, jy

(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.

$descy$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .

$incy$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

y

Overwritten by $\text{sub}(y) := \text{sub}(y) + a * \text{sub}(x)$.

p?copy

Copies one distributed vector to another vector.

Syntax

Fortran:

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call picopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void pscopy (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
void pdcopy (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
void pccopy (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
void pzcopy (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
void picopy (MKL_INT *n , MKL_INT *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , MKL_INT *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where sub(x) and sub(y) are n -element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$.

This array contains the entries of the distributed vector `sub(x)`.

`ix, jx`

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix `sub(x)`, respectively.

`descx`

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

`incx`

(global) INTEGER. Specifies the increment for the elements of `sub(x)`. Only two values are supported, namely 1 and m_x . `incx` must not be zero.

`y`

(local) REAL for `pscopy`

DOUBLE PRECISION for `pdcopy`

COMPLEX for `pccopy`

DOUBLE COMPLEX for `pzccopy`

INTEGER for `picopy`

Array, size $(jy-1) * m_y + iy + (n-1) * \text{abs}(incy)$.

This array contains the entries of the distributed vector `sub(y)`.

`iy, jy`

(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix `sub(y)`, respectively.

`descy`

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .

`incy`

(global) INTEGER. Specifies the increment for the elements of `sub(y)`. Only two values are supported, namely 1 and m_y . `incy` must not be zero.

Output Parameters

`y`

Overwritten with the distributed vector `sub(x)`.

p?dot

Computes the dot product of two distributed real vectors.

Syntax

Fortran:

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void psdot (MKL_INT *n , float *dot , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

```
void pddot (MKL_INT *n , double *dot , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

```
dot = sub(x)'*sub(y)
```

where *sub(x)* and *sub(y)* are *n*-element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if *incx=m_x*, and $X(ix: ix+n-1, jx)$ if *incx= 1*;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if *incy=m_y*, and $Y(iy: iy+n-1, jy)$ if *incy= 1*.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	<p>(local) REAL for psdot</p> <p>DOUBLE PRECISION for pddot</p> <p>Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$.</p> <p>This array contains the entries of the distributed vector <i>sub(x)</i> .</p>
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	<p>(local)REAL for psdot</p> <p>DOUBLE PRECISION for pddot</p> <p>Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$.</p> <p>This array contains the entries of the distributed vector <i>sub(y)</i> .</p>
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

`dot` (local) REAL for psdot
 DOUBLE PRECISION for pddot
 Dot product of `sub(x)` and `sub(y)` only in their scope.

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

Fortran:

```
call pcdotc(n, dotc, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotc(n, dotc, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void pcdotc (MKL_INT *n , float *dotc , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
void pzdotc (MKL_INT *n , double *dotc , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The `p?dotc` functions compute the dot product `dotc` of two distributed vectors, with one vector conjugated:

```
dotc = conjg(sub(x)')*sub(y)
```

where `sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx=m_x`, and $X(ix: ix+n-1, jx)$ if `incx= 1`;
`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy=m_y`, and $Y(iy: iy+n-1, jy)$ if `incy= 1`.

Input Parameters

`n` (global) INTEGER. The length of distributed vectors, $n \geq 0$.
`x` (local) COMPLEX for pcdotc
 DOUBLE COMPLEX for pzdotc
 Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$.
 This array contains the entries of the distributed vector `sub(x)`.
`ix, jx` (global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix `sub(x)`, respectively.

<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, size $(jy-1) * m_y + iy + (n-1) * \text{abs}(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>dotc</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Dot product of <i>sub(x)</i> and <i>sub(y)</i> only in their scope.
-------------	--

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

Fortran:

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void pcdotu (MKL_INT *n , float *dotu , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
void pzdotu (MKL_INT *n , double *dotu , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?dotu functions compute the dot product $dotu$ of two distributed vectors defined as

```
dotu = sub(x)' * sub(y)
```

where $sub(x)$ and $sub(y)$ are n -element distributed vectors.

$sub(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$sub(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
x	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $sub(X)$, respectively.
$descx$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
$incx$	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
y	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
iy, jy	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
$descy$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
$incy$	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

$dotu$	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Dot product of $sub(x)$ and $sub(y)$ only in their scope.
--------	--

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

Fortran:

```
call psnrm2(n, norm2, x, ix, jx, descx, incx)
call pdnrm2(n, norm2, x, ix, jx, descx, incx)
call pscnrm2(n, norm2, x, ix, jx, descx, incx)
call pdznrm2(n, norm2, x, ix, jx, descx, incx)
```

C:

```
void psnrm2 (MKL_INT *n , float *norm2 , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdnrm2 (MKL_INT *n , double *norm2 , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pscnrm2 (MKL_INT *n , float *norm2 , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdznrm2 (MKL_INT *n , double *norm2 , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

Include Files

- C: mkl_pblas.h

Description

The p?nrm2 functions compute the Euclidean norm of a distributed vector $\text{sub}(x)$, where $\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.
x	(local) REAL for psnrm2 DOUBLE PRECISION for pdnrm2 COMPLEX for pscnrm2 DOUBLE COMPLEX for pdznrm2 Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
$descx$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

incx (global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

norm2 (local) REAL for psnrm2 and pscfrm2 .
 DOUBLE PRECISION for pdnrm2 and pdznm2

Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

Fortran:

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
```

C:

```
void psscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pcscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pzscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pcscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

Include Files

- C: mkl_pblas.h

Description

The $p?\text{scal}$ routines multiplies a n -element distributed vector $\text{sub}(x)$ by the scalar a :

$\text{sub}(x) = a * \text{sub}(x)$,

where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<i>a</i>	(global) REAL for <code>psscal</code> and <code>pcsscal</code> DOUBLE PRECISION for <code>pdscal</code> and <code>pdscal</code> COMPLEX for <code>pcscal</code> DOUBLE COMPLEX for <code>pzscal</code> Specifies the scalar <i>a</i> .
<i>x</i>	(local) REAL for <code>psscal</code> DOUBLE PRECISION for <code>pdscal</code> COMPLEX for <code>pcscal</code> and <code>pcsscal</code> DOUBLE COMPLEX for <code>pzscal</code> and <code>pdscal</code> Array, size $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the updated distributed vector <code>sub(x)</code>
----------	---

p?swap

Swaps two distributed vectors.

Syntax

Fortran:

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

C:

```
void psswap (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```

void pdswap (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

void pcswap (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

void pzswap (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

```

Include Files

- C: mkl_pblas.h

Description

Given two distributed vectors `sub(x)` and `sub(y)`, the p?swap routines return vectors `sub(y)` and `sub(x)` swapped, each replacing the other.

Here `sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx=m_x`, and $X(ix: ix+n-1, jx)$ if `incx= 1`;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy=m_y`, and $Y(iy: iy+n-1, jy)$ if `incy= 1`.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, size $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.
<code>y</code>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, size $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .

<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(Y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by distributed vector $\text{sub}(y)$.
<i>y</i>	Overwritten by distributed vector $\text{sub}(x)$.

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table "PBLAS Level 2 Routine Groups and Their Data Types"](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?agemv	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?ahemv	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?asymv	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
p?sy	s, d	Rank-1 update of a distributed symmetric matrix
p?sy2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix

Routine Groups	Data Types	Description
p?atrmv	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix.

Syntax

Fortran:

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)
```

C:

```
void psgemv (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT
             *ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT

             MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT
             *jy , MKL_INT *descy , MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

alpha and *beta* are scalars,

sub(A) is a m -by- n submatrix, *sub(A)* = $A(ia:ia+m-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are subvectors.

When *trans* = 'N' or 'n', *sub(x)* denotes $X(ix, jx:jx+n-1)$ if *incx* = *m_x*, and $X(ix: ix+n-1, jx)$ if *incx* = 1, *sub(y)* denotes $Y(iy, jy:jy+m-1)$ if *incy* = *m_y*, and $Y(iy: iy+m-1, jy)$ if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', *sub(x)* denotes $X(ix, jx:jx+m-1)$ if *incx* = *m_x*, and $X(ix: ix+m-1, jx)$ if *incx* = 1, *sub(y)* denotes $Y(iy, jy:jy+n-1)$ if *incy* = *m_y*, and $Y(iy: iy+m-1, jy)$ if *incy* = 1.

Input Parameters

trans

(global) CHARACTER*1. Specifies the operation:

```
if trans= 'N' or 'n', then sub(y) := alpha*sub(A)'*sub(x) +
beta*sub(y);

if trans= 'T' or 't', then sub(y) := alpha*sub(A)'*sub(x) +
beta*sub(y);

if trans= 'C' or 'c', then sub(y) := alpha*conjg(subA)')*sub(x) +
beta*sub(y).
```

m

(global) INTEGER. Specifies the number of rows of the distributed matrix *sub(A)*, $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix *sub(A)*, $n \geq 0$.

alpha

(global) REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Specifies the scalar *alpha*.

a

(local) REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Array, size (*lld_a*, LOC_q(*ja*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix *sub(A)*.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>descA</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local)REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, size $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$ when $\text{trans} = 'N'$ or ' n ', and $(jx-1)*m_x + ix+(m-1)*\text{abs}(incx)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descX</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global)REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local)REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, size $(jy-1)*m_y + iy+(m-1)*\text{abs}(incy)$ when $\text{trans} = 'N'$ or ' n ', and $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descY</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .

incy (global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . *incy* must not be zero.

Output Parameters

y Overwritten by the updated distributed vector $\text{sub}(y)$.

p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

Syntax

Fortran:

```
call psagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pdagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pcagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pzagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?agemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(conjg(sub(A')))*abs(sub(x)) + abs(beta*sub(y)),
```

where

alpha and *beta* are scalars,

sub(A) is a m -by- n submatrix, *sub(A)* = $A(ia:ia+m-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are subvectors.

When *trans* = 'N' or 'n',

sub(x) denotes $X(ix:ix, jx:jx+n-1)$ if *incx* = *m_x*, and

$X(ix:ix+n-1, jx:jx)$ if *incx* = 1,

sub(y) denotes $Y(iy:iy, jy:jy+m-1)$ if *incy* = *m_y*, and

$Y(iy:iy+m-1, jy:jy)$ if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(x) denotes $X(ix:ix, jx:jx+m-1)$ if *incx* = *m_x*, and

$X(ix:ix+m-1, jx:jx)$ if *incx* = 1,

sub(y) denotes $Y(iy:iy, jy:jy+n-1)$ if *incy* = *m_y*, and

$Y(iy:iy+n-1, jy:jy)$ if *incy* = 1.

Input Parameters

trans

(global) CHARACTER*1. Specifies the operation:

```
if trans= 'N' or 'n', then sub(y) := |alpha|*|sub(A)|*|sub(x)| + |beta*sub(y)|
```

```
if trans= 'T' or 't', then sub(y) := |alpha|*|sub(A')|*|sub(x)| + |beta*sub(y)|
```

```
if trans= 'C' or 'c', then sub(y) := |alpha|*|sub(A')|*|sub(x)| + |beta*sub(y)|.
```

m

(global) INTEGER. Specifies the number of rows of the distributed matrix *sub(A)*, $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix *sub(A)*, $n \geq 0$.

alpha

(global) REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Specifies the scalar *alpha*.

a

(local) REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Array, size ($l1d_a$, LOC $q(ja+n-1)$). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desc_a$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

x

(local)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Array, size $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$ when $\text{trans} = 'N'$ or ' n ', and $(jx-1)*m_x + ix + (m-1)*\text{abs}(incx)$ otherwise.

This array contains the entries of the distributed vector $\text{sub}(x)$.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

$desc_x$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

$incx$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

$beta$

(global)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Specifies the scalar β . When β is set to zero, then $\text{sub}(y)$ need not be set on input.

y

(local)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Array, size $(jy-1)*m_y + iy + (m-1)*\text{abs}(incy)$ when $\text{trans} = 'N'$ or ' n ', and $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$ otherwise.

This array contains the entries of the distributed vector $\text{sub}(y)$.

<i>i_y, j_y</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>Y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .
----------	---

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

Fortran:

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

C:

```
void psger (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdger (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- C: mkl_pblas.h

Description

The p?ger routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(A) is a *m*-by-*n* distributed general matrix, sub(A)=A(ia:ia+m-1, ja:ja+n-1),

sub(x) is an *m*-element distributed vector, sub(y) is an *n*-element distributed vector,

sub(x) denotes X(ix, jx:jx+m-1) if incx = *m_x*, and X(ix: ix+m-1, jx) if incx = 1,

sub(y) denotes Y(iy, jy:jy+n-1) if incy = *m_y*, and Y(iy: iy+n-1, jy) if incy = 1.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for psger DOUBLE REAL for pdger Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for psger DOUBLE REAL for pdger Array, size at least $(jx-1)*m_x + ix + (m-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psger DOUBLE REAL for pdger Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) REAL for psger DOUBLE REAL for pdger Array, size $(l1d_a, \text{LOCq}(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $\text{sub}(A)$.
----------	---

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

Fortran:

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

C:

```
void pcgerc (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzgerc (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- C: mkl_pblas.h

Description

The p?gerc routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(y))' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*) = $A(ia:ia+m-1, ja:ja+n-1)$,

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes $X(ix, jx:jx+m-1)$ if *incx* = *m_x*, and $X(ix: ix+m-1, jx)$ if *incx* = 1,

sub(*y*) denotes $Y(iy, jy:jy+n-1)$ if *incy* = *m_y*, and $Y(iy: iy+n-1, jy)$ if *incy* = 1.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Array, size at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Array, size at least $(l1d_a, \text{LOCq}(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

`descA` (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

`a` Overwritten by the updated distributed matrix $\text{sub}(A)$.

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

Fortran:

```
call pcgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
descA)
```

```
call pzgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
descA)
```

C:

```
void pcgeru (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *descA );
void pzgeru (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*descA );
```

Include Files

- C: mkl_pblas.h

Description

The p?geru routines perform a matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

`alpha` is a scalar,

`sub(A)` is a m -by- n distributed general matrix, `sub(A)=A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an m -element distributed vector, `sub(y)` is an n -element distributed vector,

`sub(x)` denotes $X(ix, jx:jx+m-1)$ if `incx = m_x`, and $X(ix: ix+m-1, jx)$ if `incx = 1`,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy = m_y`, and $Y(iy: iy+n-1, jy)$ if `incy = 1`.

Input Parameters

`m` (global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.

<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, size at least $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, size at least $(jy-1) * m_y + iy + (n-1) * \text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, size at least $(lld_a, \text{LOCq}(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

*a*Overwritten by the updated distributed matrix $\text{sub}(A)$.

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

Fortran:

```
call pchemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
           jy, descy, incy)

call pzhemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
           jy, descy, incy)
```

C:

```
void pchemv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT
             *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT
             *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
             *incy );

void pzhemv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
             MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
             *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy ,
             MKL_INT *descy , MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?hemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* Hermitian distributed matrix, $\text{sub}(A)=A(i_a:i_a+n-1, j_a:j_a+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, j_x:j_x+n-1)$ if *incx* = *m_x*, and $X(ix: i_x+n-1, j_x)$ if *incx* = 1,

sub(y) denotes $Y(i_y, j_y:j_y+n-1)$ if *incy* = *m_y*, and $Y(i_y: i_y+n-1, j_y)$ if *incy* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.

If *uplo* = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, size $(\text{lld}_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry when <i>uplo</i> = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the n -by- n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>descA</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>x</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, size at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descX</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, size at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$.

This array contains the entries of the distributed vector $\text{sub}(y)$.

i_y, j_y	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
desc_y	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
incy	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . incy must not be zero.

Output Parameters

Y	Overwritten by the updated distributed vector $\text{sub}(y)$.
-----	---

p?ahemv

Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.

Syntax

Fortran:

```
call pcahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
            jy, descy, incy)

call pzahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
            jy, descy, incy)
```

C:

```
void pcahemv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
               MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
               MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
               MKL_INT *incy );

void pzahemv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
               MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
               *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy ,
               MKL_INT *descy , MKL_INT *incy );
```

Include Files

- C: mkl_pblas.h

Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

α and β are scalars,

$\text{sub}(A)$ is a n -by- n Hermitian distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ and $\text{sub}(y)$ are distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $\text{inc}_x = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{inc}_x = 1$,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(A)</code> is used: If <code>uplo</code> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used. If <code>uplo</code> = 'L' or 'l', then the low triangular part of the <code>sub(A)</code> is used.
<code>n</code>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<code>alpha</code>	(global) COMPLEX for <code>pcahemv</code> DOUBLE COMPLEX for <code>pzahemv</code> Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) COMPLEX for <code>pcahemv</code> DOUBLE COMPLEX for <code>pzahemv</code> Array, size $(lld_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix <code>sub(A)</code> . Before entry when <code>uplo</code> = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix <code>sub(A)</code> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <code>sub(A)</code> is not referenced, and when <code>uplo</code> = 'L' or 'l', the n -by- n lower triangular part of the distributed matrix <code>sub(A)</code> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>x</code>	(local) COMPLEX for <code>pcahemv</code> DOUBLE COMPLEX for <code>pzahemv</code> Array, size at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

<i>beta</i>	(global) COMPLEX for <code>pcahemv</code> DOUBLE COMPLEX for <code>pzahemv</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <code>sub(y)</code> need not be set on input.
<i>y</i>	(local) COMPLEX for <code>pcahemv</code> DOUBLE COMPLEX for <code>pzahemv</code> Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <code>sub(y)</code> .
----------	---

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

Fortran:

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

C:

```
void pcher (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
void pzher (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?her` routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(x)') + sub(A),
```

where:

alpha is a real scalar,

sub(A) is a n -by- n distributed Hermitian matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

sub(x) is distributed vector.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for pcher DOUBLE REAL for pzher Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, size at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, size $(1ld_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the n -by- n lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	With $\text{uplo} = 'U'$ or ' <u>u</u> ', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$. With $\text{uplo} = 'L'$ or ' <l>', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.</l>
----------	--

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

Fortran:

```
call pcher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
call pzher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

C:

```
void pcher2 (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzher2 (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- C: mkl_pblas.h

Description

The p?her2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conj(sub(y)') + conj(alpha)*sub(y)*conj(sub(x)') + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed Hermitian matrix, sub(*A*)=*A*(*ia*:*ia+n-1*, *ja*:*ja+n-1*),

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx+n-1*) if *incx* = *m_x*, and *X*(*ix*: *ix+n-1*, *jx*) if *incx* = 1,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix <code>sub(A)</code> is used: If <code>uplo</code> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used. If <code>uplo</code> = 'L' or 'l', then the low triangular part of the <code>sub(A)</code> is used.
<code>n</code>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<code>alpha</code>	(global) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Specifies the scalar <code>alpha</code> .
<code>x</code>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Array, size at least $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.
<code>y</code>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Array, size at least $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<code>incy</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <code>incy</code> must not be zero.
<code>a</code>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code>

Array, size (lld_a , $\text{LOCq}(ja+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.

Before entry with $uplo = 'U'$ or ' u ', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $uplo = 'L'$ or ' l ', the n -by- n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desc_a$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a

With $uplo = 'U'$ or ' u ', the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$.

With $uplo = 'L'$ or ' l ', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

Fortran:

```
call pssymv(uplo, n, alpha, a, ia, ja, desc_a, x, ix, jx, desc_x, inc_x, beta, y, iy, jy, desc_y, inc_y)
```

```
call pdsymv(uplo, n, alpha, a, ia, ja, desc_a, x, ix, jx, desc_x, inc_x, beta, y, iy, jy, desc_y, inc_y)
```

C:

```
void pssymv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc_a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *desc_x , MKL_INT *inc_x , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *desc_y , MKL_INT *inc_y );
```

```
void pdsymv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc_a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *desc_x , MKL_INT *inc_x , double *beta , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *desc_y , MKL_INT *inc_y );
```

Include Files

- C: mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

alpha and *beta* are scalars,

sub(A) is a n -by- n symmetric distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = m_y$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for pssymv DOUBLE REAL for pdsymv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, size $(\text{lld}_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo</i> = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the n -by- n lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, size at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$.

This array contains the entries of the distributed vector `sub(x)`.

<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.
<code>beta</code>	(global) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Specifies the scalar <code>beta</code> . When <code>beta</code> is set to zero, then <code>sub(y)</code> need not be set on input.
<code>y</code>	(local) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<code>incy</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <code>incy</code> must not be zero.

Output Parameters

<code>y</code>	Overwritten by the updated distributed vector <code>sub(y)</code> .
----------------	---

p?asymv

Computes a distributed matrix-vector product using absolute values for a symmetric matrix.

Syntax

Fortran:

```
call psasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
            jy, descy, incy)

call pdasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
            jy, descy, incy)
```

C:

```

void psasymv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );

void pdasymv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy );

```

Include Files

- C: mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* symmetric distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+n-1)*,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if *incx = m_x*, and $X(ix: ix+n-1, jx)$ if *incx = 1*,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if *incy = m_y*, and $Y(iy: iy+n-1, jy)$ if *incy = 1*.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo = 'U'</i> or <i>'u'</i> , then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo = 'L'</i> or <i>'l'</i> , then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0 .
<i>alpha</i>	(global) REAL for psasymv DOUBLE REAL for pdasymv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local)REAL for psasymv DOUBLE REAL for pdasymv Array, size (<i>lld_a, LOCq(ja+n-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo = 'U'</i> or <i>'u'</i> , the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo = 'L'</i> or <i>'l'</i> , the <i>n</i> -by- <i>n</i> lower

triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

descA

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

x

(local) REAL for psasymv

DOUBLE PRECISION for pdasymv

Array, size at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$.

This array contains the entries of the distributed vector $\text{sub}(x)$.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

descX

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

incx

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

beta

(global) REAL for psasymv

DOUBLE PRECISION for pdasymv

Specifies the scalar β . When β is set to zero, then $\text{sub}(y)$ need not be set on input.

y

(local) REAL for psasymv

DOUBLE PRECISION for pdasymv

Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$.

This array contains the entries of the distributed vector $\text{sub}(y)$.

iy, jy

(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.

descY

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .

incy

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

y

Overwritten by the updated distributed vector $\text{sub}(y)$.

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax**Fortran:**

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pdssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

C:

```
void pssyr (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
void pdssyr (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- C: mkl_pblas.h

Description

The p?syr routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(A) is a *n*-by-*n* distributed symmetric matrix, *sub(A)=A(ia:ia+n-1, ja:ja+n-1)*,

sub(x) is distributed vector.

sub(x) denotes *X(ix, jx:jx+n-1)* if *incx = m_x*, and *X(ix: ix+n-1, jx)* if *incx = 1*,

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for pssyr DOUBLE REAL for pdssyr Specifies the scalar <i>alpha</i> .
<i>x</i>	(local)REAL for pssyr DOUBLE REAL for pdssyr

Array, size at least $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$.

This array contains the entries of the distributed vector $\text{sub}(x)$.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

$descx$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

$incx$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

a

(local) REAL for pssyr

DOUBLE REAL for pdssyr

Array, size $(lld_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$.

Before entry with $uplo = 'U'$ or ' u ', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $uplo = 'L'$ or ' l ', the n -by- n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a

With $uplo = 'U'$ or ' u ', the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$.

With $uplo = 'L'$ or ' l ', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

Fortran:

```
call pssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

```
call pdssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

C:

```
void pssyr2 (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdssyr2 (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- C: mkl_pblas.h

Description

The p?ssyr2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + alpha*sub(y)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(A) is a *n*-by-*n* distributed symmetric matrix, *sub(A)*=*A*(*ia*:*ia+n-1*, *ja*:*ja+n-1*) ,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X*(*ix*, *jx*:*jx+n-1*) if *incx* = *m_x*, and *X*(*ix*: *ix+n-1*, *jx*) if *incx* = 1,

sub(y) denotes *Y*(*iy*, *jy*:*jy+n-1*) if *incy* = *m_y*, and *Y*(*iy*: *iy+n-1*, *jy*) if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for pssyr2 DOUBLE REAL for pdssyr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, size at least (<i>jx-1</i> * <i>m_x</i> + <i>ix</i> +(<i>n-1</i>)*abs(<i>incx</i>)). This array contains the entries of the distributed vector <i>sub(x)</i> .

<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.
<i>a</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, size $(lld_a, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <i>sub(A)</i> .
----------	--

With $uplo = 'L'$ or ' l ', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

Fortran:

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

C:

```
void pstrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdtrmv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pctrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pztrmv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$, or $\text{sub}(x) := \text{sub}(A)' * \text{sub}(x)$, or $\text{sub}(x) := \text{conjg}(\text{sub}(A)') * \text{sub}(x)$,
where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;
 if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans

(global) CHARACTER*1. Specifies the form of *op*(*sub*(*A*)) used in the matrix equation:

if *transa* = 'N' or 'n', then *sub*(*x*) := *sub*(*A*) * *sub*(*x*);
 if *transa* = 'T' or 't', then *sub*(*x*) := *sub*(*A*)' * *sub*(*x*);
 if *transa* = 'C' or 'c', then *sub*(*x*) := *conjg*(*sub*(*A*)') * *sub*(*x*).

diag

(global) CHARACTER*1. Specifies whether the matrix *sub*(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;
 if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n

(global) INTEGER. Specifies the order of the distributed matrix *sub*(*A*), *n*≥0.

a

(local)REAL for *pstrmv*

DOUBLE PRECISION for *pdtrmv*

COMPLEX for *pctrmv*

DOUBLE COMPLEX for *pztrmv*

Array, size at least (*lld_a*, *LOCq*(1, *ja*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix *sub*(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix *sub*(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub*(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub*(*A*) is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub*(*A*) are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub*(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)REAL for *pstrmv*

DOUBLE PRECISION for *pdtrmv*

COMPLEX for *pctrmv*

DOUBLE COMPLEX for *pztrmv*

Array, size at least (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector `sub(x)`.

<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

<code>x</code>	Overwritten by the transformed distributed vector <code>sub(x)</code> .
----------------	---

p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

Syntax

Fortran:

```
call psatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

Description

The p?atrmv routines perform one of the following distributed matrix-vector operations defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)), or
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)), or
sub(y) := abs(alpha)*abs(conjg(sub(A')))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)* = *A*(ia:ia+n-1, ja:ja+n-1),

sub(x) is an *n*-element distributed vector.

sub(x) denotes *X(ix, jx:jx+n-1)* if *incx* = *m_x*, and *X(ix: ix+n-1, jx)* if *incx* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of <i>op</i> (<i>sub(A)</i>) used in the matrix equation: if <i>trans</i> = 'N' or 'n', then <i>sub(y)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> ; if <i>trans</i> = 'T' or 't', then <i>sub(y)</i> := <i>alpha</i> * <i>sub(A)</i> ' * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> ; if <i>trans</i> = 'C' or 'c', then <i>sub(y)</i> := <i>alpha</i> * <i>conjg</i> (<i>sub(A)</i> ') * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> .
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix <i>sub(A)</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥0.
<i>alpha</i>	(global) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Array, size at least ($l1d_a$, LOCq(1, $ja+n-1$)).

Before entry with $uplo = 'U'$ or ' u ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.

Before entry with $uplo = 'L'$ or ' l ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.

When $diag = 'U'$ or ' u ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desc_a$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

x

(local)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Array, size at least ($jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$).

This array contains the entries of the distributed vector $\text{sub}(x)$.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

$desc_x$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

$incx$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

$beta$

(global)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Specifies the scalar β . When β is set to zero, then $\text{sub}(y)$ need not be set on input.

<i>y</i>	(local)REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Array, size $(jy-1)*m_y + iy + (m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m_y + iy + (n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>i_y, j_y</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>desc_y</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the transformed distributed vector <i>sub(y)</i> .
----------	---

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

Fortran:

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrsrv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

C:

```
void pstrsv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pdtrsv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
void pctrsrv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT

Description

The p?trsv routines solve one of the systems of equations:

$\text{sub}(A) * \text{sub}(x) = b$, or $\text{sub}(A)' * \text{sub}(x) = b$, or $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(i_a:i_a+n-1, j_a:j_a+n-1)$,

b and $\text{sub}(x)$ are n -element distributed vectors,

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if $\text{uplo} = 'U'$ or ' <u>u</u> ', then the matrix is upper triangular; if $\text{uplo} = 'L'$ or ' <l>', then the matrix is low triangular.</l>
<i>trans</i>	(global) CHARACTER*1. Specifies the form of the system of equations: if $\text{transa} = 'N'$ or ' <n>', then $\text{sub}(A) * \text{sub}(x) = b$; if $\text{transa} = 'T'$ or '<t>', then $\text{sub}(A)' * \text{sub}(x) = b$; if $\text{transa} = 'C'$ or '<c>', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$.</c></t></n>
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if $\text{diag} = 'U'$ or ' <u>u</u> ' then the matrix is unit triangular; if $\text{diag} = 'N'$ or ' <n>', then the matrix is not unit triangular.</n>
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>a</i>	(local) REAL for pstrsv DOUBLE PRECISION for pdtrsv COMPLEX for pctrs DOUBLE COMPLEX for pztrsv Array, size at least $(\text{lld}_a, \text{LOCq}(1, j_a+n-1))$. Before entry with $\text{uplo} = 'U'$ or ' <u>u</u> ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.

Before entry with $\text{uplo} = \text{'L'}$ or 'l' , this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced .

When $\text{diag} = \text{'U'}$ or 'u' , the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desc_a$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

x

(local)REAL for pstrsv

DOUBLE PRECISION for pdtrsv

COMPLEX for pcptrsv

DOUBLE COMPLEX for pzptrsv

Array, size at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$.

This array contains the entries of the distributed vector $\text{sub}(x)$. Before entry, $\text{sub}(x)$ must contain the n -element right-hand side distributed vector b .

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.

$desc_x$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .

$incx$

(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

x

Overwritten with the solution vector.

PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table "PBLAS Level 3 Routine Groups and Their Data Types"](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
<code>p?geadd</code>	s, d, c, z	Distributed matrix-matrix sum of general matrices
<code>p?tradd</code>	s, d, c, z	Distributed matrix-matrix sum of triangular matrices

Routine Group	Data Types	Description
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?somm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?geadd

Performs sum operation for two distributed general matrices.

Syntax

Fortran:

```
call psgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)

Description

The p?geadd routines perform sum operation for two distributed general matrices. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*op(sub(A)),
```

where:

op(x) is one of *op(x) = x*, or *op(x) = x'*,

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, *sub(C)=C(ic:ic+m-1, jc:jc+n-1)*.

sub(A) is a distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+m-1)*.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>op(sub(A)) := sub(A)</i> ; if <i>trans</i> = 'T' or 't', then <i>op(sub(A)) := sub(A)'</i> ; if <i>trans</i> = 'C' or 'c', then <i>op(sub(A)) := sub(A)''</i> .
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(C)</i> and the number of columns of the submatrix <i>sub(A)</i> , <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(C)</i> and the number of rows of the submatrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, size (<i>lld_a, LOCq(ja+m-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

<i>beta</i>	(global)REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local)REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, size (<i>lld_c</i> , LOCq(<i>jc+n-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tradd

Performs sum operation for two distributed triangular matrices.

Syntax

Fortran:

```
call pstradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pdtradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pctradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pztradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

C:

```
void pstradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descC );
void pdtradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descC );
```

```
void pcstradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *desc );
void pzstradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *desc );
```

Include Files

- C: mkl_pblas.h

Description

The p?stradd routines perform sum operation for two distributed triangular matrices. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*op(sub(A)),
```

where:

op(x) is one of *op(x) = x*, or *op(x) = x'*, or *op(x) = conjg(x')*.

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, *sub(C)=C(ic:ic+m-1, jc:jc+n-1)*.

sub(A) is a distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+m-1)*.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(C)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>op(sub(A)) := sub(A)</i> ; if <i>trans</i> = 'T' or 't', then <i>op(sub(A)) := sub(A)'</i> ; if <i>trans</i> = 'C' or 'c', then <i>op(sub(A)) := conjg(sub(A)')</i> .
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(C)</i> and the number of columns of the submatrix <i>sub(A)</i> , <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(C)</i> and the number of rows of the submatrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for pcstradd DOUBLE PRECISION for pdstradd COMPLEX for pcstradd DOUBLE COMPLEX for pdstradd Specifies the scalar <i>alpha</i> .
<i>a</i>	(local)REAL for pcstradd DOUBLE PRECISION for pdstradd

	COMPLEX for <code>pctradd</code> DOUBLE COMPLEX for <code>pztradd</code> Array, size (lld_a , $\text{LOCq}(ja+m-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>beta</i>	(global) REAL for <code>pstradd</code> DOUBLE PRECISION for <code>pdtradd</code> COMPLEX for <code>pctradd</code> DOUBLE COMPLEX for <code>pztradd</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for <code>pstradd</code> DOUBLE PRECISION for <code>pdtradd</code> COMPLEX for <code>pctradd</code> DOUBLE COMPLEX for <code>pztradd</code> Array, size (lld_c , $\text{LOCq}(jc+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c Overwritten by the updated submatrix.

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

Fortran:

```
call psgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
```

```
call pdgemm(transa, transb, m, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,  

c, ic, jc, descc)  
  

call pcgemm(transa, transb, m, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,  

c, ic, jc, descc)  
  

call pzgemm(transa, transb, m, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,  

c, ic, jc, descc)
```

C:

```
void psgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,  

float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b ,  

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic ,  

MKL_INT *jc , MKL_INT *descc );  
  

void pdgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,  

double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b ,  

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic ,  

MKL_INT *jc , MKL_INT *descc );  
  

void pcgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,  

float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b ,  

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic ,  

MKL_INT *jc , MKL_INT *descc );  
  

void pzgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,  

double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b ,  

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic ,  

MKL_INT *jc , MKL_INT *descc );
```

Include Files

- C: mkl_pblas.h

Description

The *p?gemm* routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

```
sub(C) := alpha*op(sub(A))*op(sub(B)) + beta*sub(C),
```

where:

op(x) is one of *op(x) = x*, or *op(x) = x'*,

alpha and *beta* are scalars,

sub(A)=A(ia:ia+m-1, ja:ja+k-1), *sub(B)=B(ib:ib+k-1, jb:jb+n-1)*, and *sub(C)=C(ic:ic+m-1, jc:jc+n-1)*, are distributed matrices.

Input Parameters

<i>transa</i>	(global) CHARACTER*1. Specifies the form of <i>op(sub(A))</i> used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then <i>op(sub(A)) = sub(A)</i> ; if <i>transa</i> = 'T' or 't', then <i>op(sub(A)) = sub(A)'</i> ; if <i>transa</i> = 'C' or 'c', then <i>op(sub(A)) = sub(A)''</i> .
---------------	---

<i>transb</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(B))$ used in the matrix multiplication: if $\text{transb} = \text{'N'}$ or 'n' , then $\text{op}(\text{sub}(B)) = \text{sub}(B)$; if $\text{transb} = \text{'T'}$ or 't' , then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$; if $\text{transb} = \text{'C'}$ or 'c' , then $\text{op}(\text{sub}(B)) = \text{sub}(B)''$.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$, $n \geq 0$. The value of <i>n</i> must be at least zero.
<i>k</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$. The value of <i>k</i> must be greater than or equal to 0.
<i>alpha</i>	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>alpha</i> . When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices $\text{sub}(A)$ and $\text{sub}(B)$ respectively need not be set on input.
<i>a</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, size $l1d_a$ by <i>kla</i> , where <i>kla</i> is $\text{LOCc}(ja+k-1)$ when $\text{transa} = \text{'N'}$ or 'n' , and is $\text{LOCq}(ja+m-1)$ otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm

Array, size lld_b by klb , where klb is $\text{LOCc}(jb+n-1)$ when $\text{transb} = \text{'N'}$ or ' n ', and is $\text{LOCq}(jb+k-1)$ otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.

ib, jb	(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively
$descb$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix B .
β	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar β . When β is equal to zero, then $\text{sub}(C)$ need not be set on input.
c	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, size $(lld_a, \text{LOCq}(jc+n-1))$. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$.
ic, jc	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively
$descC$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c	Overwritten by the m -by- n distributed matrix $\alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C)$.
-----	---

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

Fortran:

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
call pzhemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
```

C:

```
void pchemm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descc );

void pzhemm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- C: mkl_pblas.h

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as
 $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C)$,

or

$\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C)$,

where:

alpha and *beta* are scalars,

sub(A) is a Hermitian distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$, if *side* = 'L', and
 $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, if *side* = 'R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

$\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

side

(global) CHARACTER*1. Specifies whether the Hermitian distributed matrix *sub(A)* appears on the left or right in the operation:

if *side* = 'L' or 'l', then $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C)$;

if *side* = 'R' or 'r', then $\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C)$.

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix *sub(A)* is used:

if *uplo* = 'U' or 'u', then the upper triangular part is used;

if *uplo* = 'L' or 'l', then the lower triangular part is used.

m

(global) INTEGER. Specifies the number of rows of the distribute submatrix *sub(C)*, $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distribute submatrix *sub(C)*, $n \geq 0$.

alpha

(global) COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Specifies the scalar *alpha*.

a

(local) COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Array, size (*lld_a*, LOCq(*ja+na-1*)).

Before entry this array must contain the local pieces of the symmetric distributed matrix sub(*A*), such that when *uplo* = 'U' or 'u', the *na*-by-*na* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *na*-by-*na* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively

desc_a

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b

(local) COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Array, size (*lld_b*, LOCq(*jb+n-1*)). Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

desc_b

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta

(global) COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Specifies the scalar *beta*.

When *beta* is set to zero, then sub(*C*) need not be set on input.

c

(local) COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Array, size (*lld_c*, LOCq(*jc+n-1*)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively

desc_c

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c Overwritten by the m -by- n updated distributed matrix.

p?herk

Performs a rank- k update of a distributed Hermitian matrix.

Syntax

Fortran:

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
```

C:

```
void pcherk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *desc );
void pzherk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *desc );
```

Include Files

- C: mkl_pblas.h

Description

The p?herk routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha*sub(A)*conjg(sub(A)') + beta*sub(C),
```

or

```
sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an n -by- n Hermitian distributed matrix, *sub(C)* = $C(ic:ic+n-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, *sub(A)* = $A(ia:ia+n-1, ja:ja+k-1)$, if *trans* = 'N' or 'n', and *sub(A)* = $A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>sub(C)</i> := $\alpha\text{sub}(A)\text{conjg}(\text{sub}(A)') + \beta\text{sub}(C);$

if *trans* = 'C' or 'c', then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A)$
+ $\beta * \text{sub}(C)$.

n (global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix $\text{sub}(A)$, and on entry with *trans* = 'T' or 't' or 'C' or 'c', *k* specifies the number of rows of the distributed matrix $\text{sub}(A)$, $k \geq 0$.

alpha (global) REAL for pcherk

DOUBLE PRECISION for pzherk

Specifies the scalar *alpha*.

a (local) COMPLEX for pcherk

DOUBLE COMPLEX for pzherk

Array, size (*lld_a*, *kla*), where *kla* is $\text{LOCq}(ja+k-1)$ when *trans* = 'N' or 'n', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

beta (global) REAL for pcherk

DOUBLE PRECISION for pzherk

Specifies the scalar *beta*.

c (local) COMPLEX for pcherk

DOUBLE COMPLEX for pzherk

Array, size (*lld_c*, $\text{LOCq}(jc+n-1)$).

Before entry with *uplo* = 'U' or 'u', this array contains n -by- n upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains n -by- n lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c

With *uplo* = 'U' or 'u', the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

FORTRAN 77:

```
call pcher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)
```

```
call pzher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)
```

C:

```
void pcher2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

```
void pzher2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- C: mkl_pblas.h

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

```
sub(C):=alpha*sub(A)*conjg(sub(B)')+ conjg(alpha)*sub(B)*conjg(sub(A)')+beta*sub(C),
```

or

```
sub(C):=alpha*conjg(sub(A)')*sub(A)+ conjg(alpha)*conjg(sub(B)')*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* Hermitian distributed matrix, *sub(C)* = $C(ic:ic+n-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, *sub(A)*= $A(ia:ia+n-1, ja:ja+k-1)$, if *trans* = 'N' or 'n', and *sub(A)* = $A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

sub(B) is a distributed matrix, *sub(B)* = $B(ib:ib+n-1, jb:jb+k-1)$, if *trans* = 'N' or 'n', and *sub(B)*= $B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used: If $\text{uplo} = 'U'$ or ' <u>u</u> ', then the upper triangular part of the $\text{sub}(C)$ is used. If $\text{uplo} = 'L'$ or ' <u>l</u> ', then the low triangular part of the $\text{sub}(C)$ is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: $\text{if } \text{trans} = 'N' \text{ or } 'n', \text{ then } \text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)) + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)) + \beta * \text{sub}(C);$ $\text{if } \text{trans} = 'C' \text{ or } 'c', \text{ then } \text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)) * \text{sub}(A) + \beta * \text{sub}(C).$
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>k</i>	(global) INTEGER. On entry with $\text{trans} = 'N'$ or ' <u>n</u> ', <i>k</i> specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, and on entry with $\text{trans} = 'C'$ or ' <u>c</u> ', <i>k</i> specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, $k \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Array, size $(\text{lld}_a, \text{kla})$, where kla is $\text{LOCq}(ja+k-1)$ when $\text{trans} = 'N'$ or ' <u>n</u> ', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or ' <u>n</u> ', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>b</i>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Array, size $(\text{lld}_b, \text{klb})$, where klb is $\text{LOCq}(jb+k-1)$ when $\text{trans} = 'N'$ or ' <u>n</u> ', and is $\text{LOCq}(jb+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or ' <u>n</u> ', this array contains the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.

<i>descb</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for pcher2k DOUBLE PRECISION for pzher2k Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Array, size (<i>lld_c</i> , LOCq(<i>jc+n-1</i>)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	--

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

FORTRAN 77:

```
call pssymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
call pdsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
call pcsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
call pzsimm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descC)
```

C:

```

Description

The p?ssymm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha*sub(A)*sub(B) + beta*sub(C),
```

or

```
sub(C) := alpha*sub(B)*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(A) is a symmetric distributed matrix, *sub(A)* = $A(ia:ia+m-1, ja:ja+m-1)$, if *side* = 'L', and
sub(A) = $A(ia:ia+n-1, ja:ja+n-1)$, if *side* = 'R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

sub(B) = $B(ib:ib+m-1, jb:jb+n-1)$, *sub(C)* = $C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the symmetric distributed matrix <i>sub(A)</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(B)</i> + <i>beta</i> * <i>sub(C)</i> ; if <i>side</i> = 'R' or 'r', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(B)</i> * <i>sub(A)</i> + <i>beta</i> * <i>sub(C)</i> .
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>alpha</i>	(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, size (<i>lld_a</i> , LOCq(<i>ja+na-1</i>)). Before entry this array must contain the local pieces of the symmetric distributed matrix $\text{sub}(A)$, such that when <i>uplo</i> = 'U' or 'u', the <i>na</i> -by- <i>na</i> upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na</i> -by- <i>na</i> lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, size (<i>lld_b</i> , LOCq(<i>jb+n-1</i>)). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for pssymm

DOUBLE PRECISION for pdssymm

COMPLEX for pcssymm

DOUBLE COMPLEX for pzssymm

Specifies the scalar *beta*.

When *beta* is set to zero, then *sub(C)* need not be set on input.

c

(local)REAL for pdssymm

DOUBLE PRECISION for pdssymm

COMPLEX for pcssymm

DOUBLE COMPLEX for pzssymm

Array, size (*lld_c*, LOC_q(*jc+n-1*)). Before entry this array must contain the local pieces of the distributed matrix *sub(C)*.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c

Overwritten by the *m*-by-*n* updated matrix.

p?syrk

Performs a rank-*k* update of a symmetric distributed matrix.

Syntax

Fortran:

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pdssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha*sub(A)*sub(A)' + beta*sub(C),
```

or

```
sub(C) := alpha*sub(A)'*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, *sub(C)* = *C*(*ic*:*ic+n-1*, *jc*:*jc+n-1*).

sub(A) is a distributed matrix, *sub(A)* = *A*(*ia*:*ia+n-1*, *ja*:*ja+k-1*), if *trans* = 'N' or 'n', and *sub(A)* = *A*(*ia*:*ia+k-1*, *ja*:*ja+n-1*) otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(A)'</i> + <i>beta</i> * <i>sub(C)</i> ; if <i>trans</i> = 'T' or 't', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)'</i> * <i>sub(A)</i> + <i>beta</i> * <i>sub(C)</i> .
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(C)</i> , <i>n</i> ≥ 0.
<i>k</i>	(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <i>sub(A)</i> , and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrix <i>sub(A)</i> , <i>k</i> ≥ 0.
<i>alpha</i>	(global) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyrk Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for pssyrk

DOUBLE PRECISION for pdssyrk

COMPLEX for pcssyrk

DOUBLE COMPLEX for pzssyrk

Array, size ($l1d_a, \ kla$), where kla is $\text{LOCq}(ja+k-1)$ when $trans = 'N'$ or ' n ', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $trans = 'N'$ or ' n ', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

beta

(global)REAL for pdssyrk

DOUBLE PRECISION for pdssyrk

COMPLEX for pcssyrk

DOUBLE COMPLEX for pzssyrk

Specifies the scalar *beta*.

c

(local)REAL for pdssyrk

DOUBLE PRECISION for pdssyrk

COMPLEX for pcssyrk

DOUBLE COMPLEX for pzssyrk

Array, size ($l1d_c, \ \text{LOCq}(jc+n-1)$).

Before entry with $uplo = 'U'$ or ' u ', this array contains n -by- n upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced.

Before entry with $uplo = 'L'$ or ' l ', this array contains n -by- n lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c

With $uplo = 'U'$ or ' u ', the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

With $uplo = 'L'$ or ' l ', the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?syr2k

Performs a rank- $2k$ update of a symmetric distributed matrix.

Syntax

Fortran:

```
call pssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)

call pdssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)

call pcssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)

call pzssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descc)
```

C:

```
void pssyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );

void pdssyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );

MKL_INT *descc );
```

Include Files

- C: mkl_pblas.h

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha * sub(A) * sub(B)' + alpha * sub(B) * sub(A)' + beta * sub(C),
```

or

```
sub(C) := alpha * sub(A)' * sub(B) + alpha * sub(B)' * sub(A) + beta * sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an n -by- n symmetric distributed matrix, *sub(C)=C(ic:ic+n-1, jc:jc+n-1)*.

sub(A) is a distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+k-1)*, if *trans = 'N'* or '*n*', and *sub(A)=A(ia:ia+k-1, ja:ja+n-1)* otherwise.

`sub(B)` is a distributed matrix, `sub(B)=B(ib:ib+n-1, jb:jb+k-1)`, if `trans = 'N' or 'n'`, and `sub(B)=B(ib:ib+k-1, jb:jb+n-1)` otherwise.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <code>sub(C)</code> is used: If <code>uplo = 'U' or 'u'</code> , then the upper triangular part of the <code>sub(C)</code> is used. If <code>uplo = 'L' or 'l'</code> , then the low triangular part of the <code>sub(C)</code> is used.
<code>trans</code>	(global) CHARACTER*1. Specifies the operation: <code>if trans = 'N' or 'n', then sub(C) := alpha*sub(A)*sub(B)' + alpha*sub(B)*sub(A)' + beta*sub(C);</code> <code>if trans = 'T' or 't', then sub(C) := alpha*sub(B)'*sub(A) + alpha*sub(A)'*sub(B) + beta*sub(C).</code>
<code>n</code>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(C)</code> , $n \geq 0$.
<code>k</code>	(global) INTEGER. On entry with <code>trans = 'N' or 'n'</code> , k specifies the number of columns of the distributed matrices <code>sub(A)</code> and <code>sub(B)</code> , and on entry with <code>trans = 'T' or 't'</code> , k specifies the number of rows of the distributed matrices <code>sub(A)</code> and <code>sub(B)</code> , $k \geq 0$.
<code>alpha</code>	(global) REAL for <code>pssyr2k</code> DOUBLE PRECISION for <code>pdsyr2k</code> COMPLEX for <code>pcsyrr2k</code> DOUBLE COMPLEX for <code>pzsyr2k</code> Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) REAL for <code>pssyr2k</code> DOUBLE PRECISION for <code>pdsyr2k</code> COMPLEX for <code>pcsyrr2k</code> DOUBLE COMPLEX for <code>pzsyr2k</code> Array, size <code>(lld_a, kla)</code> , where <code>kla</code> is <code>LOCq(ja+k-1)</code> when <code>trans = 'N'</code> or <code>'n'</code> , and is <code>LOCq(ja+n-1)</code> otherwise. Before entry with <code>trans = 'N'</code> or <code>'n'</code> , this array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>b</code>	(local) REAL for <code>pssyr2k</code> DOUBLE PRECISION for <code>pdsyr2k</code>

COMPLEX for `pcsy2k`

DOUBLE COMPLEX for `pzsyr2k`

Array, size (lld_b, klb) , where klb is $\text{LOCq}(jb+k-1)$ when $trans = 'N'$ or ' n ', and is $\text{LOCq}(jb+n-1)$ otherwise. Before entry with $trans = 'N'$ or ' n ', this array contains the local pieces of the distributed matrix $\text{sub}(B)$.

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.

descb

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix B .

beta

(global)REAL for `pssyr2k`

DOUBLE PRECISION for `pdsyr2k`

COMPLEX for `pcsy2k`

DOUBLE COMPLEX for `pzsyr2k`

Specifies the scalar *beta*.

c

(local)REAL for `pssyr2k`

DOUBLE PRECISION for `pdsyr2k`

COMPLEX for `pcsy2k`

DOUBLE COMPLEX for `pzsyr2k`

Array, size $(lld_c, \text{LOCq}(jc+n-1))$.

Before entry with $uplo = 'U'$ or ' u ', this array contains n -by- n upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced.

Before entry with $uplo = 'L'$ or ' l ', this array contains n -by- n lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c

With $uplo = 'U'$ or ' u ', the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

With $uplo = 'L'$ or ' l ', the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

Fortran:

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

C:

```
void pstran (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descC );
void pdtran (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descC );
```

Include Files

- C: mkl_pblas.h

Description

The p?tran routines transpose a real distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*sub(A)'
```

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, *sub(C)=C(ic:ic+m-1, jc:jc+n-1)*.

sub(A) is a distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+m-1)*.

Input Parameters

m (global) INTEGER. Specifies the number of rows of the distributed matrix
sub(C), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrix
sub(C), $n \geq 0$.

alpha (global) REAL for pstran
 DOUBLE PRECISION for pdtran
 Specifies the scalar *alpha*.

a (local) REAL for pstran
 DOUBLE PRECISION for pdtran
 Array, size (*l1d_a*, LOCq(*ja+m-1*)). This array contains the local pieces
 of the distributed matrix *sub(A)*.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for pstran DOUBLE PRECISION for pdtran Array, size (<i>l1d_c</i> , LOCq(<i>jc+n-1</i>)). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tranu

Transposes a distributed complex matrix.

Syntax

Fortran:

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

C:

```
void pctranu (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descC );
void pztranu (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descC );
```

Include Files

- C: mkl_pblas.h

Description

The `p?tranu` routines transpose a complex distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*sub(A)',
```

where:

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(C)</code> , $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(C)</code> , $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Array, size <code>(lld_a, LOCq(ja+m-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.
<i>c</i>	(local) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Array, size <code>(lld_c, LOCq(jc+n-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<i>ic</i> , <i>jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.

descC (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c Overwritten by the updated submatrix.

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

Fortran:

```
call pcstranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pzstranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

C:

```
void pcstranc (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descC );
void pzstranc (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descC );
```

Include Files

- C: mkl_pblas.h

Description

The p?tranc routines transpose a complex distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic+m-1*, *jc*:*jc+n-1*).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia+n-1*, *ja*:*ja+m-1*).

Input Parameters

m (global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), *m* ≥ 0 .

n (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*), *n* ≥ 0 .

alpha (global) COMPLEX for pcstranc
DOUBLE COMPLEX for pzstranc
Specifies the scalar *alpha*.

a (local) COMPLEX for pcstranc

DOUBLE COMPLEX for pztranc

Array, size (lld_a , LOCq($ja+m-1$)). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

descA

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

beta

(global) COMPLEX for pcstranc

DOUBLE COMPLEX for pztranc

Specifies the scalar *beta*.

When *beta* is equal to zero, then $\text{sub}(C)$ need not be set on input.

c

(local) COMPLEX for pcstranc

DOUBLE COMPLEX for pztranc

Array, size (lld_c , LOCq($jc+n-1$)).

This array contains the local pieces of the distributed matrix $\text{sub}(C)$.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c

Overwritten by the updated submatrix.

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

Fortran:

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB)
call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB)
call pcstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB)
call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB)
```

C:

```
void pstrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *descA ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descB );
```

```

void pdtrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pcstrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pztrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

```

Include Files

- C: mkl_pblas.h

Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

```
sub(B) := alpha*op(sub(A))*sub(B)
```

or

```
sub(B) := alpha*sub(B)*op(sub(A))
```

where:

alpha is a scalar,

sub(B) is an *m*-by-*n* distributed matrix, *sub(B)*=*B*(*ib*:*ib+m-1*, *jb*:*jb+n-1*).

A is a unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)*=*A*(*ia*:*ia+m-1*, *ja*:*ja+m-1*), if *side* = 'L' or 'l', and *sub(A)*=*A*(*ia*:*ia+n-1*, *ja*:*ja+n-1*), if *side* = 'R' or 'r'.

op(sub(A)) is one of *op(sub(A))* = *sub(A)*, or *op(sub(A))* = *sub(A)'*, or *op(sub(A))* = *conjg(sub(A))'*.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether <i>op(sub(A))</i> appears on the left or right of <i>sub(B)</i> in the operation: if <i>side</i> = 'L' or 'l', then <i>sub(B)</i> := <i>alpha</i> * <i>op(sub(A))</i> * <i>sub(B)</i> ; if <i>side</i> = 'R' or 'r', then <i>sub(B)</i> := <i>alpha</i> * <i>sub(B)</i> * <i>op(sub(A))</i> .
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	(global) CHARACTER*1. Specifies the form of <i>op(sub(A))</i> used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then <i>op(sub(A))</i> = <i>sub(A)</i> ; if <i>transa</i> = 'T' or 't', then <i>op(sub(A))</i> = <i>sub(A)'</i> ; if <i>transa</i> = 'C' or 'c', then <i>op(sub(A))</i> = <i>conjg(sub(A))'</i> .

<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if $diag = 'U'$ or ' <u>' then the matrix is unit triangular; if $diag = 'N'$ or '<n>', then the matrix is not unit triangular.</n></u>
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code> COMPLEX for <code>pctrmm</code> DOUBLE COMPLEX for <code>pztrmm</code> Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then the array <i>b</i> need not be set before entry.
<i>a</i>	(local) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code> COMPLEX for <code>pctrmm</code> DOUBLE COMPLEX for <code>pztrmm</code> Array, size lld_a by <i>ka</i> , where <i>ka</i> is at least $\text{LOCq}(1, ja+m-1)$ when <i>side</i> = ' <i>L</i> ' or ' <i>l</i> ' and is at least $\text{LOCq}(1, ja+n-1)$ when <i>side</i> = ' <i>R</i> ' or ' <i>r</i> '. Before entry with <i>uplo</i> = ' <i>U</i> ' or ' <i>u</i> ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = ' <i>L</i> ' or ' <i>l</i> ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced . When <i>diag</i> = ' <i>U</i> ' or ' <i>u</i> ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code> COMPLEX for <code>pctrmm</code>

	DOUBLE COMPLEX for pztrmm Array, size (<i>lld_b</i> , LOCq(1, <i>jb+n-1</i>)).
	Before entry, this array contains the local pieces of the distributed matrix sub(<i>B</i>).
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	Overwritten by the transformed distributed matrix.
----------	--

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

Fortran:

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

C:

```
void pstrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pdtrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pctrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pztrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- C: mkl_pblas.h

Description

The p?trsm routines solve one of the following distributed matrix equations:

$\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B)$,

or

$X^* \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B)$,

where:

α is a scalar,

X and $\text{sub}(B)$ are m -by- n distributed matrices, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$;

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$, if $\text{side} = 'L'$ or ' l ', and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, if $\text{side} = 'R'$ or ' r ';

$\text{op}(\text{sub}(A))$ is one of $\text{op}(\text{sub}(A)) = \text{sub}(A)$, or $\text{op}(\text{sub}(A)) = \text{sub}(A)'$, or $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.

The distributed matrix $\text{sub}(B)$ is overwritten by the solution matrix X .

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of X in the equation: if $\text{side} = 'L'$ or ' l ', then $\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B)$; if $\text{side} = 'R'$ or ' r ', then $X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B)$.
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if $\text{uplo} = 'U'$ or ' u ', then the matrix is upper triangular; if $\text{uplo} = 'L'$ or ' l ', then the matrix is low triangular.
<i>transa</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if $\text{transa} = 'N'$ or ' n ', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if $\text{transa} = 'T'$ or ' t ', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$; if $\text{transa} = 'C'$ or ' c ', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if $\text{diag} = 'U'$ or ' u ' then the matrix is unit triangular; if $\text{diag} = 'N'$ or ' n ', then the matrix is not unit triangular.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pcstrsm DOUBLE COMPLEX for pzstrsm Specifies the scalar α .

When α is zero, then a is not referenced and b need not be set before entry.

a

(local)REAL for pstrsm
 DOUBLE PRECISION for pdtrsm
 COMPLEX for pctrsm
 DOUBLE COMPLEX for pztrsm

Array, size lld_a by ka , where ka is at least $\text{LOCq}(1, ja+m-1)$ when $\text{side} = 'L'$ or ' l ' and is at least $\text{LOCq}(1, ja+n-1)$ when $\text{side} = 'R'$ or ' r '.

Before entry with $\text{uplo} = 'U'$ or ' u ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.

Before entry with $\text{uplo} = 'L'$ or ' l ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced .

When $\text{diag} = 'U'$ or ' u ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

descA

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

b

(local)REAL for pstrsm
 DOUBLE PRECISION for pdtrsm
 COMPLEX for pctrsm
 DOUBLE COMPLEX for pztrsm
 Array, size $(lld_b, \text{LOCq}(1, jb+n-1))$.

Before entry, this array contains the local pieces of the distributed matrix $\text{sub}(B)$.

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.

descB

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix B .

Output Parameters

b

Overwritten by the solution distributed matrix X .

Partial Differential Equations Support

12

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Solver (see [Fast Poisson Solver Routines](#)).

Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the Intel MKL Poisson Solver. As it may be hard enough to modify the original code so as to make it work with Poisson Solver, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Solver routines can be called from C and Fortran.

NOTE

Intel MKL Trigonometric Transform and Poisson Solver routines support Fortran versions starting with Fortran 90.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter "[Fast Fourier Transforms](#)", Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to [Calling PDE Support Routines from Fortran](#).

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in [Appendix F](#) for details). However, you are strongly

encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} [f(0) + f(n) \cos k\pi] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} [F(0) + F(n) \cos i\pi] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

NOTE

The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "TT Interface Routines"](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

TT Interface Routines

Routine	Description
?_init_trig_transform	Initializes basic data structures of Trigonometric Transforms.

Routine	Description
?_commit_trig_transform	Checks consistency and correctness of user-defined data and creates a data structure to be used by Intel MKL FFT interface ¹ .
?_forward_trig_transform	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
?_backward_trig_transform	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
free_trig_transform	Releases the memory used by a data structure needed for calling FFT interface ¹ .

¹TT routines call Intel MKL FFT interface for better performance.

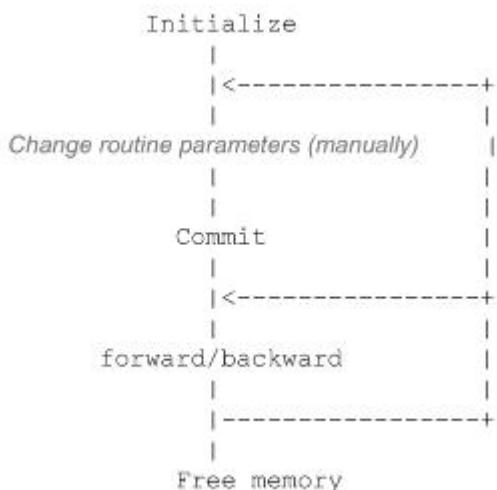

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table "TT Interface Routines"](#).

NOTE

Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking TT Interface Routines"](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f. If you want to preserve the data stored in f,
save it to another location before the function call below */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
  
```

You can find examples of Fortran and C code that uses TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdettf\source` and `examples\pdettc\source` folders in your Intel MKL directory.

Interface Description

All types in this documentation are either standard C types `float` and `double` or `MKL_INT` integer type. Fortran users can call the routines with `REAL` and `DOUBLE PRECISION` types of floating-point values and `INTEGER` or `INTEGER*8` integer type depending on the programming interface (LP64 or ILP64). For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the *Intel(R) MKL User's Guide*. To better understand usage of the types, see examples in the `examples\pdettf\source` and `examples\pdettc\source` folders in your Intel MKL directory.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE

If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *User's Guide* (search the document for coding techniques to improve performance).

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], double dpar[],  
MKL_INT *stat);  
  
void s_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], float spar[],  
MKL_INT *stat);
```

Include Files

- Fortran 90: mkl_trig_transforms.f90
- C: mkl.h

Input Parameters

<i>n</i>	MKL_INT*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size n .
<i>tt_type</i>	MKL_INT*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> . The status should be 0 to proceed to other TT routines.

Description

The `?_init_trig_transform` routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. You can skip a call to the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task.

`?_commit_trig_transform`

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- Fortran 90: mkl_trig_transforms.f90
- C: mkl.h

Input Parameters

<i>f</i>	double for <code>d_commit_trig_transform</code> , float for <code>s_commit_trig_transform</code> , array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:
	<ul style="list-style-type: none"> $f[0]$ and $f[n]$ for sine transforms $f[n]$ for staggered cosine transforms $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see Fast Poisson Solver Routines).</p>
<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, $ipar[6]$ is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

`stat` MKL_INT*. Contains the routine completion status, which is also written to `ipar[6]`.

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: `handle`, `dpar` in case of `d_commit_trig_transform`, and `spar` in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of `dpar` or `spar` that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the `ipar` array. The size of the problem `n`, which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, you must call the `?_commit_trig_transform` routine in your code.

Return Values

`stat= 11`

The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning `ipar[6]=0` if you are sure that the parameters are correct.

`stat= 10`

The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning `ipar[6]=0` if you are sure that the parameters are correct.

`stat= 1`

The routine produced some warnings. You may proceed with computations by assigning `ipar[6]=0` if you are sure that the parameters are correct.

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

NOTE

Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- Fortran 90: mkl_trig_transforms.f90
- C: mkl.h

Input Parameters

<i>f</i>	double for <i>d_forward_trig_transform</i> , float for <i>s_forward_trig_transform</i> , array of size <i>n</i> for staggered2 transforms and of size <i>n</i> +1 for all other transforms, where <i>n</i> is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:
	<ul style="list-style-type: none"> • <i>f</i>[0] and <i>f</i>[<i>n</i>] for sine transforms • <i>f</i>[<i>n</i>] for staggered cosine transforms • <i>f</i>[0] for staggered sine transforms.
	Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see Fast Poisson Solver Routines).
<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, see FFT Functions).
<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE

If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -100	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> • An error in the user's data was encountered. • Data in <i>ipar</i>, <i>dpar</i> or <i>spar</i> parameters became incorrect and/or inconsistent as a result of modifications.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -10000	The routine stopped because its commit step failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);

void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- Fortran 90: `mkl_trig_transforms.f90`
- C: `mkl.h`

Input Parameters

<code>f</code>	<pre>double for d_backward_trig_transform,</pre> <pre>float for s_backward_trig_transform,</pre> <p>array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> $f[0]$ and $f[n]$ for sine transforms $f[n]$ for staggered cosine transforms $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see Fast Poisson Solver Routines).</p>
<code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, see FFT Functions).
<code>ipar</code>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<code>dpar</code>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<code>spar</code>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<code>f</code>	Contains the transformed vector on output.
<code>ipar</code>	Contains integer data needed for Trigonometric Transform computations. On output, <code>ipar[6]</code> is updated with the <code>stat</code> value.
<code>stat</code>	MKL_INT*. Contains the routine completion status, which is also written to <code>ipar[6]</code> .

Description

The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the `ipar` array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in `dpar` or `spar`. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine

has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector f with the transformed vector.

NOTE

If you need a copy of the data vector f to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

<code>stat= 0</code>	The routine completed the task normally.
<code>stat= -100</code>	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> • An error in the user's data was encountered. • Data in <code>ipar</code>, <code>dpar</code> or <code>spar</code> parameters became incorrect and/or inconsistent as a result of modifications.
<code>stat= -1000</code>	The routine stopped because of an FFT interface error.
<code>stat= -10000</code>	The routine stopped because its commit step failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], MKL_INT *stat);
```

Include Files

- Fortran 90: `mkl_trig_transforms.f90`
- C: `mkl.h`

Input Parameters

<code>ipar</code>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").

Output Parameters

<code>handle</code>	The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.
---------------------	---

<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The `free_trig_transform` routine cleans the memory used by the `handle` structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE

Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

<i>ipar</i>	MKL_INT array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in Table "Elements of the ipar Array" :
-------------	---

Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <i>ipar[0]=n</i> , and all subsequently called TT routines use <i>ipar[0]</i> as the size of the transform.
1	Contains error messaging options: <ul style="list-style-type: none"> • <i>ipar[1]=-1</i> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[1]=0</i> indicates that no error messages will be printed. • <i>ipar[1]=1</i> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). In case of errors, each TT routine assigns a non-zero value to <i>stat</i> regardless of the <i>ipar[1]</i> setting.
2	Contains warning messaging options:

Index	Description
	<ul style="list-style-type: none"> • <i>ipar[2]</i>=-1 indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]</i>=0 indicates that no warning messages will be printed. • <i>ipar[2]</i>=1 (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen).
	<p>In case of warnings, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[2]</i> setting.</p>
3 through 4	<p>Reserved for future use.</p>
5	<p>Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <i>ipar[5]</i>=<i>tt_type</i>, and all subsequently called TT routines use <i>ipar[5]</i> as the type of the transform.</p>
6	<p>Contains the <i>stat</i> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <i>stat</i>=0.</p>
7	<p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <i>dpar</i> (<i>spar</i>) and <i>handle</i>. <i>ipar[7]</i>=0 indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p>
	<p>The possibility to check correctness and consistency of input data without initializing data structures <i>dpar</i>, <i>spar</i> and <i>handle</i> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <i>ipar[7]</i> gives only if you are sure to have supplied proper tolerance value in the <i>dpar</i> or <i>spar</i> array. Otherwise, avoid tuning this parameter.</p>
8	<p>Contains message style options for TT routines. If <i>ipar[8]</i>=0 then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1.</p>
	<p>When specifying message style options, be aware that by default, numbering of elements in C arrays starts at 0, while in Fortran arrays, it starts at 1. For example, for a C-style message "parameter <i>ipar[0]</i>=3 should be an even integer", the corresponding Fortran-style message will be "parameter <i>ipar(1)</i>=3 should be an even integer". The use of <i>ipar[8]</i> enables you to view messages in a more convenient style.</p>
9	<p>Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Intel MKL Poisson Solver. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications.</p>
10	<p>Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix F. See also Caveat on Parameter Modifications.</p>
11 through 127	<p>Reserved for future use.</p>

NOTE

While you can declare the `ipar` array as `MKL_INT ipar[11]`, for future compatibility you should declare `ipar` as `MKL_INT ipar[128]`.

Arrays `dpar` and `spar` are the same except in the data precision:

<code>dpar</code>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the <code>d_init_trig_transform</code> and <code>d_commit_trig_transform</code> routines.
<code>spar</code>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the <code>s_init_trig_transform</code> and <code>s_commit_trig_transform</code> routines.

As `dpar` and `spar` have similar elements in respective positions, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

Elements of the dpar and spar Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate <code>?_commit_trig_transform</code> routine. For a staggered cosine or a sine transform, <code>f[n]</code> should be equal to 0.0 and for a staggered sine or a sine transform, <code>f[0]</code> should be equal to 0.0. The <code>?_commit_trig_transform</code> routine checks whether absolute values of these parameters are below <code>dpar[0]*n</code> or <code>spar[0]*n</code> , depending on the routine precision. To suppress warnings resulting from tolerance checks, set <code>dpar[0]</code> or <code>spar[0]</code> to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <code>tt_type</code> , set up in the <code>?_commit_trig_transform</code> routine: <ul style="list-style-type: none"> If <code>tt_type=MKL_SINE_TRANSFORM</code>, the transform uses only the first $n/2$ array elements, which contain tabulated sine values. If <code>tt_type=MKL_STAGGERED_SINE_TRANSFORM</code>, the transform uses only the first $3n/2$ array elements, which contain tabulated sine and cosine values. If <code>tt_type=MKL_STAGGERED2_SINE_TRANSFORM</code>, the transform uses all the $5n/2$ array elements, which contain tabulated sine and cosine values. If <code>tt_type=MKL_COSINE_TRANSFORM</code>, the transform uses only the first n array elements, which contain tabulated cosine values. If <code>tt_type=MKL_STAGGERED_COSINE_TRANSFORM</code>, the transform uses only the first $3n/2$ elements, which contain tabulated sine and cosine values. If <code>tt_type=MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the $5n/2$ elements, which contain tabulated sine and cosine values.

NOTE

To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip a call to the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of `ipar`, `dpar` and `spar` arrays after initialization. When doing so, provide correct and consistent data in the arrays.

Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE

To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the `ipar`, `spar` and `dpar` arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING

The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of `ipar`, `dpar` and `spar` arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, Intel MKL provides you with the TT language-specific header files to include in your code:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran programs.

NOTE

- Intel MKL TT interface supports Fortran versions starting with Fortran 90.
 - Use of the Intel MKL TT software without including the above language-specific header files is not supported.
-

C-specific Header File

The C-specific header file below defines the following function prototypes:

```
void d_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, double *, MKL_INT *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);

void s_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, float *, MKL_INT *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, MKL_INT *);
```

Fortran-Specific Header File

The Fortran-Specific header file below defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
  INTEGER, INTENT(IN) :: n, tt_type
  INTEGER, INTENT(INOUT) :: ipar(*)
```

```

REAL(8), INTENT(INOUT) :: dpar(*)
INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_INIT_TRIG_TRANSFORM

END SUBROUTINE S_BACKWARD_TRIG_TRANSFORM

SUBROUTINE FREE_TRIG_TRANSFORM(handle, ipar, stat)

```

```

INTEGER, INTENT(INOUT) :: ipar(*)
TYPE(DFTI_DESCRIPTOR), POINTER :: handle
INTEGER, INTENT(OUT) :: stat
END SUBROUTINE FREE_TRIG_TRANSFORM

```

Fortran specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran](#) section.

Fast Poisson Solver Routines

In addition to the Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel MKL supports the the Poisson Solver interface. This interface implements a group of routines (Poisson Solver routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of a special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems that are solved by the Poisson Solver interface are defined more exactly in the [Poisson Solver Implementation](#) subsection. The Poisson Solver interface provides much flexibility of use: you can call routines with the default parameter values or adjust routines to your particular needs by manually tuning routine parameters. You can adjust the style of error and warning messages to a C or Fortran notation by setting up a dedicated parameter. This adds convenience to debugging, because you can read information in the way that is natural for your code. The Intel MKL Poisson Solver interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel MKL Poisson Solver interface, the C convention is used. Fortran usage specifics can be found in the [Calling PDE Support Routines from Fortran](#) section.

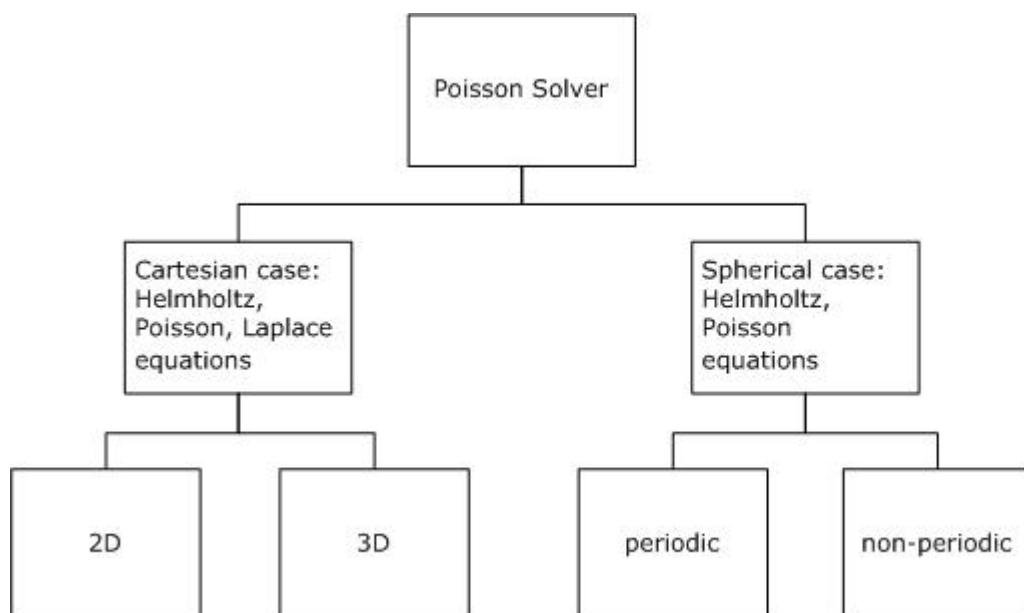

NOTE

Fortran users should keep in mind that array indices in Fortran start at 1 instead of 0, as they do in C.

Poisson Solver Implementation

Poisson Solver routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure "Structure of the Poisson Solver"](#) shows the general structure of the Poisson Solver.

Structure of the Poisson Solver

NOTE

Although in the Cartesian case, both periodic and non-periodic solvers are also supported, they use the same interfaces.

Sections below provide details of the problems that can be solved using Intel MKL Poisson Solver.

Two-Dimensional Problems

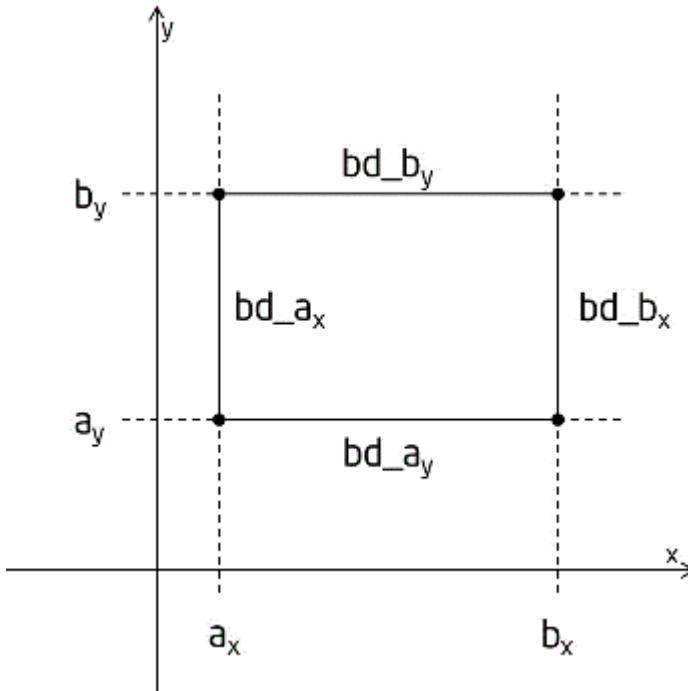

Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x, a_y < y < b_y$ on a Cartesian plane:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y , so bd_+ denotes any of the above boundaries.

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_\phi < \phi < b_\phi, a_\theta < \theta < b_\theta$ on a sphere $0 \leq \phi \leq 2\pi, 0 \leq \theta \leq \pi$:

$$bd_a_\phi = \{\phi = a_\phi, a_\theta \leq \theta \leq b_\theta\}, bd_b_\phi = \{\phi = b_\phi, a_\theta \leq \theta \leq b_\theta\}$$

$$bd_a_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = a_\theta\}, bd_b_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols $a_\phi, b_\phi, a_\theta, b_\theta$, so $bd_~$ denotes any of the above boundaries.

Two-dimensional Helmholtz problem on a Cartesian plane

The two-dimensional (2D) Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), q = \text{const} \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x, a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$n = -x$ on bd_a_x , $n = x$ on bd_b_x ,

$n = -y$ on bd_a_y , $n = y$ on bd_b_y .

- Periodic boundary conditions

$$u(a_x, y) = u(b_x, y), \frac{\partial}{\partial x} u(a_x, y) = \frac{\partial}{\partial x} u(b_x, y),$$

$$u(x, a_y) = u(x, b_y), \frac{\partial}{\partial y} u(x, a_y) = \frac{\partial}{\partial y} u(x, b_y)$$

Two-dimensional Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_{-+} .

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = const \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a domain bounded by angles $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$ (spherical rectangle), with boundary conditions for particular domains listed in [Table "Details of Helmholtz Problem on a Sphere"](#).

Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary bd_{-+}	non-periodic
Where $a_\phi = 0, b_\phi = 2\pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_{-a_θ} and bd_{-b_θ}	periodic
Entire sphere, that is, $a_\phi = 0, b_\phi = 2\pi, a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\theta \rightarrow 0}^{0 \rightarrow \pi} = 0$	periodic

at the poles.

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table "Details of Helmholtz Problem on a Sphere"](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, in the rectangular domain a uniform mesh can be defined for the Cartesian case as:

$$\begin{aligned} & \left\{ x_i = a_x + i h_x, y_j = a_y + j h_y \right\}, \\ & i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y} \end{aligned}$$

and for the spherical case as:

$$\begin{aligned} & \left\{ \varphi_i = a_\varphi + i h_\varphi, \theta_j = a_\theta + j h_\theta \right\}, \\ & i = 0, \dots, n_\varphi, j = 0, \dots, n_\theta, h_\varphi = \frac{b_\varphi - a_\varphi}{n_\varphi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta} \end{aligned}$$

The Poisson Solver uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that you can supply the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (φ_i, θ_j) provided that you can supply the values of the right-hand side $f(\varphi, \theta)$ in these points.

NOTE

The number of mesh intervals n_φ in the φ direction of a spherical mesh must be even in the periodic case. The Poisson Solver does not support spherical meshes that do not meet this condition.

Three-Dimensional Problems

Notational Conventions

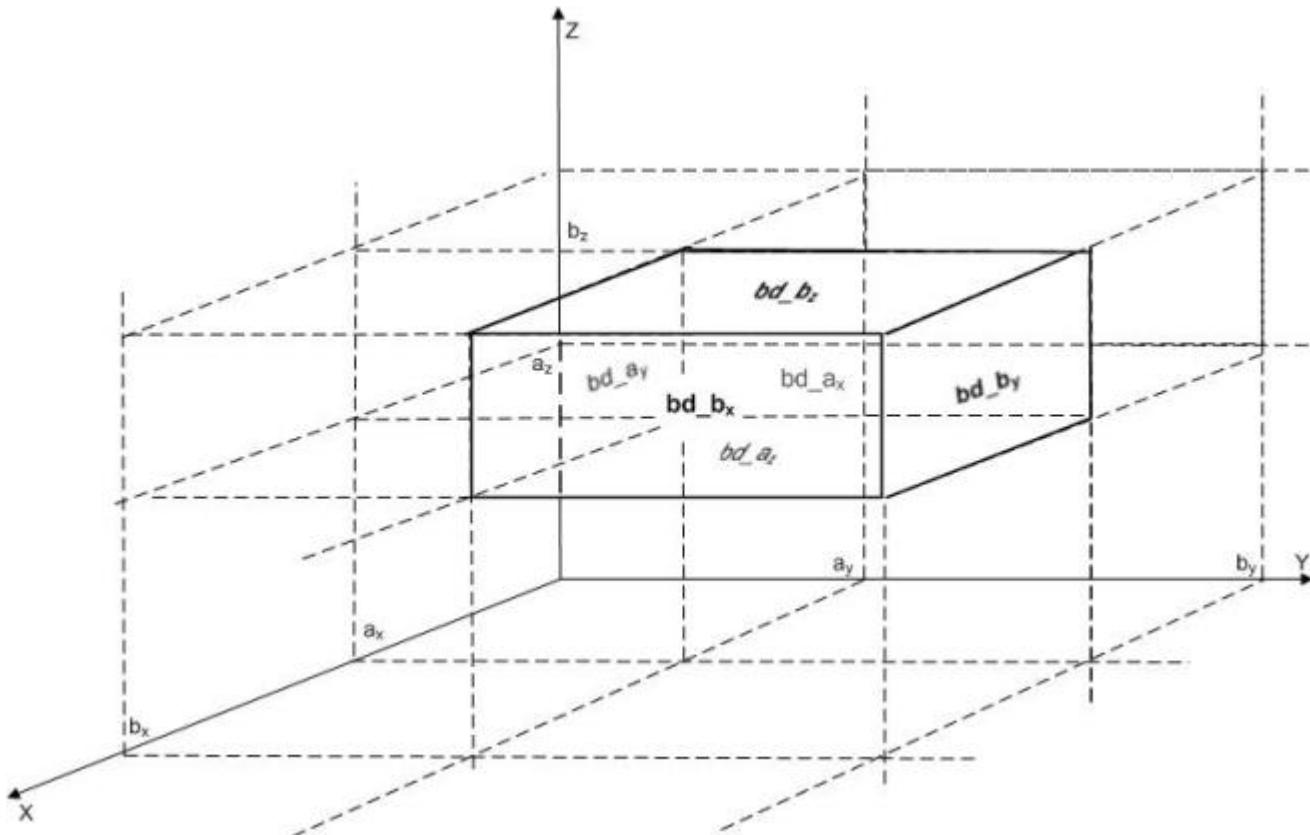

The Poisson Solver interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, \quad bd_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, \quad bd_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\}$$

$$bd_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, \quad bd_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd_a_x, n = x \text{ on } bd_b_x,$$

$n = -y$ on bd_a_y , $n = y$ on bd_b_y ,

$n = -z$ on bd_a_z , $n = z$ on bd_b_z .

- Periodic boundary conditions

$$u(a_x, y, z) = u(b_x, y, z), \frac{\partial}{\partial x} u(a_x, y, z) = \frac{\partial}{\partial x} u(b_x, y, z),$$

$$u(x, a_y, z) = u(x, b_y, z), \frac{\partial}{\partial y} u(x, a_y, z) = \frac{\partial}{\partial y} u(x, b_y, z),$$

$$u(x, y, a_z) = u(x, y, b_z), \frac{\partial}{\partial z} u(x, y, a_z) = \frac{\partial}{\partial z} u(x, y, b_z)$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_+ .

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_+ .

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh can be defined in the parallelepiped domain as:

$$\{x_i = a_x + i h_x, y_j = a_y + j h_y, z_k = a_z + k h_z\}$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Solver uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that you can supply the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking Poisson Solver Routines

NOTE

This description always shows the solution process for the Helmholtz problem, because Fast Poisson Solvers and Fast Laplace Solvers are special cases of Fast Helmholtz Solvers (see [Poisson Solver Implementation](#)).

The Poisson Solver interface enables you to compute a solution of the Helmholtz problem in four steps. Each step is performed by a dedicated routine. [Table "Poisson Solver Interface Routines"](#) lists the routines and briefly describes their purpose.

Most Poisson Solver routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "`s`" and "`d`". The wildcard "?" stands for either of these symbols in routine names. The routines for the Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "`2D`" and "`3D`". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "`p`" and "`np`".

Poisson Solver Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/</code> <code>?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/</code> <code>?_commit_sph_p/?_commit_sph_np</code>	Checks consistency and correctness of input data and initializes data structures for the solver, including those used by the Intel MKL FFT interface ¹ .
<code>?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np</code>	Computes an approximate solution of the 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Solver Implementation) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/</code> <code>free_sph_p/free_sph_np</code>	Releases the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ Poisson Solver routines call the Intel MKL FFT interface for better performance.

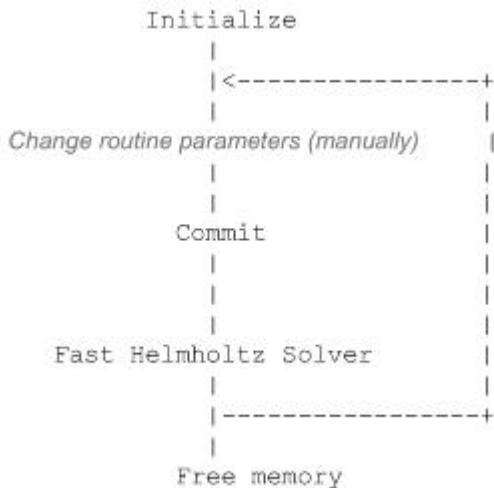

To find an approximate solution of Helmholtz problem only once, the Intel MKL Poisson Solver interface routines are normally invoked in the order in which they are listed in [Table "Poisson Solver Interface Routines"](#).

NOTE

Though the order of invoking Poisson Solver routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking Poisson Solver Routines"](#) indicates the typical order in which Poisson Solver routines can be invoked in a general case.

[Typical Order of Invoking Poisson Solver Routines](#)

A general scheme of using Poisson Solver routines for double-precision computations in a 3D Cartesian case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below from the 3D to 2D case by changing the ending of the Poisson Solver routine names.

```

...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar, &stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...

```

A general scheme of using Poisson Solver routines for double-precision computations in a spherical periodic case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below to a scheme for a non-periodic case by changing the ending of the Poisson Solver routine names from "p" to "np".

```

...
d_init_sph_p(&ap,&bp,&at,&bt,&np,&nt,&q,ipar,dpar,&stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
d_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
free_sph_p(&handle_s,&handle_c,ipar,&stat);
/* here you may clean the memory used by f, dpar, ipar */
...

```

You can find examples of Fortran and C code that uses Poisson Solver routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonf\source` and `examples\pdepoissons\source` folders in your Intel MKL directory.

Interface Description

All numerical types in this section are either standard C types `float` and `double` or `MKL_INT` integer type. Fortran users can call the routines with `REAL` and `DOUBLE PRECISION` types of floating-point values and either `INTEGER` or `INTEGER*8` integer type depending on the programming interface (LP64 or ILP64). For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the [Intel\(R\) MKL User's Guide](#). To better understand usage of the types, see examples in the `examples\pdepoissonf\source` and `examples\pdepoissons\source` folders in your Intel MKL directory.

Routine Options

All Poisson Solver routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar`, and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs. For more details, see the descriptions of specific routines.

WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

Poisson Solver routines take arrays of user data as input. For example, the `d_Helmholtz_3D` routine takes user arrays to compute an approximate solution to the 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL Poisson Solver routines do not make copies of user input arrays.

NOTE

If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *User's Guide* (search the document for coding techniques to improve performance).

Routines for the Cartesian Solver

The section describes Poisson Solver routines for the Cartesian case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and 2D and 3D.

NOTE

Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

Poisson Solver routines call Intel MKL FFT routines (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhance performance of the Poisson Solver routines.

[?_init_Helmholtz_2D/?_init_Helmholtz_3D](#)

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```

void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by, MKL_INT* nx,
                           MKL_INT* ny, char* BCtype, double* q, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, MKL_INT* nx,
                           MKL_INT* ny, char* BCtype, float* q, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by, double* az,
                           double* bz, MKL_INT* nx, MKL_INT* ny, MKL_INT* nz, char* BCtype, double* q, MKL_INT* ipar,
                           double* dpar, MKL_INT* stat);
void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float* az, float* bz,
                           MKL_INT* nx, MKL_INT* ny, MKL_INT* nz, char* BCtype, float* q, MKL_INT* ipar,
                           float* spar, MKL_INT* stat);

```

Include Files

- Fortran 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

ax double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
 The coordinate of the leftmost boundary of the domain along the x-axis.

bx double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
 The coordinate of the rightmost boundary of the domain along the x-axis.

ay double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
 The coordinate of the leftmost boundary of the domain along the y-axis.

by double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
 The coordinate of the rightmost boundary of the domain along the y-axis.

az double* for d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_3D.
 The coordinate of the leftmost boundary of the domain along the z-axis.
 This parameter is needed only for the ?_init_Helmholtz_3D routine.

bz double* for d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_3D.
 The coordinate of the rightmost boundary of the domain along the z-axis.
 This parameter is needed only for the ?_init_Helmholtz_3D routine.

nx MKL_INT*. The number of mesh intervals along the x-axis.

ny MKL_INT*. The number of mesh intervals along the y-axis.

<i>nz</i>	MKL_INT*. The number of mesh intervals along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCtype</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition), 'D' (Dirichlet boundary condition), or 'P' (periodic boundary conditions). Specify the types of boundary conditions for the boundaries in the following order: <i>bd_ax</i> , <i>bd_bx</i> , <i>bd_ay</i> , <i>bd_by</i> , <i>bd_az</i> , and <i>bd_bz</i> . Specify periodic boundary conditions on the respective boundaries in pairs (for example, 'PPDD' or 'NNPP' in the 2D case). The types of boundary conditions for the last two boundaries are needed only in the 3D case.
<i>q</i>	<pre>double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D .</pre> <p>The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of <i>q</i> to 0.</p>

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to ipar).
<i>dpar</i>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The ?_init_Helmholtz_2D/?_init_Helmholtz_3D routines initialize basic data structures for Poisson Solver computations of the appropriate precision. All routines invoked after a call to a ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

CAUTION

Data structures initialized and created by 2D flavors of the routine cannot be used by 3D flavors of any Poisson Solver routines, and vice versa.

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

Return Values

<code>stat= 0</code>	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

[_commit_Helmholtz_2D/?_commit_Helmholtz_3D](#)

Checks consistency and correctness of input data and initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_commit_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, float* spar, MKL_INT* stat);

void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- Fortran 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>f</code>	<code>double*</code> for <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> , <code>float*</code> for <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> . Contains the right-hand side of the problem packed in a single vector:
	<ul style="list-style-type: none"> • 2D problem: The size of the vector for the is $(nx+1)*(ny+1)$. The value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$. • 3D problem: The size of the vector for the is $(nx+1)*(ny+1)*(nz+1)$. The value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.
	Note that to solve the Laplace problem, you should set all the elements of the array <code>f</code> to 0.
	Note also that the array <code>f</code> may be altered by the routine. To preserve the <code>f</code> vector, save it to another memory location.

<code>ipar</code>	<code>MKL_INT</code> array of size 128. Contains integer data to be used by the Fast Helmholtz Solver (for details, refer to ipar).
-------------------	--

<i>dpar</i>	double array of size depending on the dimension of the problem:
	<ul style="list-style-type: none"> • 2D problem: $5*nx/2+7$ • 3D problem: $5*(nx+ny)/2+9$
	Contains double-precision data to be used by the Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>spar</i>	float array of size depending on the dimension of the problem:
	<ul style="list-style-type: none"> • 2D problem: $5*nx/2+7$ • 3D problem: $5*(nx+ny)/2+9$
	Contains single-precision data to be used by the Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>bd_ax</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
	Contains values of the boundary condition on the leftmost boundary of the domain along the <i>x</i> -axis (for more information, refer to a detailed description of bd_ax).
<i>bd_bx</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
	Contains values of the boundary condition on the rightmost boundary of the domain along the <i>x</i> -axis (for more information, refer to a detailed description of bd_bx).
<i>bd_ay</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
	Contains values of the boundary condition on the leftmost boundary of the domain along the <i>y</i> -axis (for more information, refer to a detailed description of bd_ay).
<i>bd_by</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
	Contains values of the boundary condition on the rightmost boundary of the domain along the <i>y</i> -axis (for more information, refer to a detailed description of bd_by).
<i>bd_az</i>	double* for d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_3D.
	Used only by ?_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the <i>z</i> -axis (for more information, refer to a detailed description of bd_az).
<i>bd_bz</i>	double* for d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_3D.

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of `bd_bz`](#)).

Output Parameters

<code>f</code>	Contains right-hand side of the problem, possibly altered on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in ipar .
<code>dpar</code>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in dpar and spar .
<code>spar</code>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in dpar and spar .
<code>xhandle, yhandle</code>	<code>DFTI_DESCRIPTOR_HANDLE*</code> . Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <code>yhandle</code> is used only by <code>?_commit_Helmholtz_3D</code> .
<code>stat</code>	<code>MKL_INT*</code> . Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines check the consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize the `xhandle` and `yhandle` data structures, `ipar` array, and `dpar` or `spar` array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#).

Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, you must call

the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines in your code. Values of `ax, bx, ay, by, az,` and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx, ny, nz`, and `BCType` are passed with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the input data was found, or the data in the <code>dpar, spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of the 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- Fortran 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

`f`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine, at this point results in an incorrect solution.

- 2D problem: the size of the vector is $(nx+1)*(ny+1)$. The value of the modified right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$.
- 3D problem: the size of the vector is $(nx+1)*(ny+1)*(nz+1)$. The value of the modified right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.

`xhandle, yhandle`

`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). `yhandle` is used only by `?_Helmholtz_3D`.

`ipar`

`MKL_INT` array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to `ipar`).

`dpar`

`double` array of size depending on the dimension of the problem:

- 2D problem: $5*nx/2+7$

- 3D problem: $5*(nx+ny)/2+9$

Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to [dpar](#) and [spar](#)).

spar

float array of size depending on the dimension of the problem:

- 2D problem: $5*nx/2+7$
- 3D problem: $5*(nx+ny)/2+9$

Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to [dpar](#) and [spar](#)).

bd_ax

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis (for more information, refer to [a detailed description of bd_ax](#)).

bd_bx

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis (for more information, refer to [a detailed description of bd_bx](#)).

bd_ay

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the leftmost boundary of the domain along the y-axis for more information, refer to [a detailed description of bd_ay](#)).

bd_by

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the rightmost boundary of the domain along the y-axis (for more information, refer to [a detailed description of bd_by](#)).

bd_az

double* for d_Helmholtz_3D,
float* for s_Helmholtz_3D.

Used only by ?_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of bd_az](#)).

bd_bz

double* for d_Helmholtz_3D,
float* for s_Helmholtz_3D.

Used only by ?_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of bd_bz](#)).

NOTE

To avoid incorrect computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle</code> , <code>yhandle</code>	Data structures used by the Intel MKL FFT interface. Although the addresses do not change, the structures are modified on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in <code>ipar</code> .
<code>stat</code>	<code>MKL_INT*</code> . Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_Helmholtz_2D/?_Helmholtz_3D` routines compute the approximate solution of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Solver Implementation](#) section. The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `ax`, `bx`, `ay`, `by`, `az`, and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx`, `ny`, `nz`, and `BCtype` are passed with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with some warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the sufficient memory was unavailable for the computations.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, MKL_INT* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- Fortran 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

<i>xhandle</i> , <i>yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structure <i>yhandle</i> is used only by free_Helmholtz_3D.
<i>ipar</i>	MKL_INT array of size 128. Contains integer data used by Fast Helmholtz Solver (for details, refer to <i>ipar</i>).

Output Parameters

<i>xhandle</i> , <i>yhandle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data used by Fast Helmholtz Solver. On output, the status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The free_Helmholtz_2D-free_Helmholtz_3D routine releases the memory used by the *xhandle* and *yhandle* structures, which are needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

Routines for the Spherical Solver

The section describes Poisson Solver routines for the spherical case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and periodic (having names ending in "p") and non-periodic (having names ending in "np").

These Poisson Solver routines also call the Intel MKL FFT routines (described in section "FFT Functions" in chapter "Fast Fourier Transforms"), which enhance the performance of the Poisson Solver routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the periodic and non-periodic Fast Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, MKL_INT* np, MKL_INT* nt, double* q, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_init_sph_p(float* ap, float* at, float* bp, float* bt, MKL_INT* np, MKL_INT* nt, float* q, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_init_sph_np(double* ap, double* at, double* bp, double* bt, MKL_INT* np, MKL_INT* nt, double* q, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_init_sph_np(float* ap, float* at, float* bp, float* bt, MKL_INT* np, MKL_INT* nt, float* q, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- Fortran 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

<i>ap</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np.
	The coordinate (angle) of the leftmost boundary of the domain along the ϕ -axis.
<i>bp</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np.
	The coordinate (angle) of the rightmost boundary of the domain along the ϕ -axis.
<i>at</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np.
	The coordinate (angle) of the leftmost boundary of the domain along the θ -axis.
<i>bt</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np.
	The coordinate (angle) of the rightmost boundary of the domain along the θ -axis.
<i>np</i>	MKL_INT*. The number of mesh intervals along the ϕ -axis. Must be even in the periodic case.
<i>nt</i>	MKL_INT*. The number of mesh intervals along the θ -axis.
<i>q</i>	double* for d_init_sph_p/d_init_sph_np,

```
float* for s_init_sph_p/s_init_sph_np.
```

The constant Helmholtz coefficient. To solve the Poisson problem, set the value of q to 0.

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to ipar).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Solver computations. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar*, and *spar* array parameters returned by the routine. A detailed description of the array parameters can be found in [Common Parameters](#).

CAUTION

Data structures initialized and created by periodic flavors of the routine cannot be used by non-periodic flavors of any Poisson Solver routines for Helmholtz Solver on a sphere, and vice versa.

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

[?_commit_sph_p/?_commit_sph_np](#)

Checks consistency and correctness of input data and initializes certain data structures required to solve the periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE** handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- Fortran 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

<i>f</i>	double* for <code>d_commit_sph_p/d_commit_sph_np</code> , float* for <code>s_commit_sph_p/s_commit_sph_np</code> .
	Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.
	Note that the array <i>f</i> may be altered by the routine. Save this vector to another memory location if you want to preserve it.
<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to ipar).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).

Output Parameters

<i>f</i>	Contains the right-hand side of the problem, possibly altered on output.
<i>ipar</i>	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in ipar .
<i>dpar</i>	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar .
<i>spar</i>	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i> DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .	
<i>stat</i> MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.	

Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures `handle_s` and `handle_c`, and `?_commit_sph_np` initializes `handle`. The routines also initialize the `ipar` array and `dpar` or `spar` array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#).

Unlike `?_init_sph_p/?_init_sph_np`, you must call the `?_commit_sph_p/?_commit_sph_np` routines. Values of `np` and `nt` are passed to each of the routines with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

`?_sph_p/?_sph_np`

Computes the solution of the spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);

void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- Fortran 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<i>f</i>	<pre>double* for d_sph_p/d_sph_np, float* for s_sph_p/s_sph_np.</pre> <p>Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_sph_p/?_commit_sph_np</code> routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the <code>?_commit_sph_p/?_commit_sph_np</code> routine, at this point results in an incorrect solution.</p> <p>The size of the vector is $(np+1)*(nt+1)$ and the value of the modified right-hand side in the mesh point (i, j) is stored in <code>f[i+j*(np+1)]</code>.</p>
<i>handle_s</i> , <i>handle_c</i> , <i>handleDFTI_DESCRIPTOR_HANDLE*</i>	Data structures used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_sph_p</code> and <i>handle</i> is used only in <code>?_sph_np</code> .
<i>ipar</i>	<code>MKL_INT</code> array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <code>ipar</code>).
<i>dpar</i>	<code>double</code> array of size $5*np/2+nt+10$. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <code>dpar</code> and <code>spar</code>).
<i>spar</i>	<code>float</code> array of size $5*np/2+nt+10$. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <code>dpar</code> and <code>spar</code>).

Output Parameters

<i>f</i>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<i>handle_s</i> , <i>handle_c</i> , <i>handleData</i>	Data structures used by the Intel MKL FFT interface.
<i>ipar</i>	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <code>ipar</code> .
<i>dpar</i>	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <code>dpar</code> and <code>spar</code> .
<i>spar</i>	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <code>dpar</code> and <code>spar</code> .
<i>stat</i>	<code>MKL_INT*</code> . Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The `sph_p/sph_np` routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to the formulas given in the [Poisson Solver Implementation](#) section. The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `np` and `nt` are passed to each of the routines with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the memory was insufficient to complete the computations.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
                 MKL_INT* ipar, MKL_INT* stat);

void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- Fortran 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

`handle_s`, `handle_c`, `handle` `DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structures `handle_s` and `handle_c` are used only in `free_sph_p`, and `handle` is used only in `free_sph_np`.

`ipar` `MKL_INT` array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to `ipar`).

Output Parameters

<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. On output, the status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The `free_sph_p/free_sph_np` routine releases the memory used by the `handle_s`, `handle_c` or `handle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

Common Parameters

ipar

<i>ipar</i>	MKL_INT array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table "Elements of the ipar Array" :
-------------	--

NOTE

Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

Elements of the ipar Array

Index	Description
0	Contains status value of the last Poisson Solver routine called. In general, it should be 0 on exit from a routine to proceed with the Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure "Typical Order of Invoking Poisson Solver Routines"). A non-zero value of <i>ipar[0]</i> with decimal representation

$$\overline{abc} = 100a + 10b + c$$

Index	Description
<p>=100a+10b+c, where each of a, b, and c is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.</p>	
<ul style="list-style-type: none"> • If c=9, the routine omits checking of parameters and initialization of the data structures. • If b=9, <ul style="list-style-type: none"> • In the Cartesian case, the routine omits the adjustment of the right-hand side vector f to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function g) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function G). • For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the <i>dpar</i>/<i>spar</i> array. • If a=9, the routine omits the normalization of the right-hand side vector f. Depending on the solver, the normalization means: <ul style="list-style-type: none"> • 2D Cartesian case: multiplication by h_y^2, where h_y is the mesh size in the y direction (for details, see Poisson Solver Implementation). • 3D (Cartesian) case: multiplication by h_z^2, where h_z is the mesh size in the z direction. • Helmholtz solver on a sphere: multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Solver Implementation). 	
<p>Using <i>ipar[0]</i> you can adjust the routine to your needs and improve efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious when using this method, because any misunderstanding of the commit process may cause incorrect results or program failure (see also Caveat on Parameter Modifications).</p>	
1	Contains error messaging options:
<ul style="list-style-type: none"> • <i>ipar[1]</i>=-1 indicates that all error messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device (usually, screen). • <i>ipar[1]</i>=0 indicates that no error messages will be printed. • <i>ipar[1]</i>=1 is the default value. It indicates that all error messages are printed to the standard output device. 	
<p>In case of errors, the <i>stat</i> parameter contains a non-zero value on exit from a routine regardless of the <i>ipar[1]</i> setting.</p>	
2	Contains warning messaging options:
<ul style="list-style-type: none"> • <i>ipar[2]</i>=-1 indicates that all warning messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]</i>=0 indicates that no warning messages will be printed. • <i>ipar[2]</i>=1 is the default value. It indicates that all warning messages are printed to the standard output device. 	
<p>In case of warnings, the <i>stat</i> parameter contains a non-zero value on exit from a routine regardless of the <i>ipar[2]</i> setting.</p>	
3	Unused.
<p>Parameters 4 through 9 are used only in the Cartesian case.</p>	
4	Takes this value:
<ul style="list-style-type: none"> • 2, if <i>BCType[0]</i>='P' • 1, if <i>BCType[0]</i>='N' 	

Index	Description
	<ul style="list-style-type: none"> • 0, if <code>BCType[0] = 'D'</code> • -1, otherwise
5	<p>Takes this value:</p> <ul style="list-style-type: none"> • 2, if <code>BCType[1] = 'P'</code> • 1, if <code>BCType[1] = 'N'</code> • 0, if <code>BCType[1] = 'D'</code> • -1, otherwise
6	<p>Takes this value:</p> <ul style="list-style-type: none"> • 2, if <code>BCType[2] = 'P'</code> • 1, if <code>BCType[2] = 'N'</code> • 0, if <code>BCType[2] = 'D'</code> • -1, otherwise
7	<p>Takes this value:</p> <ul style="list-style-type: none"> • 2, if <code>BCType[3] = 'P'</code> • 1, if <code>BCType[3] = 'N'</code> • 0, if <code>BCType[3] = 'D'</code> • -1, otherwise
8	<p>Takes this value:</p> <ul style="list-style-type: none"> • 2, if <code>BCType[4] = 'P'</code> • 1, if <code>BCType[4] = 'N'</code> • 0, if <code>BCType[4] = 'D'</code> • -1, otherwise
9	<p>Takes this value:</p> <ul style="list-style-type: none"> • 2, if <code>BCType[5] = 'P'</code> • 1, if <code>BCType[5] = 'N'</code> • 0, if <code>BCType[5] = 'D'</code> • -1, otherwise
10	<p>Takes the value of</p> <ul style="list-style-type: none"> • nx, that is, the number of intervals along the x-axis, in the Cartesian case. • np, that is, the number of intervals along the φ-axis, in the spherical case.
11	<p>Takes the value of</p> <ul style="list-style-type: none"> • ny, that is, the number of intervals along the y-axis, in the Cartesian case • nt, that is, the number of intervals along the θ-axis, in the spherical case.
12	<p>Takes the value of nz, the number of intervals along the z-axis. This parameter is used only in the 3D case (Cartesian).</p>
13	<p>Has the value of 6, which specifies the internal partitioning of the <code>dpar/spar</code> array.</p>
14	<p>Takes the value of $ipar[13]+ipar[10]+1$, which specifies the internal partitioning of the <code>dpar/spar</code> array.</p>

Index		Description		Cartesian Solver	
				2D case	3D case
15	Unused				Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.
16	Unused				Takes the value of $ipar[14]+ipar[11]+1$, which specifies the internal partitioning of the $dpar/spar$ array.
17	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.				Takes the value of $ipar[16]+1$, which specifies the internal partitioning of the $dpar/spar$ array.
18	Takes the value of $ipar[14]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.		Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+3*ipar[10]/4+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.
19	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the $dpar/spar$ array.			Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Unused
20	Takes the value of $ipar[19]+3*ipar[12]/4$, which specifies the internal partitioning of the $dpar/spar$ array.		Takes the value of $ipar[18]+3*ipar[11]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[18]+3*ipar[10]/4+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Unused
21	Contains message style options:				
		<ul style="list-style-type: none"> • $ipar[21]=0$ indicates that Poisson Solver routines print all error and warning messages in Fortran-style notations. • $ipar[21]=1$ (default) indicates that Poisson Solver routines print the messages in C-style notations. 			
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1 in the serial mode, and the result returned by the <code>mkl_get_max_threads</code> function otherwise.				
23	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the $dpar/spar$ array in the periodic Cartesian case.				
24	Takes the value of $ipar[23]+3*ipar[12]/4$, which specifies the internal partitioning of the $dpar/spar$ array in the periodic Cartesian case.				

Index	Description
25	Takes the value of <code>ipar[20]+1</code> , which specifies the internal partitioning of the <code>dpar/spar</code> array in the periodic 3D Cartesian case.
26	Takes the value of <code>ipar[25]+3*ipar[13]/4</code> , which specifies the internal partitioning of the <code>dpar/spar</code> array in the periodic 3D Cartesian case.
27 through 39	Unused.
40 through 59	Contain the first twenty elements of the <code>ipar</code> array of the first Trigonometric Transform that the solver uses. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
60 through 79	Contain the first twenty elements of the <code>ipar</code> array of the second Trigonometric Transform that the 3D Cartesian and periodic spherical solvers use. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
80 through 99	Contain the first twenty elements of the <code>ipar</code> array of the third Trigonometric Transform that the solver uses in case of periodic boundary conditions along the <code>x</code> -axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
100 through 119	Contain the first twenty elements of the <code>ipar</code> array of the fourth Trigonometric Transform used by periodic spherical solvers and 3D Cartesian solvers with periodic boundary conditions along the <code>y</code> -axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)

NOTE

While you can declare the `ipar` array as `MKL_INT ipar[120]`, for future compatibility you should declare `ipar` as `MKL_INT ipar[128]`.

dpar and spar

Arrays `dpar` and `spar` are the same except in the data precision:

<code>dpar</code>	Holds data needed for double-precision Fast Helmholtz Solver computations.
	<ul style="list-style-type: none"> For the Cartesian solver, double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case; initialized in the <code>d_init_Helmholtz_2D/d_init_Helmholtz_3D</code> and <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> routines. For the spherical solver, double array of size $5*np/2+nt+10$; initialized in the <code>d_init_sph_p/d_init_sph_np</code> and <code>d_commit_sph_p/d_commit_sph_np</code> routines.
<code>spar</code>	Holds data needed for single-precision Fast Helmholtz Solver computations.
	<ul style="list-style-type: none"> For the Cartesian solver, float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case; initialized in the <code>s_init_Helmholtz_2D/s_init_Helmholtz_3D</code> and <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> routines. For the spherical solver, float array of size $5*np/2+nt+10$; initialized in the <code>s_init_sph_p/s_init_sph_np</code> and <code>s_commit_sph_p/s_commit_sph_np</code> routines.

Because `dpar` and `spar` have similar elements in each position, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

Elements of the dpar and spar Arrays

Index	Description
0	<p>In the Cartesian case, contains the length of the interval along the x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the x direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along the ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
1	<p>In the Cartesian case, contains the length of the interval along the y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along the θ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
2	<p>In the Cartesian case, contains the length of the interval along the z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case.</p> <p>In the spherical solver, contains the coordinate of the leftmost boundary along the θ-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.</p>
3	Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.
4	<p>Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p> <ul style="list-style-type: none"> • In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BCtype="NNNN"</code> in the 2D case; <code>BCtype="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. The Poisson Solver verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, the Poisson Solver computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs you that the solution may not exist in a classical sense (up to rounding errors). • In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the Cartesian case with pure Neumann boundary conditions. Here the Poisson Solver computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. <p>The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.</p>

Index	Description
<i>ipar</i> [13]-1 through <i>ipar</i> [14]-1	In the Cartesian case, contain the spectrum of the one-dimensional (1D) problem along the x -axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.
<i>ipar</i> [15]-1 through <i>ipar</i> [16]-1	In the spherical case, contains the spectrum of the 1D problem along the ϕ -axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<i>ipar</i> [17]-1 through <i>ipar</i> [18]-1	In the Cartesian case, contain the spectrum of the 1D problem along the y -axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case.
<i>ipar</i> [19]-1 through <i>ipar</i> [20]-1	In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<i>ipar</i> [21]-1 through <i>ipar</i> [22]-1	Take the values of the (staggered) sine/cosine in the mesh points:
<ul style="list-style-type: none"> • along the x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver • along the ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver. 	
<i>ipar</i> [23]-1 through <i>ipar</i> [24]-1	Take the values of the (staggered) sine/cosine in the mesh points:
<ul style="list-style-type: none"> • along the y-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver • along the ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. 	
<i>ipar</i> [25]-1 through <i>ipar</i> [26]-1	These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.
<i>ipar</i> [27]-1 through <i>ipar</i> [28]-1	Take the values of the (staggered) sine/cosine in the mesh points along the x -axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic Cartesian case.
<i>ipar</i> [29]-1 through <i>ipar</i> [30]-1	Take the values of the (staggered) sine/cosine in the mesh points along the x -axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic 3D Cartesian case.

NOTE

You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the Poisson Solver interface enables you to skip calls to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of the *ipar*, *dpar*, and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or incorrect results. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE

To supply correct and consistent parameters to Poisson Solver routines, you should have considerable experience in using the Poisson Solver interface and good understanding of the solution process, as well as elements contained in the *ipar*, *spar*, and *dpar* arrays and dependencies between values of these elements.

In rare occurrences when you fail in tuning parameters for the Fast Helmholtz Solver, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING

The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar*, and *spar* arrays unless it is necessary.

Parameters That Define Boundary Conditions

Poisson Solver routines for the Cartesian solver use the following common parameters to define the boundary conditions.

Parameters to Define Boundary Conditions for the Cartesian Solver

Parameter	Description
<i>bd_ax</i>	<p>double* for <i>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_2D/d_Helmholtz_3D</i>,</p> <p>float* for <i>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_2D/s_Helmholtz_3D</i>.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the <i>x</i>-axis.</p> <ul style="list-style-type: none"> 2D problem: the size of the array is <i>ny</i>+1. Its contents depend on the boundary conditions as follows: <ul style="list-style-type: none"> Dirichlet boundary condition (value of <i>BCtype</i>[0] is 'D'): values of the function $G(ax, y_j), j=0, \dots, ny$. Neumann boundary condition (value of <i>BCtype</i>[0] is 'N'): values of the function $g(ax, y_j), j=0, \dots, ny$. The value corresponding to the index <i>j</i> is placed in <i>bd_ax[j]</i>. 3D problem: the size of the array is $(ny+1)*(nz+1)$. Its contents depend on the boundary conditions as follows: <ul style="list-style-type: none"> Dirichlet boundary condition (value of <i>BCtype</i>[0] is 'D'): values of the function $G(ax, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz$. Neumann boundary condition (value of <i>BCtype</i>[0] is 'N'): the values of the function $g(ax, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <i>bd_ax[j+k*(ny+1)]</i>. <p>For periodic boundary conditions (the value of <i>BCtype</i>[0] is 'P'), this parameter is not used, so it can accept a dummy pointer.</p>
<i>bd_bx</i>	<p>double* for <i>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_2D/d_Helmholtz_3D</i>,</p> <p>float* for <i>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_2D/s_Helmholtz_3D</i>.</p>

Implementation Details

Several aspects of the Intel MKL Poisson Solver interface are platform-specific and language-specific. To promote portability of the Intel MKL Poisson Solver interface across platforms and ease of use across different languages, Intel MKL provides you with the Poisson Solver language-specific header files to include in your code:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`, for Fortran programs.

NOTE

- Intel MKL Poisson Solver interface supports Fortran versions starting with Fortran 90.
- Use of the Intel MKL Poisson Solver software without including the above language-specific header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, MKL_INT*, MKL_INT*, char*, double*, MKL_INT*, double*, MKL_INT*);
void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);
void d_Helmholtz_2D(double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);
void s_init_Helmholtz_2D(float*, float*, float*, float*, MKL_INT*, MKL_INT*, char*, float*, MKL_INT*, float*, MKL_INT*);
void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);
void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);

void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, MKL_INT*);

void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, MKL_INT*, MKL_INT*, MKL_INT*, char*, double*, MKL_INT*, double*, MKL_INT*);
void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);
void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);

void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, MKL_INT*, MKL_INT*, MKL_INT*, char*, float*, MKL_INT*, float*, MKL_INT*);
void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);
```

```
void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*,  
DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);  
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, MKL_INT*);
```

The C-specific header file defines the following function prototypes for the spherical solver:

```
void d_init_sph_p(double*, double*, double*, double*, MKL_INT*, MKL_INT*, double*, MKL_INT*,  
MKL_INT*);  
void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*,  
MKL_INT*);  
void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);  
void s_init_sph_p(float*, float*, float*, float*, MKL_INT*, MKL_INT*, float*, MKL_INT*, float*,  
MKL_INT*);  
void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*,  
MKL_INT*);  
void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);  
void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, MKL_INT*);  
  
void d_init_sph_np(double*, double*, double*, double*, MKL_INT*, MKL_INT*, double*, MKL_INT*,  
MKL_INT*);  
void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);  
void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, double*, MKL_INT*);  
void s_init_sph_np(float*, float*, float*, float*, MKL_INT*, MKL_INT*, float*, MKL_INT*, float*,  
MKL_INT*);  
void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);  
void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, float*, MKL_INT*);  
void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, MKL_INT*, MKL_INT*);
```

Fortran specifics of the Poisson Solver routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran](#) section.

Calling PDE Support Routines from Fortran

The calling interface for all the Intel MKL TT and Poisson Solver routines is designed to be easily used in C. However, you can invoke each TT or Poisson Solver routine directly from Fortran 90 or higher if you are familiar with the inter-language calling conventions of your platform.

The TT or Poisson Solver interface cannot be invoked from FORTRAN 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran, and how C external names are decorated on the platform.

To promote portability and relieve you of dealing with the calling conventions specifics, the Fortran header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for Poisson Solver routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length n . C users access such a function as follows:

```
MKL_INT n;
double *x;
...
foo(x, &n);
```

As noted above, to invoke `foo`, Fortran users would need to know what Fortran data types correspond to C types `MKL_INT` and `double` (or `float` for single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran program will look as follows for the LP64 interface (for the ILP64 interface, `INTEGER*8` type will be used instead of `INTEGER*4`):

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER*4 n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

- For Poisson Solver interface,

```
use mkl_dfti
use mkl_poisson
INTEGER*4 n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of Poisson Solver or TT routines in Fortran, the general approach of providing Fortran definitions of names is used throughout the libraries. Specifically, if a name from a Poisson Solver or TT interface is documented as having the C-specific name `foo`, then the Fortran header files provide an appropriate Fortran language type definition `FOO`.

One of the key differences between Fortran and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran programs use pass-by-reference semantics. The Fortran headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Nonlinear Optimization Problem Solvers

13

Intel® Math Kernel Library (Intel® MKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The solver routines are grouped according to their purpose as follows:

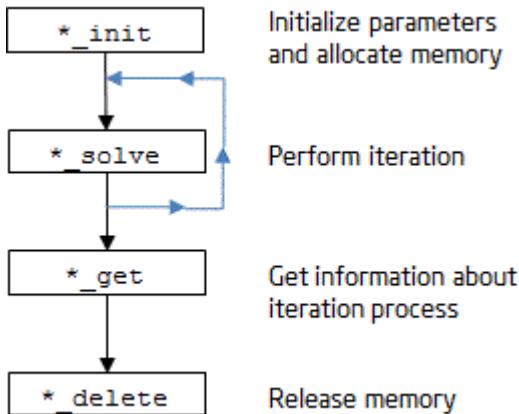

- Nonlinear Least Squares Problem without Constraints
- Nonlinear Least Squares Problem with Linear (Boundary) Constraints
- Jacobian Matrix Calculation Routines

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [Conn00].

Organization and Implementation

The Intel MKL solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

Typical order for invoking RCI solver routines

The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with the OpenMP* support. You can manage the threads using [threading control functions](#). The TR solvers use BLAS and LAPACK routines, and offer the same parallelism as those domains. The ?jacobi and ?jacobix routines of Jacobi matrix calculations are parallel. These routines (?jacobi and ?jacobix) make calls to the user-supplied functions with different x parameters for multiple threads.

Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each TR solver routine creates, uses, or deletes a handle. To declare a handle, include `mkl_rci.h` or `mkl_rci.fi`.

For a C and C++ program, declare a handle as one of the following:

```
#include "mkl_rci.h"
_TRNSP_HANDLE_t handle;
```

or

```
_TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

For a Fortran program using compilers that support eight byte integers, declare a handle as:

```
INCLUDE "mkl_rci.fi"
INTEGER*8 handle
```

Routine Naming Conventions

The TR routine names have the following structure:

```
<character><name>_<action>( )
```

where

- *<character>* indicates the data type:

s	real, single precision
d	real, double precision

- *<name>* indicates the task type:

trnlsp	nonlinear least squares problem without constraints
trnlspbc	nonlinear least squares problem with boundary constraints
jacobi	computation of the Jacobian matrix using central differences

- *<action>* indicates an action on the task:

init	initializes the solver
check	checks correctness of the input parameters
solve	solves the problem
get	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
delete	releases the allocated data

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m \geq n,$$

where

$F(x) : R^n \rightarrow R^m$ is a twice differentiable function in R^n .

Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See usage examples in Fortran and C in the `examples\solverf\source` and `examples\solverc\source` folders of your Intel MKL directory, respectively. Specifically, see `ex_nlsqp_f.f` and `ex_nlsqp_c.c`.

RCI TR Routines

Routine Name	Operation
?trnlsp_init	Initializes the solver.
?trnlsp_check	Checks correctness of the input parameters.
?trnlsp_solve	Solves a nonlinear least squares problem using the Trust-Region algorithm.
?trnlsp_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
?trnlsp_delete	Releases allocated data.

?trnlsp_init

Initializes the solver of a nonlinear least squares problem.

Syntax

Fortran:

```
res = strnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
MKL_INT strnlsp_init (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, float* x,
float* &eps, MKL_INT* &iter1, MKL_INT* &iter2, float* &rs);
MKL_INT dtrnlsp_init (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, double* x,
double* &eps, MKL_INT* &iter1, MKL_INT* &iter2, double* &rs);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The `?trnlsp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsp_solve` routine should use the values of the handle returned by `?trnlsp_init`.

The `eps` array contains the stopping criteria:

eps Value	Description
1	$\Delta < \text{eps}(1)$
2	$\ F(x)\ _2 < \text{eps}(2)$

eps Value	Description
3	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)} \ _2 < \text{eps}(3), j = 1, \dots, n$
4	$\ s \ _2 < \text{eps}(4)$
5	$\ F(x) \ _2 - \ F(x) - \mathcal{J}(x)s \ _2 < \text{eps}(5)$
6	The trial step precision. If $\text{eps}(6) = 0$, then the trial step meets the required precision ($\leq 1.0D-10$).

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of x .
<i>m</i>	INTEGER. Length of $F(x)$.
<i>x</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Array of size <i>n</i> . Initial guess.
<i>eps</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Array of size 6; contains stopping criteria. See the values in the Description section.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Definition of initial size of the trust region (boundary of the trial step). The recommend minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <i>rs</i> to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

<i>handle</i>	Type _TRNSP_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
<i>res</i>	INTEGER. Indicates task completion status.

- `res = TR_SUCCESS` - the routine completed the task normally.
- `res = TR_INVALID_OPTION` - there was an error in the input parameters.
- `res = TR_OUT_OF_MEMORY` - there was a memory error.

`TR_SUCCESS`, `TR_INVALID_OPTION`, and `TR_OUT_OF_MEMORY` are defined in the `mkl_rci.fi` (Fortran) and `mkl_rci.h` (C) include files.

See Also

[?trnlsp_solve](#)

?trnlsp_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

Syntax

Fortran:

```
res = strnlsp_check(handle, n, m, fjac, fvec, eps, info)
res = dtrnlsp_check(handle, n, m, fjac, fvec, eps, info)
```

C:

```
MKL_INT strnlsp_check (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, float* fjac,
float* fvec, float* eps, MKL_INT* info);

MKL_INT dtrnlsp_check (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, double* fjac,
double* fvec, double* eps, MKL_INT* info);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The `?trnlsp_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `Nan` values, the routine sets the flag in output array `info` (see the description of the values returned in the Output Parameters section for the `info` array).

Input Parameters

<code>handle</code>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<code>n</code>	<code>INTEGER</code> . Length of x .
<code>m</code>	<code>INTEGER</code> . Length of $F(x)$.
<code>fjac</code>	<code>REAL</code> for <code>strnlsp_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlsp_check</code> Array of size m by n . Contains the Jacobian matrix of the function.
<code>fvec</code>	<code>REAL</code> for <code>strnlsp_check</code>

DOUBLE PRECISION for `dtrnlsp_check`
 Array of size m . Contains the function values at x , where $fvec(i) = (y_i - f_i(x))$.

`eps` REAL for `strnlsp_check`

DOUBLE PRECISION for `dtrnlsp_check`

Array of size 6; contains stopping criteria. See the values in the Description section of the [?trnlsp_init](#).

Output Parameters

`info` INTEGER

Array of size 6.

Results of input parameter checking:

Parameter	Used for	Value	Description
<code>FORTRAN: info(1)</code> <code>C: info[0]</code>	Flags for handle	0 1	The handle is valid. The handle is not allocated.
<code>FORTRAN: info(2)</code> <code>C: info[1]</code>	Flags for <i>fjac</i>	0 1 2 3	The <i>fjac</i> array is valid. The <i>fjac</i> array is not allocated The <i>fjac</i> array contains NaN. The <i>fjac</i> array contains Inf.
<code>FORTRAN: info(3)</code> <code>C: info[2]</code>	Flags for <i>fvec</i>	0 1 2 3	The <i>fvec</i> array is valid. The <i>fvec</i> array is not allocated The <i>fvec</i> array contains NaN. The <i>fvec</i> array contains Inf.
<code>FORTRAN: info(4)</code> <code>C: info[3]</code>	Flags for <i>eps</i>	0 1 2 3 4	The <i>eps</i> array is valid. The <i>eps</i> array is not allocated The <i>eps</i> array contains NaN. The <i>eps</i> array contains Inf. The <i>eps</i> array contains a value less than or equal to zero.

`res` INTEGER. Information about completion of the task.

`res = TR_SUCCESS` - the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlsp_solve

Solves a nonlinear least squares problem using the TR algorithm.

Syntax

Fortran:

```
res = strnlsp_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
MKL_INT strnlsp_solve (_TRNSP_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT* &RCI_Request);
MKL_INT dtrnlsp_solve (_TRNSP_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT* &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?trnlsp_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

- $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$
- $m \geq n$

From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \|F(x_{current}) + J(x_{current})(x_{new} - x_{current})\|_2^2 \quad \text{subject to } \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{s \in \mathbb{R}^n} \|J^T(x)J(x)s + J^T F(x)\|_2^2$$

where

- $J(x)$ is the Jacobian matrix
- s is the trial step

- $\|s\|_2 \leq \Delta_{current}$

The *RCI_Request* parameter provides additional information:

<i>RCI_Request</i> Value	Description
2	Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1	Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0	One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < \text{eps}(1)$
-3	$\ F(x)\ _2 < \text{eps}(2)$
-4	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m, j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
-5	$\ s\ _2 < \text{eps}(4)$
-6	$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	REAL for <code>strnlsp_solve</code> DOUBLE PRECISION for <code>dtrnlsp_solve</code> Array of size <i>m</i> . Contains the function values at <i>x</i> , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	REAL for <code>strnlsp_solve</code> DOUBLE PRECISION for <code>dtrnlsp_solve</code> Array of size (m, n) . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	REAL for <code>strnlsp_solve</code> DOUBLE PRECISION for <code>dtrnlsp_solve</code> Array of size <i>m</i> . Updated function evaluated at <i>x</i> .
<i>RCI_Request</i>	INTEGER. Informs about the task stage. See the Description section for the parameter values and their meaning.

res INTEGER. Indicates the task completion.
res = TR_SUCCESS - the routine completed the task normally.
 TR_SUCCESS is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = strnlsp_get(handle, iter, st_cr, r1, r2)
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
MKL_INT strnlsp_get(_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, float* &r1, float* &r2);
MKL_INT dtrnlsp_get (_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, double* &r1, double* &r2);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional $(\|y - f(x)\|)$ of the initial x values provided by the user.

The final residual is the value of the functional $(\|y - f(x)\|)$ of the final x resulting from the algorithm operation.

The *st_cr* parameter contains the stop criterion:

st_cr Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < \text{eps}(1)$
3	$\ F(x)\ _2 < \text{eps}(2)$
4	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
5	$\ s\ _2 < \text{eps}(4)$
6	$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

iter `INTEGER`. Contains the current number of iterations.

st_cr `INTEGER`. Contains the stop criterion.

See the Description section for the parameter values and their meanings.

r1 `REAL` for `strnlsp_get`

`DOUBLE PRECISION` for `dtrnlsp_get`

Contains the residual, $(| | y - f(x) | |)$ given the initial x .

r2 `REAL` for `strnlsp_get`

`DOUBLE PRECISION` for `dtrnlsp_get`

Contains the final residual, that is, the value of the functional $(| | y - f(x) | |)$ of the final x resulting from the algorithm operation.

res `INTEGER`. Indicates the task completion.

`res = TR_SUCCESS` - the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlsp_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlsp_delete(handle)
res = dtrnlsp_delete(handle)
```

C:

```
MKL_INT strnlsp_delete(_TRNSP_HANDLE_t* &handle);
MKL_INT dtrnlsp_delete(_TRNSP_HANDLE_t* &handle);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The `?trnlsp_delete` routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function `mkl_free_buffers`.

Input Parameters

`handle` Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

`res` `INTEGER`. Indicates the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

See usage examples in Fortran and C in the `examples\solverf\source` and `examples\solverc\source` folders of your Intel MKL directory, respectively. Specifically, see `ex_nlsqp_bc_f.f` and `ex_nlsqp_bc_c.c`.

RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>?trnlspbc_init</code>	Initializes the solver.
<code>?trnlspbc_check</code>	Checks correctness of the input parameters.
<code>?trnlspbc_solve</code>	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
<code>?trnlspbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>?trnlspbc_delete</code>	Releases allocated data.

`?trnlspbc_init`

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = strnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
res = dtrnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```

MKL_INT strnlspbc_init (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, float* x,
float* LW, float* UP, float* eps, MKL_INT* &iter1, MKL_INT* &iter2, float* &rs);

MKL_INT dtrnlspbc_init (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, double* x,
double* LW, double* UP, double* eps, MKL_INT* &iter1, MKL_INT* &iter2, double* &rs);

```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?trnlspbc_init routine initializes the solver.

After initialization all subsequent invocations of the ?trnlspbc_solve routine should use the values of the handle returned by ?trnlspbc_init.

The *eps* array contains the stopping criteria:

<i>eps</i> Value	Description
1	$\Delta < \text{eps}(1)$
2	$\ F(x) \ _2 < \text{eps}(2)$
3	The Jacobian matrix is singular. $\ J(x)_{(1:m, j)} \ _2 < \text{eps}(3), j = 1, \dots, n$
4	$\ s \ _2 < \text{eps}(4)$
5	$\ F(x) \ _2 - \ F(x) - J(x)s \ _2 < \text{eps}(5)$
6	The trial step precision. If $\text{eps}(6) = 0$, then the trial step meets the required precision ($\leq 1.0D-10$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of $F(x)$.
<i>x</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Array of size <i>n</i> . Initial guess.
<i>LW</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init

	Array of size n .
	Contains low bounds for x ($lw_i < x_i$).
<i>UP</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init
	Array of size n .
	Contains upper bounds for x ($up_i > x_i$).
<i>eps</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init
	Array of size 6; contains stopping criteria. See the values in the Description section.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Definition of initial size of the trust region (boundary of the trial step). The recommended minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <i>rs</i> to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

<i>handle</i>	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
<i>res</i>	INTEGER. Informs about the task completion. <ul style="list-style-type: none"> • <i>res</i> = TR_SUCCESS - the routine completed the task normally. • <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters. • <i>res</i> = TR_OUT_OF_MEMORY - there was a memory error. TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

?trnlspbc_check

Checks the correctness of *handle* and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.

Syntax

Fortran:

```
res = strnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
res = dtrnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
```

C:

```
MKL_INT strnlspbc_check (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, float* fjac, float* fvec, float* LW, float* UP, float* eps, MKL_INT* info);

MKL_INT dtrnlspbc_check (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, double* fjac, double* fvec, double* LW, double* UP, double* eps, MKL_INT* info);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The `?trnlspbc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NAN` values, the routine sets the flag in output array `info` (see the description of the values returned in the Output Parameters section for the `info` array).

Input Parameters

<code>handle</code>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<code>n</code>	INTEGER. Length of x .
<code>m</code>	INTEGER. Length of $F(x)$.
<code>fjac</code>	REAL for <code>strnlspbc_check</code> DOUBLE PRECISION for <code>dtrnlspbc_check</code> Array of size m by n . Contains the Jacobian matrix of the function.
<code>fvec</code>	REAL for <code>strnlspbc_check</code> DOUBLE PRECISION for <code>dtrnlspbc_check</code> Array of size m . Contains the function values at x , where $fvec(i) = (y_i - f_i(x))$.
<code>LW</code>	REAL for <code>strnlspbc_check</code> DOUBLE PRECISION for <code>dtrnlspbc_check</code> Array of size n . Contains low bounds for x ($lw_i < x_i$).
<code>UP</code>	REAL for <code>strnlspbc_check</code> DOUBLE PRECISION for <code>dtrnlspbc_check</code> Array of size n . Contains upper bounds for x ($up_i > x_i$).
<code>eps</code>	REAL for <code>strnlspbc_check</code> DOUBLE PRECISION for <code>dtrnlspbc_check</code> Array of size 6; contains stopping criteria. See the values in the Description section of the <code>?trnlspbc_init</code> .

Output Parameters

info

INTEGER

Array of size 6.

Results of input parameter checking:

Parameter	Used for	Value	Description
FORTTRAN: <i>info</i> (1) C: <i>info</i> [0]	Flags for handle	0 1	The handle is valid. The handle is not allocated.
FORTTRAN: <i>info</i> (2) C: <i>info</i> [1]	Flags for <i>fjac</i>	0 1 2 3	The <i>fjac</i> array is valid. The <i>fjac</i> array is not allocated The <i>fjac</i> array contains NaN. The <i>fjac</i> array contains Inf.
FORTTRAN: <i>info</i> (3) C: <i>info</i> [2]	Flags for <i>fvec</i>	0 1 2 3	The <i>fvec</i> array is valid. The <i>fvec</i> array is not allocated The <i>fvec</i> array contains NaN. The <i>fvec</i> array contains Inf.
FORTTRAN: <i>info</i> (4) C: <i>info</i> [3]	Flags for <i>LW</i>	0 1 2 3 4	The <i>LW</i> array is valid. The <i>LW</i> array is not allocated The <i>LW</i> array contains NaN. The <i>LW</i> array contains Inf. The lower bound is greater than the upper bound.
FORTTRAN: <i>info</i> (5) C: <i>info</i> [4]	Flags for <i>up</i>	0 1 2 3 4	The <i>up</i> array is valid. The <i>up</i> array is not allocated The <i>up</i> array contains NaN. The <i>up</i> array contains Inf. The upper bound is less than the lower bound.
FORTTRAN: <i>info</i> (6) C: <i>info</i> [5]	Flags for <i>eps</i>	0 1 2 3	The <i>eps</i> array is valid. The <i>eps</i> array is not allocated The <i>eps</i> array contains NaN. The <i>eps</i> array contains Inf.

Parameter	Used for	Value	Description
		4	The <i>eps</i> array contains a value less than or equal to zero.

res

INTEGER. Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.TR_SUCCESS is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = strnlspbc_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
MKL_INT strnlspbc_solve (_TRNSPBC_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT* &RCI_Request);
MKL_INT dtrnlspbc_solve (_TRNSPBC_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT* &RCI_Request);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The ?trnlspbc_solve routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n$$

where

$$l_i \leq x_i \leq u_i$$

$$i = 1, \dots, n.$$

The *RCI_Request* parameter provides additional information:

RCI_Request Value	Description
2	Request to calculate the Jacobian matrix and put the result into <i>fjac</i>

RCI_Request Value	Description
1	Request to recalculate the function at vector x and put the result into $fvec$
0	One successful iteration step on the current trust-region radius (that does not mean that the value of x has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < \text{eps}(1)$
-3	$\ F(x)\ _2 < \text{eps}(2)$
-4	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
-5	$\ s\ _2 < \text{eps}(4)$
-6	$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m . Contains the function values at x , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m by n . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m . Updated function evaluated at x .
<i>RCI_Request</i>	<code>INTEGER</code> . Informs about the task stage. See the Description section for the parameter values and their meaning.
<i>res</i>	<code>INTEGER</code> . Informs about the task completion. $res = \text{TR_SUCCESS}$ means the routine completed the task normally. <code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> and <code>mkl_rci.fi</code> include files.

?trnlspbc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax**Fortran:**

```
res = strnlspbc_get(handle, iter, st_cr, r1, r2)
res = dtrnlspbc_get(handle, iter, st_cr, r1, r2)
```

C:

```
MKL_INT strnlspbc_get (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr,
float* &r1, float* &r2);

MKL_INT dtrnlspbc_get (_TRNSPBC_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr,
double* &r1, double* &r2);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The *st_cr* parameter contains the stop criterion:

st_cr Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < \text{eps}(1)$
3	$\ F(x)\ _2 < \text{eps}(2)$
4	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
5	$\ s\ _2 < \text{eps}(4)$
6	$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

<i>iter</i>	INTEGER. Contains the current number of iterations.
<i>st_cr</i>	INTEGER. Contains the stop criterion. See the Description section for the parameter values and their meanings.
<i>r1</i>	
	REAL for strnlspbc_get DOUBLE PRECISION for dtrnlspbc_get Contains the residual, $(y - f(x))$ given the initial x .
<i>r2</i>	REAL for strnlspbc_get DOUBLE PRECISION for dtrnlspbc_get Contains the final residual, that is, the value of the function $(y - f(x))$ of the final x resulting from the algorithm operation.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = TR_SUCCESS - the routine completed the task normally. TR_SUCCESS is defined in the <code>mkl_rci.h</code> and <code>mkl_rci.fi</code> include files.

?trnlspbc_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlspbc_delete(handle)
res = dtrnlspbc_delete(handle)
```

C:

```
MKL_INT strnlspbc_delete (_TRNSPBC_HANDLE_t* &handle);
MKL_INT dtrnlspbc_delete (_TRNSPBC_HANDLE_t* &handle);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`
- C: `mkl_rci.h`

Description

The ?trnlspbc_delete routine releases all memory allocated for the handle.

NOTE

This routine flags memory as not used, but to actually release all memory you must call the support function `mkl_free_buffers`.

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res INTEGER. Informs about the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

Jacobian Matrix Calculation Routines

Routine Name	Operation
?jacobi_init	Initializes the solver.
?jacobi_solve	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
?jacobi_delete	Removes data.
?jacobi	Computes the Jacobian matrix of the <code>fcn</code> function using the central difference algorithm.
?jacobix	Presents an alternative interface for the ?jacobi function enabling you to pass additional data into the objective function.

?jacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = sjacobi_init(handle, n, m, x, fjac, eps)
res = djacobi_init(handle, n, m, x, fjac, eps)
```

C:

```
MKL_INT sjacobi_init (_JACOBIMATRIX_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, float* x, float* fjac, float* &eps);
MKL_INT djacobi_init (_JACOBIMATRIX_HANDLE_t* &handle, MKL_INT* &n, MKL_INT* &m, double* x, double* fjac, double* &eps);
```

Include Files

- Fortran: `mkl_rci.fi`
- Fortran 90: `mkl_rci.f90`

- C: mkl_rci.h

Description

The routine initializes the solver.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Precision of the Jacobian matrix calculation.
<i>fjac</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size (<i>m,n</i>). Contains the Jacobian matrix of the function.

Output Parameters

<i>handle</i>	Data object of the _JACOBIMATRIX_HANDLE_t type in C/C++ and INTEGER*8 in FORTRAN.
<i>res</i>	INTEGER. Indicates task completion status. <ul style="list-style-type: none"> • <i>res</i> = TR_SUCCESS - the routine completed the task normally. • <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters. • <i>res</i> = TR_OUT_OF_MEMORY - there was a memory error. TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

?jacobi_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

Syntax

Fortran:

```
res = sjacobi_solve(handle, f1, f2, RCI_Request)
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
MKL_INT sjacobi_solve (_JACOBIMATRIX_HANDLE_t* &handle, float* f1, float* f2, MKL_INT*
&RCI_Request);
```

```
MKL_INT djacobi_solve (_JACOBIMATRIX_HANDLE_t* &handle, double* f1, double* f2,
MKL_INT* &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?jacobi_solve routine computes the Jacobian matrix of the function using RCI and the central difference algorithm.

See usage examples in Fortran and C in the examples\solverf\source and examples\solverc\source folders of your Intel MKL directory, respectively. Specifically, see sjacobi_rci_f.f and djacobi_rci_f.f for Fortran and sjacobi_rci_c.c and djacobi_rci_c.c for C.

Input Parameters

handle Type _JACOBIMATRIX_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

<i>f1</i>	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Contains the updated function values at $x + \text{eps}$.
<i>f2</i>	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Array of size m . Contains the updated function values at $x - \text{eps}$.
<i>RCI_Request</i>	INTEGER. Informs about the task completion. When equal to 0, the task has completed successfully. $RCI_Request = 1$ indicates that you should compute the function values at the current x point and put the results into <i>f1</i> . $RCI_Request = 2$ indicates that you should compute the function values at the current x point and put the results into <i>f2</i> .
<i>res</i>	INTEGER. Indicates the task completion status. <ul style="list-style-type: none"> • <i>res</i> = TR_SUCCESS - the routine completed the task normally. • <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters. TR_SUCCESS and TR_INVALID_OPTION are defined in the mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?jacobi_init

?jacobi_delete

Releases allocated data.

Syntax

Fortran:

```
res = sjacobi_delete(handle)
res = djacobi_delete(handle)
```

C:

```
MKL_INT sjacobi_delete (_JACOBIMATRIX_HANDLE_t* &handle);
MKL_INT djacobi_delete (_JACOBIMATRIX_HANDLE_t* &handle);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?jacobi_delete routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl_free_buffers](#).

Input Parameters

handle Type _JACOBIMATRIX_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

res INTEGER. Informs about the task completion.

res = TR_SUCCESS means the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?jacobi

Computes the Jacobian matrix of the objective function using the central difference algorithm.

Syntax

Fortran:

```
res = sjacobi(fcn, n, m, fjac, x, eps)
res = djacobi(fcn, n, m, fjac, x, eps)
```

C:

```
MKL_INT sjacobi (USRFCNS fcn, MKL_INT* &n, MKL_INT* &m, float* fjac, float* x, float* &eps);
MKL_INT djacobi (USRFCND fcn, MKL_INT* &n, MKL_INT* &m, double* fjac, double* x, double* &eps);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?jacobi routine computes the Jacobian matrix for function *fcn* using the central difference algorithm. This routine has a "Black-Box" interface, where you input the objective function via parameters. Your objective function must have a fixed interface.

See calling and usage examples in FORTRAN and C in the examples\solverf\source and examples\solverc\source folders of your Intel MKL directory, respectively. Specifically, see ex_nlsqp_f.f and ex_nlsqp_bc_f.f for Fortran and ex_nlsqp_c.c and ex_nlsqp_bc_c.c for C.

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>	INTEGER	Length of <i>f</i>
<i>n</i>	INTEGER	Length of <i>x</i>
<i>x</i>	REAL for sjacobi DOUBLE PRECISION for djacobi	Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
Output Parameters		
<i>f</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>m</i> ; contains the function values at <i>x</i> .

You need to declare *fcn* as EXTERNAL in the calling program.

<i>n</i>	INTEGER. Length of <i>X</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobi DOUBLE PRECISION for djacobi Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	REAL for sjacobi DOUBLE PRECISION for djacobi Precision of the Jacobian matrix calculation.

Output Parameters

fjac REAL for sjacobi
 DOUBLE PRECISION for djacobi
 Array of size (*m,n*). Contains the Jacobian matrix of the function.

res INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?jacobix

?jacobix

Alternative interface for ?jacobi function for passing additional data into the objective function.

Syntax

Fortran:

```
res = sjacobix(fcn, n, m, fjac, x, eps, user_data)
res = djacobix(fcn, n, m, fjac, x, eps, user_data)
```

C:

```
MKL_INT sjacobix (USRFCNXS fcn, MKL_INT* &n, MKL_INT * &m, float* fjac, float* x,
float* &eps, void* user_data);

MKL_INT djacobix (USRFCNXD fcn, MKL_INT* &n, MKL_INT * &m, double* fjac, double* x,
double* &eps, void* user_data);
```

Include Files

- Fortran: mkl_rci.fi
- Fortran 90: mkl_rci.f90
- C: mkl_rci.h

Description

The ?jacobix routine presents an alternative interface for the ?jacobi function that enables you to pass additional data into the objective function *fcn*.

See calling and usage examples in Fortran and C in the examples\solverf\source and examples\solverc\source folders of your Intel MKL directory, respectively. Specifically, see ex_nlsqp_f90_x.f90 and ex_nlsqp_bc_f90_x.f90 for Fortran and ex_nlsqp_c_x.c and ex_nlsqp_bc_c_x.c for C.

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m, n, x, f, user_data*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>	INTEGER	Length of <i>f</i>
<i>n</i>	INTEGER	Length of <i>x</i>
<i>x</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
<i>user_data</i>	INTEGER(C_INTPTR_T) , for Fortran void*, for C	(Fortran) Reference to your additional data, if any, passed by value: <i>user_data</i> =%VAL(LOC(<i>data</i>)). Otherwise, a dummy argument. (C) Pointer to your additional data, if any. Otherwise, a dummy argument.
Output Parameters		
<i>f</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>m</i> ; contains the function values at <i>x</i> .

You need to declare *fcn* as EXTERNAL in the calling program.

<i>n</i>	INTEGER. Length of <i>X</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobix DOUBLE PRECISION for djacobix Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	REAL for sjacobix DOUBLE PRECISION for djacobix Precision of the Jacobian matrix calculation.
<i>user_data</i>	(Fortran) INTEGER(C_INTPTR_T). Reference to your additional data, passed by value: <i>user_data</i> =%VAL(LOC(<i>data</i>)). Otherwise, a dummy argument. (C) void*. Pointer to your additional data. If there is no additional data, this is a dummy argument.

Output Parameters

<i>fjac</i>	REAL for sjacobix DOUBLE PRECISION for djacobix Array of size (<i>m,n</i>). Contains the Jacobian matrix of the function.
<i>res</i>	INTEGER. Indicates task completion status.

- `res = TR_SUCCESS` - the routine completed the task normally.
- `res = TR_INVALID_OPTION` - there was an error in the input parameters.
- `res = TR_OUT_OF_MEMORY` - there was a memory error.

`TR_SUCCESS`, `TR_INVALID_OPTION`, and `TR_OUT_OF_MEMORY` are defined in the `mkl_rci.fi` (Fortran) and `mkl_rci.h` (C) include files.

Support Functions

Intel® Math Kernel Library (Intel® MKL) support functions are subdivided into the following groups according to their purpose:

[Version Information](#)

[Threading Control](#)

[Error Handling](#)

[Character Equality Testing](#)

[Timing](#)

[Memory Management](#)

[Single Dynamic Library Control](#)

[Intel® Many Integrated Core \(Intel® MIC\) Architecture Support](#)

[Conditional Numerical Reproducibility Control](#)

[Miscellaneous](#)

The following table lists Intel MKL support functions.

Intel MKL Support Functions

Function Name	Operation
Version Information	
<code>mkl_get_version</code>	A C function that returns the Intel MKL version.
<code>mkl_get_version_string</code>	Returns the Intel MKL version in a character string.
Threading Control	
<code>mkl_set_num_threads</code>	Specifies the number of threads to use.
<code>mkl_domain_set_num_threads</code>	Specifies the number of threads for a particular function domain.
<code>mkl_set_num_threads_local</code>	Specifies the number of threads for all Intel MKL functions on the current execution thread.
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of threads.
<code>mkl_get_max_threads</code>	Gets the number of threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Gets the number of threads targeted for parallelism for a particular function domain.
<code>mkl_get_dynamic</code>	Determines whether Intel MKL is enabled to dynamically change the number of threads.
Error Handling	
<code>xerbla</code>	Handles error conditions for the BLAS, LAPACK, VSL, VML routines.
<code>pixerbla</code>	Handles error conditions for the ScaLAPACK routines.

Function Name	Operation
<code>mkl_set_exit_handler</code>	Sets the custom handler of fatal errors.
Character Equality Testing	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing	
<code>second/dsecnd</code>	Returns elapsed time in seconds. Use to estimate real time between two calls to this function.
<code>mkl_get_cpu_clocks</code>	Returns elapsed CPU clocks.
<code>mkl_get_cpu_frequency</code>	Returns CPU frequency value in GHz.
<code>mkl_get_max_cpu_frequency</code>	Returns the maximum CPU frequency value in GHz.
<code>mkl_get_clocks_frequency</code>	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
Memory Management	
<code>mkl_free_buffers</code>	Frees unused memory allocated by the Intel MKL Memory Allocator.
<code>mkl_thread_free_buffers</code>	Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.
<code>mkl_mem_stat</code>	Reports the status of the Intel MKL Memory Allocator.
<code>mkl_peak_mem_usage</code>	Reports the peak memory allocated by the Intel MKL Memory Allocator.
<code>mkl_disable_fast_mm</code>	Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system <code>malloc/free</code> functions.
<code>mkl_malloc</code>	Allocates an aligned memory buffer.
<code>mkl_calloc</code>	Allocates and initializes an aligned memory buffer.
<code>mkl_realloc</code>	Changes the size of memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .
<code>mkl_free</code>	Frees the aligned memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .
Single Dynamic Library (SDL) Control	
<code>mkl_set_interface_layer</code>	Sets the interface layer for Intel MKL at run time.
<code>mkl_set_threading_layer</code>	Sets the threading layer for Intel MKL at run time.
<code>mkl_set_xerbla</code>	Replaces the error handling routine. Use with SDL on Windows* OS.
<code>mkl_set_progress</code>	Replaces the progress information routine. Use with SDL on Windows* OS.
Intel MIC Architecture Support	

Function Name	Operation
<code>mkl_mic_enable</code>	Enables Automatic Offload mode.
<code>mkl_mic_disable</code>	Disables Automatic Offload mode.
<code>mkl_mic_get_device_count</code>	Returns the number of Intel® Xeon Phi™ coprocessors on the system when called on the host CPU.
<code>mkl_mic_set_workdivision</code>	For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.
<code>mkl_mic_get_workdivision</code>	For computations in the Automatic Offload mode, retrieves the fraction of the work for the specified coprocessor or host CPU to do.
<code>mkl_mic_set_max_memory</code>	Sets the maximum amount of coprocessor memory reserved for Automatic Offload computations.
<code>mkl_mic_free_memory</code>	Frees the coprocessor memory reserved for Automatic Offload computations.
<code>mkl_mic_register_memory</code>	Enables/disables the <code>mkl_malloc</code> function running in Automatic Offload mode to register allocated memory.
<code>mkl_mic_set_device_num_threads</code>	Sets the maximum number of threads to use on an Intel Xeon Phi coprocessor for the Automatic Offload computations.
<code>mkl_mic_set_resource_limit</code>	For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.
<code>mkl_mic_get_resource_limit</code>	For computations in the Automatic Offload mode, retrieves the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.
<code>mkl_mic_set_offload_report</code>	Turns on/off reporting of Automatic Offload profiling.
Conditional Numerical Reproducibility (CNR) Control	
<code>mkl_cbwr_set</code>	Configures the CNR mode of Intel MKL.
<code>mkl_cbwr_get</code>	Returns the current CNR settings.
<code>mkl_cbwr_get_auto_branch</code>	Automatically detects the CNR code branch for your platform.
Miscellaneous	
<code>mkl_progress</code>	Tracks computational progress of selective Intel MKL routines.
<code>mkl_enable_instructions</code>	Enables Intel MKL to dispatch a new Intel® architecture on hardware (or simulation) supporting the appropriate instruction set.
<code>mkl_set_env_mode</code>	Sets up the mode that ignores environment settings specific to Intel MKL.
<code>mkl_verbose</code>	Enables or disables Intel MKL Verbose mode.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Using a Fortran Interface Module for Support Functions

To call a support function from your Fortran application, include one of the following statements in your code:

- INCLUDE mkl_service.fi or INCLUDE mkl.fi
- USE mkl_service

The USE statement references the mkl_service.mod interface module corresponding to your architecture and programming interface. The module provides an application programming interface to Intel MKL support entities, such as subroutines and constants. Because Fortran interface modules are compiler-dependent, Intel MKL offers the mkl_service.f90 source file for the module, as well as architecture-specific and interface-specific mkl_service modules precompiled with the Intel® Fortran or Intel® Visual Fortran compiler. These modules are available in the following subdirectories of the Intel MKL include directory:

Architecture, Interface	Subdirectory of the Intel MKL Installation Directory
IA-32	include\ia32
Intel® 64, LP64	include\intel64\lp64
Intel® 64, ILP64	include\intel64\ilp64

To ensure that your application searches the right module, specify the appropriate subdirectory during compilation as an additional directory for the include path (through the /I option on Windows* OS or the -I option on Linux* OS or OS X*).

If you are using a non-Intel Fortran compiler, you need to build the module yourself by compiling the mkl_service.f90 file, available in the Intel MKL include directory.

For more information on compiler-dependent functions and modules, refer to the *Intel MKL User's Guide*.

Version Information

Intel® MKL provides methods for extracting information about the library version number, such as:

- extracting a version string using the mkl_get_version_string function
- using the mkl_get_version function to obtain an MKLVersion structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

mkl_get_version

A C function that returns the Intel MKL version.

Syntax

```
void mkl_get_version( MKLVersion* pVersion );
```

Include Files

- mkl.h

Output Parameters

pVersion Pointer to the MKLVersion structure.

Description

The `mkl_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the *pVersion* address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

MajorVersion	is the major number of the current library version.
MinorVersion	is the minor number of the current library version.
UpdateVersion	is the update number of the current library version.
ProductStatus	is the status of the current library version. Possible variants are "Beta" or "Product".
Build	is the string that contains the build date and the internal build number.
Platform	is the string that contains the current architecture. Possible variants are "IA-32 architecture" or "Intel(R) 64 architecture".
Processor	is the processor optimization. Normally it is targeted for the processor installed on your system and based on the detection of the Intel MKL library that is optimal for the installed processor. In the Conditional Numerical Reproducibility (CNR) mode, the processor optimization matches the selected CNR branch.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_get_version` Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl_service.h"
```

```

int main(void)
{
    MKLVersion Version;

    mkl_get_version(&Version);

    printf("Major version:          %d\n", Version.MajorVersion);
    printf("Minor version:         %d\n", Version.MinorVersion);
    printf("Update version:        %d\n", Version.UpdateVersion);
    printf("Product status:       %s\n", Version.ProductStatus);
    printf("Build:                 %s\n", Version.Build);
    printf("Platform:              %s\n", Version.Platform);
    printf("Processor optimization: %s\n", Version.Processor);
    printf("=====================\n");
    printf("\n");

    return 0;
}

```

Output:

Major Version	11
Minor Version	0
Update Version	2
Product status	Product
Build	20121113
Platform	Intel(R) 64 architecture
Processor optimization	Intel(R) Core(TM) i7 Processor

[mkl_get_version_string](#)

Returns the Intel MKL version in a character string.

Syntax

Fortran:

```
call mkl_get_version_string( buf )
```

C:

```
void mkl_get_version_string (char* buf, int len);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>buf</i>	FORTRAN: CHARACTER*198 C: char*	Source string
C: <i>len</i>	int	Length of the source string

Description

The function returns a string that contains the Intel MKL version.

For usage details, see the code example below:

Example

Fortran

```
program mkl_get_version_string
character*198  buf
call mkl_get_version_string(buf)
write(*,'(a)') buf
end
```

C

```
#include <stdio.h>
#include "mkl_service.h"

int main(void)
{
    int len=198;
    char buf[198];
    mkl_get_version_string(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control

Intel® MKL computational functions can create internal regions for parallel execution. Because Intel MKL operates within an OpenMP* execution environment, you can control the number of threads for Intel MKL using OpenMP* run-time library routines and environment variables (see the OpenMP* specification for details). Additionally Intel MKL provides *optional* threading control functions and environment variables that enable you to specify the number of threads for Intel MKL and to control dynamic adjustment of the number of threads *independently* of the OpenMP* settings. The settings made with the Intel MKL threading control functions and environment variables do not affect OpenMP* settings but take precedence over them.

This section describes how to control the number of threads using Intel MKL functions for threading control. If none of the threading control functions is used, Intel MKL environment variables may control Intel MKL threading. For details of those environment variables, see the *Intel MKL User's Guide*.

You can specify the number of threads for Intel MKL function domains with the `mkl_set_num_threads` or `mkl_domain_set_num_threads` function. While `mkl_set_num_threads` specifies the number of threads for the entire Intel MKL, `mkl_domain_set_num_threads` does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

Intel MKL Function Domains

Function Domain	Named Constant
Basic Linear Algebra Subroutines (BLAS)	<code>MKL_DOMAIN_BLAS</code>
Fast Fourier Transform (FFT) functions, except Cluster FFT functions	<code>MKL_DOMAIN_FFT</code>
Vector Math Library (VML) Functions	<code>MKL_DOMAIN_VML</code>
Parallel Direct Solver (PARDISO) functions	<code>MKL_DOMAIN_PARDISO</code>
All Intel MKL functions except the functions from the domains where the number of threads is set explicitly	<code>MKL_DOMAIN_ALL</code>

WARNING

Do not increase the number of threads used for Intel MKL PARDISO between the first call to `pardiso` and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of threads, increasing it after the initial call can cause incorrect results.

Both `mkl_set_num_threads` and `mkl_domain_set_num_threads` functions set the number of threads globally, which means that the setting applies to all execution threads. Use the `mkl_set_num_threads_local` function to specify different numbers of threads for Intel MKL on different execution threads of your application. The thread-local settings take precedence over the global settings. However, the thread-local settings may have undesirable side effects (see the description of the `mkl_set_num_threads_local` function for details).

By default, Intel MKL can adjust the specified number of threads dynamically. For example, Intel MKL may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP* parallel region. Although Intel MKL may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel MKL attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel MKL User's Guide*). Use the `mkl_set_dynamic` function to control dynamic adjustment of the number of threads.

`mkl_set_num_threads`

Specifies the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( nt )
```

C:

```
void mkl_set_num_threads( int nt );
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER C: int	$nt > 0$ - The number of threads suggested by the user. $nt \leq 0$ - Invalid value, which is ignored.

Description

This function allows you to specify how many threads Intel MKL should use for internal parallel regions. If this number is not set (default), Intel MKL functions use the OpenMP* number of threads. The specified number of threads applies:

- To all Intel MKL functions except the functions from the domains where the number of threads is set with [mkl_domain_set_num_threads](#)
- To all execution threads except the threads where the number of threads is set with [mkl_set_num_threads_local](#)

The number specified is a hint, and Intel MKL may actually use a different number.

NOTE

This function takes precedence over the `MKL_NUM_THREADS` environment variable.

Example

```
// C/C++
#include "mkl_service.h"
...
mkl_set_num_threads(4);
my_compute_using_mkl(); // Intel MKL uses up to 4 threads

! Fortran
use mkl_service
...
call mkl_set_num_threads(4)
call my_compute_using_mkl !Intel MKL uses up to 4 threads
```

mkl_domain_set_num_threads

Specifies the number of threads for a particular function domain.

Syntax

Fortran:

```
ierr = mkl_domain_set_num_threads( nt, domain )
```

C:

```
int mkl_domain_set_num_threads (int nt, int domain);
```

Fortran Include Files/Modules

- Include file: mkl.fi

- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER C: int	<i>nt</i> > 0 - The number of threads suggested by the user. <i>nt</i> = 0 - A request to reset the number of threads and use the OpenMP* number of threads. <i>nt</i> < 0 - Invalid value, which is ignored.
<i>domain</i>	FORTRAN: INTEGER C: int	The named constant that defines the targeted domain.

Description

This function specifies how many threads a particular function domain of Intel MKL should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel MKL will use the OpenMP* number of threads. The number of threads specified applies to the specified function domain on all execution threads except the threads where the number of threads is set with [mkl_set_num_threads_local](#). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

The number of threads specified is only a hint, and Intel MKL may actually use a different number.

NOTE

This function takes precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER C: int	1 - Indicates no error, execution is successful. 0 - Indicates a failure, possibly because of invalid input parameters.

Example

```
// C/C++
#include "mkl_service.h"
...
mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS);
my_compute_using_mkl blas(); // Intel MKL BLAS functions use up to 4 threads
my_compute_using_mkl dft(); // Intel MKL FFT functions use the default number of threads
```

```
! Fortran
use mkl_service
integer(4) :: status
...
status = mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS)
call my_compute_with_mkl blas() !Intel MKL BLAS functions use up to 4 threads
call my_compute_with_mkl dft() !Intel MKL FFT functions use the default number of threads
```

mkl_set_num_threads_local

Specifies the number of threads for all Intel MKL functions on the current execution thread.

Syntax

Fortran:

```
save_nt = mkl_set_num_threads_local( nt )
```

C:

```
int mkl_set_num_threads_local( int nt );
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER*4 C: int	<p><i>nt</i> > 0 - The number of threads for Intel MKL functions to use on the current execution thread.</p> <p><i>nt</i> = 0 - A request to reset the thread-local number of threads and use the global number.</p>

Description

This function sets the number of threads that Intel MKL functions should request for parallel computation. The number of threads is thread-local, which means that it only affects the current execution thread of the application. If the thread-local number is not set or if this number is set to zero in a call to this function, Intel MKL functions use the global number of threads. You can set the global number of threads using the [mkl_set_num_threads](#) or [mkl_domain_set_num_threads](#) function.

The thread-local number of threads takes precedence over the global number: if the thread-local number is non-zero, changes to the global number of threads have no effect on the current thread.

CAUTION

If your application is threaded with OpenMP* and parallelization of Intel MKL is based on nested OpenMP parallelism, different OpenMP parallel regions reuse OpenMP threads. Therefore a thread-local setting in one OpenMP parallel region may continue to affect not only the master thread after the parallel region ends, but also subsequent parallel regions. To avoid performance implications of this side effect, reset the thread-local number of threads before leaving the OpenMP parallel region (see [Examples](#) for how to do it).

Return Values

Name	Type	Description
save_nt	FORTRAN: INTEGER*4 C: int	The value of the thread-local number of threads that was used before this function call. Zero means that the global number of threads was used.

Examples

This example shows how to avoid the side effect of a thread-local number of threads by reverting to the global setting:

```
// C/C++
#include "omp.h"
#include "mkl_service.h"
...
mkl_set_num_threads(16);
my_compute_using_mkl();           // Intel MKL functions use up to 16 threads
#pragma omp parallel num_threads(2)
{
    if (0 == omp_get_thread_num())
        mkl_set_num_threads_local(4);
    else
        mkl_set_num_threads_local(12);

    my_compute_using_mkl();       // Intel MKL functions use up to 4 threads on thread 0
//    and up to 12 threads on thread 1
}
my_compute_using_mkl();           // Intel MKL functions use up to 4 threads (!)
mkl_set_num_threads_local( 0 );   // make master thread use global setting
my_compute_using_mkl();           // Intel MKL functions use up to 16 threads
```

```
! Fortran
use omp_lib
use mkl_service
integer(4) :: dummy
...
call mkl_set_num_threads(16)
call my_compute_using_mkl()      ! Intel MKL functions use up to 16 threads
 !$omp parallel num_threads(2)
    if (0 == omp_get_thread(num))  dummy = mkl_set_num_threads_local(4)
    if (1 == omp_get_thread(num))  dummy = mkl_set_num_threads_local(12)
    call my_compute_using_mkl()    ! Intel MKL functions use up to 4 threads on thread 0
                                  ! and up to 12 threads on thread 1
 !$omp end parallel
call my_compute_using_mkl()      ! Intel MKL functions use up to 4 threads (!)
dummy = mkl_set_num_threads_local(0) ! make master thread use global setting
call my_compute_using_mkl()      ! Now Intel MKL functions use up to 16 threads
```

This example shows how to avoid the side effect of a thread-local number of threads by saving and restoring the existing setting:

```
// C/C++
#include "mkl_service.h"
void my_compute( int nt )
{
    int save = mkl_set_num_threads_local( nt );    // save the Intel MKL number of threads
    my_compute_using_mkl();                         // Intel MKL functions use up to nt threads on this thread
    mkl_set_num_threads_local( save );              // restore the Intel MKL number of threads
}
```

```

! Fortran
subroutine my_compute(nt)
  use mkl_service
  integer(4) :: nt, save
  save = mkl_set_num_threads_local( nt )      ! save the Intel MKL number of threads
  call my_compute_using_mkl()      ! Intel MKL functions use up to nt threads on this thread
  save = mkl_set_num_threads_local( save )      ! restore the Intel MKL number of threads
end subroutine my_compute

```

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( flag )
```

C:

```
void mkl_set_dynamic (int flag);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
flag	<small>FORTRAN:</small> INTEGER <small>C:</small> int	<small>flag</small> = 0 - Requests disabling dynamic adjustment of the number of threads. <small>flag</small> ≠ 0 - Requests enabling dynamic adjustment of the number of threads.

Description

This function indicates whether Intel MKL can dynamically change the number of threads or should avoid doing this. The setting applies to all Intel MKL functions on all execution threads. This function takes precedence over the `MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel MKL may use fewer threads in parallel regions than the number returned by the [mkl_get_max_threads](#) function. Disabling dynamic adjustment of the number of threads does not ensure that Intel MKL actually uses the specified number of threads, although the library attempts to use that number.

TIP

If you call Intel MKL from within an OpenMP* parallel region and want to create internal parallel regions, either disable dynamic adjustment of the number of threads or set the thread-local number of threads (see [mkl_set_num_threads_local](#) for how to do it).

Example

```
// C/C++
#include "mkl_service.h"
...
mkl_set_num_threads( 8 );
#pragma omp parallel
{
    my_compute_with_mkl();      // Intel MKL uses 1 thread, being called from OpenMP parallel region
    mkl_set_dynamic( 0 );      // disable adjustment of the number of threads
    my_compute_with_mkl();      // Intel MKL uses 8 threads
}

! Fortran
use mkl_service
...
call mkl_set_num_threads( 8 )
 !$omp parallel
    call my_compute_with_mkl      ! Intel MKL uses 1 thread, being called from OpenMP parallel region
    call mkl_set_dynamic(0)       ! disable adjustment of the number of threads
    call my_compute_with_mkl     ! Intel MKL uses 8 threads
 !$omp end parallel
```

mkl_get_max_threads

Gets the number of threads targeted for parallelism.

Syntax

Fortran:

```
nt = mkl_get_max_threads()
```

C:

```
int mkl_get_max_threads (void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

This function returns the number of threads for Intel MKL to use in internal parallel regions. This number depends on whether dynamic adjustment of the number of threads by Intel MKL is disabled (by an environment setting or in a function call):

- If the dynamic adjustment is disabled, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:
 - A call to `mkl_set_num_threads_local`
 - The last of the calls to `mkl_set_num_threads` or `mkl_domain_set_num_threads(..., MKL_DOMAIN_ALL)`
 - The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_DOMAIN_ALL` tag
 - The `MKL_NUM_THREADS` environment variable
 - A call to `omp_set_num_threads`

- The `OMP_NUM_THREADS` environment variable
- If the dynamic adjustment is enabled, the function returns the number of physical cores on your system.

The number of threads returned by this function is a hint, and Intel MKL may actually use a different number.

Return Values

Name	Type	Description
<code>nt</code>	<code>FORTRAN: INTEGER*4</code> <code>C: int</code>	The maximum number of threads for Intel MKL functions to use in internal parallel regions.

Example

```
// C/C++
#include "mkl_service.h"
...
if (1 == mkl_get_max_threads()) puts("Intel MKL does not employ threading");

! Fortran
use mkl_service
...
if (1 == mkl_get_max_threads()) print *, "Intel MKL does not employ threading"
```

See Also

[mkl_set_dynamic](#)
[mkl_get_dynamic](#)

[Using a Fortran Interface Module for Support Functions](#)

mkl_domain_get_max_threads

Gets the number of threads targeted for parallelism for a particular function domain.

Syntax

Fortran:

```
nt = mkl_domain_get_max_threads( domain )
```

C:

```
int mkl_domain_get_max_threads (int domain);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>domain</code>	<code>FORTRAN: INTEGER</code>	The named constant that defines the targeted domain.

Name	Type	Description
	C: int	

Description

Computational functions of the Intel MKL function domain defined by the *domain* parameter use the value returned by this function as a limit of the number of threads they should request for parallel computations. The `mkl_domain_get_max_threads` function returns the thread-local number of threads or, if that value is zero or not set, the global number of threads. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to `mkl_set_num_threads_local`
- The last of the calls to `mkl_set_num_threads` or `mkl_domain_set_num_threads(..., MKL_DOMAIN_ALL)`
- A call to `mkl_domain_set_num_threads(..., domain)`
- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_DOMAIN_ALL` tag
- The `MKL_DOMAIN_NUM_THREADS` environment variable (with the specific domain tag)
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

Actual number of threads used by the Intel MKL computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description of `mkl_set_dynamic`). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

Return Values

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER*4 C: int	The maximum number of threads for Intel MKL functions from a given domain to use in internal parallel regions. If an invalid value of <i>domain</i> is supplied, the function returns the number of threads for <code>MKL_DOMAIN_ALL</code>

Example

```
// C/C++
#include "mkl_service.h"
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS))
puts("Intel MKL BLAS functions employ threading");

! Fortran
use mkl_service
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS)) then
print *, "Intel MKL BLAS functions employ threading"
end if
```

`mkl_get_dynamic`

Determines whether Intel MKL is enabled to dynamically change the number of threads.

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
int mkl_get_dynamic(void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

This function returns the status of dynamic adjustment of the number of threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to `mkl_set_dynamic`
- The `MKL_DYNAMIC` environment variable

NOTE

Dynamic adjustment of the number of threads is enabled by default.

The dynamic adjustment works as follows. Suppose that the `mkl_get_max_threads` function returns the number of threads equal to N . If dynamic adjustment is enabled, Intel MKL may request up to N threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel MKL requests exactly N threads for internal parallel regions (provided it uses a threaded algorithm with at least N computations that can be done in parallel). However, the OpenMP* run-time library may be configured to supply fewer threads than Intel MKL requests, depending on the OpenMP* setting of dynamic adjustment.

Return Values

Name	Type	Description
ret	FORTRAN: INTEGER*4 C: int	0 - Dynamic adjustment of the number of threads is disabled. 1 - Dynamic adjustment of the number of threads is enabled.

Example

```
// C/C++
#include "mkl_service.h"
...
int nt = mkl_get_max_threads();
if (1 == mkl_get_dynamic())
printf("Intel MKL may use less than %i threads for a large problem", nt);
else
printf("Intel MKL should use %i threads for a large problem", nt);
```

```

! Fortran
use mkl_service
integer(4) :: nt
...
nt = mkl_get_max_threads()
if (1 == mkl_get_dynamic()) then
    print'("Intel MKL may use less than "I0" threads for a large problem")', nt
else
    print'("Intel MKL should use "I0" threads for a large problem")', nt
end if

```

Error Handling

Error Handling for Linear Algebra Routines

xerbla

Error handling function called by BLAS, LAPACK, VML, and VSL functions.

Syntax

Fortran:

```
call xerbla( srname, info )
```

C:

```
void xerbla( const char * srname, const int* info, const int len );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Input Parameters

Name	Type	Description
<i>srname</i>	FORTRAN: CHARACTER*(*) C: const char*	The name of the routine that called <code>xerbla</code>
<i>info</i>	FORTRAN: INTEGER C: const int*	The position of the invalid parameter in the parameter list of the calling function or an error code
C: <i>len</i>	const int	Length of the source string

Description

The `xerbla` function is an error handler for Intel MKL BLAS, LAPACK, VML, and VSL functions. It is called by a BLAS, LAPACK, VML, or VSL function if an issue is encountered on entry or during the function execution.

`xerbla` operates as follows:

1. Prints a message that depends on the value of the *info* parameter as explained in the [Error Messages Printed by xerbla](#) table.

NOTE

A specific message can differ from the listed messages in numeric values and/or function names.

- 2.** Returns to the calling application.

Comments in the Netlib LAPACK reference code (http://www.netlib.org/lapack/explore-html/d1/dc0/_b_l_a_s_2_s_r_c_2xerbla_8f.html) suggest this behavior although the LAPACK User's Guide recommends that the execution should stop when an error occurs.

Error Messages Printed by xerbla

Value of <i>info</i>	Error Message
1001	Intel MKL ERROR: Incompatible optional parameters on entry to DGEMM.
1212	Intel MKL INTERNAL ERROR: Issue accessing coprocessor in function CGEEV.
1000 or 1089	Intel MKL INTERNAL ERROR: Insufficient workspace available in function CGELSD.
< 0	Intel MKL INTERNAL ERROR: Condition 1 detected in function DLASD8.
Other	Intel MKL ERROR: Parameter 6 was incorrect on entry to DGEMM.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. The following examples illustrate usage of `xerbla`.

Example

Fortran:

```
subroutine xerbla(srname, info)
character*(*) srname !Name of subprogram that called xerbla
integer*4 info !Position of the invalid parameter in the parameter list
return !Return to the calling subprogram end
end
```

C:

```
void xerbla(char* srname, int* info, int len){
// srname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",srname,*info);
}
```

See Also

[mkl_set_xerbla](#)

pixerbla

[Error handling routine called by ScaLAPACK routines.](#)

Syntax

```
void pixerbla(MKL_INT* ictxt, char* srname, MKL_INT* info);
```

Include Files

- C: mkl_scalapack.h

Input Parameters

<i>ictxt</i>	(global) MKL_INT
	The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>srname</i>	(global) char
	The name of the routine which called <code>pixerbla</code> .
<i>info</i>	(global) MKL_INT.
	The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScalAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScalAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pixerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level *ScalAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pixerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a non-zero value of *info* on return from a *ScalAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Handling Fatal Errors

A fatal error is a circumstance under which Intel MKL cannot continue the computation. For example, a fatal error occurs when Intel MKL cannot load a dynamic library or confronts an unsupported CPU type. In case of a fatal error, the default Intel MKL behavior is to print an explanatory message to the console and call an internal function that terminates the application with a call to the system `exit()` function. Intel MKL enables you to override this behavior by setting a custom handler of fatal errors. The custom error handler can be configured to throw a C++ exception, set a global variable indicating the failure, or otherwise handle cannot-continue situations. It is not necessary for the custom error handler to call the system `exit()` function. Once execution of the error handler completes, a call to Intel MKL returns to the calling program without performing any computations and leaves no memory allocated by Intel MKL and no OpenMP* synchronization pending on return.

To specify a custom fatal error handler, call the `mkl_set_exit_handler` function.

`mkl_set_exit_handler`

Sets the custom handler of fatal errors.

Syntax

Fortran:

```
external :: myexit
interface = mkl_set_exit_handler( myexit )
```

C:

```
int mkl_set_exit_handler (MKLExitHandler myexit);
```

Fortran Include Files/Modules

None.

C Include Files

- mkl.h

Input Parameters

Name	Interface/Prototype	Description
myexit	<p>FORTRAN:</p> <pre>interface subroutine myexit(iwhy) integer,value :: iwhy end subroutine myexit end interface</pre> <p>C:</p> <pre>void (*myexit)(int why);</pre>	The error handler to set.

Description

This function sets the custom handler of fatal errors. If the input parameter is *NULL*, the system `exit()` function is set.

The following example shows how to use a custom handler of fatal errors in your C++ application:

```
#include "mkl.h"
void my_exit(int why){
    throw my_exception();
}
int ComputationFunction()
{
    mkl_set_exit_handler( my_exit );
    try {
        compute_using_mkl();
    }
    catch (const my_exception& e) {
        handle_exception();
    }
}
```

The following example shows how to use a custom handler of fatal errors in your Fortran application:

```
subroutine myexit(rsn)
integer,value :: rsn
call msgbox("Application is terminating")
end myexit

program app
external :: myexit
call mkl_set_exit_handler(myexit)
!.... compute using Intel MKL...
```

Character Equality Testing

Isame

Tests two characters for equality regardless of the case.

Syntax

Fortran:

```
val = lsame( ca, cb )
```

C:

```
int lsame( const char* ca, const char* cb, int lca, int lcb );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Input Parameters

Name	Type	Description
ca, cb	<small>FORTRAN:</small> CHARACTER*1 <small>C:</small> const char*	<small>FORTRAN:</small> The single characters to be compared <small>C:</small> Pointers to the single characters to be compared
C: lca, lcb	int	Lengths of the input character strings, equal to one.

Description

This logical function checks whether two characters are equal regardless of the case.

Return Values

Name	Type	Description
val	<small>FORTRAN:</small> LOGICAL <small>C:</small> int	Result of the comparison: <ul style="list-style-type: none">• .TRUE. in Fortran and a non-zero value in C if ca is the same letter as cb, maybe except for the case.• .FALSE. in Fortran and zero in C if ca and cb are different letters for whatever cases.

Isamen

Tests two character strings for equality regardless of the case.

Syntax

Fortran:

```
val = lsamen( n, ca, cb )
```

C:

```
MKL_INT lsamen( const MKL_INT* n, const char* ca, const char* cb );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER C: const MKL_INT*	FORTRAN: The number of characters in <i>ca</i> and <i>cb</i> to be compared. C: Pointer to the number of characters in <i>ca</i> and <i>cb</i> to be compared.
<i>ca</i> , <i>cb</i>	FORTRAN: CHARACTER* (*) C: const char*	Character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed.

Description

This logical function tests whether the first *n* letters of one string are the same as the first *n* letters of the other string, regardless of the case.

Return Values

Name	Type	Description
<i>val</i>	FORTRAN: LOGICAL C: MKL_INT	Result of the comparison: <ul style="list-style-type: none"> .TRUE. in Fortran and a non-zero value in C if the first <i>n</i> letters in <i>ca</i> and <i>cb</i> character strings are equal, maybe except for the case, or if the length of character string <i>ca</i> or <i>cb</i> is less than <i>n</i>. .FALSE. in Fortran and zero in C if the first <i>n</i> letters in <i>ca</i> and <i>cb</i> character strings are different for whatever cases.

Timing

second/dsecnd

Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

Syntax

Fortran:

```
val = second()
val = dsecnd()
```

C:

```
float second( void );
double dsecnd( void );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The second/dsecnd function returns time in seconds to be used to estimate real time between two calls to the function. The difference between these functions is in the precision of the floating-point type of the result: while second returns the single-precision type, dsecnd returns the double-precision type.

Use these functions to measure durations. To do this, call each of these functions twice. For example, to measure performance of a routine, call the appropriate function directly before a call to the routine to be measured, and then after the call of the routine. The difference between the returned values shows real time spent in the routine.

Initializations may take some time when the second/dsecnd function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to second/dsecnd in advance.

Do not use second to measure short time intervals because the single-precision format is not capable of holding sufficient timer precision.

Return Values

Name	Type	Description
val	FORTRAN: REAL for second DOUBLE PRECISION for dsecnd C: float for second double for dsecnd	Elapsed real time in seconds

mkl_get_cpu_clocks

Returns elapsed CPU clocks.

Syntax

Fortran:

```
call mkl_get_cpu_clocks( clocks )
```

C:

```
void mkl_get_cpu_clocks (unsigned MKL_INT64 *clocks);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>clocks</i>	FORTRAN: INTEGER*8 C: unsigned MKL_INT64	Elapsed CPU clocks

Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like second/dsecnd. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_get_cpu_frequency`

Returns the current CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_cpu_frequency()
```

C:

```
double mkl_get_cpu_frequency(void);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Description

The function `mkl_get_cpu_frequency` returns the current CPU frequency in GHz.

NOTE

The returned value may vary from run to run if power management or Intel® Turbo Boost Technology is enabled.

Return Values

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	Current CPU frequency value in GHz

mkl_get_max_cpu_frequency

Returns the maximum CPU frequency value in GHz.

Syntax**Fortran:**

```
freq = mkl_get_max_cpu_frequency()
```

C:

```
double mkl_get_max_cpu_frequency(void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

Return Values

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	Maximum CPU frequency value in GHz

mkl_get_clocks_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

Syntax**Fortran:**

```
freq = mkl_get_clocks_frequency()
```

C:

```
double mkl_get_clocks_frequency (void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

NOTE

Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

Return Values

Name	Type	Description
<code>freq</code>	<code>FORTRAN: DOUBLE PRECISION</code> <code>C: double</code>	Frequency value in GHz

Using a Fortran Interface Module for Support Functions

Memory Management

This section describes the Intel MKL memory functions. See the *Intel® MKL User's Guide* for more memory usage information.

mkl_free_buffers

Frees unused memory allocated by the Intel MKL Memory Allocator.

Syntax

Fortran:

```
call mkl_free_buffers
```

C:

```
void mkl_free_buffers (void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_free_buffers` function frees unused memory allocated by the Memory Allocator.

See the *Intel MKL User's Guide* for details.

You should call `mkl_free_buffers` after the last call to Intel MKL functions. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

In a threaded application, avoid calling `mkl_free_buffers` from each thread because the function has a global effect. Call `mkl_thread_free_buffers` instead.

Usage of `mkl_free_buffers` with FFT Functions (C Example)

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . .
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here because the hand2 descriptor will be corrupted! */
. . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here you finish using Intel MKL FFT */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
```

[mkl_thread_free_buffers](#)

Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.

Syntax

Fortran:

```
call mkl_thread_free_buffers
```

C:

```
void mkl_thread_free_buffers (void);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod

- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Description

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_thread_free_buffers` function frees unused memory allocated by the Memory Allocator in the current thread only.

You should call `mkl_thread_free_buffers` after the last call to Intel MKL functions in the current thread. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

[Using a Fortran Interface Module for Support Functions](#)

`mkl_disable_fast_mm`

Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system malloc/free functions.

Syntax

Fortran:

```
mm = mkl_disable_fast_mm
```

C:

```
int mkl_disable_fast_mm (void);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Description

The `mkl_disable_fast_mm` function turns the Intel MKL Memory Allocator off for Intel MKL functions to directly use the system `malloc/free` functions. Intel MKL Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The Memory Allocator is turned on by default for better performance. To turn it off, you can use the `mkl_disable_fast_mm` function or the `MKL_DISABLE_FAST_MM` environment variable (See the *Intel MKL User's Guide* for details.) Call `mkl_disable_fast_mm` before calling any Intel MKL functions that require allocation of memory buffers.

NOTE

Turning the Memory Allocator off negatively impacts performance of some Intel MKL routines, especially for small problem sizes.

Return Values

Name	Type	Description
<i>mm</i>	FORTAN: INTEGER*4 C: int	1 - The Memory Allocator is successfully turned off. 0 - Turning the Memory Allocator off failed.

mkl_mem_stat

Reports the status of the Intel MKL Memory Allocator.

Syntax

Fortran:

```
AllocatedBytes = mkl_mem_stat( AllocatedBuffers )
```

C:

```
MKL_INT64 mkl_mem_stat (int* AllocatedBuffers);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>AllocatedBuffers</i>	FORTAN: INTEGER*4 C: int	The number of buffers allocated by Intel MKL.

Description

The function returns the number of buffers allocated by Intel MKL and the amount of memory in these buffers. Intel MKL can allocate the memory buffers internally or in a call to [mkl_malloc/mkl_calloc](#). If no buffers are allocated at the moment, the `mkl_mem_stat` function returns 0. Call `mkl_mem_stat` to check the Intel MKL memory status.

NOTE

If you free all the memory allocated in calls to `mkl_malloc` or `mkl_calloc` and then call `mkl_free_buffers`, a subsequent call to `mkl_mem_stat` normally returns 0.

Return Values

Name	Type	Description
<i>AllocatedBytes</i>	FORTAN: INTEGER*8 C: MKL_INT64	The amount of allocated memory (in bytes).

See Also

[Usage Examples for the Memory Functions](#)

[Using a Fortran Interface Module for Support Functions](#)

mkl_peak_mem_usage

Reports the peak memory allocated by the Intel MKL Memory Allocator.

Syntax**Fortran:**

```
AllocatedBytes = mkl_peak_mem_usage( mode )
```

C:

```
MKL_INT64 mkl_peak_mem_usage (int mode);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
mode	FORTRAN: INTEGER*4 C: int	Requested mode of the function's operation. Possible values: <ul style="list-style-type: none"> MKL_PEAK_MEM_ENABLE - start gathering the peak memory data MKL_PEAK_MEM_DISABLE - stop gathering the peak memory data MKL_PEAK_MEM - return the peak memory MKL_PEAK_MEM_RESET - return the peak memory and reset the counter to start gathering the peak memory data from scratch

Description

The `mkl_peak_mem_usage` function reports the peak memory allocated by the Intel MKL Memory Allocator.

Gathering the peak memory data is turned off by default. If you need to know the peak memory, explicitly turn the data gathering mode on by calling the function with the `MKL_PEAK_MEM_ENABLE` value of the parameter. Use the `MKL_PEAK_MEM` and `MKL_PEAK_MEM_RESET` values only when the data gathering mode is turned on. Otherwise the function returns -1. The data gathering mode leads to performance degradation, so when the mode is turned on, you can turn it off by calling the function with the `MKL_PEAK_MEM_DISABLE` value of the parameter.

- If Intel MKL is running in a threaded mode, the `mkl_peak_mem_usage` function may return different amounts of memory from run to run.

- The function reports the peak memory for the entire application, not just for the calling thread.

Return Values

Name	Type	Description
<i>AllocatedBytes</i>	FORTRAN: INTEGER*8 C: MKL_INT64	The peak memory allocated by the Memory Allocator (in bytes) or -1 in case of errors.

mkl_malloc

Allocates an aligned memory buffer.

Syntax

Fortran:

```
a_ptr = mkl_malloc( alloc_size, alignment )
```

C:

```
void* mkl_malloc (size_t alloc_size, int alignment);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>alloc_size</i>	FORTRAN: INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems C: size_t	Size of the buffer to be allocated.
<i>alignment</i>	FORTRAN: INTEGER*4 C: int	Alignment of the buffer.

Description

The function allocates an *alloc_size*-byte buffer aligned on the *alignment*-byte boundary.

If *alignment* is not a power of 2, the 32-byte alignment is used.

Return Values

Name	Type	Description
<code>a_ptr</code>	FORTRAN: POINTER C: <code>void*</code>	Pointer to the allocated buffer if <code>alloc_size ≥ 1</code> , NULL if <code>alloc_size < 1</code> .

See Also

mkl_calloc

Allocates and initializes an aligned memory buffer.

Syntax

Fortran:

```
a_ptr = mkl_calloc( num, size, alignment )
```

C:

```
void* mkl_calloc (size_t num, size_t size, int alignment);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>num</code>	FORTRAN: INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems C: <code>size_t</code>	The number of elements in the buffer to be allocated.
<code>size</code>	FORTRAN: INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems C: <code>size_t</code>	The size of the element.
<code>alignment</code>	FORTRAN: INTEGER*4 C: int	Alignment of the buffer.

Description

The function allocates a `num*size`-byte buffer, aligned on the `alignment`-byte boundary, and initializes the buffer with zeros.

If *alignment* is not a power of 2, the 64-byte alignment is used.

Return Values

Name	Type	Description
<i>a_ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the allocated buffer if <i>size</i> ≥ 1 , NULL if <i>size</i> < 1.

See Also

[mkl_malloc](#)

[mkl_realloc](#)

[mkl_free](#)

[Usage Examples for the Memory Functions](#)

[Using a Fortran Interface Module for Support Functions](#)

mkl_realloc

Changes the size of memory buffer allocated by mkl_malloc/mkl_calloc.

Syntax

Fortran:

```
a_ptr = mkl_realloc( ptr, size )
```

C:

```
void* mkl_realloc (void *ptr, size_t size);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the memory buffer allocated by the <code>mkl_malloc</code> or <code>mkl_calloc</code> function or a NULL pointer.
<i>size</i>	FORTTRAN: INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems C: size_t	New size of the buffer.

Description

The function changes the size of the memory buffer allocated by the `mkl_malloc` or `mkl_calloc` function to `size` bytes. The first bytes of the returned buffer up to the minimum of the old and new sizes keep the content of the input buffer. The returned memory buffer can have a different location than the input one. If `ptr` is `NULL`, the function works as `mkl_malloc`.

Return Values

Name	Type	Description
<code>a_ptr</code>	<code>FORTRAN:</code> <code>POINTER</code> <code>C:</code> <code>void*</code>	Pointer to the re-allocated buffer.

See Also

[mkl_malloc](#)
[mkl_calloc](#)
[mkl_free](#)

[Usage Examples for the Memory Functions](#)

[Using a Fortran Interface Module for Support Functions](#)

mkl_free

Frees the aligned memory buffer allocated by mkl_malloc/mkl_calloc.

Syntax

Fortran:

```
call mkl_free( a_ptr )
```

C:

```
void mkl_free (void *a_ptr);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>a_ptr</code>	<code>FORTRAN:</code> <code>POINTER</code> <code>C:</code> <code>void*</code>	Pointer to the buffer to be freed

Description

The function frees the buffer pointed by `ptr` and allocated by the `mkl_malloc()` or `mkl_calloc()` function.

ALPHA = 1.1; BETA = -1.2
ALLOC_SIZE = 8*N*N
A_PTR = MKL_MALLOC(ALLOC_SIZE,64)
B_PTR = MKL_MALLOC(ALLOC_SIZE,64)
C_PTR = MKL_MALLOC(ALLOC_SIZE,64)
DO I=1,N
    DO J=1,N
        A(I,J) = I
        B(I,J) = -I
        C(I,J) = 0.0
    END DO
END DO

CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N);

ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
PRINT *, 'DGEMM uses ',ALLOCATED_BYTES,' bytes in ',
$ ALLOCATED_BUFFERS,' buffers '

CALL MKL_FREE_BUFFERS

```

```

CALL MKL_FREE(A_PTR)
CALL MKL_FREE(B_PTR)
CALL MKL_FREE(C_PTR)

ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
IF (ALLOCATED_BYTES > 0) THEN
    PRINT *, 'MKL MEMORY LEAK!'
    PRINT *, 'AFTER MKL_FREE_BUFFERS there are ',
$      ALLOCATED_BYTES, ' bytes in ',

Usage Example in C

```

#include <stdio.h>
#include <mkl.h>

int main(void) {
    double *a, *b, *c;
    int n, i;
    double alpha, beta;
    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    mkl_peak_mem_usage(MKL_PEAK_MEM_ENABLE);
    a = (double*)mkl_malloc(n*n*sizeof(double), 64);
    b = (double*)mkl_malloc(n*n*sizeof(double), 64);
    c = (double*)mkl_calloc(n*n, sizeof(double), 64);
    for (i=0;i<(n*n);i++) {
        a[i] = (double)(i+1);
        b[i] = (double)(-i-1);
    }

    dgemm("N","N",&n,&n,&n,&alpha,a,&n,b,&n,&beta,c,&n);
    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    printf("\nDGEMM uses %d bytes in %d buffers",AllocatedBytes,N_AllocatedBuffers);

    mkl_free_buffers();
    mkl_free(a);
    mkl_free(b);
    mkl_free(c);

    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    if (AllocatedBytes > 0) {
        printf("\nMKL memory leak!");
        printf("\nAfter mkl_free_buffers there are %d bytes in %d buffers",
               AllocatedBytes,N_AllocatedBuffers);
    }
    printf("\nPeak memory allocated by Intel MKL memory allocator %d bytes. Start to count new memory
peak",
           mkl_peak_mem_usage(MKL_PEAK_MEM_RESET));
    a = (double*)mkl_malloc(n*n*sizeof(double), 64);
    a = (double*)mkl_realloc(a,2*n*n*sizeof(double));
    mkl_free(a);
    printf("\nPeak memory allocated by Intel MKL memory allocator after reset of peak memory counter %d
bytes\n",

```

```
mkl_peak_mem_usage(MKL_PEAK_MEM)) ;

return 0;
}
```

Single Dynamic Library Control

Intel® MKL provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel MKL at run time. See *Intel® MKL User's Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

mkl_set_interface_layer

Sets the interface layer for Intel MKL at run time. Use with the Single Dynamic Library.

Syntax

Fortran:

```
interface = mkl_set_interface_layer( required_interface )
```

C:

```
int mkl_set_interface_layer (int required_interface);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>required_interface</i>	<small>FORTRAN: INTEGER C: int</small>	<p>Determines the interface layer. Possible values depend on the system architecture. Some of the values are only available on Linux* OS:</p> <ul style="list-style-type: none"> Intel® 64 architecture: <ul style="list-style-type: none"> MKL_INTERFACE_LP64 for the Intel LP64 interface. MKL_INTERFACE_ILP64 for the Intel ILP64 interface. MKL_INTERFACE_LP64+MKL_INTERFACE_GNU for the GNU* LP64 interface on Linux OS. MKL_INTERFACE_ILP64+MKL_INTERFACE_GNU for the GNU ILP64 interface on Linux OS. IA-32 architecture: <ul style="list-style-type: none"> MKL_INTERFACE_LP64 for the Intel interface on Linux OS. MKL_INTERFACE_LP64+MKL_INTERFACE_GNU or

Name	Type	Description
		MKL_INTERFACE_GNU for the GNU interface on Linux OS.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets the specified interface layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
<code>FORTRAN: INTEGER</code>	<ul style="list-style-type: none"> Current interface layer if it is set in a call to <code>mkl_set_interface_layer</code> or specified by environment variables or defaults.
<code>C: int</code>	<ul style="list-style-type: none"> Possible values are specified in Input Parameters. -1, if the layer was not specified prior to the call and the input parameter is incorrect.

`mkl_set_threading_layer`

Sets the threading layer for Intel MKL at run time. Use with the Single Dynamic Library (SDL).

Syntax

Fortran:

```
threading = mkl_set_threading_layer( required_threading )
```

C:

```
int mkl_set_threading_layer (int required_threading);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>required_threading</code>	<code>FORTRAN:</code> INTEGER <code>C:</code> int	Determines the threading layer. Possible values: <code>MKL_THREADING_INTEL</code> for Intel threading. <code>MKL_THREADING_SEQUENTIAL</code> for the sequential mode of Intel MKL. <code>MKL_THREADING_PGI</code> for PGI threading on Windows* or Linux* operating system only. Do not use this value with the SDL for Intel® Many Integrated Core (Intel® MIC) Architecture. <code>MKL_THREADING_GNU</code> for GNU threading on Linux* operating system only. Do not use this value with the SDL for Intel MIC Architecture.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
<code>FORTRAN:</code> INTEGER <code>C:</code> int	<ul style="list-style-type: none"> Current threading layer if it is set in a call to <code>mkl_set_threading_layer</code> or specified by environment variables or defaults. Possible values are specified in Input Parameters. -1, if the layer was not specified prior to the call and the input parameter is incorrect.

`mkl_set_xerbla`

Replaces the error handling routine. Use with the Single Dynamic Library on Windows OS.*

Syntax

Fortran:

```
old_xerbla_ptr = mkl_set_xerbla( new_xerbla_ptr )
```

C:

```
XerblaEntry mkl_set_xerbla (XerblaEntry new_xerbla_ptr);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`

- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>new_xerbla_ptr</code>	XerblaEntry	Pointer to the error handling routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_xerbla` function replaces the error handling routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced error handling routine.

See Also

`xerbla`

[Using a Fortran Interface Module for Support Functions](#)

`mkl_set_progress`

Replaces the progress information routine. Use with the Single Dynamic Library (SDL) on Windows OS.*

Syntax

Fortran:

```
old_progress_ptr mkl_set_progress( new_progress_ptr )
```

C:

```
ProgressEntry mkl_set_progress (ProgressEntry new_progress_ptr);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>new_progress_ptr</code>	ProgressEntry	Pointer to the progress information routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced progress information routine.

See Also

`mkl_progress`

Using a Fortran Interface Module for Support Functions

Intel Many Integrated Core Architecture Support

Intel MKL functions to support the use of Intel Xeon Phi coprocessors are as follows:

Fortran

```
rc = mkl_mic_enable( )
rc = mkl_get_device_count( )
rc = mkl_mic_set_workdivision( MKL_TARGET_MIC, MKL_MIC_DEFAULT_TARGET_NUMBER, 0.0 )
rc = mkl_mic_set_workdivision( MKL_TARGET_MIC, 0, MKL_MIC_AUTO_WORKDIVISION )
rc = mkl_mic_get_workdivision( MKL_TARGET_MIC, 0, wd )
rc = mkl_mic_set_max_memory( MKL_TARGET_MIC, 0, mem_size)
rc = mkl_mic_set_device_num_threads( MKL_TARGET_MIC, 0, num_threads)
rc = mkl_mic_set_resource_limit( fraction )
rc = mkl_mic_get_resource_limit( fraction )
rc = mkl_mic_set_offload_report( 1 )
rc = mkl_mic_free_memory( MKL_TARGET_MIC, 0 )
rc = mkl_mic_disable( )
```

C

```
#include "mkl.h" // Required for Intel MIC Architecture functions
rc = mkl_mic_enable();
rc = mkl_get_device_count();
rc = mkl_mic_set_workdivision(MKL_TARGET_MIC, MKL_MIC_DEFAULT_TARGET_NUMBER, 0.0);
rc = mkl_mic_set_workdivision(MKL_TARGET_MIC, 0, MKL_MIC_AUTO_WORKDIVISION);
rc = mkl_mic_get_workdivision(MKL_TARGET_MIC, 0, &wd);
rc = mkl_mic_set_max_memory(MKL_TARGET_MIC, 0, mem_size);
rc = mkl_mic_set_device_num_threads(MKL_TARGET_MIC, 0, num_threads);
rc = mkl_mic_set_resource_limit(fraction);
rc = mkl_mic_get_resource_limit(fraction);
rc = mkl_mic_set_offload_report(1);
rc = mkl_mic_free_memory(MKL_TARGET_MIC, 0);
rc = mkl_mic_disable();
```

The `mkl_mic_enable` function enables Intel MKL to offload computations to Intel Xeon Phi coprocessors automatically, while the `mkl_mic_disable` function disables automatic offloading.

Optional work-division control functions enable you to specify the fractional amount of work to distribute between the host CPU and the coprocessors. Work division is a fractional measure ranging from 0.0 to 1.0. For example, setting work division for the host CPU to 0.5 means to keep half of the computational work on the host CPU and move half to the coprocessor(s). Setting work division to 0.25 for a coprocessor means to offload a quarter of the computational work to this coprocessor while leaving the rest on the host CPU.

Other functions enable more control over computational resources of Intel Xeon Phi coprocessors.

NOTE

The support functions for Intel MIC Architecture take precedence over the respective environment variables.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_mic_enable

Enables Automatic Offload mode.

Syntax**Fortran:**

```
ierr = mkl_mic_enable( )
```

C:

```
int mkl_mic_enable();
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

The `mkl_mic_enable` function enables Automatic Offload mode and initializes Intel Xeon Phi coprocessors available on your system. This function takes precedence over the `MKL_MIC_ENABLE` environment variable. Unlike the function, the environment variable enables Automatic Offload mode, but the initialization is delayed until a call to an Intel MKL function supporting Automatic Offload. For functions supporting Automatic Offload, see the *Intel MKL Release Notes*.

Return Values

Name	Type	Description
<code>ierr</code>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that Automatic Offload mode is successfully enabled. < 0 Indicates a failure to enable Automatic Offload mode.

mkl_mic_disable

Disables Automatic Offload mode.

Syntax

Fortran:

```
ierr = mkl_mic_disable( )
```

C:

```
int mkl_mic_disable();
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

The `mkl_mic_disable` function disables Automatic Offload mode. To enable Automatic Offload mode back, use the `mkl_mic_enable` function.

NOTE

If Automatic Offload mode is not enabled, a call to `mkl_mic_disable` completes successfully if Intel Xeon Phi coprocessors are available on your system.

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that Automatic Offload mode is successfully disabled. < 0 Indicates a failure to disable Automatic Offload mode.

mkl_mic_get_device_count

Returns the number of Intel Xeon Phi coprocessors on the system when called on the host CPU.

Syntax

Fortran:

```
ndevices = mkl_mic_get_device_count( )
```

C:

```
int mkl_mic_get_device_count();
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Description

The `mkl_get_device_count` function returns the number of Intel Xeon Phi coprocessors on your system. You may need this number to specify a custom work-division scheme.

CAUTION

Call this function only on the host CPU.

Return Values

Name	Type	Description
<code>ndevices</code>	<code>FORTRAN:</code> INTEGER*4 <code>C:</code> int	The number of Intel Xeon Phi coprocessors available on the system. Equals zero if there are none.

See Also

[mkl_mic_enable](#)
[Using a Fortran Interface Module for Support Functions](#)

[mkl_mic_set_workdivision](#)

For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.

Syntax

Fortran:

```
ierr = mkl_mic_set_workdivision( target_type, target_number, wd )
```

C:

```
int mkl_mic_set_workdivision (MKL_MIC_TARGET_TYPE target_type, int target_number,  
double wd);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>target_type</code>	<code>FORTRAN</code> : INTEGER*4 <code>C</code> : MKL_MIC_TARGET_TYPE	Type of the target device. Use one of the following values: <ul style="list-style-type: none">• <code>MKL_TARGET_HOST</code> - host CPU• <code>MKL_TARGET_MIC</code> - Intel Xeon Phi coprocessor, default
<code>target_number</code>	<code>FORTRAN</code> : INTEGER*4 <code>C</code> : int	The device to set the fraction of work for. Takes the following values: <ul style="list-style-type: none">• ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <code>target_number</code> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <code>target_number = 6</code> determines the coprocessor number 2.• <0. Reserved. If <code>target_type = MKL_TARGET_HOST</code> , the function ignores the <code>target_number</code> parameter, which may have any value.
<code>wd</code>	<code>FORTRAN</code> : REAL*8 <code>C</code> : double	The fractional amount of the work that the specified device should do, where $0.0 \leq wd \leq 1.0$. Specifying <code>MKL_MIC_AUTO_WORKDIVISION</code> for <code>wd</code> indicates that Intel MKL should determine the amount of the work for the specified device.

Description

If you are using Intel MKL in Automatic Offload mode, the `mkl_mic_set_workdivision` function specifies how much work each Intel Xeon Phi coprocessor or the host CPU should do. This function takes precedence over the `MKL_HOST_WORKDIVISION`, `MKL_MIC_WORKDIVISION`, and `MKL_MIC_<number>_WORKDIVISION` environment variables (see the *Intel MKL User's Guide* for details).

-
- Intel MKL interprets the fraction of work set by the `mkl_mic_set_workdivision` function as guidance toward dividing work between coprocessors, but the library may choose a different work division if necessary.
 - Intel MKL resolves the collision that arises if the sum of all the work-division fractions does not equal one.
 - For LAPACK routines, setting the fraction of work to any value other than 0.0 enables the specified processor for Automatic Offload mode. However Intel MKL LAPACK does not use the value specified to divide the workload. For example, setting the fraction to 0.5 has the same effect as setting the fraction to 1.0.
-

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that the fraction is successfully set. < 0 Indicates a failure to set the fraction.

mkl_mic_set_max_memory

Sets the maximum amount of Intel Xeon Phi coprocessor memory reserved for the Automatic Offload computations.

Syntax

Fortran:

```
ierr = mkl_mic_set_max_memory( target_type, target_number, mem_size )
```

C:

```
int mkl_mic_set_max_memory (MKL_MIC_TARGET_TYPE target_type, int target_number, size_t
mem_size);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>target_type</i>	FORTRAN: INTEGER*4 C: MKL_MIC_TARGET_TYPE	Type of the target device. Use the value of MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default.
<i>target_number</i>	FORTRAN: INTEGER*4 C: int	The coprocessor number for which the maximum memory used for Automatic Offload computations is set. Takes the following values: <ul style="list-style-type: none"> • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • <0. Reserved.
<i>mem_size</i>	FORTRAN: INTEGER*8 C: size_t	For the <i>target_number</i> device, the amount of memory in kilobytes to reserve for Automatic Offload computations. Intel MKL attempts to not exceed the specified memory size for Automatic Offload computations.

Description

The `mkl_mic_set_max_memory` function enables you to limit coprocessor memory used by the Automatic Offload computations. Intel MKL reserves the specified memory on Intel Xeon Phi coprocessors. This can improve the performance of Automatic Offload computations by reducing the cost of buffer initialization and data transfer. The specified memory is reserved for the calling process, and the threads of a process share the specified memory. Intel MKL allocates additional memory for each process that performs Automatic Offload computations.

This function takes precedence over the `MKL_MIC_MAX_MEMORY` and `MKL_MIC_<number>_MAX_MEMORY` environment variables (see the *Intel MKL User's Guide* for details).

-
- Call `mkl_mic_set_max_memory` before any Intel MKL functions that do Automatic Offload computations.
 - Use `mkl_mic_free_memory` to free the coprocessor memory reserved for the Automatic Offload computations.
-

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates the coprocessor memory reserved for Automatic Offload is set successfully. < 0 Indicates an error.

See Also

[mkl_mic_free_memory](#)

[mkl_mic_enable](#)

[Using a Fortran Interface Module for Support Functions](#)

mkl_mic_free_memory

Frees the coprocessor memory reserved for the Automatic Offload computations.

Syntax

Fortran:

```
ierr = mkl_mic_free_memory( target_type, target_number )
```

C:

```
int mkl_mic_free_memory (MKL_MIC_TARGET_TYPE target_type, int target_number);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>target_type</i>	FORTRAN: INTEGER*4 C: MKL_MIC_TARGET_TYPE	Type of the target device. Use the value of MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default.
<i>target_number</i>	FORTRAN: INTEGER*4 C: int	The coprocessor number for which the memory reserved for Automatic Offload computations is freed. Takes the following values: <ul style="list-style-type: none"> ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>.

Name	Type	Description
		<p>For example: for a system with 4 Intel Xeon Phi coprocessors, <code>target_number = 6</code> determines the coprocessor number 2.</p> <ul style="list-style-type: none"> • <0. Reserved.

Description

The `mkl_mic_free_memory` function frees the coprocessor memory reserved for the Automatic Offload computations. If you call `mkl_mic_set_max_memory` to specify the maximum coprocessor memory for Automatic Offload computations, Intel MKL reserves and reuses the specified coprocessor memory during multiple Automatic Offload calls. You can reclaim the coprocessor memory by calling `mkl_mic_free_memory`.

-
- Currently, Intel MKL reserves the coprocessor memory only if the `mkl_mic_set_max_memory` function is called. Therefore, `mkl_mic_free_memory` has no effect unless there is a prior call to the `mkl_mic_set_max_memory` function.
 - If you do not call `mkl_mic_free_memory`, Intel MKL frees the coprocessor memory at the program exit.
-

Return Values

Name	Type	Description
<code>ierr</code>	<code>FORTRAN: INTEGER*4</code> <code>C: int</code>	<p>Result status:</p> <p>= 0 Indicates the coprocessor memory reserved for Automatic Offload is freed successfully.</p> <p>< 0 Indicates an error.</p>

Enables/disables the `mkl_malloc` function running in Automatic Offload mode to register allocated memory.

Syntax

Fortran:

```
call mkl_mic_register_memory( control )
```

C:

```
void mkl_mic_register_memory (int control);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>control</code>	<code>FORTAN: INTEGER*4</code> <code>C: int</code>	Desired behavior of <code>mkl_malloc</code> . Possible values: 0 - not register allocated memory, default. 1 - register allocated memory if Automatic Offload (AO) mode is enabled.

Description

The `mkl_mic_register_memory` function enables or disables the `mkl_malloc` function to register allocated memory when `mkl_malloc` runs in AO mode.

Registration of memory may reduce the overhead introduced by the operating system during data transfers between Intel Xeon Phi coprocessors and the host CPU.

This function takes precedence over the `MKL_MIC_REGISTER_MEMORY` environment variable.

If AO mode is disabled, the function has no effect.

See Also

`mkl_malloc` Allocates an aligned memory buffer.

`mkl_mic_enable` Enables Automatic Offload mode.

[Using a Fortran Interface Module for Support Functions](#)

`mkl_mic_set_device_num_threads`

Sets the maximum number of threads to use on an Intel Xeon Phi coprocessor for the Automatic Offload computations.

Syntax

Fortran:

```
ierr = mkl_mic_set_device_num_threads( target_type, target_number, num_threads )
```

C:

```
int mkl_mic_set_device_num_threads (MKL_MIC_TARGET_TYPE target_type, int target_number,
int num_threads);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>target_type</i>	FORTRAN: INTEGER*4 C: MKL_MIC_TARGET_TYPE	Type of the target device. Use the value of MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default.
<i>target_number</i>	FORTRAN: INTEGER*4 C: int	The coprocessor number for which the maximum number of threads to be used for Automatic Offload computations is set. Takes the following values: <ul style="list-style-type: none">• ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2.• < 0. Reserved.
<i>num_threads</i>	FORTRAN: INTEGER*4 C: int	The number of threads to use for Automatic Offload computations on the <i>target_number</i> coprocessor. Must be greater than 0.

Description

The `mkl_mic_set_device_num_threads` function enables you to limit the number of threads to use for Automatic Offload computations on a specific Intel Xeon Phi coprocessor.

This function takes precedence over the `MIC_OMP_NUM_THREADS` and `MKL_MIC_<number>_OMP_NUM_THREADS` environment variables (see the *Intel MKL User's Guide* for details).

Unless the maximum number of threads is set by the environment variables or this function, Intel MKL uses all coprocessor cores.

Call `mkl_mic_set_device_num_threads` before initialization of Automatic Offload mode. Otherwise the function returns -1 without setting the number of threads.

NOTE

Automatic Offload mode can be initialized as follows:

- *explicitly*, in a call to the `mkl_mic_enable` function.
- *implicitly*, in the first call to an Intel MKL function that does Automatic Offload computations (for example: ?GEMM). See the *Intel MKL Release Notes* for which functions support Automatic Offload mode.

The `mkl_mic_set_device_num_threads` function sets the maximum number of threads to use for the Automatic Offload computations on Intel Xeon Phi coprocessors only. To control host CPU threading, use general threading control functions and see "Using Additional Threading Control" in the *Intel MKL User's Guide* for more information.

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that the number of threads is set successfully. < 0 Indicates a failure to set the number of threads.

[Threading Control](#)

mkl_mic_set_resource_limit

For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.

Syntax

Fortran:

```
ierr = mkl_mic_set_resource_limit( fraction )
```

C:

```
int mkl_mic_set_resource_limit (double fraction);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>fraction</i>	FORTRAN: REAL*8 C: double	The fractional amount of Intel Xeon Phi coprocessor computational resources that the calling process can use for Automatic Offload (AO). Possible values: $0.0 \leq \text{fraction} \leq 1.0$. Special values: <ul style="list-style-type: none"> 0.0 - you need to manage the coprocessors explicitly using the <code>mkl_mic_set_device_num_threads</code> function or the <code>MIC_KMP_AFFINITY</code> environment variable. Default.

Name	Type	Description
		<ul style="list-style-type: none"> • <code>MKL_MPI_PPN</code> constant - enables a fully automated mode for message-passing interface (MPI) applications. In this mode, Intel MKL tries to read the number of MPI processes per node (<i>ppn</i>) from the environment variables passed to the process by MPI. If this attempt is successful, Intel MKL sets the actual value of the fractional amount to $1.0/ppn$.
NOTE		
For Intel® MPI Library, Open MPI, and IBM Platform MPI, Intel MKL automatically detects <i>ppn</i> . For other MPI implementations, use the <code>MKL_MPI_PPN</code> environment variable to set <i>ppn</i> .		

Description

If you are using Intel MKL in the AO mode, the `mkl_mic_set_resource_limit` function specifies how much of the computational resources of Intel Xeon Phi coprocessors can be used by the calling process. Use this function if you need to share coprocessor cores automatically across multiple processes that call Intel MKL in the AO mode. For example, this might be useful in MPI applications.

You can also enable this functionality using the `MKL_MIC_RESOURCE_LIMIT` environment variable (see the *Intel MKL User's Guide* for details), but the `mkl_mic_set_resource_limit` function take precedence over the environment variable.

If *fraction* is set to a valid non-zero value, Intel MKL enables automatic reservation of Intel Xeon Phi coprocessor cores.

Actual reservation is made during a call to an Intel MKL AO function and works as follows:

1. Intel MKL converts *fraction* to a number of Intel Xeon Phi coprocessor cores and tries to find cores that are not reserved by other processes.

The number of available cores can be less than the requested number. Intel MKL considers cores of all available coprocessors as a single space and can find cores on different coprocessors. However, Intel MKL tends to reserve as many cores as were requested and to reserve cores compactly (using as few coprocessors as possible).

2. Intel MKL exclusively reserves cores found in the previous step.

Intel MKL makes reservation safely across a persistent shared memory region using semaphores.

3. Intel MKL performs AO computations on reserved cores only.

You do not need to set any threading parameters for Intel Xeon Phi coprocessors, such as `MIC_OMP_NUM_THREADS` or `MIC_KMP_AFFINITY` (these settings are ignored when automatic resource sharing is enabled).

4. Upon completion of an AO call, Intel MKL releases reserved cores.

Be aware of the following features of the automatic reservation:

- Execution of Intel MKL AO functions falls back to the host if Intel MKL fails to reserve the minimum number of Intel Xeon Phi coprocessor cores that provide a benefit over executing on the host.
- The last core of Intel Xeon Phi coprocessors cannot be reserved because it is used for system processes.
- Reservation works only within a space of a single user. In other words, Intel MKL cannot share Intel Xeon Phi coprocessor resources across processes from different users.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Examples

1. One Intel Xeon Phi coprocessor with 61 cores is available on the system. One process calls `mkl_mic_set_resource_limit(1.0)` and then calls `dgemm` in AO mode. As a result, 60 Intel Xeon Phi coprocessor cores are reserved at the beginning of AO `dgemm`. Then `mkl_mic_set_resource_limit(0.3)` is invoked and AO `dgemm` is called one more time. As a result, `dgemm` is run on 18 Intel Xeon Phi coprocessor cores. During this run of AO `dgemm`, another process calls `mkl_mic_set_resource_limit(1.0)` and invokes AO `dgetrf`. Because 18 cores are reserved by the first process, only 42 cores are reserved for AO `dgetrf`.
2. Two Intel Xeon Phi coprocessors with 61 cores each are available on the system. Three processes simultaneously call `mkl_mic_set_resource_limit(0.34)` and then call `dpotrf` in AO mode. As a result, one process receives 40 cores from coprocessor 1, another process receives 40 cores from coprocessor 2, and the remaining process is given 20 cores from each of the two coprocessors for a total of 40 cores.
3. Two Intel Xeon Phi coprocessors with 58 cores each are available on the system. The user sets `MKL_MIC_PPN=4` and runs an MPI application with 4 MPI ranks. The following sequence of functions is called in each MPI process:

```
mkl_mic_set_workdivision(MKL_TARGET_MIC, 2, 0.0);
mkl_mic_set_resource_limit(MKL_MPI_PPN);
MPI_Init(...);
//calls to Intel MKL AO functions;
MPI_Finalize(...);
```

As a result, actual *fraction* is set to 0.25 for each MPI process, and each MPI process receives 14 cores on Intel Xeon Phi coprocessor 1 (because the user excluded co-processor 2 from computations by setting zero workdivision for it).

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that the fraction is set successfully. < 0 Indicates a failure to set the fraction.

[mkl_mic_get_resource_limit](#)

For computations in the Automatic Offload mode, retrieves the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.

Syntax

Fortran:

```
ierr = mkl_mic_get_resource_limit( fraction )
```

C:

```
int mkl_mic_get_resource_limit (double* fraction);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>fraction</i>	FORTRAN: REAL*8 C: double*	The fractional amount of Intel Xeon Phi coprocessor computational resources that the calling process can use for Automatic Offload (AO). Possible values: $0.0 \leq \text{fraction} \leq 1.0$.

Description

If you are using Intel MKL in the AO mode, the `mkl_mic_get_resource_limit` function retrieves the fractional amount of Intel Xeon Phi coprocessor computational resources that can be used by the calling process.

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER*4 C: int	Result status: = 0 Indicates that the fraction is successfully returned. < 0 Indicates a failure to return the fraction.

mkl_mic_set_offload_report

Turns on/off reporting of Automatic Offload profiling.

Syntax

Fortran:

```
iprev = mkl_mic_set_offload_report( enabled )
```

C:

```
int mkl_mic_set_offload_report (int enabled);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
enabled	FORTRAN: INTEGER*4 C: int	This parameter specifies whether to turn the reporting on or off. Takes values with boolean semantics: <ul style="list-style-type: none"> • 0 - Reporting of Automatic Offload profiling should be turned off. • 1 - Reporting of Automatic Offload profiling should be turned on.

Description

If the OFFLOAD_REPORT environment variable has the value of 1 or 2, the `mkl_mic_set_offload_report` function turns on/off reporting of the Automatic Offload profiling at run time. If the OFFLOAD_REPORT environment variable is not set or is set to a value different from 1 and 2, the function has no effect. If OFFLOAD_REPORT is set to 1 or 2, the reporting is turned on at a program startup. The `mkl_mic_set_offload_report` function does not change the reporting level or the value of the environment variable. Instead, it determines which Intel MKL functions called in the Automatic Offload mode produce profiling reports.

For details of the reporting level and OFFLOAD_REPORT environment variable, see the *Intel MKL User's Guide*.

Return Values

Name	Type	Description
iprev	FORTRAN: INTEGER*4 C: int	The previous value that determined whether the reporting was on or off.

Conditional Numerical Reproducibility Control

The CNR mode of Intel MKL ensures bitwise reproducible results from run to run of Intel MKL functions on a fixed number of threads for a specific Intel instruction set architecture (ISA) under the following conditions:

- Calls to Intel MKL occur in a single executable
- The number of computational threads used by the library does not change in the run

Intel MKL offers both functions and environment variables to support conditional numerical reproducibility. See the *Intel MKL User's Guide* for more information on bitwise reproducible results of computations and for details about the environment variables.

The support functions enable you to configure the CNR mode and also provide information on the current and optimal CNR branch on your system. [Usage Examples for CNR Support Functions](#) illustrate usage of these functions.

Important

Call the functions that define the behavior of CNR before any of the math library functions that they control.

Intel MKL provides named constants for use as input and output parameters of the functions instead of integer values. See [Named Constants for CNR Control](#) for a list of the named constants.

Although you can configure the CNR mode using either the support functions or the environment variables, the functions offer more flexible configuration and control than the environment variables. Settings specified by the functions take precedence over the settings specified by the environment variables.

Use Intel MKL in the CNR mode only in case a need for bitwise reproducible results is critical. Otherwise, run Intel MKL as usual to avoid performance degradation.

While you can supply unaligned input and output data to Intel MKL functions running in the CNR mode, use of aligned data is recommended. Refer to [Reproducibility Conditions](#) for more details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

[**mkl_cbwr_set**](#)

Configures the CNR mode of Intel MKL.

Syntax

Fortran:

```
status = mkl_cbwr_set( setting )
```

C:

```
int mkl_cbwr_set (int setting);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>setting</i>	FORTRAN: INTEGER*4 C: int	CNR branch to set. See Named Constants for CNR Control for a list of named constants that specify the settings.

Description

The `mkl_cbwr_set` function configures the CNR mode. In this release, it sets the CNR branch and turns on the CNR mode.

NOTE

Settings specified by the `mkl_cbwr_set` function take precedence over the settings specified by the `MKL_CBWR` environment variable.

Return Values

Name	Type	Description
<i>status</i>	FORTRAN: INTEGER*4 C: int	<p>The status of the function completion:</p> <ul style="list-style-type: none"> • <code>MKL_CBWR_SUCCESS</code> - the function completed successfully. • <code>MKL_CBWR_ERR_INVALID_INPUT</code> - an invalid setting is requested. • <code>MKL_CBWR_ERR_UNSUPPORTED_BRANCH</code> - the input value of the branch does not match the instruction set architecture (ISA) of your system. See Named Constants for CNR Control for more details. • <code>MKL_CBWR_ERR_MODE_CHANGE_FAILURE</code> - the <code>mkl_cbwr_set</code> function requested to change the current CNR branch after a call to some Intel MKL function other than a CNR function.

`mkl_cbwr_get`

Returns the current CNR settings.

Syntax

Fortran:

```
setting = mkl_cbwr_get( option )
```

C:

```
int mkl_cbwr_get (int option);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>option</i>	FORTRAN: INTEGER*4 C: int	Specifies what kind of settings is requested. Named constants define possible values of <i>option</i> : <ul style="list-style-type: none">• MKL_CBWR_BRANCH - indicates the setting of the CNR branch.• MKL_CBWR_ALL - indicates all CNR-related settings.

NOTE

This release supports no CNR settings other than branch.

Description

The `mkl_cbwr_get` function returns the requested CNR settings. If the function completes successfully and the CNR mode is turned on, `mkl_cbwr_get` returns the *specific* CNR branch.

NOTE

To turn the CNR mode on, use the `mkl_cbwr_set` function or environment variables. For more details, see the *Intel MKL User's Guide*.

Return Values

Name	Type	Description
<i>setting</i>	FORTRAN: INTEGER*4 C: int	Requested CNR settings. See Named Constants for CNR Control for a list of named constants that specify the settings. If the value of the <i>option</i> parameter is not permitted, contains the MKL_CBWR_ERR_INVALID_INPUT error code.

[Usage Examples for CNR Support Functions](#)

[Using a Fortran Interface Module for Support Functions](#)

Named Constants for CNR Control

Intel MKL provides reproducible results for a certain code branch, determined by the instruction set architecture (ISA). To define CNR code branches, use the following named constants as input/output for conditional numerical reproducibility support functions. Pass named constants to the functions instead of their values.

Named Constant	Value	Description
<code>MKL_CBWR_AUTO</code>	2	CNR mode uses the standard ISA-based dispatching model while ensuring fixed cache sizes, deterministic reductions, and static scheduling CNR mode uses the branch for the following ISA:

Named Constant	Value	Description
MKL_CBWR_COMPATIBLE	3	Intel® Streaming SIMD Extensions 2 (Intel® SSE2) without rcpss/rsqrtps instructions
MKL_CBWR_SSE2	4	Intel SSE2
MKL_CBWR_SSE3	5	DEPRECATED. Intel® Streaming SIMD Extensions 3 (Intel® SSE3). This setting is kept for backward compatibility and is equivalent to MKL_CBWR_SSE2.
MKL_CBWR_SSSE3	6	Supplemental Streaming SIMD Extensions 3 (SSSE3)
MKL_CBWR_SSE4_1	7	Intel® Streaming SIMD Extensions 4-1 (SSE4-1)
MKL_CBWR_SSE4_2	8	Intel® Streaming SIMD Extensions 4-2 (SSE4-2)
MKL_CBWR_AVX	9	Intel® Advanced Vector Extensions (Intel® AVX)
MKL_CBWR_AVX2	10	Intel® Advanced Vector Extensions 2 (Intel® AVX2)

When specifying the CNR branch with the named constants, be aware of the following:

- Reproducible results are provided under [Reproducibility Conditions](#).
- Settings other than `MKL_CBWR_AUTO` or `MKL_CBWR_COMPATIBLE` are available only for Intel processors.
- Intel and Intel compatible CPUs have a few instructions, such as approximation instructions `rcpps/rsqrtps`, that may return different results. Setting the branch to `MKL_CBWR_COMPATIBLE` ensures that Intel MKL does not use these instructions and forces a single Intel SSE2 only code path to be executed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

[Usage Examples for CNR Support Functions](#)

Reproducibility Conditions

To get reproducible results from run to run, ensure that the number of threads is fixed and constant. Specifically:

- If you are running your program on different processors, explicitly specify the number of threads.
- To ensure that your application has deterministic behavior with OpenMP* parallelization and does not adjust the number of threads dynamically at run time, set `MKL_DYNAMIC` and `OMP_DYNAMIC` to FALSE. This is especially needed if you are running your program on different systems.
- As usual, you should align your data, even in CNR mode, to obtain the best possible performance. While CNR mode also fully supports unaligned input and output data, the use of it might reduce the performance of some Intel MKL functions on earlier Intel processors. To ensure proper alignment of arrays, allocate memory for them using `mkl_malloc/mkl_calloc`.

- Conditional Numerical Reproducibility does not ensure that bitwise-identical NaN values are generated when the input data contains NaN values.
- If dynamic memory allocation fails on one run but succeeds on another run, you may fail to get reproducible results between these two runs.

Usage Examples for CNR Support Functions

The following examples illustrate usage of support functions for conditional numerical reproducibility.

Setting Automatically Detected CNR Branch in C

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
    /* Find the available MKL_CBWR_BRANCH automatically */
    my_cbwr_branch = mkl_cbwr_get_auto_branch();
    /* User code without Intel MKL calls */
    /* Piece of the code where CNR of Intel MKL is needed */
    /* The performance of Intel MKL functions might be reduced for CNR mode */
    if (mkl_cbwr_set(my_cbwr_branch) != MKL_CBWR_SUCCESS) {
        printf("Error in setting MKL_CBWR_BRANCH! Aborting...\n");
        return;
    }
    /* CNR calls to Intel MKL + any other code */
}
```

Setting Automatically Detected CNR Branch in Fortran

```
PROGRAM MAIN
INCLUDE 'mkl.fi'
INTEGER*4 MY_CBWR_BRANCH
C Find the available MKL_CBWR_BRANCH automatically
  MY_CBWR_BRANCH = MKL_CBWR_GET_AUTO_BRANCH()
C User code without Intel MKL calls
C Piece of the code where CNR of Intel MKL is needed
C The performance of Intel MKL functions might be reduced for CNR mode
  IF (MKL_CBWR_SET (MY_CBWR_BRANCH) .NE. MKL_CBWR_SUCCESS) THEN
    PRINT *, 'Error in setting MKL_CBWR_BRANCH! Aborting...'
    RETURN
  ENDIF
C CNR calls to Intel MKL + any other code
END
```

Use of the `mkl_cbwr_get` Function in C

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
    /* Piece of the code where CNR of Intel MKL is analyzed */
    my_cbwr_branch = mkl_cbwr_get(MKL_CBWR_BRANCH);
    switch (my_cbwr_branch) {
        case MKL_CBWR_AUTO:
            /* actions in case of automatic mode */
            break;
        case MKL_CBWR_SSSE3:
```

```

        /* actions for SSSE3 code */
        break;
    default:
        /* all other cases */
    }
/* User code */
}

```

Use of the mkl_cbwr_get Function in Fortran

```

PROGRAM MAIN
INCLUDE 'mkl.fi'
INTEGER*4 MY_CBWR_BRANCH
C Piece of the code where CNR of Intel MKL is analyzed
    MY_CBWR_BRANCH = MKL_CBWR_GET(MKL_CBWR_BRANCH)
    IF (MY_CBWR_BRANCH .EQ. MKL_CBWR_AUTO) THEN
C actions in case of automatic mode
    ELSE IF (MY_CBWR_BRANCH .EQ. MKL_CBWR_SSSE3) THEN
C actions for SSSE3 code
    ELSE
C all other cases
    ENDIF
C User code
    END

```

Miscellaneous

mkl_progress

Provides progress information.

Syntax

Fortran:

```
stopflag = mkl_progress( thread, step, stage )
```

C:

```
int mkl_progress (int* thread, int* step, char* stage, int lstage);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
thread	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The number of the thread the progress routine is called from. 0 is passed for sequential code.

Name	Type	Description
		C: Pointer to the number of the thread the progress routine is called from. 0 is passed for sequential code.
<i>step</i>	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation. C: Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<i>stage</i>	FORTRAN: CHARACTER* (*) C: const char*	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
C: <i>lstage</i> int		The length of a stage string excluding the trailing NULL character.

Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

The progress function `mkl_progress` is regularly called from some LAPACK and DSS/PARDISO functions during the computation. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

Return Values

Name	Type	Description
<i>stopflag</i>	FORTRAN: INTEGER C: int	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Application Notes

Note that `mkl_progress` is a Fortran routine, that is, to redefine the progress routine from C, the name should be spelt differently, parameters should be passed by reference, and an extra parameter meaning the length of the stage string should be considered. The stage string is not terminated with the NULL character. The C interface of the progress routine is as follows:

```
int mkl_progress_( int* thread, int* step, char* stage, int lstage ); // Linux* OS or OS X*
int MKL_PROGRESS( int* thread, int* step, char* stage, int lstage ); // Windows* OS
```

Example

The following example in Fortran and C languages prints the progress information to the standard output device:

Fortran:

```
integer function mkl_progress( thread, step, stage )
integer*4 thread, step
character*(*) stage
print*, 'Thread:', thread, ',stage:', stage, ',step:', step
```

```
mkl_progress = 0
return
end
```

C:

```
#include <stdio.h>
#include <string.h>
#define BUFLEN 16
int mkl_progress_( int* ithr, int* step, char* stage, int lstage )
{
    char buf[BUFLEN];
    if( lstage >= BUFLEN ) lstage = BUFLEN-1;
    strncpy( buf, stage, lstage );
    buf[lstage] = '\0';
    printf( "In thread %i, at stage %s, steps passed %i\n", *ithr, buf, *step );
    return 0;
}
```

mkl_enable_instructions

Enables dispatching for new Intel® architectures.

Syntax

Fortran:

```
irc = mkl_enable_instructions(isa)
```

C:

```
int mkl_enable_instructions (int isa);
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

C Include Files

- mkl.h

Input Parameters

Name	Type	Description
isa	FORTRAN: INTEGER*4 C: int	<p>The Intel instruction-set architecture (ISA) for which to enable dispatching.</p> <p>Possible values:</p> <ul style="list-style-type: none"> • MKL_ENABLE_AVX512 - Requests to enable dispatching Intel® Advanced Vector Extensions 512 (Intel® AVX-512) on Intel® Xeon® processors. • MKL_ENABLE_AVX512_MIC - Requests to enable dispatching Intel AVX-512 on Intel® Xeon Phi™ processors and coprocessors.

For more information about the Intel AVX-512 instructions, refer to <https://software.intel.com/en-us/blogs/2013/avx-512-instructions>.

Description

If automatic dispatching is not yet enabled for the specified ISA, `mkl_enable_instructions` enables Intel MKL to dispatch the instruction set to Intel processors when the library runs on hardware (or simulation) that supports this instruction set.

Return Values

Name	Type	Description
<code>irc</code>	<code>FORTRAN: INTEGER*4</code> <code>C: int</code>	<p>Value reflecting usage status of the specified instruction set:</p> <p>1 - Intel MKL uses the specified instruction set if the hardware supports it.</p> <p>0 - The request is rejected. Most likely, <code>mkl_enable_instructions</code> has been called after another Intel MKL function.</p>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_set_env_mode`

Sets up the mode that ignores environment settings specific to Intel MKL.

Syntax

Fortran:

```
current_mode = mkl_set_env_mode( mode )
```

C:

```
int mkl_set_env_mode(int mode);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN: INTEGER*4 C: int	Specifies what mode to set. For details, see Description . Possible values: <ul style="list-style-type: none"> • 0 - Do nothing. • Use this value to query the current environment mode. • 1 - Make Intel MKL ignore environment settings specific to the library.

Description

In the default *environment mode*, Intel MKL can control its behavior using environment variables for threading, memory management, Conditional Numerical Reproducibility, automatic offload, and so on. The `mkl_set_env_mode` function sets up the environment mode that ignores all settings specified by Intel MKL environment variables except `MIC_LD_LIBRARY_PATH` and `MKLROOT`.

Return Values

Name	Type	Description
<i>current_mode</i>	FORTRAN: INTEGER*4 C: int	Environment mode that was used before the function call: <ul style="list-style-type: none"> • 0 - Default • 1 - Ignore environment settings specific to Intel MKL.

`mkl_verbose`

Enables or disables Intel MKL Verbose mode.

Syntax

Fortran:

```
status = mkl_verbose(enable)
```

C:

```
int mkl_verbose (int enable);
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

C Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>enable</i>	FORTRAN: INTEGER*4 C: int	Desired state of the Intel MKL Verbose mode. Indicates whether printing Intel MKL function call information should be turned on or off. Possible values:

Name	Type	Description
		<ul style="list-style-type: none">• 0 - disable the Verbose mode.• 1 - enable the Verbose mode.

Description

This function enables or disables the Intel MKL Verbose mode, in which computational functions print call description information. For details of the Verbose mode, see the *Intel MKL User's Guide*, available in the Intel® Software Documentation Library.

NOTE

The setting for the Verbose mode specified by the `mkl_verbose` function takes precedence over the setting specified by the `MKL_VERBOSE` environment variable.

Return Values

Name	Type	Description
<code>status</code>	<code>FORTRAN: INTEGER*4</code> <code>C: int</code>	<ul style="list-style-type: none">• If the requested operation completed successfully, contains previous state of the verbose mode:<ul style="list-style-type: none">• 0 - disabled• 1 - enabled• If the function failed to complete the operation because of an incorrect input parameter, equals -1.

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScalAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

- | | |
|-----|--|
| m | (input) INTEGER. The number of matrix rows to be operated on. |
| n | (input) INTEGER. The number of matrix columns to be operated on. |
| a | (input/output) TYPE (depends on routine), array of dimension (lda, n).
A pointer to the beginning of the (sub)array to be sent. |

lda

(input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by *m*, *n*, and *lda*, as above, but they have two additional parameters as well. These parameters are:

uplo

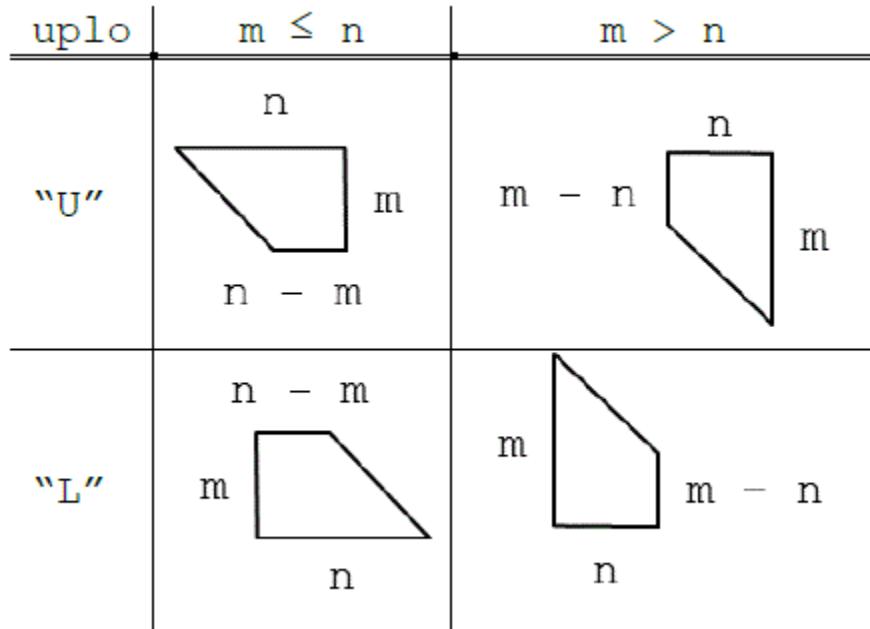

(input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

diag

(input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

Repeatability and Coherence

Floating point computations are not exact on almost all modern architectures. This lack of precision is particularly problematic in parallel operations. Since floating point computations are inexact, algorithms are classified according to whether they are *repeatable* and to what degree they guarantee *coherence*.

- Repeatable: a routine is repeatable if it is guaranteed to give the same answer if called multiple times with the same parallel configuration and input.
- Coherent: a routine is coherent if all processes selected to receive the answer get identical results.

NOTE

Repeatability and coherence do not effect correctness. A routine may be both incoherent and non-repeatable, and still give correct output. But inaccuracies in floating point calculations may cause the routine to return differing values, all of which are equally valid.

Repeatability

Because the precision of floating point arithmetic is limited, it is not truly associative: $(a + b) + c$ might not be the same as $a + (b + c)$. The lack of exact arithmetic can cause problems whenever the possibility for reordering of floating point calculations exists. This problem becomes prevalent in parallel computing due to race conditions in message passing. For example, consider a routine which sums numbers stored on different processes. Assume this routine runs on four processes, with the numbers to be added being the process numbers themselves. Therefore, process 0 has the value 0:0, process 1 has the value 1:0, and so on.

One algorithm for the computation of this result is to have all processes send their process numbers to process 0; process 0 adds them up, and sends the result back to all processes. So, process 0 would add a number to 0:0 in the first step. If receiving the process numbers is ordered so that process 0 always receives the message from process 1 first, then 2, and finally 3, this results in a repeatable algorithm, which evaluates the expression $((0:0+1:0)+2:0)+3:0$.

However, to get the best parallel performance, it is better not to require a particular ordering, and just have process 0 add the first available number to its value and continue to do so until all numbers have been added in. Using this method, a race condition occurs, because the order of the operation is determined by the order in which process 0 receives the messages, which can be effected by any number of things. This implementation is not repeatable, because the answer can vary between invocations, even if the input is the same. For instance, one run might produce the sequence $((0:0+1:0)+2:0)+3:0$, while a subsequent run could produce $((0:0+2:0)+1:0)+3:0$. Both of these results are correct summations of the given numbers, but because of floating point roundoff, they might be different.

Coherence

A routine produces coherent output if all processes are guaranteed to produce the exact same results. Obviously, almost no algorithm involving communication is coherent if communication can change the values being communicated. Therefore, if the parallel system being studied cannot guarantee that communication between processes preserves values, no routine is guaranteed to produce coherent results.

If communication is assumed to be coherent, there are still various levels of coherent algorithms. Some algorithms guarantee coherence only if floating point operations are done in the exact same order on every node. This is *homogeneous coherence*: the result will be coherent if the parallel machine is homogeneous in its handling of floating point operations.

A stronger assertion of coherence is *heterogeneous coherence*, which does not require all processes to have the same handling of floating point operations.

In general, a routine that is homogeneous coherent performs computations redundantly on all nodes, so that all processes get the same answer only if all processes perform arithmetic in the exact same way, whereas a routine which is heterogeneous coherent is usually constrained to having one process calculate the final result, and broadcast it to all other processes.

Example of Incoherence

An incoherent algorithm is one which does not guarantee that all processes get the same result even on a homogeneous system with coherent communication. The previous example of summing the process numbers demonstrates this kind of behavior. One way to perform such a sum is to have every process broadcast its number to all other processes. Each process then adds these numbers, starting with its own. The calculations performed by each process receives would then be:

- Process 0 : $((0:0+1:0)+2:0)+3:0$
- Process 1 : $((1:0+2:0)+3:0)+0:0$
- Process 2 : $((2:0+3:0)+0:0)+1:0$
- Process 3 : $((3:0+0:0)+1:0)+0:0$

All of these results are equally valid, and since all the results might be different from each other, this algorithm is incoherent. Notice, however, that this algorithm is repeatable: each process will get the same result if the algorithm is called again on the same data.

Example of Homogeneous Coherence

Another way to perform this summation is for all processes to send their data to all other processes, and to ensure the result is not incoherent, enforce the ordering so that the calculation each node performs is $((0:0 + 1:0) + 2:0) + 3:0$. This answer is the same for all processes only if all processes do the floating point arithmetic in the same way. Otherwise, each process may make different floating point errors during the addition, leading to incoherence of the output. Notice that since there is a specific ordering to the addition, this algorithm is repeatable.

Example of Heterogeneous Coherence

In the final example, all processes send the result to process 0, which adds the numbers and broadcasts the result to the rest of the processes. Since one process does all the computation, it can perform the operations in any order and it will give coherent results as long as communication is itself coherent. If a particular order is not forced on the the addition, the algorithm will not be repeatable. If a particular order is forced, it will be repeatable.

Summary

Repeatability and coherence are separate issues which may occur in parallel computations. These concepts may be summarized as:

- Repeatability: The routine will yield the exact same result if it run multiple times on an identical problem. Each process may get a different result than the others (i.e., repeatability does not imply coherence), but that value will not change if the routine is invoked multiple times.
- Homogeneous coherence: All processes selected to possess the result will receive the exact same answer if:
 - Communication does not change the value of the communicated data.
 - All processes perform floating point arithmetic exactly the same.
- Heterogeneous coherence: All processes will receive the exact same answer if communication does not change the value of the communicated data.

In general, lack of the associative property for floating point calculations may cause both incoherence and non-repeatability. Algorithms that rely on redundant computations are at best homogeneous coherent, and algorithms in which one process broadcasts the result are heterogeneous coherent. Repeatability does not imply coherence, nor does coherence imply repeatability.

Since these issues do not effect the correctness of the answer, they can usually be ignored. However, in very specific situations, these issues may become very important. A stopping criteria should not be based on incoherent results, for instance. Also, a user creating and debugging a parallel program may wish to enforce repeatability so the exact same program sequence occurs on every run.

In the BLACS, coherence and repeatability apply only in the context of the combine operations. As mentioned above, it is possible to have communication which is incoherent (for instance, two machines which store floating point numbers differently may easily produce incoherent communication, since a number stored on machine A may not have a representation on machine B). However, the BLACS cannot control this issue. Communication is assumed to be coherent, which for communication implies that it is also repeatable.

For combine operations, the BLACS allow you to set flags indicating that you would like combines to be repeatable and/or heterogeneous coherent (see `blacs_get` and `blacs_set` for details on setting these flags).

If the BLACS are instructed to guarantee heterogeneous coherency, the BLACS restrict the topologies which can be used so that one process calculates the final result of the combine, and if necessary, broadcasts the answer to all other processes.

If the BLACS are instructed to guarantee repeatability, orderings will be enforced in the topologies which are selected. This may result in loss of performance which can range from negligible to serious depending on the application.

A couple of additional notes are in order. Incoherence and nonrepeatability can arise as a result of floating point errors, as discussed previously. This might lead you to suspect that integer calculations are always repeatable and coherent, since they involve exact arithmetic. This is true if overflow is ignored. With overflow taken into consideration, even integer calculations can display incoherence and non-repeatability. Therefore, if the repeatability or coherence flags are set, the BLACS treats integer combines the same as floating point combines in enforcing repeatability and coherence guards.

By their nature, maximization and minimization should always be repeatable. In the complex precisions, however, the real and imaginary parts must be combined in order to obtain a magnitude value used to do the comparison (this is typically $|r| + |i|$ or $\text{sqr}(r^2 + i^2)$). This allows for the possibility of heterogeneous incoherence. The BLACS therefore restrict which topologies are used for maximization and minimization in the complex routines when the heterogeneous coherence flag is set.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max/min/sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4×2 array of inputs produces a 4×2 answer array.

When the `max/min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

BLACS Combines

Routine name	Results of operation
<code>gamx2d</code>	Entries of result matrix will have the value of the greatest absolute value found in that position.
<code>gamm2d</code>	Entries of result matrix will have the value of the smallest absolute value found in that position.

Routine name	Results of operation
gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (lda, n). Matrix to be compared with to produce the maximum.
lda	INTEGER. The leading dimension of the matrix A, that is, the distance between two successive elements in a matrix row.
rcflag	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
rdest	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
cdest	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra INTEGER array (*rcflag*, *n*).
If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* × *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca INTEGER array (*rcflag*, *n*).
If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* × *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

scope CHARACTER*1. Indicates what scope the combine should proceed on.
Limited to ROW, COLUMN, or ALL.

top CHARACTER*1. Communication pattern to use during the combine operation.

<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> \times <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> \times <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

[Examples of BLACS Routines Usage](#)

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
----------	--

Description

This routine performs element-wise summation, that is, each element of matrix A is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
    SEND TO PROCESS 1
    RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
```

```

SEND TO PROCESS 0
RECV FROM PROCESS 0
END IF

```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template ?xxyy2d, where the letter in the ? position indicates the data type being sent, xx is replaced to indicate the shape of the matrix, and the yy positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

BLACS Point To Point Communication

Routine name	Operation performed
gesd2d	Take the indicated matrix and send it to the destination process.
trsd2d	
gerv2d	Receive a message from the process into the matrix.
trrv2d	

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector X , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 1, 0)
    CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 0, 0)
    CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER.
	The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER.
	The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

[Examples of BLACS Routines Usage](#)

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

```
call dtrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER.
	The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER.
	The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.
	The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER.
	The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (<i>lda, n</i>) to receive the incoming message into.
----------	---

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix A . This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A .

See Also

[Examples of BLACS Routines Usage](#)

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.
	The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER.
	The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	--

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix A . This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A .

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with SCOPE = 'ALL' must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template ?xxyy2d, where the letter in the ? position indicates the data type being sent, xx is replaced to indicate the shape of the matrix, and the yy positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

BLACS Broadcast Routines

Routine name	Operation performed
gebs2d	Start a broadcast along a scope.
trbs2d	
gebr2d	Receive and participate in a broadcast along a scope.
trbr2d

Notice revision #20110804

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

[Examples of BLACS Routines Usage](#)

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

```
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo</i> , <i>diag</i> , <i>m</i> , <i>n</i> , <i>a</i> , <i>lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m</i> , <i>n</i> , <i>lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix A . Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.
	The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER.
	The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix A . Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

Initialization

Destruction

Information Purposes

Miscellaneous Tasks.

Initialization Routines

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

BLACS Initialization Routines

Routine name	Operation performed
blacs_pinfo	Returns the number of processes available for use.
blacs_setup	Allocates virtual machine and spawns processes.
blacs_get	Gets values that BLACS use for internal defaults.
blacs_set	Sets values that BLACS use for internal defaults.
blacs_gridinit	Assigns available processes into BLACS process grid.
blacs_gridmap	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

<i>mypnum</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, $nrows * ncols \leq nprocs$. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

See Also

Examples of BLACS Routines Usage

[blacs_setup](#)

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs INTEGER. On the process spawned from the keyboard rather than from pvmspawn, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to [blacs_pinfo](#). The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

See Also

[Examples of BLACS Routines Usage](#)

[blacs_get](#)

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

icontxt INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be returned in <i>val</i> . Present options are:
	<ul style="list-style-type: none"> • <i>what</i> = 0 : Handle indicating default system context. • <i>what</i> = 1 : The BLACS message ID range. • <i>what</i> = 2 : The BLACS debug level the library was compiled with. • <i>what</i> = 10 : Handle indicating the system context used to define the BLACS context whose handle is <i>icontxt</i>. • <i>what</i> = 11 : Number of rings multiring broadcast topology is presently using. • <i>what</i> = 12 : Number of branches general tree broadcast topology is presently using. • <i>what</i> = 13 : Number of rings multiring combine topology is presently using. • <i>what</i> = 14 : Number of branches general tree combine topology is presently using. • <i>what</i> = 15 : Whether topologies are forced to be repeatable or not. A non-zero return value indicates that topologies are being forced to be repeatable. See Repeatability and Coherence for more information about repeatability. • <i>what</i> = 16 : Whether topologies are forced to be heterogenous coherent or not. A non-zero return value indicates that topologies are being forced to be heterogenous coherent. See Repeatability and Coherence for more information about coherence.

Output Parameters

<i>val</i>	INTEGER. The value of the BLACS internal.
------------	---

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into [blacs_gridinit](#) or [blacs_gridmap](#).

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use [blacs_get](#) to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

[blacs_get](#) returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for TOP = 'M' (multiring broadcast/combine)
- The number of branches for TOP = 'T' (general tree broadcast/general tree gather).
- Whether topologies are being forced to be repeatable or heterogenous coherent.

See Also

[Examples of BLACS Routines Usage](#)

[blacs_set](#)

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

<i>icontxt</i>	INTEGER. For values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be set. Present values are: <ul style="list-style-type: none"> • 1 = Set the BLACS message ID range • 11 = Number of rings for multiring broadcast topology to use • 12 = Number of branches for general tree broadcast topology to use • 13 = Number of rings for multiring combine topology to use • 14 = Number of branches for general tree combine topology to use • 15 = Force topologies to be repeatable or not • 16 = Force topologies to be heterogenous coherent or not
<i>val</i>	INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on *what* values:

<i>what</i> = 1	Setting the BLACS message ID range. If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code> . Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>icontxt</i> is ignored, and <i>val</i> is defined as: <code>VAL (input) INTEGER array of dimension (2)</code> <code>VAL(1)</code> : The smallest message ID (also called message type or message tag) the BLACS should use. <code>VAL(2)</code> : The largest message ID (also called message type or message tag) the BLACS should use.
<i>what</i> = 11	Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: <code>VAL (input) INTEGER array of dimension (1)</code> <code>VAL(1)</code> : The number of rings for multiring topology to use.
<i>what</i> = 12	Set number of branches for TOP = 'T' (general tree broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: <code>VAL (input) INTEGER array of dimension (1)</code> <code>VAL(1)</code> : The number of branches for general tree topology to use.

what = 13 Set number of rings for `TOP = 'M'` (multiring combine). This quantity is tied to a context, so `ictxt` is used, and `val` is defined as:

`VAL` (input) INTEGER array of dimension (1)

`VAL(1)` : The number of rings for multiring topology to use.

what = 14 Set number of branches for `TOP = 'T'` (general tree gather). This quantity is tied to a context, so `ictxt` is used, and `val` is defined as:

`VAL` (input) INTEGER array of dimension (1)

`VAL(1)` : The number of branches for general tree topology to use.

what = 15 Force topologies to be repeatable or not (see [Repeatability and Coherence](#) for more information about repeatability).

`VAL` (input) INTEGER array of dimension (1)

`VAL(1) = 0` (default) Topologies are not required to be repeatable.

`VAL(1) ≠ 0` All used topologies are required to be repeatable, which might degrade performance.

what = 16 Force topologies to be heterogenous coherent or not (see [Repeatability and Coherence](#) for more information about coherence).

`VAL` (input) INTEGER array of dimension (1)

`VAL(1) = 0` (default) Topologies are not required to be heterogenous coherent.

`VAL(1) ≠ 0` All used topologies are required to be heterogenous coherent, which might degrade performance.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, layout, nprow, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>layout</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: <ul style="list-style-type: none"> • 'R' : Use row-major natural ordering • 'C' : Use column-major natural ordering • ELSE : Use row-major natural ordering
<i>nprov</i>	INTEGER. Indicates how many process rows the process grid should contain.

<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.
--------------	--

Output Parameters

<i>ictxt</i>	INTEGER. Integer handle to the created BLACS context.
--------------	---

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple `nproc × ncol` process grid. This process grid uses the first `nproc * ncol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( ictxt, usermap, ldumap, nproc, npcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
--------------	---

<i>usermap</i>	INTEGER. Array, dimension (<i>ldumap</i> , <i>npcol</i>), indicating the process-to-grid mapping.
----------------	---

<i>ldumap</i>	INTEGER. Leading dimension of the 2D array <i>usermap</i> . <i>ldumap</i> \geq <i>nproc</i> .
---------------	---

<i>nproc</i>	INTEGER. Indicates how many process rows the process grid should contain.
--------------	---

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontext INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in {*i*, *j*} of the process grid. On most distributed systems, this process number is a machine defined number between 0 ... *nproc*-1. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a gridmap where the first *nproc* * *npcol* processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

BLACS Destruction Routines

Routine name	Operation performed
blacs_freebuff	Frees BLACS buffer.
blacs_gridexit	Frees a BLACS context.

Routine name	Operation performed
blacs_abort	Aborts all processes.
blacs_exit	Frees all BLACS contexts and releases all allocated memory.

blacs_freebuff*Frees BLACS buffer.***Syntax**

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context.
<i>wait</i>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit*Frees a BLACS context.***Syntax**

```
call blacs_gridexit( icontxt )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context to be freed.
----------------	---

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort*Aborts all processes.***Syntax**

```
call blacs_abort( icontxt, errornum )
```

Input Parameters

<i>icontext</i>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
<i>errornum</i>	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

<i>continue</i>	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If <i>continue</i> is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.
-----------------	---

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM send/recvs will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

blacs_gridinfo

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( icontxt, nprow, npcol, myrow, mycol )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

Output Parameters

nprow INTEGER. Number of process rows in the current process grid.

npcol INTEGER. Number of process columns in the current process grid.

myrow INTEGER. Row coordinate of the calling process in the process grid.

mycol INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also

[Examples of BLACS Routines Usage](#)

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( icontxt, prow, pcol )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

prow INTEGER. Row coordinate of the process the system process number of which is to be determined.

pcol INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {PROW, PCOL} in the process grid.

See Also

[Examples of BLACS Routines Usage](#)

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( icontxt, pnum, prow, pcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <i>tid</i> for PVM.

Output Parameters

<i>prow</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Miscellaneous Routines

This section describes `blacs_barrier` routine.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

`blacs_barrier`

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Parameter that indicates whether a process row (<i>scope='R'</i>), column (<i>'C'</i>), or entire grid (<i>'A'</i>) will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```

Data Fitting Functions

Data Fitting functions in Intel® MKL provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see [Mathematical Conventions](#).

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

Task Creation and Initialization Routines - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

Task Configuration Routines - routines that set, modify, or query parameters in an existing Data Fitting task.

Computational Routines - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

Task Destructors - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The \${MKL}/include directory of the Intel® MKL contains the following Data Fitting header files:

- C/C++: mkl_df.h
- Fortran: mkl_df.f90 and mkl_df.f77

You can find examples that demonstrate C/C++ and Fortran usage of Data Fitting routines in the \${MKL}/examples/datafittingc directory and the \${MKL}/examples/datafittingf directory, respectively.

Naming Conventions

The Fortran interfaces of the Data Fitting functions are in lowercase, while the names of the types and constants are in uppercase.

The C/C++ interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

df[datatype]<base_name>

where

- df is a prefix indicating that the routine belongs to the Data Fitting component of Intel MKL.
- [datatype] field specifies the type of the input and/or output data and can be s (for the single precision real type), d (for the double precision real type), or i (for the integer type). This field is omitted in the names of the routines that are not data type dependent.

- <base_name> field specifies the functionality the routine performs. For example, this field can be NewTask1D, Interpolate1D, or DeleteTask.

Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
Fortran: TYPE(DF_TASK)	Pointer to a task
C: DFTaskPtr	

NOTE

The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the Intel® MKL User's Guide.

Mathematical Conventions for Data Fitting Functions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The Subbotin quadratic spline definition follows the conventions of [StechSub76]. The quasi-uniform partition definition is based on [Schumaker2007].

Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$, where	$\{x_i\}_{i=1,\dots,n}$, where $a = x_1 < x_2 < \dots < x_n = b$
<ul style="list-style-type: none"> • x_i denotes breakpoints. • $[x_i, x_{i+1})$ denotes a sub-interval (cell) of size $\Delta_i = x_{i+1} - x_i$. 	
Quasi-uniform partition of interpolation interval $[a, b]$	<p>Partition $\{x_i\}_{i=1,\dots,n}$ which meets the constraint with a constant C defined as</p> $1 \leq M / m \leq C,$ <p>where</p> <ul style="list-style-type: none"> • $M = \max_{i=1,\dots,n-1} (\Delta_i)$ • $m = \min_{i=1,\dots,n-1} (\Delta_i)$ • $\Delta_i = x_{i+1} - x_i$
Vector-valued function of dimension p being fit	$f(x) = (f_1(x), \dots, f_p(x))$
Piecewise polynomial (PP) function f of order $k+1$	$f(x) := P_i(x), \text{ if } x \in [x_i, x_{i+1}), i = 1, \dots, n-1$ <p>where</p> <ul style="list-style-type: none"> • $\{x_i\}_{i=1,\dots,n}$ is a strictly increasing sequence of breakpoints. • $P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$ is a polynomial of degree k (order $k+1$) over the interval $x \in [x_i, x_{i+1})$.

Concept	Mathematical Notation
Function p agrees with function f at the points $\{x_i\}_{i=1,\dots,n}$.	For every point ζ in sequence $\{x_i\}_{i=1,\dots,n}$ that occurs m times, the equality $p^{(i-1)}(\zeta) = f^{(i-1)}(\zeta)$ holds for all $i = 1, \dots, m$, where $p^{(i)}(t)$ is the derivative of the i -th order.
The k -th divided difference of function f at points x_i, \dots, x_{i+k} . This difference is the leading coefficient of the polynomial of order $k+1$ that agrees with f at x_i, \dots, x_{i+k} .	$[x_i, \dots, x_{i+k}]f$ In particular, <ul style="list-style-type: none"> • $[x_1]f = f(x_1)$ • $[x_1, x_2]f = (f(x_1) - f(x_2)) / (x_1 - x_2)$
A k -order derivative of interpolant $f(x)$ at interpolation site τ .	$f^{(k)}(\tau)$

Interpolants to the Function f at x_1, \dots, x_n and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i),$ where <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = [x_i, x_{i+1}]f$ • $i = 1, \dots, n-1$
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2, x \in [x_i, x_{i+1}]$ Coefficients $c_{1,i}, c_{2,i}$, and $c_{3,i}$ depend on the conditions: <ul style="list-style-type: none"> • $P_i(x_i) = f(x_i)$ • $P_i(x_{i+1}) = f(x_{i+1})$ • $P_i((x_{i+1} + x_i) / 2) = v_{i+1}$ where parameter v_{i+1} depends on the interpolant being continuously differentiable: $P_{i-1}^{(1)}(x_i) = P_i^{(1)}(x_i)$
Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + d_{3,i}((x - t_i)_+)^2,$ where <ul style="list-style-type: none"> • $x \in [t_i, t_{i+1}]$ • $\{t_i\}_{i=1,\dots,n+1}$ is a sequence of knots such that <ul style="list-style-type: none"> • $t_1 = x_1, t_{n+1} = x_n$ • $t_i \in (x_{i-1}, x_i), i = 2, \dots, n$ • $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$ Coefficients $c_{1,i}, c_{2,i}, c_{3,i}$, and $d_{3,i}$ depend on the following conditions: <ul style="list-style-type: none"> • $P_i(x_i) = f(x_i), P_i(x_{i+1}) = f(x_{i+1})$ • $P(x)$ is a continuously differentiable polynomial of the second degree on $[t_i, t_{i+1}], i = 1, \dots, n$.
Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ where

Concept	Mathematical Notation
	<ul style="list-style-type: none"> • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = f^{(1)}(x_i)$
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$
	where
	<ul style="list-style-type: none"> • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = (\Delta x_i[x_{i-1}, x_i]f + \Delta x_{i-1}[x_i, x_{i+1}]f) / (\Delta x_i + \Delta x_{i+1})$
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$
	where
	<ul style="list-style-type: none"> • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = (w_{i+1}[x_{i-1}, x_i]f + w_{i-1}[x_i, x_{i+1}]f) / (w_{i+1} + w_{i-1}),$
	where
	$w_i = [x_i, x_{i+1}]f - [x_{i-1}, x_i]f $
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$
	where
	<ul style="list-style-type: none"> • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • Parameter s_i depends on the condition that the interpolant is twice continuously differentiable: $P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i).$
Not-a-knot boundary condition.	Parameters s_1 and s_n provide $P_1 = P_2$ and $P_{n-1} = P_n$, so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$

Concept	Mathematical Notation
Look-up interpolator for discrete set of points $(x_1, y_1), \dots, (x_n, y_n)$.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x = x_2 \\ \dots \\ y_n, & \text{if } x = x_n \\ \text{error, otherwise} \end{cases}$
Step-wise constant continuous right interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x_1 \leq x < x_2 \\ y_2, & \text{if } x_2 \leq x < x_3 \\ \dots \\ y_{n-1}, & \text{if } x_{n-1} \leq x < x_n \\ y_n, & \text{if } x = x_n \end{cases}$
Step-wise constant continuous left interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \leq x_2 \\ y_3, & \text{if } x_2 < x \leq x_3 \\ \dots \\ y_n, & \text{if } x_{n-1} < x \leq x_n \end{cases}$

Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D( task, s_order, c_type, bc_type, bc, ic_type, ic,
                           scoeff, scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
                           dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfDeleteTask( &task );
```

Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines.

You can get both C and Fortran source code in the `.\examples\datafittingc` subdirectory and the `.\examples\datafittingf` subdirectory of the Intel MKL installation directory to perform similar examples.

The following C example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

C Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500                                /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
{
    int status;                      /* Status of a Data Fitting operation */
    DFTaskPtr task;                  /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;                     /* The size of partition x */
    double x[N];                    /* Partition x */
    MKL_INT xhint;                  /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;                     /* Function dimension */
    double y[N];                    /* Function values at the breakpoints */
    MKL_INT yhint;                  /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT s_order;                /* Spline order */

    MKL_INT ic_type;                /* Type of internal conditions */
    double* ic;                     /* Array of internal conditions */
    MKL_INT bc_type;                /* Type of boundary conditions */
    double* bc;                     /* Array of boundary conditions */

    double scoeff[(N-1)* SPLINE_ORDER]; /* Array of spline coefficients */
    MKL_INT scoeffhint;             /* Additional information about the coefficients */

    /* Initialize the partition */
    nx = N;
    /* Set values of partition x */
    ...
    xhint = DF_NO_HINT;            /* No additional information about the function is provided.
                                    By default, the partition is non-uniform. */
    /* Initialize the function */
    ny = 1;                       /* The function is scalar. */

    /* Set function values */
    ...
    yhint = DF_NO_HINT;            /* No additional information about the function is provided. */

    /* Create a Data Fitting task */
    status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );

    /* Check the Data Fitting operation status */
    ...

    /* Initialize spline parameters */
    s_order = DF_PP_LINEAR;        /* Spline is of the second order. */
    s_type = DF_PP_DEFAULT;        /* Spline is of the default type. */

    /* Define internal conditions for linear spline construction (none in this example) */
    ic_type = DF_NO_IC;
```

```

ic = NULL;

/* Define boundary conditions for linear spline construction (none in this example) */
bc_type = DF_NO_BC;
bc = NULL;
scoeffhint = DF_NO_HINT; /* No additional information about the spline. */

/* Set spline parameters in the Data Fitting task */
status = dfdEditPPSpline1D( task, s_order, s_type, bc_type, bc, ic_type,
                            ic, scoeff, scoeffhint );

/* Check the Data Fitting operation status */
...

/* Use a standard computation method to construct a linear spline: */
/* P_i(x) = c_{i,0} + c_{i,1}(x - x_i), i=0,..., N-2 */
/* The library packs spline coefficients to array scoeff. */
/* scoeff[2*i+0]=c_{i,0} and scoeff[2*i+1]=c_{i,1}, i=0,..., N-2 */
status = dfdConstruct1D( task, DF_PP_SPLINE, DF_METHOD_STD );

/* Check the Data Fitting operation status */
...

/* Process spline coefficients */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task ) ;

/* Check the Data Fitting operation status */
...
return 0 ;
}

```

The following C example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

C Example of Cubic Spline-Based Interpolation

```

#include "mkl.h"

#define NX 100           /* Size of partition, number of breakpoints */
#define NSITE 1000        /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC /* A cubic spline to construct */

int main()

    datahint = DF_NO_APRIORI_INFO; /* No additional information
                                   about breakpoints/sites is provided.*/

    /* Use a standard method to compute indices of the cells that contain
       interpolation sites. The library places the index of the cell containing
       site(i) to the cell(i), i=0,...,nsite-1 */
    status = dfsSearchCells1D( task, DF_METHOD_STD, nsite, site, sitehint,
                               datahint, cell );
    /* Check Data Fitting operation status */
    ...
}

```

```

/* Process cell indices */
...
/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );

/* Check Data Fitting operation status */
...
return 0;
}

```

Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the header file: for the C/C++ interface, these names are defined as macros via the `#define` statements; for the Fortran interface, the names are defined as integer constants via the `PARAMETER` operators.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

C/C++:	<code>#define DF_STATUS_OK 0</code>
F90/F95:	<code>INTEGER, PARAMETER::DF_STATUS_OK = 0</code>

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files for both C/C++ and Fortran languages define the following status codes:

Status Codes in the Data Fitting Component

Status Code	Description
Common Status Codes	
<code>DF_STATUS_OK</code>	Operation completed successfully.
<code>DF_ERROR_NULL_TASK</code>	Data Fitting task is a <code>NULL</code> pointer.
<code>DF_ERROR_MEM_FAILURE</code>	Memory allocation failure.
<code>DF_ERROR_METHOD_NOT_SUPPORTED</code>	Requested method is not supported.
<code>DF_ERROR_COMP_TYPE_NOT_SUPPORTED</code>	Requested computation type is not supported.
<code>DF_ERROR_NULL_PTR</code>	Pointer to parameter is null.
Data Fitting Task Creation and Initialization, and Generic Editing Operations	
<code>DF_ERROR_BAD_NX</code>	Invalid number of breakpoints.
<code>DF_ERROR_BAD_X</code>	Array of breakpoints is invalid.
<code>DF_ERROR_BAD_X_HINT</code>	Invalid hint describing the structure of the partition.
<code>DF_ERROR_BAD_NY</code>	Invalid dimension of vector-valued function y .
<code>DF_ERROR_BAD_Y</code>	Array of function values is invalid.
<code>DF_ERROR_BAD_Y_HINT</code>	Invalid flag describing the structure of function y
Data Fitting Task-Specific Editing Operations	
<code>DF_ERROR_BAD_SPLINE_ORDER</code>	Invalid spline order.

Status Code	Description
DF_ERROR_BAD_SPLINE_TYPE	Invalid spline type.
DF_ERROR_BAD_IC_TYPE	Type of internal conditions used for spline construction is invalid.
DF_ERROR_BAD_IC	Array of internal conditions for spline construction is not defined.
DF_ERROR_BAD_BC_TYPE	Type of boundary conditions used in spline construction is invalid.
DF_ERROR_BAD_BC	Array of boundary conditions for spline construction is not defined.
DF_ERROR_BAD_PP_COEFF	Array of piecewise polynomial spline coefficients is not defined.
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the df?editidxptr task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the df?editidxptr task editor is out of the pre-defined range.

Data Fitting Computation Operations

DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLIM	Array of the left-side integration limits is not defined.

Status Code	Description
DF_ERROR_BAD_RLIM	Array of the right-side integration limits is not defined.
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

NOTE

The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?newtask1d` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

df?newtask1d

Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

Syntax

Fortran:

```
status = dfsnewtask1d(task, nx, x, xhint, ny, y, yhint)
status = dfdnewtask1d(task, nx, x, xhint, ny, y, yhint)
```

C:

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>nx</i>	Fortran: INTEGER C: const MKL_INT	Number of breakpoints representing partition of interpolation interval $[a, b]$.

Name	Type	Description
<i>x</i>	<p>Fortran: <code>REAL(KIND=4) DIMENSION(*)</code> <code>for dfsnewtask1d</code></p> <p>Fortran: <code>REAL(KIND=8) DIMENSION(*)</code> <code>for dfdnewtask1d</code></p> <p>C: <code>const float* for</code> <code>dfsNewTask1D</code></p> <p><code>const double* for</code> <code>dfdNewTask1D</code></p>	One-dimensional array containing the strictly sorted breakpoints from interpolation interval $[a, b]$. The structure of the array is defined by parameter <i>xhint</i> :
		<ul style="list-style-type: none"> If partition is non-uniform or quasi-uniform, the array should contain <i>nx</i> strictly ordered values. If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval $[a, b]$.
<i>xhint</i>	<p>Fortran: INTEGER</p> <p>C: <code>const MKL_INT</code></p>	A flag describing the structure of partition <i>x</i> . For the list of possible values of <i>xhint</i> , see table " Hint Values for Partition <i>x</i> ". If you set the flag to the <code>DF_NO_HINT</code> value, the library interprets the partition as non-uniform.
<i>ny</i>	<p>Fortran: INTEGER</p> <p>C: <code>const MKL_INT</code></p>	Dimension of vector-valued function <i>y</i> .
<i>y</i>	<p>Fortran: <code>REAL(KIND=4) DIMENSION(*)</code> <code>for dfsnewtask1d</code></p> <p><code>REAL(KIND=8) DIMENSION(*)</code> <code>for dfdnewtask1d</code></p> <p>C: <code>const float* for</code> <code>dfsNewTask</code></p> <p><code>const double* for dfdNewTask</code></p>	Vector-valued function <i>y</i> , array of size <i>nx*ny</i> . The storage format of function values in the array is defined by the value of flag <i>yhint</i> .
<i>yhint</i>	<p>Fortran: INTEGER</p> <p>C: <code>const MKL_INT</code></p>	A flag describing the structure of array <i>y</i> . Valid hint values are listed in table " Hint Values for Vector-Valued Function <i>y</i> ". If you set the flag to the <code>DF_NO_HINT</code> value, the library assumes that all <i>ny</i> coordinates of the vector-valued function <i>y</i> are provided and stored in row-major format.

Output Parameters

Name	Type	Description
<i>task</i>	<p>Fortran: TYPE(DF_TASK)</p> <p>C: <code>DFTaskPtr</code></p>	Descriptor of the task.
<i>status</i>	<p>Fortran: INTEGER</p> <p>C: <code>int</code></p>	Status of the routine:
		<ul style="list-style-type: none"> <code>DF_STATUS_OK</code> if the task is created successfully. Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?newtask1d` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The `x` and `nx` parameters representing the partition of interpolation interval $[a, b]$ are mandatory. If you provide invalid values for these parameters, such as a `NULL` pointer `x` or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function `y`, make sure that the function dimension `ny` and the array of function values `y` are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function `y` in non-contiguous memory locations, you can set the `yhint` flag to `DF_1ST_COORDINATE`, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the `df?editidxptr` task editor.

If the routine fails to create the task descriptor, it returns a `NULL` task pointer.

The routine supports the following hint values for partition `x`:

Hint Values for Partition `x`

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_QUASI_UNIFORM_PARTITION</code>	Partition is quasi-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

Hint Values for Vector-Valued Function `y`

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_1ST_COORDINATE</code>	The first coordinate of vector-valued data is provided.
<code>DF_NO_HINT</code>	No hint is provided. By default, the coordinates of vector-valued function <code>y</code> are provided and stored in row-major format.

NOTE

You must preserve the arrays `x` (breakpoints) and `y` (vector-valued functions) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

Task Configuration Routines

In order to configure tasks, you can use task editors and task query routines.

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific or generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of Intel MKL provides the following task editors:

Data Fitting Task Editors

Editor	Description	Type
<code>df?editppsplin1d</code>	Changes parameters of the piecewise polynomial spline.	Task-specific
<code>df?editptr</code>	Changes a pointer in the task descriptor.	Generic
<code>dfieditval</code>	Changes a value in the task descriptor.	Generic
<code>df?editidxptr</code>	Changes a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

Task query routines are used to read the predefined Data Fitting task parameters. You can use task query routines to read the values of pointers or parameters.

Task query routines are generic (not task-specific), allowing you to read a single parameter at a time.

The Data Fitting component of the Intel MKL provides the following task query routines:

Data Fitting Task Query Routines

Editor	Description	Type
<code>df?queryptr</code>	Queries a pointer in the task descriptor.	Generic
<code>dfiqueryval</code>	Queries a value in the task descriptor.	Generic
<code>df?queryidxptr</code>	Queries a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

df?editppsplin1d

Modifies parameters representing a spline in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfseditppsplin1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

```
status = dfdeditppsplin1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

C:

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

```
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	<p>Fortran: TYPE(DF_TASK)</p> <p>C: DFTaskPtr</p>	Descriptor of the task.
s_order	<p>Fortran: INTEGER</p> <p>C: const MKL_INT</p>	Spline order. The parameter takes one of the values described in table " Spline Orders Supported by Data Fitting Functions ".
s_type	<p>Fortran: INTEGER</p> <p>C: const MKL_INT</p>	Spline type. The parameter takes one of the values described in table " Spline Types Supported by Data Fitting Functions ".
bc_type	<p>Fortran: INTEGER</p> <p>C: const MKL_INT</p>	Type of boundary conditions. The parameter takes one of the values described in table " Boundary Conditions Supported by Data Fitting Functions ".
bc	<pre> Fortran: REAL(KIND=4) DIMENSION(*) for dfreditppsplinelD REAL(KIND=8) DIMENSION(*) for dfdeditppsplinelD C: const float* for dfsEditPPSpline1D const double* for dfdEditPPSpline1D </pre>	Pointer to boundary conditions. The size of the array is defined by the value of parameter <i>bc_type</i> : <ul style="list-style-type: none"> • If you set free-end or not-a-knot boundary conditions, pass the NULL pointer to this parameter. • If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements. • If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.
ic_type	<p>Fortran: INTEGER</p> <p>C: const MKL_INT</p>	Type of internal conditions. The parameter takes one of the values described in table " Internal Conditions Supported by Data Fitting Functions ".
ic	<pre> Fortran: REAL(KIND=4) DIMENSION(*) for dfreditppsplinelD REAL(KIND=8) DIMENSION(*) for dfdeditppsplinelD C: const float* for dfsEditPPSpline1D const double* for dfdEditPPSpline1D </pre>	A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter <i>ic_type</i> : <ul style="list-style-type: none"> • If you set first derivatives or second derivatives internal conditions (<i>ic_type</i>=DF_IC_1ST_DER or <i>ic_type</i>=DF_IC_2ND_DER), pass an array of n-1 derivative values at the internal points of the interpolation interval. • If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of n+1 elements. • If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.

Name	Type	Description
<i>scoeff</i>	Fortran: REAL(KIND=4) DIMENSION(*) for <code>dfseditppsplin1D</code> REAL(KIND=8) DIMENSION(*) for <code>dfdeditppsplin1D</code> C: const float* for <code>dfsEditPPSpline1D</code> const double* for <code>dfdEditPPSpline1D</code>	Spline coefficients. An array of size $s_order * (nx-1)$. The storage format of the coefficients in the array is defined by the value of flag <i>scoeffhint</i> .
<i>scoeffhint</i>	Fortran: INTEGER C: const MKL_INT	A flag describing the structure of the array of spline coefficients. For valid hint values, see table " Hint Values for Spline Coefficients ". The library stores the coefficients in row-major format. The default value is <code>DF_NO_HINT</code> .

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "[Mathematical Conventions](#)" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

Spline Orders Supported by the Data Fitting Functions

Order	Description
<code>DF_PP_STD</code>	Artificial value. Use this value for look-up and step-wise constant interpolants only.
<code>DF_PP_LINEAR</code>	Piecewise polynomial spline of the second order (linear spline).
<code>DF_PP_QUADRATIC</code>	Piecewise polynomial spline of the third order (quadratic spline).
<code>DF_PP_CUBIC</code>	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "[Row-major Coefficient Storage Format](#)".

The table below lists the supported spline types:

Spline Types Supported by Data Fitting Functions

Type	Description
DF_PP_DEFAULT	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
DF_PP_SUBBOTIN	Quadratic splines based on Subbotin algorithm, [StechSub76].
DF_PP_NATURAL	Natural cubic spline.
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF_PP_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to DF_NO_BC and DF_NO_IC, and pass NULL pointers to the conditions. The table below defines the supported boundary conditions:

Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
DF_NO_BC	No boundary conditions provided.	All
DF_BC_NOT_A_KNOT	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
DF_BC_FREE_END	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_LEFT_DER	The first derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_RIGHT_DER	The first derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ST_LEFT_DER	The second derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ND_RIGHT_DER	The second derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_PERIODIC	Periodic boundary conditions.	Linear, all cubic splines
DF_BC_Q_VAL	Function value at point $(x_0 + x_1)/2$	Default quadratic

NOTE

To construct a natural cubic spline, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- `DF_BC_FREE_END` as the boundary condition.

To construct a cubic spline with other boundary conditions, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- the required type of boundary condition.

For Akima, Hermite, Bessel and default cubic splines use the corresponding type defined in [Table Spline Types Supported by Data Fitting Functions](#).

You can combine the values of boundary conditions with a bitwise OR operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to `DF_BC_1ST_LEFT_DER` OR `DF_BC_2ND_RIGHT_DER`.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

Boundary Requirements for Periodic Conditions

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the `ic_type` parameter are the following:

Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
DF_NO_IC	No internal conditions provided.	
DF_IC_1ST_DER	Array of first derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
DF_IC_2ND_DER	Array of second derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
DF_IC_Q_KNOT	Knot array of size $n+1$, where n is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots $t = \{t_i\}$, $i = 0, \dots, n$ according to the rule:

$$t_0 = x_0, t_n = x_{n-1}, t_i = (x_i + x_{i-1})/2, i = 1, \dots, n - 1.$$
- If you provide the knots in an array of size $n + 1$, the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

$$t_0 = x_0, t_n = x_{n-1}, t_i \in (x_{i-1}, x_i), i = 1, \dots, n - 1.$$
- If you provide the knots in an array of size 4, the knots form a uniform partition

$$t_0 = x_0, t_1 = l, t_2 = r, t_3 = x_{n-1}, \text{ where } l \in (x_0, x_1) \text{ and } r \in (x_{n-2}, x_{n-1}).$$

In this case, you need to set the value of the `ic_type` parameter holding the type of internal conditions to `DF_IC_Q_KNOT` OR `DF_UNIFORM_PARTITION`.

NOTE

Since the partition is uniform, perform an OR operation with the `DF_UNIFORM_PARTITION` partition hint value described in [Table Hint Values for Partition x](#).

For computations based on look-up and step-wise constant interpolants, you can avoid calling the `df?editppsspline1d` editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the `df?construct1d` routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the `scoeff` parameter. Make sure that the size of the array is sufficient to hold `s_order * (nx-1)` values.

The `df?editppsspline1d` routine supports the following hint values for spline coefficients:

Hint Values for Spline Coefficients

Order	Description
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.

Order	Description
DF_NO_HINT	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function y_1 to function y_n .

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$$c_{1,0}, c_{1,1}, \dots, c_{1,k}, c_{2,0}, c_{2,1}, \dots, c_{2,k}, \dots, c_{n-1,0}, c_{n-1,1}, \dots, c_{n-1,k}$$

Mapping of the coefficients to storage in the *scoeff* array is described below, where $c_{i,j}$ is the j th coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$$

See [Mathematical Conventions](#) for more details on nomenclature and interpolants.

Row-major Coefficient Storage Format

$$\begin{aligned} P_1(x) &= \overrightarrow{c_{1,0}} + \overrightarrow{c_{1,1}(x - x_1)} + \cdots + \overrightarrow{c_{1,k}(x - x_1)^k} \\ P_2(x) &= \overleftarrow{c_{2,0}} + \overrightarrow{c_{2,1}(x - x_2)} + \cdots + \overrightarrow{c_{2,k}(x - x_2)^k} \\ &\vdots & \vdots & \vdots \\ P_{n-1}(x) &= \overleftarrow{c_{n-1,0}} + \overrightarrow{c_{n-1,1}(x - x_{n-1})} + \cdots + \overrightarrow{c_{n-1,k}(x - x_{n-1})^k} \end{aligned}$$

If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the *scoeffhint* flag to DF_1ST_COORDINATE and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the df?editidxptra task editor.

Using the df?editppspine1d task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the *s_type* parameter to DF_PP_DEFAULT.
- Pointer to the array of spline coefficients in row-major format.
- The *scoeffhint* parameter describing the structure of the array:
 - Set the *scoeffhint* flag to the DF_1ST_COORDINATE value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.

- Use the default value `DF_NO_HINT` for all other cases.

Before passing an already constructed spline into the library, you should call the `dfieditval` task editor to provide the dimension of the spline `DF_NY`. See table "[Parameters Supported by the dfieditval Task Editor](#)" for details.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

NOTE

You must preserve the arrays `bc` (boundary conditions), `ic` (internal conditions), and `scoeff` (spline coefficients) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

df?editptr

Modifies a pointer to an array held in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfseditptr(task, ptr_attr, ptr)
status = dfdeditptr(task, ptr_attr, ptr)
```

C:

```
status = dfsEditPtr(task, ptr_attr, ptr)
status = dfdEditPtr(task, ptr_attr, ptr)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: <code>TYPE(DF_TASK)</code> C: <code>DFTaskPtr</code>	Descriptor of the task.
<code>ptr_attr</code>	Fortran: <code>INTEGER</code> C: <code>const MKL_INT</code>	The parameter to change. For details, see the <i>Pointer Attribute</i> column in table " Pointers Supported by the df?editptr Task Editor ".
<code>ptr</code>	Fortran: <code>REAL(KIND=4) DIMENSION(*)</code> <code>for dfseditptr</code> <code>REAL(KIND=8) DIMENSION(*)</code> <code>for dfdeditptr</code> C: <code>const float* for</code> <code>dfsEditPtr</code> <code>const double* for dfdEditPtr</code>	New pointer. For details, see the <i>Purpose</i> column in table " Pointers Supported by the df?editptr Task Editor ".

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	<p>Status of the routine:</p> <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?editptr` editor replaces the pointer of type `ptr_attr` stored in a Data Fitting task descriptor with a new pointer `ptr`. The table below describes types of pointers supported by the editor:

Pointers Supported by the `df?editptr` Task Editor

Pointer Attribute	Purpose
<code>DF_X</code>	Partition <code>x</code> of the interpolation interval, an array of strictly sorted breakpoints
<code>DF_Y</code>	Vector-valued function <code>y</code>
<code>DF_IC</code>	Internal conditions for spline construction. For details, see table " Internal Conditions Supported by Data Fitting Functions ".
<code>DF_BC</code>	Boundary conditions for spline construction. For details, see table " Boundary Conditions Supported by Data Fitting Functions ".
<code>DF_PP_SCOEFF</code>	Spline coefficients

You can use `df?editptr` to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the `df?editidxptr` editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you modify a partition of the interpolation interval, then you should call the `dfieditval` task editor with the corresponding value of `DF_XHINT`, even if the structure of the partition remains the same.

If you pass a `NULL` pointer to the `df?editptr` task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see "[Task Status and Error Reporting](#)".

NOTE

You must preserve the arrays `x` (breakpoints), `y` (vector-valued functions), `bc` (boundary conditions), `ic` (internal conditions), and `scoeff` (spline coefficients) through the entire workflow of the Data Fitting computations which use those arrays, as the task stores the addresses of the arrays for spline-based computations.

`dfieditval`

Modifies a parameter value in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfieditval(task, val_attr, val)
```

C:

```
status = dfiEditVal(task, val_attr, val)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
val_attr	Fortran: INTEGER C: const MKL_INT	The parameter to change. See table " Parameters Supported by the dfieditval Task Editor ".
val	Fortran: INTEGER C: const MKL_INT	A new parameter value. See table " Parameters Supported by the dfieditval Task Editor ".

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `dfieditval` task editor replaces the parameter of type `val_attr` stored in a Data Fitting task descriptor with a new value `val`. The table below describes valid types of parameter `val_attr` supported by the editor:

Parameters Supported by the dfieditval Task Editor

Parameter Attribute	Purpose
DF_NX	Number of breakpoints
DF_XHINT	A flag describing the structure of partition. See table " Hint Values for Partition x " for the list of available values.
DF_NY	Dimension of the vector-valued function
DF_YHINT	A flag describing the structure of the vector-valued function. See table " Hint Values for Vector Function y " for the list of available values.
DF_SPLINE_ORDER	Spline order. See table " Spline Orders Supported by Data Fitting Functions " for the list of available values.

Parameter Attribute	Purpose
DF_SPLINE_TYPE	Spline type. See table " Spline Types Supported by Data Fitting Functions " for the list of available values.
DF_BC_TYPE	Type of boundary conditions used in spline construction. See table " Boundary Conditions Supported by Data Fitting Functions " for the list of available values.
DF_IC_TYPE	Type of internal conditions used in spline construction. See table " Internal Conditions Supported by Data Fitting Functions " for the list of available values.
DF_PP_COEFF_HINT	A flag describing the structure of spline coefficients. See table " Hint Values for Spline Coefficients " for the list of available values.
DF_CHECK_FLAG	A flag which controls checking of Data Fitting parameters. See table " Possible Values for the DF_CHECK_FLAG Parameter " for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see "[Task Status and Error Reporting](#)".

[Possible Values for the DF_CHECK_FLAG Parameter](#)

Value	Description
DF_ENABLE_CHECK_FLAG	Checks the correctness of parameters of Data Fitting computational routines (default mode).
DF_DISABLE_CHECK_FLAG	Disables checking of the correctness of parameters of Data Fitting computational routines.

Use `DF_CHECK_FLAG` for `val_attr` in order to control validation of parameters of Data Fitting computational routines such as `df construct1d`, `df interpolate1d` `df interpolateex1d`, and `df searchcells1d` `df searchcellsex1d`, which can perform better with a small number of interpolation sites or integration limits (fewer than one dozen). The default mode, with checking of parameters enabled, should be used as you develop a Data Fitting-based application. After you complete development you can disable parameter checking in order to improve the performance of your application.

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the `df?editptr` task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the `df?editidxptr` editor if those arrays are stored in non-contiguous memory locations.

You must call the `dfieditidxptr` task editor to edit the structure of the partition `DF_XHINT` every time you modify a partition using `df editptr`, even if the structure of the partition remains the same.

[df?editidxptr](#)

Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

Fortran:

```
status = dfseditidxptr(task, ptr_attr, idx, ptr)
status = dfdeditidxptr(task, ptr_attr, idx, ptr)
```

C:

```
status = dfsEditIdxPtr(task, ptr_attr, idx, ptr)
status = dfdEditIdxPtr(task, ptr_attr, idx, ptr)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
ptr_attr	Fortran: INTEGER C: const MKL_INT	Type of the data to be modified. The parameter takes one of the values described in "Data Attributes Supported by the df?editidxptr Task Editor" .
idx	Fortran: INTEGER C: const MKL_INT	Index of the coordinate whose pointer is to be modified.
ptr	Fortran: REAL(KIND=4) DIMENSION(*) for dfreditidxptr REAL(KIND=8) DIMENSION(*) for dfdeditidxptr C: const float* for dfsEditIdxPtr const double* for dfdEditIdxPtr	Pointer to the data that holds values of coordinate <i>idx</i> . For details, see table "Data Attributes Supported by the df?editidxptr Task Editor" .

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations. Do not use the editor for coordinates at contiguous memory locations in row-major format.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?editpppline1d` editor.

Data Attributes Supported by the df?editidxptr Task Editor

Data Attribute	Description
DF_Y	Vector-valued function y
DF_PP_SCOEFF	Piecewise polynomial spline coefficients

When using `df?editidxptr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension `ny` of the vector-valued function.
- You pass a `NULL` pointer to the editor. In this case, the task remains unchanged.
- You pass a pointer to the `idx` coordinate of the vector-valued function you provided to contiguous memory in column-major format.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000 /* number of break points */
#define NY 2      /* dimension of vector-valued function */
int main()
{
    DFTaskPtr task;
    double x[NX];
    double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
    /* Provide first coordinate of two-dimensional function y into creation routine */
    status = dfdNewTaskID( &task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
                           DF_1ST_COORDINATE );
    /* Provide second coordinate of two-dimensional function */
    status = dfdEditIdxPtr(task, DF_Y, 1, y2 );
    ...
}
```

df?queryptr

Reads a pointer to an array held in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfsqueryptr(task, ptr_attr, ptr)
status = dfdqueryptr(task, ptr_attr, ptr)
```

C:

```
status = dfsQueryPtr(task, ptr_attr, ptr)
status = dfdQueryPtr(task, ptr_attr, ptr)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>ptr_attr</i>	Fortran: INTEGER C: const MKL_INT	The parameter to query. The query routine supports pointer attributes described in the table " Pointers Supported by the df?editptr Task Editor ". For details, see the <i>Pointer Attribute</i> column in the table.

Output Parameters

Name	Type	Description
<i>ptr</i>	Fortran: INTEGER(KIND=8) C: float** for dfsQueryPtr double** for dfdQueryPtr	Pointer to array returned by the query routine. For details, see the <i>Purpose</i> column in table " Pointers Supported by the df?editptr Task Editor ".
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?queryptr` routine returns the pointer of type `ptr_attr` stored in a Data Fitting task descriptor as parameter `ptr`. Attributes of the pointers supported by the query function are identical to those supported by the editor `df?editptr` editor in the table "[Pointers Supported by the df?editptr Task Editor](#)".

You can use `df?queryptr` to read different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory.

dfiqueryval

Reads a parameter value in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfiqueryval(task, val_attr, val)
```

C:

```
status = dfiQueryVal(task, val_attr, val)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>val_attr</i>	Fortran: INTEGER C: const MKL_INT	The parameter to query. The query function supports the parameter attributes described in " Parameters Supported by the dfieditval Task Editor ".

Output Parameters

Name	Type	Description
<i>val</i>	Fortran: INTEGER C: MKL_INT	The parameter value returned by the query function. See table " Parameters Supported by the dfieditval Task Editor ".
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfiqueryval routine returns a parameter of type *val_attr* stored in a Data Fitting task descriptor as parameter *val*. The query function supports the parameter attributes described in "[Parameters Supported by the dfieditval Task Editor](#)".

df?queryidxptr

Reads a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

Fortran:

```
status = dfsqueryidxptr(task, ptr_attr, idx, ptr)
status = dfdqueryidxptr(task, ptr_attr, idx, ptr)
```

C:

```
status = dfsQueryIdxPtr(task, ptr_attr, idx, ptr)
status = dfdQueryIdxPtr(task, ptr_attr, idx, ptr)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>ptr_attr</i>	Fortran: INTEGER C: const MKL_INT	Pointer attribute to query. The parameter takes one of the attributes described in "Data Attributes Supported by the df?editidxptr Task Editor" .
<i>idx</i>	Fortran: INTEGER C: const MKL_INT	Index of the coordinate of the pointer to query.

Output Parameters

Name	Type	Description
<i>ptr</i>	Fortran: INTEGER(KIND=8) C: float* for dfsQueryIdxPtr double* for dfdQueryIdxPtr	Pointer to the data that holds values of coordinate <i>idx</i> returned. For details, see table "Data Attributes Supported by the df?editidxptr Task Editor" .
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine returns a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the query routine if you need the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations or at a contiguous memory location in row-major format (the default storage format for spline coefficients).

Before calling this query routine, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?editppspline1d` editor.

When using `df?queryidxptr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You request the pointer to the *idx* coordinate of the vector-valued function you provided to contiguous memory in column-major format.

Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

Data Fitting Computational Routines

Routine	Description
<code>df?construct1d</code>	Constructs a spline for a one-dimensional Data Fitting task.
<code>df?interpolate1d</code>	Computes spline values and derivatives.
<code>df?interpolateex1d</code>	Computes spline values and derivatives by calling user-provided interpolants.
<code>df?integrate1d</code>	Computes spline-based integrals.
<code>df?integrateex1d</code>	Computes spline-based integrals by calling user-provided integrators.
<code>df?searchcells1d</code>	Finds indices of cells containing interpolation sites.
<code>df?searchcellsex1d</code>	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "[Task Status and Error Reporting](#)".

NOTE

Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

df?construct1d

Constructs a spline of the given type.

Syntax

Fortran:

```
status = dfsconstruct1d(task, s_format, method)
status = dfdconstruct1d(task, s_format, method)
```

C:

```
status = dfsConstruct1D(task, s_format, method)
status = dfdConstruct1D(task, s_format, method)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>s_format</i>	Fortran: INTEGER C: const MKL_INT	Spline format. The supported value is DF_PP_SPLINE.
<i>method</i>	Fortran: INTEGER C: const MKL_INT	Construction method. The supported value is DF_METHOD_STD.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

Before calling `df?construct1d`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?construct1d` routine to construct the spline. The format of the spline is defined by parameter *s_format*. The method for spline construction is defined by parameter *method*. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table "[Hint Values for Spline Coefficients](#)".

df?interpolate1d/df?interpolateex1d

Runs data fitting computations.

Syntax

Fortran:

```
status = dfsinterpolate1d(task, type, method, nsite, site, sitehint, ndorder, dorder,
                          datahint, r, rhint, cell)

status = dfdinterpolate1d(task, type, method, nsite, site, sitehint, ndorder, dorder,
                          datahint, r, rhint, cell)

status = dfsinterpolateex1d(task, type, method, nsite, site, sitehint, ndorder,
                           dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params,
                           i_cb, i_params, search_cb, search_params)

status = dfdinterpolateex1d(task, type, method, nsite, site, sitehint, ndorder,
                           dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params,
                           i_cb, i_params, search_cb, search_params)
```

C:

```
status = dfsInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
                          datahint, r, rhint, cell)
```

```

status = dfdInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
                           datahint, r, rhint, cell)

status = dfsInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
                           dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
                           search_cb, search_params)

status = dfdInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
                           dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
                           search_cb, search_params)

```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
type	Fortran: INTEGER C: const MKL_INT	Type of spline-based computations. The parameter takes one or more values combined with an OR operation. For the list of possible values, see table "Computation Types Supported by the df?interpolate1d/ df?interpolate1d Routines".
method	Fortran: INTEGER C: const MKL_INT	Computation method. The supported value is DF_METHOD_PP.
nsite	Fortran: INTEGER C: const MKL_INT	Number of interpolation sites.
site	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d C: const float* for dfsInterpolate1D/ dfsInterpolateEx1D const double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array of interpolation sites of size nsite. The structure of the array is defined by the sitehint parameter: <ul style="list-style-type: none"> If sites form a non-uniform partition, the array should contain nsite values. If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
sitehint	Fortran: INTEGER C: const MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of sitehint, see table "Hint Values for Interpolation Sites". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.

Name	Type	Description
<i>ndorder</i>	Fortran: INTEGER C: const MKL_INT	Maximal derivative order increased by one to be computed at interpolation sites.
<i>dorder</i>	Fortran: INTEGER DIMENSION(*) C: const MKL_INT*	Array of size <i>ndorder</i> that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in <i>dorder</i> are zero, the library computes the spline values only. If you do not need interpolation computations, set <i>ndorder</i> to zero and pass a NULL pointer to <i>dorder</i> .
<i>datahint</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d C: const float* for dfsInterpolate1D/ dfsInterpolateEx1D const double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array that contains additional information about the structure of partition <i>x</i> and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table "Structure of the <i>datahint</i> Array".
<i>r</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d C: float* for dfsInterpolate1D/ dfsInterpolateEx1D double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array for results. If you do not need spline-based interpolation or integration, set this pointer to NULL.
<i>rhint</i>	Fortran: INTEGER C: const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table "Hint Values for the <i>rhint</i> Parameter". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
<i>cell</i>	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Array of cell indices in partition <i>x</i> that contain the interpolation sites. Provide this parameter as input if <i>type</i> is DF_INTERP_USER_CELL. If you do not need cell indices, set this parameter to NULL.
<i>le_cb</i>	Fortran: INTEGER	User-defined callback function for extrapolation at the sites to the left of the interpolation interval.

Name	Type	Description
	C: const dfsInterpCallBack for dfsInterpolateEx1D	Set to NULL if you are not supplying a callback function.
	const dfdInterpCallBack for dfdInterpolateEx1D	
le_params	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
re_cb	Fortran: INTEGER C: const dfsInterpCallBack for dfsInterpolateEx1D	User-defined callback function for extrapolation at the sites to the right of the interpolation interval. Set to NULL if you are not supplying a callback function.
	const dfdInterpCallBack for dfdInterpolateEx1D	
re_params	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
i_cb	Fortran: INTEGER C: const dfsInterpCallBack for dfsInterpolateEx1D	User-defined callback function for interpolation within the interpolation interval. Set to NULL if you are not supplying a callback function.
	const dfdInterpCallBack for dfdInterpolateEx1D	
i_params	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
search_cb	Fortran: INTEGER C: const dfsSearchCellsCallBack for dfdInterpolateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to NULL if you are not supplying a callback function.
	const dfdSearchCellsCallBack for dfdInterpolateEx1D	
search_params	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
<i>r</i>		Contains results of computations at the interpolation sites.
<i>cell</i>		Array of cell indices in partition <i>x</i> that contain the interpolation sites, which is computed if <i>type</i> is DF_CELL.

Description

The `df?interpolate1d/df?interpolateex1d` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array *site*:

Computation Types Supported by the `df?interpolate1d/df?interpolateex1d` Routines

Type	Description
DF_INTERP	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
DF_INTERP_USER_CELL	Compute derivatives of predefined order given user-provided cell indices. The derivative of the zero order is the spline value.
	For this type of the computations you should provide a valid <i>cell</i> array, which holds the indices of cells in the <i>site</i> array containing relevant interpolation sites.
DF_CELL	Compute indices of cells in partition <i>x</i> that contain the sites.

If the indices of cells which contain interpolation types are available before the call to `df?interpolate1d/df?interpolateex1d`, you can improve performance by using the DF_INTERP_USER_CELL computation type.

NOTE

If you pass any combination of DF_INTERP, DF_INTERP_USER_CELL, and DF_CELL computation types to the routine, the library uses the DF_INTERP_USER_CELL computation mode.

If you specify DF_INTERP_USER_CELL computation mode and a user-defined callback function for computing cell indices to `df?interpolateex1d`, the library uses the DF_INTERP_USER_CELL computation mode, and the call-back function is not called.

If the sites do not belong to interpolation interval $[a, b]$, the library uses:

- polynomial P_0 of the spline constructed on interval $[x_0, x_1]$ for computations at the sites to the left of a .
- polynomial P_{n-2} of the spline constructed on interval $[x_{n-2}, x_{n-1}]$ for computations at the sites to the right of b .

Interpolation sites support the following hints:

Hint Values for Interpolation Sites

Value	Description
DF_NON_UNIFORM_PARTITION	Partition is non-uniform.
DF_UNIFORM_PARTITION	Partition is uniform.
DF_SORTED_DATA	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
DF_NO_HINT	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

NOTE

If you pass a sorted array of interpolation sites to the Intel MKL, set the *sitehint* parameter to the DF_SORTED_DATA value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- DF_UNIFORM_PARTITION describes the structure of breakpoints and the interpolation sites.
- DF_QUASI_UNIFORM_PARTITION describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

The *r* pointer defines the memory location for the sets of interpolation and integration results for all coordinates of function *y*. The sets are stored one by one, in the successive order of the function coordinates from *y₁* to *y_n*.

You can define the following settings for packing the results within each set:

- Computation type: interpolation, integration, or both.
- Computation parameters: derivative orders.
- Storage format for the results. You can specify the format using the *rhint* parameter values described in the table below:

Hint Values for the *rhint* Parameter

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_NO_HINT	No hint is provided. By default, the results are stored in row-major format.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the *dorder* array of size *ndorder* as follows:

$$dorder[i] = \begin{cases} 1, & \text{if derivative of the } i\text{-th order is required} \\ 0, & \text{otherwise} \end{cases} \quad i = 0, \dots, ndorder - 1$$

See below a common structure of the storage formats of the interpolation results within each set *r* for computing derivatives of order *i₁, i₂, ..., i_m* at *nsite* interpolation sites. In this description, *j* is the coordinate of the vector-valued function:

- Row-major format

$r_j(i_1, 0)$	$r_j(i_2, 0)$...	$r_j(i_m, 0)$
$r_j(i_1, 1)$	$r_j(i_2, 1)$...	$r_j(i_m, 1)$
...
$r_j(i_1, n_{site} - 1)$	$r_j(i_2, n_{site} - 1)$...	$r_j(i_m, n_{site} - 1)$

- Column-major format

$r_j(i_1, 0)$	$r_j(i_1, 1)$...	$r_j(i_1, n_{site} - 1)$
$r_j(i_2, 0)$	$r_j(i_2, 1)$...	$r_j(i_2, n_{site} - 1)$
...
$r_j(i_m, 0)$	$r_j(i_m, 1)$...	$r_j(i_m, n_{site} - 1)$

To speed up Data Fitting computations, use the `datahint` parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

Structure of the `datahint` Array

Element Number	Description
0	Task dimension
1	Type of additional information
2	Reserved field
3	The total number q of elements containing additional information.
4	Element (1)
...	...
$q+3$	Element (q)

Data Fitting computation functions support the following types of additional information for `datahint[1]`:

Types of Additional Information

Type	Element Number	Parameter
<code>DF_NO_APRIORI_INFO</code>	0	No parameters are provided. Information about the data structure is absent.
<code>DF_APRIORI_MOST_LIKELY_CELL</code>	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size n_{site} for the results. The library supports the following scheme of cell indexing for the given partition $\{x_i\}$, $i=1,\dots,n_x$:

$cell[j] = i$, if $site[j] \in [x_i, x_{i+1})$, $i = 0, \dots, n_x$,

where

- $x_0 = -\infty$
- $x_{n_x+1} = +\infty$

- $j = 0, \dots, nsite-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?interpolateex1d`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolation interval $[a, b]$. The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval $[a, b]$, the routine uses the default settings.

<i>rhint</i>	Fortran: INTEGER C: const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table " Hint Values for Integration Results ". If you set the flag to the DF_NO_HINT value, the library stores the results in row-major format.
<i>le_cb</i>	Fortran: INTEGER C: const dfsIntegrCallBack for dfsIntegrateEx1D const dfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval [<i>llim</i> [<i>i</i>], min(<i>rlim</i> [<i>i</i>], <i>a</i>)) for <i>llim</i> [<i>i</i>] < <i>a</i> . Set to NULL if you are not supplying a callback function.
<i>le_params</i>	Fortran: INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function.

Name	Type	Description
	C: const void*	Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>re_cb</i>	Fortran: INTEGER C: const dfsInterpCallBack for dfsIntegrateEx1D const dfdInterpCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval $[\max(l1im[i], b), rlim[i]]$ for $rlim[i] \geq b$. Set to NULL if you are not supplying a callback function.
<i>re_params</i>	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>i_cb</i>	Fortran: INTEGER C: const dfsIntegrCallBack for dfsIntegrateEx1D const dfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval $[\max(a, l1im[i],), \min(rlim[i], b))$. Set to NULL if you are not supplying a callback function.
<i>i_params</i>	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>search_cb</i>	Fortran: INTEGER C: const dfsSearchCellsCallBack for dfsIntegrateEx1D const dfdSearchCellsCallBack for dfdIntegrateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to NULL if you are not supplying a callback function.
<i>search_params</i>	Fortran: INTEGER DIMENSION(*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none">• DF_STATUS_OK if the routine execution completed successfully.

Name	Type	Description
<i>r</i>	<p>Fortran:</p> <pre>REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d</pre> <p>REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d</p> <p>C: float* for dfsIntegrate1D/ dfsIntegrateEx1D</p> <p>double* for dfdIntegrate1D/ dfdIntegrateEx1D</p>	<ul style="list-style-type: none"> Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions. <p>Array of integration results. The size of the array should be sufficient to hold $nlim*ny$ values, where ny is the dimension of the vector-valued function. The integration results are packed according to the settings in <i>rhint</i>.</p>

Description

The `df?integrate1d/df?integrateex1d` routine computes spline-based integral on user-defined intervals

$$I(i, j) = \int_{rlim[i]}^{rlim[i]} f_j(x) dx, i = 0, \dots, nlim - 1, j = 0, \dots, ny - 1$$

If $rlim[i] < llim[i]$, the routine returns

$$I(i, j) = - \int_{rlim[i]}^{llim[i]} f_j(x) dx$$

The routine supports the following hint values for integration results:

Hint Values for Integration Results

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_NO_HINT</code>	No hint is provided. By default, the coordinates of vector-valued function <i>y</i> are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

$I(0, 0)$...	$I(0, nlim - 1)$
...
$I(ny - 1, 0)$...	$I(ny - 1, nlim - 1)$

- Column-major format

$I(0, 0)$...	$I(ny - 1, 0)$
...
$I(0, nlim - 1)$...	$I(ny - 1, nlim - 1)$

Using the `llimhint` and `rlimhint` parameters, you can provide the following hint values for integration limits:

Hint Values for Integration Limits

Value	Description
<code>DF_SORTED_DATA</code>	Integration limits are sorted in the ascending order and define a non-uniform partition.
<code>DF_NON_UNIFORM_PARTITION</code>	Partition defined by integration limits is non-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition defined by integration limits is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine `df?integrateex1d`. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval $[a, b]$
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

df?searchcells1d/df?searchcellsex1d

Searches sub-intervals containing interpolation sites.

Syntax

Fortran:

```
status = dfssearchcells1d(task, method, nsite, site, sitehint, datahint, cell)
status = dfdsearchcells1d(task, method, nsite, site, sitehint, datahint, cell)
status = dfssearchcellsex1d(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
status = dfdsearchcellsex1d(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
```

C:

```
status = dfsSearchCells1D(task, method, nsite, site, sitehint, datahint, cell)
status = dfdSearchCells1D(task, method, nsite, site, sitehint, datahint, cell)
```

```
status = dfsSearchCellsEx1D(task, method, nsite, site, sitehint, datahint, cell,
search_cb, search_params)

status = dfdSearchCellsEx1D(task, method, nsite, site, sitehint, datahint, cell,
search_cb, search_params)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
method	Fortran: INTEGER C: const MKL_INT	Search method. The supported value is DF_METHOD_STD.
nsite	Fortran: INTEGER C: const MKL_INT*	Number of interpolation sites.
site	Fortran: REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d C: const float* for dfsSearchCells1D/ dfsSearchCellsEx1D const double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array of interpolation sites of size <i>nsite</i> . The structure of the array is defined by the <i>sitehint</i> parameter: <ul style="list-style-type: none"> • If the sites form a non-uniform partition, the array should contain <i>nsite</i> values. • If the sites form a uniform partition, the array should contain two entries that represent the left-most and the right-most interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
sitehint	Fortran: INTEGER C: const MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sitehint</i> , see table " Hint Values for Interpolation Sites ". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
datahint	Fortran: REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d	Array that contains additional information about the structure of the partition and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table " Structure of the datahint Array ".

Name	Type	Description
	C: const float* for dfsSearchCells1D/ dfsSearchCellsEx1D const double* for dfdSearchCells1D/ dfdSearchCellsEx1D	
<i>search_cb</i>	Fortran: INTEGER C: const dfsSearchCellsCallBack for dfsSearchCellsEx1D const dfdSearchCellsCallBack for dfdSearchCellsEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to <code>NULL</code> if you are not supplying a callback function.
<i>search_params</i>	Fortran: INTEGER DIMENSION (*) C: const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to <code>NULL</code> if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
<i>cell</i>	Fortran: INTEGER DIMENSION (*) C: MKL_INT*	Array of cell indices in the partition that contain the interpolation sites.

Description

The `df?searchcells1d/df?searchcellsex1d` routines return array *cell* of indices of sub-intervals (cells) in the partition that contain interpolation sites available in array *site*. For details on the cell indexing scheme, see the description of the `df?interpolate1d/df?interpolateex1d` computation routines.

Use the *datahint* parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the *datahint* parameter is available in the description of the `df?interpolate1d/df?interpolateex1d` computation routines.

For description of the user-defined callback for computation of cell indices, see `df?searchcellscallback`.

<i>params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	The status returned by the callback function: <ul style="list-style-type: none"> Zero indicates successful completion of the callback operation. A negative value indicates an error. A positive value indicates a warning.

Name	Type	Description
<i>r</i>	<p>Fortran:</p> <pre>REAL(KIND=4) DIMENSION(*) for dfsintegrcallback</pre> <p>REAL(KIND=8) DIMENSION(*) for dfdintegrcallback</p> <p>C: float* for dfsIntegrCallBack</p> <p>double* for dfdIntegrCallBack</p>	<p>See "Task Status and Error Reporting" for error code definitions.</p> <p>Array of integration results. For packing the results in row-major format, follow the instructions described in df?interpolate1d/df?interpolateex1d.</p>

Description

When passed into the `df?integrateex1d` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval $[a, b]$, the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of a , the extrapolation range to the right of b , and the interpolation interval $[a, b]$, as follows:

- If the left integration limit is to the left of the interpolation interval ($llim < a$), the `df?integrateex1d` routine passes $llim$ as the left integration limit and $\min(rlim, a)$ as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval ($rlim > b$), the `df?integrateex1d` routine passes $\max(llim, b)$ as the left integration limit and $rlim$ as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?integrateex1d` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

df?searchcellscallback

A callback function for user-defined search to be passed into `df?interpolateex1d` or `df?searchcellsex1d`.

Syntax

Fortran:

```
status = dfssearchcellscallback(n, site, cell, flag, params)
status = dfdsearchcellscallback(n, site, cell, flag, params)
```

C:

```
status = dfsSearchCellsCallBack(n, site, cell, flag, params)
status = dfdSearchCellsCallBack(n, site, cell, flag, params)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	Fortran: INTEGER(KIND=8) C: long long*	Number of interpolation sites.
<i>site</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfssearchcellcallback REAL(KIND=8) DIMENSION(*) for dfdsearchcellcallback C: float* for dfsSearchCellsCallBack double* for dfdSearchCellsCallBack	Array of interpolation sites of size <i>n</i> .
<i>flag</i>	Fortran: INTEGER(KIND=4) DIMENSION(*) C: int*	Array of size <i>n</i> , with values set as follows: <ul style="list-style-type: none"> • If the cell with index <i>cell</i>[<i>i</i>] contains <i>site</i>[<i>i</i>], set <i>flag</i>[<i>i</i>] to 1. • Otherwise, set <i>flag</i>[<i>i</i>] to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing <i>site</i>[<i>i</i>] by using the provided index as a starting point for the search.
<i>params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	The status returned by the callback function: <ul style="list-style-type: none"> • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • The DF_STATUS_EXACT_RESULT status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the <i>flag</i> array. • A positive value indicates a warning.
		See " Task Status and Error Reporting " for error code definitions.

Name	Type	Description
cell	Fortran: INTEGER(KIND=8) DIMENSION(*) C: long long*	Array of size n that returns indices of the cells computed by the callback function.

Description

When passed into the `df?interpolateex1d` or `df?searchcellsex1d` routine, this function performs a user-defined search.

See Also

`df?interpolate1d/df?interpolateex1d`
`df?interpcallback`

Task Destructors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfdeletetask` destroys a Data Fitting task and frees the memory.

dfdeletetask

Destroys a Data Fitting task object and frees the memory.

Syntax

Fortran:

```
status = dfdeletetask(task)
```

C:

```
status = dfDeleteTask(&task)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
task	Fortran: <code>TYPE(DF_TASK)</code> C: <code>DFTaskPtr</code>	Descriptor of the task to destroy.

Output Parameters

Name	Type	Description
status	Fortran: <code>INTEGER</code> C: <code>int</code>	Status of the routine: <ul style="list-style-type: none"> <code>DF_STATUS_OK</code> if the task is deleted successfully. Non-zero error code if the operation failed. See "Task Status and Error Reporting" for error code definitions.

Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to NULL. Otherwise, the routine returns an error code.

A

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m -by- n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section [Sparse Linear Systems](#) that follows.

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i, j)$. For example, a 3 by 4 matrix A , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i,j) = a(j,i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i,j) = \text{conj}(a(j,i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i,j)$ and $a(j,i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T Ax$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUX &= b \\ \Rightarrow L(Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1} y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is a symmetric positive definite sparse matrix, and A and b are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & 5 & * \\ 3 & * & * & 8 & 16 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$\dots \begin{matrix} 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{matrix} \dots$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row

of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^TP)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

1. Solve $Ly = Pb$.
 2. Solve $Uz = y$.
 3. Set $x = P^T z$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$L_Y = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

$$\text{This gives: } Y^r = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{\frac{3}{5}}}{12}.$$

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since a Cholesky factorization is used, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{5}}{4} \end{bmatrix}^T = \begin{bmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \\ z_5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ -979\sqrt{\frac{3}{5}} \end{bmatrix}$$

This gives $z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

Storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of *rowIndex(i)* and *rowIndex(i+1)*.

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE

The Intel MKL sparse storage scheme for the direct sparse solvers supports both one-based indexing and zero-based indexing.

Consider the symmetric matrix *A*:

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix A are as follows:

Storage Arrays for a Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(1	2	4	2	3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	8	9	10)			

zero-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(0	1	3	1	2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	7	8	9)			

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix B :

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix B has 13 non-zero elements, and all of them are stored as follows:

Storage Arrays for a Non-Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a_{j,i}$ is not zero if and only if $a_{i,j}$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is

equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Storage Arrays for a Symmetrically Structured Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
<i>columns</i>	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)
<i>rowIndex</i>	=	(1	4	7	10	13	16)									

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
<i>columns</i>	=	(0	1	3	0	1	4	2	3	4	0	2	3	1	2	4)
<i>rowIndex</i>	=	(0	3	6	9	12	15)									

The distributed assembled matrix input format can be used by the Parallel Direct Sparse Solver for Clusters Interface.

In this format, the symmetric input matrix *A* is divided into sequential row subsets, or domains. Each domain belongs to an MPI process. Neighboring domains can overlap. For such intersections, the element values of the full matrix can be obtained by summing the respective elements of both domains.

As in the centralized format, the distributed format uses three arrays to describe the input data, but the *values*, *columns*, and *rowIndex* arrays on each processor only describe the domain belonging to the that particular processor and not the entire matrix.

For example, consider a symmetric matrix *A*:

$$A = \begin{bmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 11 & 5 & 4 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{bmatrix}$$

This array could be distributed between two domains corresponding to two MPI processes, with the first containing rows 1 through 3, and the second containing rows 3 through 5.

NOTE

For the symmetric input matrix, it is not necessary to store the values from the lower triangle.

$$A_{\text{Domain1}} = \begin{bmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 3 & * & 2 \end{bmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 1**one-based indexing**

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(1	2	4	2	3	5)
<i>rowIndex</i>	=	(1	4	5	7)		

zero-based indexing

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(0	1	3	1	2	4)
<i>rowIndex</i>	=	(0	3	4	6)		

$$A_{\text{Domain2}} = \begin{bmatrix} * & * & 8 & 5 & 2 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{bmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 2**one-based indexing**

<i>values</i>	=	(8	5	2	10	5)
<i>columns</i>	=	(3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	6)	

zero-based indexing

<i>values</i>	=	(8	5	2	10	5)
<i>columns</i>	=	(2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	5)	

The third row of matrix A is common between domain 1 and domain 2. The values of row 3 of matrix A are the sums of the respective elements of row 3 of matrix A_{Domain1} and row 1 of matrix A_{Domain2} .

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j)</i> - <i>pointerB(1)</i> + 1 .
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE(j)</i> - <i>pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE

Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix *B*

$$\dots \begin{pmatrix} 1 & 2 & 4 & 1 & 2 & 3 & 4 & 5 & 1 & 3 & 4 & 2 & 7 & 8 & -5 \end{pmatrix} \dots$$

can be represented in the CSR format as:

Storage Arrays for a Matrix in CSR Format

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	6	9	12)								
<i>pointerE</i>	=	(4	6	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	5	8	11)								
<i>pointerE</i>	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [Rem05].

Note that the storage format accepted for the direct sparse solvers and described above (see [Storage Formats for the Direct Sparse Solvers](#)) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix B can be represented in this format (referred to as the 3-array variation of the CSR format or CSR3) as:

[Storage Arrays for a Matrix in CSR Format \(3-Array Variation\)](#)

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row J goes just after the set of non-zero elements in the row $J-1$.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the [Table "Storage Arrays for a Non-Symmetric Example Matrix"](#) with the arrays *pointerB* and *pointerE* from the [Table "Storage Arrays for an Example Matrix in CSR Format"](#) it is easy to see that

```
pointerB(i) = rowIndex(i) for i=1, ..5;
pointerE(i) = rowIndex(i+1) for i=1, ..5.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
Subroutine name_routine(.... , values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
call name_routine(.... , values, columns, rowIndex, rowindex(2), ...).
```

[CSC Format](#)

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix A .

<i>values</i>	A real or complex array that contains the non-zero elements of A . Values of the non-zero elements of A are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element i of the integer array <i>rows</i> is the number of the row in A that contains the i -th value in the <i>values</i> array.
<i>pointerB</i>	Element j of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column j of A . Note that this index is equal to $pointerB(j) - pointerB(1)+1$.

<i>pointerE</i>	An integer array that contains column indices, such that $\text{pointerE}(j) - \text{pointerB}(1)$ is the index of the element in the <i>values</i> array that is last non-zero element in a column j of A .
-----------------	--

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in A . The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in A .

NOTE

Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix B can be represented in the CSC format as:

Storage Arrays for a Matrix in CSC Format

one-based indexing

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	7	9	12)								
<i>pointerE</i>	=	(4	7	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(0	1	3	0	1	4	2	3	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	6	8	11)								
<i>pointerE</i>	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in A . All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix A .

<i>values</i>	A real or complex array that contains the non-zero elements of A in any order.
<i>rows</i>	Element i of the integer array <i>rows</i> is the number of the row in A that contains the i -th value in the <i>values</i> array.
<i>columns</i>	Element i of the integer array <i>columns</i> is the number of the column in A that contains the i -th value in the <i>values</i> array.

NOTE

Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix C

$$c = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing

$$\begin{array}{lcl} \text{values} & = & (1 \quad -1 \quad -3 \quad -2 \quad 5 \quad 4 \quad 6 \quad 4 \quad -4 \quad 2 \quad 7 \quad 8 \quad -5) \\ \text{rows} & = & (1 \quad 1 \quad 1 \quad 2 \quad 2 \quad 3 \quad 3 \quad 3 \quad 4 \quad 4 \quad 4 \quad 5 \quad 5) \\ \text{columns} & = & (1 \quad 2 \quad 3 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 1 \quad 3 \quad 4 \quad 2 \quad 5) \end{array}$$

zero-based

indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
<i>columns</i>	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

values A real or complex two-dimensional array is dimensioned as *lval* by *ndiag*. Each column of it contains the non-zero elements of certain diagonal of *A*. The key point of the storage is that each element in *values* retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of *distance*(*i*) is the number of elements to be padded for diagonal *i*.

distance An integer array with dimension *ndiag*. Element *i* of the array *distance* is the distance between *i*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix C can be represented in the diagonal storage format as follows:

[View all posts by **John Doe**](#) [View all posts in **Category A**](#) [View all posts in **Category B**](#)

1990-1991: *Journal of the American Academy of Child and Adolescent Psychiatry*, 29(12), 1811-1812.

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$, where m is the number of rows for lower triangle (columns for the upper triangle). $\text{pointers}(i) - \text{pointers}(1)+1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) i . The value of $\text{pointers}(m+1)$ is set to $\text{nnz} + \text{pointers}(1)$, where nnz is the number of elements in the array <i>values</i> .

For example, the low triangle of the matrix C given above can be stored as follows:

```
values = ( 1 -2 5 4 -4 0 2 7 8 0 0 -5 )
pointers = ( 1 2 4 5 9 13 )
```

and the upper triangle of this matrix C can be stored as follows:

```
values = ( 1 -1 5 -3 0 4 6 7 4 0 -5 )
pointers = ( 1 2 4 7 9 12 )
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format do not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them are equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
---------------	---

<i>columns</i>	Element i of the integer array <i>columns</i> is the number of the column in the block matrix that contains the i -th non-zero block.
<i>pointerB</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row j of the block matrix.
<i>pointerE</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row j of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE

Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix D

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3×3 block matrix E with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

```

values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
columns = (1 2 2 3)
pointerB = (1 3 4)
pointerE = (3 4 6)

```

zero-based indexing

```

values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 2]
pointerB = [0 2 3]
pointerE = [2 3 5]

```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>rowIndex</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of *rowIndex*(*i*) and *rowIndex*(*i*+1).

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zero blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```

values = (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)
columns = (1 2 2 3)
rowIndex = (1 3 4 6)

```

zero-based indexing

```

values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
columns = (0 1 1 2)
rowIndex = (0 2 3 5)

```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3×3 block matrix G with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only the upper triangular part) as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)
columns = (1 2 2 3)
rowIndex = (1 3 4 5)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)
columns = (0 1 1 2)
rowIndex = (0 2 3 4)
```

Routine and Function Arguments

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as

```
x(1), x(1+|incx|), ..., x(1+(n-1)* |incx|)
```

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x(1+(n-1)* |incx|)$. If $incx$ is zero, then all elements of the vector have the same value, $x(1)$. The dimension of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)* |incx|
```

Example. One-dimensional Real Array

Let $x(1:7)$ be the one-dimensional real array

```
x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0).
```

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $(1.0, 5.0, 9.0)$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $(13.0, 9.0, 5.0, 1.0)$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $(1.0, 1.0, 1.0, 1.0)$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the m -by- n matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$.

Example. Two-dimensional Real Matrix

Let a be the real 5×4 matrix declared as `REAL A (5, 4)`.

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE

The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as $a[0]$, $a[1]$, ..., $a[n-1]$ (for the C interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0 ,..., n-1
```

Constraint: $\text{incy} > 0$ and $\text{inca} > 0$.

For example, setting $\text{incy} = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

```
kj = iy[j], mj = ia[j], j = 0 ,..., n-1,
```

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj , mj are such that:

```
my[kj] ≠ 0, ma[mj] ≠ 0 , j = 0,..., n-1,
```

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- [conventional full storage](#) (in a two-dimensional array)
- [packed storage](#) for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- [band storage](#) for band matrices (in a two-dimensional array)
- [rectangular full packed storage](#) for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the simplest scheme. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$, where lda is the leading dimension of array a .

If a matrix is triangular (upper or lower, as specified by the argument $uplo$), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if $uplo = 'U'$, a_{ij} is stored as described for $i \leq j$, other elements of a need not be set.

if $uplo = 'L'$, a_{ij} is stored as described for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument $uplo$) is packed by columns in a one-dimensional array ap :

if $uplo = 'U'$, a_{ij} is stored in $ap(i + j(j - 1)/2)$ for $i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ap(i + (2*n - j)*(j - 1)/2)$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in p .

Band storage is as follows: an m -by- n band matrix with k_l non-zero sub-diagonals and k_u non-zero super-diagonals is stored compactly in a two-dimensional array ab with k_l+k_u+1 rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in $ab(k_u+1+i-j, j)$ for $\max(1, j-k_u) \leq i \leq \min(n, j+k_l)$.

Use the band storage scheme only when k_l and k_u are much less than the matrix size n . Although the routines work correctly for all values of k_l and k_u , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6$, $k_l = 2$, $k_u = 1$

Array elements marked * are not used by the routines:

Banded matrix A						Band storage of A					
$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$						*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
						a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
						a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
						a_{31}	a_{42}	a_{53}	a_{64}	*	*

When a general band matrix is supplied for *LU factorization*, space must be allowed to store k_l additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $k_l + k_u$ super-diagonals. Thus,

a_{ij} is stored in $ab(k_l+k_u+1+i-j, j)$ for $\max(1, j-k_u) \leq i \leq \min(n, j+k_l)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $k_l = 2$, $k_u = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+

0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

100 | 100
100 | 100
100 | 100

where u_{ij} are the elements of the upper triangular matrix U , and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl = 0$ if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if $uplo = 'U'$, a_{ij} is stored in $ab(k+1+i-j, j)$ for $\max(1, j-k) \leq i \leq j$

if $uplo = 'L'$, $a_{i,j}$ is stored in $ab(1+i-j,j)$ for $j \leq i \leq \min(n, j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n' normal (no conjugation, no transposition)

'T' or 't' transpose

'C' or 'c' conjugate transpose.

Example. Two-Dimensional Complex Array

Suppose A (1:5, 1:4) is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let $transa$ be the transposition parameter, m be the number of rows, n be the number of columns, and lda be the leading dimension. Then if

$transa = 'N'$, $m = 4$, $n = 2$, and $lda = 5$, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If $transa = 'T'$, $m = 4$, $n = 2$, and $lda = 5$, the matrix argument would be

$$\begin{bmatrix} \dots & \boxed{(1.1, 0.11)} & \dots & \dots & \dots \\ \dots & \boxed{(1.2, 0.12)} & \dots & \dots & \dots \end{bmatrix}$$

If $transa = 'C'$, $m = 4$, $n = 2$, and $lda = 5$, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array A above is declared as `COMPLEX A (5,4)`.

Then if $transa = 'N'$, $m = 3$, $n = 4$, and $lda = 4$, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an n -by- n triangle (and suppose for simplicity that n is even), you partition the triangle into three parts: two $n/2$ -by- $n/2$ triangles and an $n/2$ -by- $n/2$ square, then pack this as an n -by- $n/2$ rectangle (or $n/2$ -by- n rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when n is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, A is lower triangular

Intel MKL provides a number of routines such as [?hfrk](#), [?sfrk](#) performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, [?pttf](#) goes from the standard packed format to RFP and [?trttf](#) goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

Specific Features of Fortran 95 Interfaces for LAPACK Routines

C

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see "[MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation](#)"). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::= <name of interface> '(' <arguments list> ')'
<arguments list> ::= <first argument> {<argument>}*
<first argument> ::= <identifier>
<argument> ::= <required argument>|<optional argument>
<required argument> ::= ',' <identifier>
<optional argument> ::= '[' ,<identifier> ']'
<name of interface> ::= <identifier>
```

where defined notions are separated from definitions by ::=, notion names are marked by angle brackets, terminals are given in quotes, and {...}* denotes repetition zero, one, or more times.

<first argument> and each <required argument> should be present in all calls of denoted interface, <optional argument> may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character !.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Interfaces Identical to Netlib

FFTW Interface to Intel® Math Kernel Library

Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of C and Fortran wrappers providing FFTW 2.x interface to Intel MKL. The wrappers translate calls to FFTW 2.x functions into the calls of the Intel MKL Fast Fourier Transform interface (FFT interface).

Note that Intel MKL FFT interface operates on both single- and double-precision floating-point data types.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at www.fftw.org.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

[Limitations of the FFTW2 Interface to Intel MKL](#)

One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist, fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
            fftw_complex *out, int ostride, int odist);
void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);
void fftwnd_destroy_plan(fftwnd_plan plan);
```

One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size N in a real array of the same size N consists of $N/2+1$ real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel MKL FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using rfftwnd functions with $rank=1$.

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int istride, int idist,
                             fftw_complex *out, int ostride, int odist);
void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
                             fftw_real *out, int ostride, int odist);
void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
```

```
void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in, fftw_real *out);
void rfftwnd_destroy_plan(rfftwnd_plan plan);
```

Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel MKL provides multithreaded computation by default, with the number of threads defined by the number of processors available on the system (see [section "Managing Performance and Memory" in the Intel MKL User's Guide](#)). To limit the number of threads that use the FFTW interface, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
  istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
  *out);
...
void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int
  howmany, fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int
  odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter `nthreads`. Set the `nthreads` parameter to the thread limit to ensure that the computation requires at most that number of threads.

FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void *(*fftw_malloc_hook) (size_t n);
void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook)(const char *error_string);
void fftw_die(const char *s);
```

Calling Wrappers from Fortran

The FFTW2 wrappers to Intel MKL provide the following subroutines for calling from Fortran:

```
call fftw_f77_create_plan(plan, n, dir, flags)
call fftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftw_f77_one(plan, in, out)
call fftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftw_f77_threads_one(nthreads, plan, in, out)
```

```

call fftw_f77_destroy_plan(plan)

call fftwnd_f77_create_plan(plan, rank, n, dir, flags)
call fftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call fftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call fftwnd_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftwnd_f77_one(plan, in, out)
call fftwnd_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftwnd_f77_threads_one(nthreads, plan, in, out)
call fftwnd_f77_destroy_plan(plan)

call rfftw_f77_create_plan(plan, n, dir, flags)
call rfftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftw_f77_one(plan, in, out)
call rfftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftw_f77_threads_one(nthreads, plan, in, out)
call rfftw_f77_destroy_plan(plan)

call rfftwnd_f77_create_plan(plan, rank, n, dir, flags)
call rfftw2d_f77_create_plan(plan, nx, ny, dir, flags)

```

The FFTW Fortran functions are wrappers to FFTW C functions. So, their functionality and limitations are the same as of the corresponding C wrappers.

See also these resources:

[Wrappers Reference](#)

for a description of the FFTW2 C wrappers to Intel MKL.

www.fftw.org

for the original FFTW 2.x documentation.

[Limitations of the FFTW2 Interface to Intel MKL](#) for limitations of the wrappers.

Limitations of the FFTW2 Interface to Intel MKL

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel MKL can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel MKL implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel MKL FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. So, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the `flags` parameter. These functions take into account only the following values of `flags`:

- `FFTW_IN_PLACE`

If this value of `flags` is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (`out`, `ostride`, and `odist`). Unlike the original FFTW interface, the wrappers never use the `out` parameter as a scratch space for in-place transforms.

- `FFTW_THREADSAFE`

If this value of `flags` is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2xc` or `.\interfaces\fftw2xf` subdirectory in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the `.\interfaces\fftw2xf\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries for both interfaces and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw2xc` or `.\interfaces\fftw2xf` subdirectory in the Intel MKL directory for C or Fortran wrappers, respectively.

A wrapper library contains C or Fortran wrappers for complex and real transforms in a serial and multi-threaded mode for double- or single-precision floating-point data types. A makefile parameter manages the data type.

Parameters of a makefile also specify the platform (required), compiler, and data precision. The makefile comment heading provides the exact description of these parameters.

Because a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf\source` subdirectory in the Intel MKL directory defines function names according to the names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name before building the library.

To build the library, run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler (Compilers and data precision are chosen by default.)

Each makefile creates the library in the directory with Intel MKL libraries corresponding to the platform used. For example, `./lib/ia32` (on Linux OS and OS X) or `.\lib\ia32` (on Windows* OS).

In the names of a wrapper library, the suffix corresponds to the compiler used and the letter preceding the underscore is "f" for the Fortran and "c" for the C programming language.

For example,

```
fftw2xf_intel.lib (on Windows OS); libfftw2xf_intel.a (on Linux OS and OS X);
fftw2xc_intel.lib (on Windows OS); libfftw2xc_intel.a (on Linux OS and OS X);
fftw2xc_ms.lib (on Windows OS); libfftw2xc_gnu.a (on Linux OS and OS X).
```

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

Intel MKL provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2xc` or `.\examples\fftw2xf` subdirectory in the Intel MKL directory for C or Fortran, respectively. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.i`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters of the corresponding wrapper library makefile (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `_results` is created, and the results are stored there in the `<example_name>.res` files.

MPI FFTW Wrappers

MPICH wrappers for FFTW 2 are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int flags);
void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work);
void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int *local_n_after_transform, int *local_start_after_transform, int *total_local_size);
void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLED_INPUT and FFTW_SCRAMBLED_OUTPUT. The same algorithm corresponds to all these values of the *flags* parameter. If any other *flags* value is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);

void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work, fftwnd_mpi_output_order output_order);
void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int *local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);
void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Real MPI FFTW

Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
```

```
rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);

void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real *work, fftwnd_mpi_output_order output_order);

void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int *local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

-
- Function *rfftwnd_mpi_create_plan* can be used for both one-dimensional and multi-dimensional transforms.
 - Both values of the *output_order* parameter are supported: FFTW_NORMAL_ORDER and FFTW_TRANSPOSED_ORDER.
-

Creating MPI FFTW Wrapper Library

The source code for the wrappers, makefiles, and files with lists of wrappers are located in the .\interfaces\fftw2x_cdft subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

Parameters of a makefile specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI and the Intel® C++ Compiler (compilers and data precision are chosen by default.).

A makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS) or `.\lib\ia32` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on Windows OS;

`libfftw2x_cdft_DOUBLE.a` on Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and files with lists of examples are located in the .\examples\fftw2x_cdft subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in .\include\fftw. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the parameters of the wrapper library makefiles (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the .\examples\fftw2x_cdft\source subdirectory.

Examples of MPI FFTW Wrappers

Source file for the example	Description
<code>wrappers_c1d.c</code>	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
<code>wrappers_c2d.c</code>	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
<code>wrappers_c3d.c</code>	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
<code>wrappers_c4d.c</code>	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>
<code>wrappers_r1d.c</code>	One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>
<code>wrappers_r2d.c</code>	Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>
<code>wrappers_r3d.c</code>	Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>
<code>wrappers_r4d.c</code>	Four-dimensional Real MPI FFTW transform, using <code>plan = rfftwnd_mpi_create_plan(...)</code>

FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.x library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

See also these resources:

Intel MKL Release Notes

for the version of the FFTW3 library supported by the wrappers.

www.fftw.org	for a description of the FFTW interface.
Fourier Transform Functions	for a description of the Intel MKL FFT interface.
Trigonometric Transform Routines	for a description of Intel MKL TT interface.

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This manual does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- The FFTW3 wrappers do not support long double precision because Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the `long double` data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in the `fftw3.h` and `fftw3.f` header files. These files are borrowed from the FFTW3.x package and distributed within Intel MKL with permission. Additionally, the `fftw3_mkl.h`, `fftw3_mkl.f`, and `fftw3_mkl_f77.h` header files define supporting structures and supplementary constants and macros, as well as expose Fortran interface in C.
- Actual functionality of the plan creation wrappers is implemented in guru64 set of functions. Basic interface, advanced interface, and guru interface plan creation functions call the guru64 interface functions. So, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
 - c2r and r2c problems with a split storage of complex data.
 - r2r problems with *kind* values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported r2r kinds are even/odd DFTs (sine/cosine transforms).
 - Multidimensional r2r transforms.
 - Transforms of multidimensional vectors. That is, the only supported values for parameter `howmany_rank` in guru and guru64 plan creation functions are 0 and 1.
 - Multidimensional transforms with `rank > MKL_MAXRANK`.
- The `MKL_RODFT00` value of the *kind* parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this *kind* value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the `in2/out2` arrays have one extra zero element at location 0. For example, if $n=3$, `in1={x,y,z}` and `out1={u,v,w}`, then `in2={0,x,y,z}` and `out2={0,u,v,w}`.

- The *flags* parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, *flags* values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.

- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use `guru64` FFTW3 interfaces for 64-bit sizes.
- Fortran wrappers (see [Calling Wrappers from Fortran](#)) use the `INTEGER` type, which is 32-bit in LP64 interfaces and 64-bit in ILP64 interfaces.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
 - For saving, loading, and printing plans
 - For saving and loading wisdom
 - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel MKL.
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.

Calling Wrappers from Fortran

Intel MKL also provides Fortran 77 interfaces of the FFTW3 wrappers. The Fortran wrappers are available for all FFTW3 interface functions and are based on C interface of the FFTW3 wrappers. Therefore they have the same functionality and restrictions as the corresponding C interface wrappers.

The Fortran wrappers use the default `INTEGER` type for integer arguments. The default `INTEGER` is 32-bit in Intel MKL LP64 interfaces and 64-bit in ILP64 interfaces. Argument `plan` in a Fortran application must have type `INTEGER*8`.

The wrappers that are double-precision subroutines have prefix `dfftw_`, single-precision subroutines have prefix `sfftw_` and provide an equivalent functionality. Long double subroutines (with prefix `lfftw_`) are not provided.

The Fortran FFTW3 wrappers use the default Intel® Fortran compiler convention for name decoration. If your compiler uses a different convention, or if you are using compiler options affecting the name decoration (such as `/Qlowercase`), you may need to compile the wrappers from sources, as described in section [Building Your Own Wrapper Library](#).

For interoperability with C, the declaration of the Fortran FFTW3 interface is provided in header file `include/fftw/fftw3_mkl_f77.h`.

You can call Fortran wrappers from a FORTRAN 77 or Fortran 90 application, although Intel MKL does not provide a Fortran 90 module for the wrappers. For a detailed description of the FFTW Fortran interface, refer to FFTW3 documentation (www.fftw.org).

The following example illustrates calling the FFTW3 wrappers from Fortran:

```
INTEGER*8 plan
INTEGER N
INCLUDE 'fftw3.f'
COMPLEX*16 IN(*), OUT(*)
!...initialize array IN
CALL DFFT_W_PLAN_DFT_1D(PLAN, N, IN, OUT, -1, FFTW_ESTIMATE)
IF (PLAN .EQ. 0) STOP
CALL DFFT_W_EXECUTE
!...result is in array OUT
```

Building Your Own Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself. However, if your Fortran application is compiled with a compiler that uses a different name decoration than the Intel® Fortran compiler or if you are using compiler options altering the Fortran name decoration, you may need to build the wrappers that use the appropriate name changing convention.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw3xc` or `.\interfaces\fftw3xf` subdirectory in the Intel MKL directory for C or Fortran wrappers, respectively.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default integer type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 Fortran wrappers to Intel MKL for use from the GNU g77* Fortran compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xf
make libintel64 compiler=gnu fname=a_name__ INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler, decorates the name with the second underscore, and places the result, named `libfftw3xf_gnu.a`, into the `/my/path` directory. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter `INSTALL_LIBNAME`.

Building an Application

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section *"Linking Your Application with Intel® Math Kernel Library" in the Intel MKL User's Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

```
#include "fftw3.h" ,
```

 which it probably already includes.
- The application does not require

```
#include "mkl_dfti.h" .
```
- The application does not require

```
#include "fftw3_mkl.h" .
```

It is required only in case you want to use the `MKL_RODFT00` constant.

- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the .\examples\fftw3xc or .\examples\fftw3xf subdirectory in the Intel MKL directory for C or Fortran, respectively. To build Fortran examples, one additional file fftw3.f is needed. This file is distributed with permission from FFTW and is available in the .\include\fftw subdirectory of the Intel MKL directory. The original file can also be found in FFTW 3.2 at <http://www.fftw.org/download.html>.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory ._results in files with extension .res.

For detailed information about options for the example makefile, refer to the makefile.

MPI FFTW Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® MKL.

MPI FFTW wrappers are available only with Intel MKL for the Linux* and Windows* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel MKL cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW3 because of differences between MPI FFTW and Intel MKL CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see [Building Your Own Wrapper Library](#)).

See also these resources:

[Intel MKL Release Notes](#) for the version of the FFTW3 library supported by the wrappers.

www.fftw.org for a description of the MPI FFTW interface.

[Cluster FFT Functions](#) for a description of the Intel MKL CFFT interface.

Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and files with lists of functions are located in subdirectory .\interfaces\fftw3x_cdft in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel MKL for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces\fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final executable can use Open MPI, and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel MKL and the wrapper library at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL User's Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\\examples\\fftw3x_cdft` subdirectory in the Intel MKL directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `._results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors x and y .

Parameters

<code>n</code>	Specifies the number of elements in vectors x and y .
<code>incx</code>	Specifies the increment for the elements of x .
<code>incy</code>	Specifies the increment for the elements of y .

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
  x(i) = 2.0e0
  y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = `, res
end
```

As a result of this program execution, the following line is printed:

`SDOT = 10.000`

Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector x to a vector y .

Parameters

<code>n</code>	Specifies the number of elements in vectors x and y .
<code>incx</code>	Specifies the increment for the elements of x .

Parameters

incy Specifies the increment for the elements of *y*.

```

program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
incx = 3
incy = 1
do i = 1, 10
    x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, `Y = `, (y(i), i = 1, n)
end

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

a := *alpha***x***y*' + *a*.

Parameters

α	Specifies a scalar α .
x	m -element vector.
y	n -element vector.
A	m -by- n matrix.

```

program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
  x(i) = 1.0
  y(i) = 1.0
end do
do i = 1, m
  do j = 1, n
    a(i,j) = j
  end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
  print*, (a(i,j), j = 1, n)
end do
end

```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```
1.50000 2.50000 3.50000
1.50000 2.50000 3.50000
```

Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c := alpha*a*b' + beta*c.
```

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```
program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
  do j = 1, m
    a(i,j) = 1.0
  end do
end do
do i = 1, m
  do j = 1, n
    c(i,j) = 1.0
    b(i,j) = 2.0
  end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, `Matrix C: `
do i = 1, m
  print*, (c(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

```
5.00000 5.00000
```

5.00000 5.00000

5.00000 5.00000

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure `c`.

```
#include <cstdio>
#include "mkl blas.h"
#define N 5
void main()
{
    int n, inca = 1, incb = 1, i;
    MKL_Complex16 a[N], b[N], c;
    void zdotc();
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].real = (double)i; a[i].imag = (double)i * 2.0;
        b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
    }
    zdotc( &c, &n, a, &inca, b, &incb );
    printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.real, c.imag );
}
```

NOTE

Instead of calling BLAS directly from C programs, you might wish to use the C interface to the Basic Linear Algebra Subprograms (CBLAS) implemented in Intel® MKL. See [C Interface Conventions](#) for more information.

Fourier Transform Functions Code Examples

This section presents code examples for functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

FFT Code Examples

This section presents examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter.

Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

In the Fortran examples, the `use mkl_dfti` statement assumes that:

- The `mkl_dfti.f90` module definition file is already compiled.
- The `mkl_dfti.mod` module file is available.

One-dimensional In-place FFT (Fortran Interface)

```
! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
```

```

Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE, &
    DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor( My_Desc1_Handle )
! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE, &
    DFTI_REAL, 1, 32 )
Status = DftiCommitDescriptor( My_Desc2_Handle )
Status = DftiComputeForward( My_Desc2_Handle, Y )
Status = DftiFreeDescriptor( My_Desc2_Handle )
! result is given in CCS format.

```

One-dimensional Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor( My_Desc1_Handle )
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32 )
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiCommitDescriptor( My_Desc2_Handle )
Status = DftiComputeForward( My_Desc2_Handle, Y_in, Y_out )
Status = DftiFreeDescriptor( My_Desc2_Handle )
! result is given by Y_out in CCS format.

```

One-dimensional In-place FFT (C Interface)

```

/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x[32];

```

```

float y[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
                               DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x );
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
                               DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle );
status = DftiComputeForward( my_desc2_handle, y );
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/

```

One-dimensional Out-of-place FFT (C Interface)

```

/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
                               DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
                               DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc2_handle );
status = DftiComputeForward( my_desc2_handle, y_in, y_out);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/

```

Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```

! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI

```

```

Complex :: X_2D(32,100)
Real :: Y_2D(34, 102)
Complex :: X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j<=32,1<=k<=100
!...set L(1) = 32, L(2) = 100
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE, &
    DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor( My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE, &
    DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor( My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format

```

Two-dimensional FFT (C Interface)

```

/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 2, l);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 2, l);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/

```

The following example in C and Fortran demonstrates how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

The code below illustrates how this can be done:

Changing Default Settings (Fortran Interface)

```
! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle, & DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor (My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)
```

Changing Default Settings (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Using Status Checking Functions

This example illustrates the use of status checking functions described in [Chapter 11](#).

```
! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status = DftiCommitDescriptor(desc)
if (status .ne. 0) then
  if (.not. DftiErrorClass(status,DFTI_NO_ERROR) then
    print *, 'Error: ', DftiErrorMessage(status)
  endif
```

```
endif

/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
    printf ('Error: %s\n', DftiErrorMessage(status));
}
```

Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran
use mkl_dfti
Complex :: X_2D(20,40)
Complex :: X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
! ...
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 20 )
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 40 )
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"
float _Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
```

```

DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
    DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
    DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &desc_handle_dim1 );
status = DftiFreeDescriptor( &desc_handle_dim2 );

```

The following code illustrates real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example “Two-Dimensional REAL In-place FFT \(Fortran Interface\)](#)” is two-dimensional in-place transform and [Example “Two-Dimensional REAL Out-of-place FFT \(Fortran Interface\)](#)” is two-dimensional out-of-place transform in Fortran interface. [Example “Three-Dimensional REAL FFT \(C Interface\)](#)” is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Two-Dimensional REAL In-place FFT (Fortran Interface)

```

! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(34,100) ! 34  = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X_2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j<=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )

```

```

Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.

```

Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)

! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )

Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.

```

Three-Dimensional REAL FFT (C Interface)

```

/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

```

```

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, 1 );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */

```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation.

To specify the number of threads inside Intel MKL, use the following settings:

```

set MKL_NUM_THREADS = 1 for one-threaded mode;
set MKL_NUM_THREADS = 4 for multi-threaded mode.

```

Using Intel MKL Internal Threading Mode (C Example)

```

#include "mkl_dfti.h"

int main ()
{
    float x[200][100];
    DFTI_DESCRIPTOR_HANDLE fft;
    MKL_LONG len[2] = {200, 100};
    // initialize x
    DftiCreateDescriptor ( &fft, DFTI_SINGLE, DFTI_REAL, 2, len );
    DftiCommitDescriptor ( fft );
    DftiComputeForward ( fft, x );
    DftiFreeDescriptor ( &fft );
    return 0;
}

```

The following [Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region”](#) and [Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread”](#) illustrate a parallel customer program with each descriptor instance used only in a single thread.

Specify the number of threads for [Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region”](#) like this:

```

set MKL_NUM_THREADS = 1 for Intel MKL to work in the single-threaded mode (recommended);
set OMP_NUM_THREADS = 4 for the customer program to work in the multi-threaded mode.

```

Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL. To achieve this, you need to set the parameter

DFTI_NUMBER_OF_TRANSFORMS = 4 and to set the corresponding parameter DFTI_INPUT_DISTANCE = 5000.

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    int th;
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(len, x)
    for (th = 0; th < nth; th++)
    {
        DFTI_DESCRIPTOR_HANDLE myFFT;

        DftiCreateDescriptor (&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
        DftiCommitDescriptor (myFFT);
        DftiComputeForward (myFFT, x[th]);
        DftiFreeDescriptor (&myFFT);
    }
    return 0;
}
```

Fortran code for the example is as follows:

```
program fft2d_private_descr_main
    use mkl_dfti

    integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
    parameter (nth = 4, len = (/50, 100/))
    complex x(len(2)*len(1), nth)

    type(dfti_descriptor), pointer :: myFFT
    integer th, myStatus

! assume x is initialized and do 2D FFTs
 !$OMP PARALLEL DO SHARED(len, x) PRIVATE(myFFT, myStatus)
    do th = 1, nth
        myStatus = DftiCreateDescriptor (myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
        myStatus = DftiCommitDescriptor (myFFT)
        myStatus = DftiComputeForward (myFFT, x(:, th))
        myStatus = DftiFreeDescriptor (myFFT)
    end do
 !$OMP END PARALLEL DO
end
```

Specify the number of threads for Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread” like this:

set MKL_NUM_THREADS = 1 for Intel MKL to work in the single-threaded mode (obligatory);
set OMP_NUM_THREADS = 4 for the customer program to work in the multi-threaded mode.

Using Parallel Mode with Multiple Descriptors Initialized in One Thread

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(x)];
    int th;

    for (th = 0; th < nth; th++)
        DftiCreateDescriptor (&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    for (th = 0; th < nth; th++)
        DftiCommitDescriptor (FFT[th]);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT[th], x[th]);
    for (th = 0; th < nth; th++)
        DftiFreeDescriptor (&FFT[th]);
    return 0;
}
```

Fortran code for the example is as follows:

```
program fft2d_array_descr_main
    use mkl_dfti

    integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
    parameter (nth = 4, len = (/50, 100/))
    complex x(len(2)*len(1), nth)

    type thread_data
        type(dfti_descriptor), pointer :: FFT
    end type thread_data
    type(thread_data) :: workload(nth)

    integer th, status, myStatus

    do th = 1, nth
        status = DftiCreateDescriptor (workload(th)%FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
        status = DftiCommitDescriptor (workload(th)%FFT)
    end do
    ! assume x is initialized and do 2D FFTs
    !$OMP PARALLEL DO SHARED(len, x, workload) PRIVATE(myStatus)
        do th = 1, nth
            myStatus = DftiComputeForward (workload(th)%FFT, x(:, th))
        end do
    !$OMP END PARALLEL DO
    do th = 1, nth
        status = DftiFreeDescriptor (workload(th)%FFT)
    end do
end
```

The following Example “Using Parallel Mode with a Common Descriptor” illustrates a parallel customer program with a common descriptor used in several threads.

Using Parallel Mode with a Common Descriptor

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT;
    int th;

    DftiCreateDescriptor (&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    DftiCommitDescriptor (FFT);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT, x[th]);
    DftiFreeDescriptor (&FFT);
    return 0;
}
```

Fortran code for the example is as follows:

```
program fft2d_shared_descr_main
  use mkl_dfti

  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)
  type(dfti_descriptor), pointer :: FFT

  integer th, status, myStatus

  status = DftiCreateDescriptor (FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
  status = DftiCommitDescriptor (FFT)
! assume x is initialized and do 2D FFTs
 !$OMP PARALLEL DO SHARED(len, x, FFT) PRIVATE(myStatus)
  do th = 1, nth
    myStatus = DftiComputeForward (FFT, x(:, th))
  end do
 !$OMP END PARALLEL DO
  status = DftiFreeDescriptor (FFT)
end
```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2], v, i, j, n, s;
Complex *in, *out;
```

```

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFL_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFL_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFL_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();

```

1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```

DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len,v,i,n_out,s_out;
Complex *in,*work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFL_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFL_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFL_LOCAL_X_START,&s);
// Set work array as a workspace
DftiSetValueDM(desc,CDFL_WORKSPACE,work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc,CDFL_LOCAL_OUT_NX,&n_out);

```

```

DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();

```

Auxiliary Data Transformations

This section presents C examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Conversion from Cartesian to polar representation of complex data

```

// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                         double *r,double *phi)
{
    vdHypot(n,re,im,r);           // compute radii r[]
    vdAtan2(n,im,re,phi);        // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                         double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);               // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}

```

Conversion from polar to Cartesian representation of complex data

```

// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp( I*phi )
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                         double *re,double *im)
{
    vdSinCos(n,phi,im,re);       // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,re,re);           // scale real part
    vdMul(n,r,im,im);           // scale imaginary part
}

void

```

```
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                         MKL_Complex16 *z,
                         double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . See also conjugate matrix.
A^T	Denotes the transpose of a general matrix A . See also transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > l$, where $1 \leq l \leq \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. See BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable X . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event $A: X \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (X_1 \leq x_1 \& X_2 \leq x_2, \& \dots, \& X_n \leq x_n)$.

Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = LL^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = A \cdot A^{-1} $.
conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i$. Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \times 10^{-308} < x < 1.79 \times 10^{308}$. For this data type, the machine precision ϵ is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.

i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = (L \ 0)Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$,
	where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.
LU factorization	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ε determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable X . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is

$$F(x) = \int_{-\infty}^x f(t)dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n$$

positive-definite matrix

A square matrix A such that $\mathbf{Ax} \cdot \mathbf{x} > 0$ for any non-zero vector x . Here \cdot denotes the dot product.

pseudorandom number generator

A completely deterministic algorithm that imitates truly random sequences.

QR factorization

Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.

random stream

An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.

RNG

Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.

Rectangular Full Packed (RFP) storage

A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.

s

When found as the first letter of routine names, s indicates the usage of single-precision real data type.

ScaLAPACK

Stands for Scalable Linear Algebra PACKage.

Schur factorization

Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.

single precision

A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < |x| < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture*.

singular matrix

A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).

singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . See also SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. See full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. See also Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^HA = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
